For experiment 3, survival will be described using Kaplan-Meier curves and compared between groups using the log rank test. If 60 day survival is 50% in the control group and 99% in the treated group, a sample size of 16 for each of the two groups will

have 80% power to detect a significant difference based on a log rank test with 5%, two-sided significance level.

For experiments 4, survival will be described using Kaplan-Meier curves and compared between groups using the log rank test. If survival is 50% in the control group and 95% in the comparison group, a sample size of 20 for each of the two groups will have 80% power to detect significant differences based on a log rank test with 5% two-sided significance level. The expected survival will be higher for the group receiving the (b)(4) and G-CSF combination compared to group administered only (b)(4)

For additional parameters (blood components and blood biochemistry), data mean values with standard errors (when applicable) will be reported. Independent samples *t*-tests or analysis of variance (ANOVA) will be used to detect if there are significant differences between experimental groups. All statistical tests will be two-sided, with a 5% significance level. Statistical software SPSS version 22 (IBM, Armonk, NY, USA) and GraphPad Prism 5 (GraphPad Software, Inc., La Jolla, CA, USA) will be used for analyses. A sample size of 10 per group (experiment 1) will have 80% power to detect differences of 1.3 standard deviations between groups, and a sample size of 16-20 NHPs per group (experiments 3 and 4) will have 80% power to detect differences of approximately 1 standard deviation between groups, based on a *t*-test for independent samples with 5%, two-sided significance level.

V.3. Laboratory Animals Required and Justification

V.3.1. Non-animal Alternatives Considered

Both computer models and tissue culture have been considered as alternatives to animals. These alternatives lack the knowledge base and complexity needed to evaluate the effects of radiation and radiation countermeasures on the immune system. The phenomena under study involve complex information-processing networks comprising of a large number of cell types and biological signal transduction molecules. Responses to irradiation and radioprotective agents involve interactions between the central nervous system, the peripheral nervous system including the enteric nervous system, endocrine glands, the immune and inflammatory systems, hematopoietic system, GI system, etc. We do not know all of the cell types and tissues involved and many of the signal transduction molecules have not been discovered yet. Even if all of the tissues, cell types and signaling molecules were known, the present state of tissue culture would be incapable of reproducing *in vivo* relationships. One would have to reproduce much of an entire mammalian organism in culture to study these phenomena *in vitro*. As for computer models, the most powerful supercomputers available in the near future would be incapable of analyzing interactions between so many elements in the network. Thus these drugs necessitate investigation in whole animal models to see overall outcome.

V.3.2. Animal Model and Species Justification

Demonstrating efficacy of a countermeasure in a large animal species (LAS) is a critical requirement of the FDA Animal Rule. Rhesus macaque has 95+% DNA sequence identity with humans. NHPs are necessary for the pre-clinical development of a drug candidate intended for use in humans, because drug metabolism and physiology are so similar between NHPs and humans. Rhesus macaques are the model of choice for investigations of toxicity, pharmacokinetics, biomarkers, radiation injury, and

countermeasures, because the large database available from the existing literature. The FDA has accepted rhesus macaques as the appropriate animal model for pivotal efficacy testing of radiation countermeasures under the Animal Efficacy Rule, when efficacy testing cannot be performed in humans. Our ultimate goal is to generate data suitable for submission to US FDA to support the approval of the radiation countermeasure. The pig model (specifically Gottingen minipig) is currently under initial stages of development for studying radiation injury and this model is not defined or mature enough to evaluate radiation countermeasures nor has the minipig model reached a stage of acceptance in the scientific community (b)(4) Therefore, this study utilizes the rhesus macaque to guide future development of this class of radiation countermeasures. There are several reports of using NHPs in radiation research and countermeasure development [23, (b)(4) 29].

V.3.3. Laboratory Animals

V.3.3.1. Genus / Species
Macaca mulatta (Rhesus macaques)

V.3.3.2. Strain / Stock

Chinese origin

V.3.3.3. Source / Vendor

Animals will be procured from vendors registered with the USDA or DoD.

V.3.3.4. Age: 3 - 7 years

V.3.3.5. Weight: 4 - 6 Kg

V.3.3.6. Sex: Male

V.3.3.7. Special Considerations

Animals should test antibody negative for Herpes B virus (aka *Macacine herpesvirus*), Simian T-cell leukemia virus type 1 (STLV-1), Simian Immunodeficiency virus (SIV) and Simian Retrovirus (SRV) Types 1, 2, 3, and 5. Animals shall also test negative by means of virus isolation or polymerase chain reaction (PCR) for SRV Type 2. NHPs will either be vaccinated for measles or, in the case of previously measles-vaccinated NHPs, tested for the presence of measles antibodies. NHPs shall come from the vendor colony negative for *Salmonella*, *Shigella* and *Yersinia*. Vendor must provide the health reports indicating the pathogen free status of the NHPs for the agents listed in this section. The animals will be pole and collar trained by the vendor before their use in above experiment.

V.3.4. Number of Animals Required (by species): 136

V.3.5. Refinement, Reduction, Replacement (3 R's)

V.3.5.1. Refinement

For efficacy studies, the endpoint currently mandated by the FDA for approval of radiation countermeasures is mortality or major morbidity. Moribundity will be used as a surrogate for mortality, and euthanasia will be used in order to minimize pain and distress, using an extensive set of criteria (listed under section V.4.5). The actual irradiation procedure does not cause pain or distress. Animal care and use procedures will only be performed by trained and certified personnel.

V.3.5.2. Reduction

As we move forward with experiments, plans will be reevaluated at every stage of the experiments, in light of incoming data in an attempt to reduce the numbers of experiments and groups, if possible. If deemed not necessary based on incoming data, some investigations may not be carried out to optimize the use of experimental animals.

V.3.5.3. Replacement

There are no *in vitro* techniques available to demonstrate that this drug will counter the effects of whole-body irradiation in humans. Efficacy and safety have already been demonstrated in rodents. The preferred large animal model for preclinical evaluation of radiation countermeasures intended for use in humans is NHP primates. This study represents the next step necessary to develop this drug for FDA approval. According to FDA scientists and the radiobiology community, the large database of radiation studies in *Macaca mulatta* makes this the most useful large animal model to evaluate interactions of radiation injury and drugs intended for use in humans.

V.4. Technical Methods

V.4.1. Pain / Distress Assessment

V.4.1.1. APHIS Form 7023 Information

V.4.1.1.1. Number of Animals 136

V.4.1.1.1.1. Column C 0 (# of animals)

V.4.1.1.1.2.Column D 0 (# of animals)

V.4.1.1.1.3. Column E 136 (# of animals)

V.4.1.1.1.4. Pain Category Assignments

Exp. #	Experimental/Control Group	C	D	E	Totals
Experiment 1	$LD_{50\text{-}70}$ estimation			20	20
Experiment 2	PD of (b)(4)			4	4
Experiment 3	Pilot efficacy study with (b)(4)			32	32
Experiment 4	Efficacy study with (b)(4) in combination with G-CSF			80	80
Totals:				136	136

V.4.1.2. Pain Relief / Prevention

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization

As mentioned under section 'V.4.4.7. Other Procedures' animals will be sedated with ketamine (5 -15 mg/kg, im, 22 - 25 G needle length of ¾-1") or Telazol (2 - 5 mg/kg, im, 22 - 25 G needle length of ¾-1") to place in restraint box for transporting to cobalt facility.

Microchips: These are inserted under ketamine anesthesia after animals clear the quarantine period. The chips are used to monitor body temperature and are pre-loaded in a specially designed needle/syringe device that is inserted sc between the shoulder blades. Once the chip is placed, the needle is withdrawn and the skin is pinched between 2 fingers for about 10 - 20 seconds to ensure that the chip itself (about the size of a grain of rice) does not dislodge out through the punctured site. If a chip fails, a

second chip will be inserted. If necessary, a drop of surgical glue will be placed at the punctured site to ensure that the chip stays in place.

***Supportive Care*:** Antibiotics will be administered prophylactically and initiated on day 3 and will continue through day 30. The primary antibiotic will be enrofloxacin (Baytril Bayer HealthCare LLC, Shawnee Mission, KS). The dose will be 10 +/- 0.5 mg/kg administered sc daily (QD). If the body temperature is > 103 ^{o}F, gentamicin sulfate (GentaMax, Phoenix Scientific, Inc.) (5 mg/kg, sc or iv, QD) will be administered in combination with Baytril, and this treatment will continue for 24 h. If high fever persists, ceftriaxone (Rocephin, Roche Laboratories Inc., Nutley, NJ) (50 mg/kg, im, every 24 h) will be administered after gentamicin sulfate is discontinued. An alternative antibiotic to be used under such situation will be clindamycin, 12.5 mg/kg, administered intramuscularly (im) every 8 h. Based on veterinarian suggestion, Ceftiofur sodium free acid (EXCEDE) sc at 5 mg/kg (lasting 2 days) or sc at 20 mg/kg (lasting 7 days) will be used. For this purpose, a bacterial sensitivity culture may be arranged by Veterinary Science Department.

***Fluid support*:** Administration of iv fluid to animals in restraint chair is not possible. Additionally, frequent parenteral route administration to animals with low platelet counts increases the risk of uncontrolled bleeding and every time animals need to be put in restraint chair causing significant stress. Without anesthetizing animals, iv administration of iv fluid is not practicable and frequent sedation will also cause stress. Thus, we will provide water/electrolytes in bottles and fruits and vegetables with high water content (such as watermelon, oranges, cantaloupes etc.) for the dehydrated NHPs.

***Analgesics and non-steroidal anti-inflammatory drugs*:** Buprenorphine SR (0.12 – 0.2 mg/kg, sc, lasting for 3 days) will be administered when there is sign of pain. Rimadyl (Carprofen, 15 mg tab, BID, po or injectable 50 mg/ml; 1 - 5 mg/kg/dose, BID, sc) can be administered as an alternative to buprenorphine when evidence of pain is still present.

V.4.1.2.2. Pre- and Post-procedural Provisions

Animals will be observed for signs of pain and distress by either the veterinary or research staff at least twice daily. After specialized procedures, NHPs will be monitored at least twice daily for signs of complications that may have occurred by the investigative staff. Study staff will adhere to IACUC Policy #10, Guidelines for Establishment of Early Endpoints in Experiments with Expected Mortality during the critical period and with additional checks (maximum 10 h between two checks).

V.4.1.2.3. Paralytics: No paralytic agent will be used in this study.

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures

V.4.1.3.1. Sources Searched

IVIS: International Veterinary Information Service
PubMed: United States National Library of Medicine
Web of Science

V.4.1.3.2. Date of Search: 10/22/2015 - 1/4/2016

V.4.1.3.3. Period of Search

IVIS: 1998 - 2016

PubMed: 1965 - 2016
Web of Science: 1970 - 2016

V.4.1.3.4. Key Words of Search: See table below

V.4.1.3.5. Results of Search

#	Keywords of Search	Literature Sources and Periods of search		
		IVIS: 1998 - 2016	**PubMed: 1965 - 2016**	**Web Of Science: 1970 - 2016**
		Results of Search		
1	Pain and radiation	341	11618	5967
2	Ionizing radiation and pain	22	539	268
3	Ionizing radiation and pain and supportive care	0	1	0
4	Ionizing radiation and pain and sepsis	0	1	0
5	Ionizing radiation and pain and bone marrow depletion	0	0	0
6	Ionizing radiation and pain and intestinal damage	0	0	0
7	Alternative and radiation	213	13382	32031
8	Alternative and radiation and pain	118	463	522
9	Thrombopoietin and pain	0	21	9
10	Alternative and thrombopoietin and pain	0	1	0
11	Thrombopoietin and pain and radiation	0	0	0
12	Alternative and Thrombopoietin and pain and radiation	0	0	0
13	(b)(4) and pain	0	0	0
14	Alternative and (b)(4) and pain	0	0	0
15	(b)(4) and side effects	0	2	0
16	and toxicity	0	1	1
17	and pain and radiation	0	0	0

Summary of Results: No citations for pain were associated with exposure to ionizing radiation, the use of analgesia in conjunction with sub-lethal doses of ionizing radiation, or the use of analgesia in conjunction with (b)(4) in all of the searched databases. The use of (b)(4) was not associated with any reports of pain. GLP studies conducted in rats and canines show (b)(4) to be well tolerated and low toxicity even when administered at a high dose (300 mg/kg given *iv*) (b)(4),(b)(6)

(b)(4),(b)(6)

(b)(4),(b)(6)

(b)(4) The non-clinical safety studies of (b)(4) as well as the results from safety pharmacology, genetic and reproductive toxicology studies demonstrate that (b)(4) is safe and well tolerated with large safety margins for a clinical dose. No alternatives were cited as being a replacement for irradiation.

The literature search did not indicate specific alternatives to pain, other than, what is described below.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification:

Irradiated animals finally succumb due to a compromised immune response and microbial infections. In the event that there is pain and distress to animals, we will use antibiotics, analgesics, and antipyretic agent, food supplements, and oral electrolyte supplements in this study as minimal symptomatic supportive care to relieve pain and discomfort to the animals. Since we are not sure about the extent of pain by irradiation and to what we are able to relieve the pain, we decided to put all irradiated animals under category E.

V.4.2. Prolonged Restraint

Animals to be irradiated will be placed in restraint devices for irradiation in the cobalt facility. Animals will be sedated for this purpose as outlined in section V.4.1.2.1. Anesthesia/Analgesia/Tranquilization.

For blood collection, NHPs will be placed in a primate restraint chair. NHPs will not be left in the restraint chair for more than 1 hour.

V.4.3. Surgery

V.4.3.1. Pre-surgical Provisions: N/A

V.4.3.2. Procedure(s): N/A

V.4.3.3. Post-surgical Provisions: N/A

V.4.3.4. Location: N/A

V.4.3.5. Surgeon: N/A

V.4.3.6. Multiple Major Survival Operative Procedures:

V.4.3.6.1. Procedures: N/A

V.4.3.6.2 Scientific Justification: N/A

V.4.4. Animal Manipulations

V.4.4.1. Injections

Injections of test drug, vehicle (normal saline), and G-CSF will be performed with a sterile 21 - 25 gauge needle length of ¾-1". The site for injection will be prepared as a surgical site before the injection: hair will be clipped using # 40 surgical blade and the site will be scrubbed at least 3 times using either betadine or chlorhexidine and 70%

alcohol. Injections will be performed by appropriately trained staff listed in this protocol under section VI. Injections for ketamine, Telazol, Buprenorphine, Rimadyl, and antibiotics will be administered im with 22 - 25 gauge needle length of ¾-1". The injection volume for this will be 0.1 - 1.0 ml.

Sodium pentobarbital sodium will be used as outlined in section V.4.6 Euthanasia.

V.4.4.1.1. Pharmaceutical Grade Drugs

Pharmaceutical grade drugs (G-CSF, antibiotics, analgesics, anesthetics, and fluids) will be procured from the USUHS pharmacy or VSD pharmacy at the discretion of the veterinary staff.

V.4.4.1.2. Non-Pharmaceutical Grade Drugs

(b)(4) is a white to off-white powder with a molecular weight of 3,295 Daltons for the parent compound without polyethylene glycol (PEG) and approximately 43,295 Daltons with 2 PEG chains (MW ~20,000 Daltons each). (b)(4) is composed of 2 identical 14 chain amino acid peptide chains linked by a lysyl residue and linked on each N-terminal to a PEG chain. GLP toxicology studies were performed with (b)(4) (b)(4) which were accepted on the basis of the manufacturer's certificate of analysis and released for use in clinical studies.

(b)(4) comes from a batch of GMP grade drug substance that requires requalification for GMP use and has been stored at -20 °C under sterile conditions and has been tested for endotoxins. The batch of (b)(4) that will be used in this study comes from the same batch that showed significant survival benefits in the mouse studies conducted at AFRRI (Protocol (b)(6) Biopotency will be confirmed in the NHP PD study just prior to efficacy study. Appropriate safety precautions including osmomolarity and pH of final solutions will be in the range stipulated by IACUC Policy #9, non-Pharmaceutical Grade Experimental Drug Formulations to be Used in Experimental Animals. All procedures will be performed under sterile conditions.

V.4.4.2. Biosamples

Blood withdrawals will be carried out according to the schedules presented above and on necropsy. Blood will be collected from a peripheral vessel (saphenous or cephalic veins) rather than a femoral vein with a 21 - 25 gauge sterile needle length of ¾-1"attached to a 2 - 3 ml syringe, to reduce the chances of bleeding in irradiated animals. The femoral vein will be used if necessary for blood collection prior to euthanasia.

For aseptic collection for bacterial samples, the area surrounding the saphenous vein (dorsal region of the lower limb) will be swabbed three times with Providone-iodine. After each application of the Providone-iodine, the area will be wiped off with alcohol. Samples collected for other tests will only utilize alcohol swabs. The blood sample will be drawn as described above. While withdrawing the needle, pressure will be applied at the same time with a sterile bandage to reduce bleeding from the venipuncture site. While making regular routine observation of animals, the venipuncture site will be checked for bleeding. In the event the site becomes infected, topical triple antibiotics (bacitracin, neomycin, and polymyxin) or similar agent will be applied as needed.

Partial necropsies will be performed on all animals following euthanasia by pathology necropsy technicians and/or trained non-pathology personnel. The following tissues will be collected; brain, heart, lung, kidney, spleen, duodenum, jejunum, ileum, large intestine, bladder, and sternum will be collected.

V.4.4.3. Adjuvants: N/A

V.4.4.4. Monoclonal Antibody (MAb) Production: N/A

V.4.4.5. Animal Identification

Animals arrive tattooed and such tattoos will be used for identification. Additionally, cage tags or ID's written on cages with permanent markers are used for identification.

V.4.4.6. Behavioral Studies: No behavioral studies will be performed in this protocol.

V.4.4.7. Other Procedures

Transport plan: For whole body irradiation, the sedated animals will be placed in positioning aide devices and will be transported inside a cart to the High Level Gamma Radiation (HLGR) facility. HEPA filtered transport carts will be used for transportation of animals through common hallways/areas. At no time will the animals be removed from the restraint boxes while outside of the VSD vivarium. At least two personnel will accompany the animals. Additional ketamine may be administered as needed for chemical restraint (animals are not awake during irradiation), and to provide animal handling support. After irradiation, the NHPs in their restraint boxes will be removed from the irradiation platform, returned to the transport cart and returned to the vivarium.

V.4.4.8. Tissue Sharing: None

V.4.4.9. Animal By-Products

No animal by-products will be used in the proposed study.

V.4.5. Study Endpoint

The primary endpoint used in the efficacy study will be mortality. Moribundity will be used as a surrogate for mortality, and euthanasia will be used in order to minimize pain and distress. Necropsy and histopathological analysis will be performed on all euthanized animals. The following parameters will provide the guidelines for moribundity.

1. Weight loss: Significant weight loss (10%) from the baseline (NHPs will be weighed whenever the animal is placed on the restraint chair attached to the scale for blood collection),

2. Inappetance: Complete anorexia for 2 days with deteriorating conditions based on clinical examination,

3. Weakness/inability to obtain feed or water: Inability or extreme reluctance to stand which persists for 1 h,

4. Minimal or absence of response to stimuli (animal does not move when prodded),

5. Core body temperature: Below 96.6º F following a period of febrile neutropenia (such as >103º F and <500 neutrophils/ml),

6. Severe anemia: <13% hematocrit due to acute blood loss or <40 g/L hemoglobin (decision in consultation with AFRRI veterinarians),

7. Severe thrombocytopenia (<10,000 platelets/μl)

8. Other signs of severe organ system dysfunction with a poor prognosis as determined by a veterinarian:

8.1 Respiratory: any dyspnea or severe cyanosis.

8.2 Gastrointestinal: sustained vomiting or diarrhea, obstruction, intussusceptions; peritonitis (transient vomiting and diarrhea are expected results of whole-body gamma irradiation, therefore, as criteria for euthanasia, these symptoms should be severe and life-threatening per se, i.e., hemorrhagic diarrhea to the point of causing anemia as listed above or severe uncompensated dehydration).

8.3 Urogenital: renal failure based on clinical chemistry parameters (BUN, creatinine) and urinalysis (urine specific gravity).

8.4 Nervous: sustained CNS depression, seizures, paralysis of one or more extremities.

8.5 Integumentary: non-healing wounds, repeated self-trauma, severe skin infections, indicating severe organ system dysfunction with a poor prognosis.

When an animal reaches a state of moribundity (i.e. point of no return) the animal will be euthanized. Any single parameter listed under this section will not lead to euthanasia of the animal, unless in conjunction with the recommendation to euthanize by an AFRRI veterinarian. Moribundity status of the animal will be determined by a team effort between institutional veterinarian, principal investigator, research staff, veterinary technicians and husbandry staff based on the combination of criterions described above.

Surviving animals at the end of the study (60 d post-irradiation) will be euthanized for gross necropsy and tissue collection as described under section V.4.6. Histopathology of various organs will be conducted to study the effects of radiation and drug.

V.4.6. Euthanasia

Animals will be humanely euthanized using the most current American Veterinary Medical Association (2013 AVMA) guidelines. These animals will be given sodium pentobarbital sodium iv (saphenous or cephalic), needle size 20-25 gauge ¾-1" length, (100 mg/kg, 1 - 5 ml). Prior to pentobarbital sodium administration, the animal will be sedated using ketamine (5 - 15 mg/kg, im). Intra-cardiac administration will be performed if unable to administer pentobarbital sodium through peripheral veins. The animal will be deeply anesthetized by Isoflurane (1 - 5%) with O_2 at 1 - 4 liters per minute via mask before giving intra-cardiac injection. The animals will be euthanized only under the guidance of a staff veterinarian or a trained technician in consultation with the veterinarian if the animal becomes moribund. After pentobarbital sodium administration, the animals will be examined (heart auscultation and pulse) to confirm death.

V.5. Veterinary Care

V.5.1. Husbandry Considerations

All non-human primates will be housed individually in cages with at least 4.3 square feet of floor space per NHP in accordance with *The Guide for the Care and Use of Laboratory Animals*. In addition, every cage will be equipped with built in perches. Excreta and food waste will be removed from inside each indoor primary enclosure, once per day, to prevent the primates from becoming soiled, and to reduce disease hazards, insects, pests, and odors. Care will be exercised when washing the primary enclosure so that the animals remain dry at all times. Primary enclosures will be sanitized every two weeks. This period can be extended to four weeks for animals in the critical period. The secondary enclosure (room) will be sanitized once per month. Foraging boards as well as other enrichment devices will follow the same schedule as the primary enclosures of the primate.

Special care will be given to animals that have been irradiated as their natural immunity will be suppressed (more prone to infections). Irradiation boxes will be sanitized after every use or more often as needed.

V.5.1.1. Study Room: Study rooms will be assigned by VSD.

V.5.1.2. Special Husbandry Provisions: None

V.5.1.3. Exceptions: None

V.5.2. Veterinary Medical Care

V.5.2.1. Routine Veterinary Medical Care

All animals will be quarantined for 45 days prior to any experiment. For this study, NHPs will arrive at AFRRI after completing quarantine at supplier's facility. As per VSD SOP VS0202, Animal Health Rounds, veterinary staff will monitor all animals at least twice daily during morning and afternoon rounds. Any abnormalities will be reported immediately to the on-call veterinarian and PI/his staff. In addition, animals will be observed daily by this protocol's research staff. Any sick animal will be observed at least twice a day (early morning and late afternoon/night) by the research staff. When animals become ill or debilitated, a veterinarian will be contacted immediately to assess the animal and provide adequate/emergency care. If the animal becomes moribund, it will be euthanized as described in section V.4.6. Euthanasia.

V.5.2.2. Emergency Veterinary Medical Care

The on-call veterinary officer will be available via telephone 24 hours a day. The on-call roster is located outside the VSD conference room (Room # (b)(6) on the bulletin board and at the security watch desk. These procedures are in accordance with VSD SOPs.

V.5.3. Environmental Enrichment

V.5.3.1. Enrichment Strategy

In this study, all primates will receive regular enrichment IAW VSD SOP VS0226, Nonhuman Primate Environmental Enrichment. Enrichment provided will include sanitizable toys, contact with husbandry and research staff, and visualization of conspecifics. To facilitate the consumption of food post-irradiation, the primates may be provided with an array of drinking and food products that will heighten their interest. Such items will include kool-aid type drinks, jello and yogurt (as examples of soft type

foods), and bananas, sweet potatoes, and celery with peanut butter (as examples of harder type foods). This brief listing is not meant to exclude any drink or food product that will aid in the consumption of diet designated for the animals depending on clinical observations; monthly enrichment can be modified per the veterinarian.

V.5.3.2. Enrichment Restrictions

None

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING

NAME	DEGREE	TRAINING	DATE	PROCEDURES	YRS/MOS EXPERIENCE
(b)(6)				7 (off-hour observations)	(b)(6)
				1,3a,3b,3d,4,5,7 (off-hour observation)	
				1,3a, 3b, 3d,4,5,7 (off-hour observation)	
				1,7 (off-hour observations)	
				1, 3b, 5	
				7 (off-hour observations)	
				7 (off-hour observations)	
				7 (off-hour observations)	

Procedure and manipulation codes:
Code 1= Animal handling and euthanasia
Code 2= Surgery (aseptic technique) pre- and post-operative care
Code 3= Injections (3a–ip, 3b-sc, 3c-gavage, 3d-iv) - can say 3 if trained in all manipulations or add 3d-iv
Code 4= Blood collection under anesthesia (4a-cardiac, 4b-inferior vena cava)
Code 5= Tissue collection (after euthanasia) - doesn't need to be specific
Code 6 = Implantation (provide details)
Code 7 = Others - (provide protocol specific manipulations or procedures for e.g., retro-orbital bleeding, tail vein injection, or drug delivery)

Hands-on training for additional personnel will be provided by study staff designated as trainers by VSD or by VSD technicians using the animals and procedures described in the approved protocol. This will include pole and collar handling of NHPs as well as blood collection and injections. The IACUC will be provided with updated records as training is accomplished.

VII. BIOHAZARDS/SAFETY

There is no plan to use any potential biohazard. Standard laboratory safety precautions will be observed throughout this study.

VIII. ENCLOSURES

Form 310

X. ASSURANCES

Protocol Title: Evaluation of a promising countermeasure (b)(4) as a radiation mitigator in Rhesus macaque (*Macaca mulatta)*

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made every effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with a qualified individual who evaluated the experimental design with respect to the statistical analysis, and that the minimum number of animals needed for scientific validity will be used.

D. Biohazard / Safety: I have taken into consideration and made the proper coordinations regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R", namely, "Responsibility," which the DOD has embraced for implementing animal use alternatives where feasible and conducting humane and lawful research.

G. Scientific Review: This proposed animal use protocol has received appropriate peer scientific review and is consistent with good scientific research practice.

H. Painful Procedure(s): I (**AM**) / **AM NOT** (*circle one*) conducting biomedical experiments, which may potentially cause more than momentary or slight pain or distress to animals. If applicable, potential pain and/or distress (**WILL**) / **WILL NOT** (*circle one*) be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

I. NON-TECHNICAL SYNOPSIS

Due to increased terrorist activity and the dissemination of nuclear materials, the chances of military or civilian personnel being exposed to radiation from dirty bombs or improvised nuclear devices have risen dramatically in recent years. There are currently no FDA-approved drugs for use by the military or civilian populations for the prevention or treatment of whole body radiation-induced injury. At present, there is no effective treatment for acute radiation gastrointestinal syndrome and only one FDA approved treatment for hematopoietic syndrome, which can be used only after radiation exposure and requires close patient monitoring by a highly skilled medical team.

In an effort to identify suitable radiation countermeasures (agents given before or after radiation exposure that can prevent/treat injuries), many strategies have been investigated during the past several years. In order to develop future countermeasures, we need to develop the lethality curve for cobalt-60 γ-radiation with supportive care. This study will develop the lethality curve of γ-radiation before investigating any radiation countermeasure for efficacy.

II. BACKGROUND

II.1. Background

Although the search for radiation countermeasures for acute radiation syndrome (ARS) was initiated more than half a century ago, only one radiation countermeasure, granulocyte colony-stimulating factor (G-CSF), has been approved by the United States Food and Drug Administration (US FDA) for the ARS (b)(4) There is a need to develop additional radiation countermeasures for use by our military and civilians.

To achieve the goal of having suitable radiation countermeasures approved by the US FDA, we need to investigate radiation countermeasures against various subsyndromes of acute radiation syndrome such as hematopoietic and gastrointestinal subsyndromes. For this purpose, we need to determine the lethality curve of cobalt-60 γ-radiation for NHPs with supportive care. In the past, experiments have been performed for evaluation of different radiation countermeasures without any supportive care using historic or values from other institutions. Thus, we need to determine the lethality curve of our cobalt γ-radiation in a NHP model before proceeding to an efficacy study with any radiation countermeasure.

Summary of Results

No publications addressing the questions of this protocol were found. Above literature searches rule out any possibility of duplication.

III. OBJECTIVE / HYPOTHESIS

The long term objective of the present study is to investigate the beneficial effects of future radiation countermeasures as evaluated by significant increase in 60-day post-irradiation survival when the drug is administered post-irradiation (as a radiomitigator) in conjunction with supportive care (antibiotics, fluid, analgesics, blood products). The secondary objectives include studying hematopoietic recovery including neutrophil and platelet profiles, mean survival time (MST), incidence of febrile neutropenia, infection, and incidence/severity of diarrhea in NHPs.

To achieve these objectives, we need to determine the lethality curve of cobalt-60 γ-radiation for NHPs. In the past, experiments have been performed for evaluation of different radiation countermeasures without any supportive care using historic or values from other institutions. Lethality curve for cobalt-60 γ-radiation at our institute has not been determined, particularly with supportive care as mentioned above. Thus, we need to determine lethality curve of our institute cobalt-60 γ-radiation in a NHP model before proceeding to an efficacy study with the proposed radiation countermeasure. This lethality curve will be helpful in the future for investigating efficacy of radiation countermeasures against specific lethal doses of radiation.

IV. MILITARY RELEVANCE

Radiation-associated casualties, whether caused by acute injuries that occur soon after exposure or those resulting from chronic effects, or combined injury, have the potential to impact military operations in various ways. (a) Radiation-associated incapacitating events (such as nausea, vomiting, diarrhea) are some of the early hazards on exposure to lethal radiation. (b) Non-lethal low doses of radiation may not affect military operation immediately but can cause late life pathologies (cancer, pulmonary complications). (c) Lack of readily available radiation countermeasures may cause fear and panic among exposed individuals, and can severely impact the readiness for rescue operations. (d) The impact of chemical and biological weapons can be significantly enhanced by simultaneous exposure to radiological exposure. A non-lethal dose of radiation may become lethal upon simultaneous exposure to a chemical or biological agent or thermal burn.

The above concerns reinforce the urgent need to develop an appropriate modality to sustain the war-fighting capabilities of our military. Developing effective therapies for sepsis following lethal doses of ionizing radiation remains a challenge. The proposed study presents a novel approach to solve the problem of ARS. With the deployment of a radiation countermeasure, forces exposed to moderate to high doses of ionizing radiation, combined injury of radiation and blast/burn will demonstrate enhanced survivability, expanding the range of operable threat environments. The options available to our military will increase, and the morale of personnel at risk of radiation and combined injury exposures will significantly improve. Determination of lethality curve for AFRRI cobalt-60 γ-radiation with supportive care is a first step in this direction.

V. MATERIALS AND METHODS

V.1. Experimental Design and General Procedures

We propose to carry-out the following experiments to develop the lethality curve for cobalt-60 γ-radiation in NHPs with supportive care. After determining lethality curve, various LD values will be used to investigate the radiomitigative efficacy of identified radiation countermeasures in the future.

V.1.1. Experiment 1 . Establish lethality curve for AFRRI cobalt-60 γ-radiation in NHPs with supportive care

A recent publication extensively reviewing supportive care for NHPs exposed to radiation suggests that supportive care studies such as the one proposed in this protocol have been executed only to a limited extent [4]. In the publication cited above,

the $LD_{50/60}$ value and probit curve for supportive care has been provided using a 6 MV linear accelerator (LINAC). This study suggests a dose modifying factor of 1.13 for animals provided supportive care compared to animals receiving no supportive care. The radiation source and type of radiation exposure in the published report differ from the AFRRI cobalt-60 pool type facility. To the best of our knowledge, there is no published report for with cobalt-60 γ–radiation and supportive care. Though such study was initiated at AFRRI earlier, it was abandoned and thus, the proposed study still needs to be conducted.

Based on extensive discussion and modeling by the statistician of the sponsor of this study (b)(4) (see data analysis section and also annexure with the protocol for details), we propose to use 6 radiation doses (6.5, 7.0, 7.5, 8.0, 8.5, and 9.0 Gy) with 6 NHPs in each group (total 36 NHPs). Animals will be irradiated in groups of no more than 6 at a time, 1 or more weeks apart or at the discretion of the VSD & Cobalt schedules. Animals will be provided supportive care as described below and monitored for blood profile as stated in table 1. There will be 26 blood donor animals.

Table 1. Blood sample collection for lethality curve determination study

Time of blood draw in relation to irradiation	Blood		
	CBC 0.5 ml	Biochemistry 0.5 ml	Total blood ml
-7 d	+	+	1.0
-4 d	+	+	1.0
-1	+	+	1.0
Day 1 (24 h)	+		0.5
Day 2	+		0.5
Day 4	+		0.5
Day 6	+		0.5
Day 8	+		0.5
Day 10	+	+	1.0
Day 12	+		0.5
Day 14	+		0.5
Day 16	+		0.5
Day 18	+		0.5
Day 20	+	+	1.0
Day 22	+		0.5
Day 24	+		0.5
Day 26	+		0.5
Day 28	+	+	1.0
Day 30	+		0.5
Day 34	+		0.5
Day 38	+	+	1.0
Day 42	+		0.5
Day 50	+	+	1.0
Day 60	+	+	1.0

We will be well within the acceptable published blood collection volumes [5] that are followed at AFRRI. According to these guidelines 1% blood (2.8 ml per day for 4 kg NHP – the minimum body weight of this experiment) can be withdrawn every 24 h. Up

to 10% of circulating blood volume can be drawn in a single day repeated every 3-4 weeks. For the entire span of the study, the total blood drawn will be well below the recommended maximum limits [5] as outlined in section V.4.4.2 Biosamples.

Donor blood draw: A maximum of 12.5% of blood will be collected once every 30 days if needed in consultation with VSD veterinarians. Donor animals will get a CBC done prior to donation to confirm they do not have anemia.

Donor animals will be used for collecting blood for transfusion to recipients. The donor animals will not receive any agents before or after blood collection unless some health issue comes up for that individual donor during the course of this study.

A 4 kg recipient will need 40 ml of blood based on an average transfusion volume of 10 ml/kg (ranging 7 - 14 ml/kg). According to good practice guide [5], NHPs can donate 15% of total blood volume every four weeks. In this protocol, we have projected to take 12.5% upon veterinarian recommendation. A 6 kg donor animal, with a 336 ml blood volume (56 ml/kg), can donate 42 ml per transfusion. Based on radiation doses used in this study, we expect, on average, two transfusions for each recipient within a 4 wk period, thus, for each recipient we will need 2 donors. Following this logic, for 12 recipients we will need 24 donors.

We have projected 26 donors so that if two animals, for any reason are not able to donate the blood, our experiment will not suffer. If needy animals are not supplied with necessary blood, it will be a serious health issue and the study will be wasted.

We will be conducting this experiment in a manner that limits each donor to one donation during the experimental time frame. These donor animals will be used again as donors for future evaluations of countermeasure efficacy using a model of supportive care.

V.2. Data Analysis

A probit model will be used to establish the lethality curve for AFRRI cobalt-60 γ-radiation in NHPs with supportive care. A series of simulations (see attachment at the end of this protocol) indicates that a design with six different doses of radiation (6.5, 7.0, 7.5, 8.0, 8.5, and 9.0 Gy) and 6 animals in each group will be sufficient to estimate the LD_{30}, LD_{50} and LD_{70} to within 0.5 Gy of the true value 90% of the time. The simulations show that this design has greater precision than similar designs with more doses or a wider range of doses, and only marginally less precision than a design using 48 NHPs instead of 36.

For additional parameters (blood components and blood biochemistry), data mean values with standard errors (when applicable) will be reported. Independent samples *t*-tests or analysis of variance (ANOVA) will be used to detect if there are significant differences between experimental groups. All statistical tests will be two-sided, with a 5% significance level. Statistical software SPSS version 22 (IBM, Armonk, NY, USA) and GraphPad Prism 5 (GraphPad Software, Inc., La Jolla, CA, USA) will be used for analyses.

V.3. Laboratory Animals Required and Justification

V.3.1. Non-animal Alternatives Considered

Both computer models and tissue culture have been considered as alternatives to animals. These alternatives lack the knowledge base and complexity needed to evaluate the effects of radiation and radiation countermeasures on the immune system. The phenomena under study involve complex information-processing networks comprising large number of cell types and biological signal transduction molecules. Responses to irradiation and radioprotective agents involve interactions between the central nervous system, the peripheral nervous system including the enteric nervous system, endocrine glands, the immune and inflammatory systems, hematopoietic system, the GI system, etc. We do not know all of the cell types and tissues involved and many of the signal transduction molecules have not been discovered yet. Even if all of the tissues, cell types and signaling molecules were known, the present state of tissue culture would be incapable of reproducing *in vivo* relationships. One would have to reproduce much of an entire mammalian organism in culture to study these phenomena *in vitro*. As for computer models, the most powerful supercomputers available in the near future would be incapable of analyzing interactions between so many elements in the network. Thus, these drugs merit investigation in whole animal models to see the overall outcome.

V.3.2. Animal Model and Species Justification

Demonstrating efficacy of a countermeasure in a large animal species (LAS) is a critical requirement of the FDA Animal Rule. Rhesus macaque has 95+% DNA sequence identity with humans. NHPs are necessary for the pre-clinical development of a drug candidate intended for use in humans, because the drug metabolism and physiology are so similar between NHPs and humans. Rhesus macaques are the model of choice for investigations of toxicity, pharmacokinetics, biomarkers, radiation injury, and countermeasures, because of the large database available from the existing literature. The FDA has accepted Rhesus macaques as the appropriate animal model for pivotal efficacy testing of radiation countermeasures under the Animal Efficacy Rule, where efficacy testing cannot be performed in humans. Our ultimate goal is to generate data which will be submitted to US FDA and our data should be acceptable to them for approval of the radiation countermeasure. The use of pig (specifically Gottingen minipig) is currently under the initial stage of development for studying radiation injury. This model is not well defined and mature enough to evaluate radiation countermeasures. The minipig model has not reached that stage of acceptance yet in the scientific research community (b)(4) Therefore, this study in the rhesus macaque is being undertaken to guide future development of this class of radiation countermeasures. There are several reports for use of NHPs in radiation research and countermeasure development [9-12].

V.3.3. Laboratory Animals

V.3.3.1. Genus / Species

Rhesus macaques (*Macaca mulatta*)

V.3.3.2. Strain / Stock

Chinese or Indian origin

V.3.3.3. Source / Vendor

Animals will be procured from vendors registered with the USDA or DoD.

V.3.3.4. Age: 3 to 7 years

V.3.3.5. Weight: 4 to 12 kg

V.3.3.6. Sex: Male and Female

V.3.3.7. Special Considerations

Animals should test antibody negative for Herpes B virus (aka *Macacine herpesvirus 1*), Simian T-cell leukemia virus type 1 (STLV-1), Simian Immunodeficiency virus (SIV) and Simian Retrovirus (SRV) Types 1, 2, 3, and 5. Animals shall also test negative by means of virus isolation or polymerase chain reaction (PCR) for SRV Type 2. NHPs will either be vaccinated for measles or, in the case of previously measles-vaccinated NHPs, tested for the presence of measles antibodies. NHPs shall come from the vendor colony negative for *Salmonella, Shigella* and *Yersinia*. Vendor must provide the health reports indicating the pathogen free status of the NHPs for the agents listed in this section. The animals will be pole and collar trained by the vendor before their use in above experiment.

V.3.4. Number of Animals Required (by species): 62 Rhesus macaque (*Macaca mulatta)*

V.3.5. Refinement, Reduction, Replacement (3 R's)

V.3.5.1. Refinement

For efficacy studies, the endpoint currently mandated by the FDA for approval of radiation countermeasures is mortality. Moribundity will be used as a surrogate for mortality, and euthanasia will be used in order to minimize pain and distress, using an extensive set of criteria (listed under section V.4.5, Study Endpoint). The actual irradiation procedure does not cause pain or distress. Animal care and use procedures will only be performed by trained and certified personnel.

V.3.5.2. Reduction

As we move forward with experiments, plans will be reevaluated at every stage of the experiments, in light of incoming data in an attempt to reduce the numbers of experiments and groups, if possible. If deemed not necessary based on incoming data, some investigations may not be carried out to optimize the use of experimental animals. The simulations show that our experimental design has greater precision than similar designs with more doses or a wider range of doses, and only marginally less precision than a design using 48 NHPs instead of 36.The donor animals will be reused in future study for PK/PD of any drug or donor in experiment evaluating countermeasure for efficacy study with any drug.

V.3.5.3. Replacement

There are no *in vitro* techniques available to demonstrate that any drug will counter the effects of whole-body irradiation in humans. The preferred large animal model for preclinical evaluation of radiation countermeasures intended for use in humans is NHPs. This study represents the next step necessary to develop a drug for FDA approval. According to US FDA scientists and the radiobiology community, the large database of radiation studies in *Macaca mulatta* makes this the most useful large animal model to evaluate interactions of radiation injury and drugs intended for use in humans.

V.4. Technical Methods

V.4.1. Pain / Distress Assessment

V.4.1.1. APHIS Form 7023 Information

V.4.1.1.1. Number of Animals:

V.4.1.1.1.1. Column C 0 (# of animals)

V.4.1.1.1.2. Column D 26 (# of animals)

V.4.1.1.1.3. Column E 36 (# of animals)

V.4.1.1.1.4. Pain Category Assignments

Exp. #	Experimental/Control Group	C	D	E	Totals
Expt 1	Lethality curve - six radiation doses with 6 NHPs each i.e. 36 recipients			36	36
Expt 1	Donors - 26		26		26
Totals:			26	36	62

V.4.1.2. Pain Relief / Prevention

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization

As mentioned under section 'V.4.4.7. Other Procedures, animals will be sedated with ketamine (5 -15 mg/kg, im, 22 - 25 G needle length of ¾-1") or Telazol (2 - 5 mg/kg, im, 22 - 25 G needle length of ¾-1") to place in restraint box for transporting to cobalt facility.

Monitoring of Sedated NHPs: During procedures which require short duration of anesthesia, but which the animal is un-restrained (such as blood tranfusions), anesthetic monitoring will be achieved through use of anesthetic monitors which will include the minimum of SpO2 % and heart rate measurement. Visual assessment of respiratory rate will be conducted during the procedure. Other measurements such as ECG, EtCO2, and blood pressure will be used as available and circumstances allow. The animal will be sedated with an im injectable agent as described in V.4.1.2.1 and checked for appropriate sedation by signs of prostration, limb flaccidity, and lack of palpebral reflex. Once these signs are achieved, the animal is removed from the cage and transported to a warmed table in the treatment room and maintained on 1 - 5% (more commonly 2 - 3%) isoflurane delivered through face mask with 1 L/min of 100% oxygen. The dose of isoflurane will be subjectively determined by the technician or veterinarian based on any signs of alertness or increased heart & respiratory rate (above approximately 150-160 bpm and 40 rpm, respectively).

After sedating animal for transport to the cobalt facility, the animal is checked for appropriate sedation by signs of prostration, limb flaccidity, and lack of palpebral reflex. Once these signs are achieved, the animal is removed from the cage and placed in the restraint box and subsequently the HEPA transport cart. The transport cart has a Plexiglas window to observe the NHP during transport and staging prior irradiation. Signs of increasing alertness such as yawning, extremity movement, and blinking will necessitate an anesthetic "bump" which may be administered within the box. This dose will be subjectively determined by technician or veterinarian based on extent of alertness and will be equivalent to approximately ¼ dose to the full dose originally

given to the NHP. Once transported from cobalt back to the home cage, NHPs are placed in their cages and monitored visually until fully awake, alert, and ambulatory.

Analgesics and non-steroidal anti-inflammatory drugs: Buprenorphine SR (0.12 – 0.02 mg/kg, sc, 22 - 25 G needle length of ¾-1", lasting for 3 days) will be administered when there is signs of pain. Rimadyl (Carprofen 15 mg/tab, BID, po or injectable 50 mg/ml; 1 – 5 mg/kg/dose, BID, sc, 22 - 25 G needle length of ¾-1") can be administered as an alternative to buprenorphine when evidence of pain is still present.

V.4.1.2.2. Pre- and Post-procedural Provisions

Animals will be observed for signs of pain and distress by either the veterinary or research staff at least twice daily. After specialized procedures, NHPs will be monitored at least twice daily for signs of complications. Study staff will adhere to IACUC Policy #10, Guidelines for Establishment of Early Endpoints in Experiments with Expected Mortality during the critical period and with additional checks (maximum 10 h between two checks).

V.4.1.2.3. Paralytics No paralytic agent will be used in this study.

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures

V.4.1.3.1. Sources Searched

Stem cells and pain and radiation	45	46	100
Pain and primate and radiation	7	6	4

The literature search did not indicate specific alternatives to pain, other than, what is described below.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification: N/A

Irradiated animals experience symptoms of Acute Radiation Syndrome (ARS) due to a compromised immune response and potential microbial infections. In the event that there is pain and distress to animals, we will administer therapies as described previously to provide symptomatic supportive care to relieve pain and discomfort to the animals. Since we are not sure about the extent of pain by irradiation and the potential for pain or distress to persist despite intervention, we decided to put all irradiated animals under category E.

V.4.2. Prolonged Restraint

Animals to be irradiated will be placed in restraint devices for irradiation in the cobalt facility. Animals will be sedated for this purpose as outlined in section V.4.1.2.1. Anesthesia/Analgesia/Tranquilization.

For blood collection, NHPs will be placed in a primate restraint chair. NHPs will not be left in the restraint chair for more than 1 hour.

Animals are acclimated to restraint chair before any procedure. This training starts with vendor before NHPs are sent to our quarantine facility at Poolesville and continued during the acclimatization period at AFRRI. NHPs do not need training for the irradiation procedure's radiation box, as they are sedated throughout the procedure to minimize movement and stress of the animal.

Simple blood draw takes significantly less time than an hour, however, while restrained we take vital sign measurements, do a thorough evaluation of the animals overall health, clean any wounds and provide any other treatment the NHPs may need. Most of the time, it will be less than one hour. Only when a veterinarian examination is requested, NHPs may be in the chair for a maximum of an hour.

V.4.3. Surgery

V.4.3.1. Pre-surgical Provisions: N/A

V.4.3.2. Procedure(s): N/A

V.4.3.3. Post-surgical Provisions: N/A

V.4.3.4. Location: N/A

V.4.3.5. Surgeon: N/A

V.4.3.6. Multiple Major Survival Operative Procedures:

V.4.3.6.1. Procedures: N/A

V.4.3.6.2 Scientific Justification: N/A

V.4.4. Animal Manipulations

V.4.4.1. Injections

Injections will be performed by appropriately trained staff listed in this protocol under section VI, Study Personnel Qualifications and Training. Injections will be performed by appropriately trained staff listed in this protocol under section VI. Injections for ketamine, Telazol, Buprenorphine, and Rimadyl will be administered as

outlined in section V.4.1.2.1 Anesthesia/Analgesia/Tranquilization. Antibiotics will be administered iv, im or sc as outlined in section V.4.4.7 Other Procedures using a 22 - 25 gauge needle length of ¾-1". The injection volume for this will be 0.1 - 1.0 ml. Lactated Ringers Solution and Anti-emetics will be administered as outlined in section V.4.4.7 Other Procedures using a 22 - 25 gauge needle length of ¾-1". Sodium pentobarbital sodium will be used as outlined in section V.4.6 Euthanasia.

V.4.4.1.1. Pharmaceutical Grade Drugs

Pharmaceutical grade drugs (antibiotics, analgesics, anesthetics, and fluids) will be procured from the USUHS pharmacy or VSD pharmacy at the discretion of the veterinary staff.

V.4.4.1.2. Non-Pharmaceutical Grade Drugs

V.4.4.2. Biosamples

Blood withdrawals will be carried out according to the schedules presented above and on necropsy. Blood will be collected from a peripheral vessel (saphenous or cephalic veins) rather than a femoral vein with a 21 - 25 gauge sterile needle length of ¾-1"attached to a 2 - 3 ml syringe, to reduce the chances of bleeding in irradiated animals. The femoral vein will be used if necessary for blood collection prior to euthanasia.

For aseptic collection for bacterial samples, the area surrounding the saphenous vein (dorsal region of the lower limb) will be swabbed three times with Providone-iodine. After each application of the Providone-iodine, the area will be wiped off with alcohol. Samples collected for other tests will only utilize alcohol swabs. The blood sample will be drawn as described above. While withdrawing the needle, pressure will be applied at the same time with a sterile bandage to reduce bleeding from the venipuncture site. While making regular routine observation of animals, the venipuncture site will be checked for bleeding. In the event the site becomes infected, topical triple antibiotics (bacitracin, neomycin, and polymyxin) or similar agent will be applied as needed.

Partial necropsies will be performed on all animals following euthanasia by pathology necropsy technicians and/or trained non-pathology personnel. The following tissues will be collected; brain, heart, lung, kidney, spleen, duodenum, jejunum, ileum, large intestine, bladder, and sternum will be collected. An outside laboratory (Histoserv) will process the tissue and mount on slides for the VSD pathologist to read. The VSD pathologist will review the gross necropsy observations.

V.4.4.3. Adjuvants: N/A

V.4.4.4. Monoclonal Antibody (MAb) Production: N/A

V.4.4.5. Animal Identification

Animals arrive tattooed and such tattoos will be used for identification. Additionally, cage tags or ID's written on cages with permanent markers are used for identification.

V.4.4.6. Behavioral Studies: No behavioral studies will be performed in this protocol.

V.4.4.7. Other Procedures

As mentioned under section 'V.4.1.2.1. Anesthesia/Analgesia/Tranquilization', animals will be sedated with ketamine or Telazol to place in restraint box for transporting to cobalt facility.

Transport plan: For whole body irradiation, the sedated animals will be placed in positioning aide devices and will be transported inside a cart to the High Level Gamma Radiation (HLGR) facility. HEPA filtered transport carts will be used for transportation of animals through common hallways/areas. At no time will the animals be removed from the restraint boxes while outside of the VSD vivarium. At least two personnel will accompany the animals. Additional ketamine may be administered as needed for chemical restraint (animals are not awake during irradiation), and to provide animal handling support. After irradiation, the NHPs in their restraint boxes will be removed from the irradiation platform, returned to the transport cart and returned to the vivarium.

Microchips: These are inserted under ketamine anesthesia after animals clear the quarantine period. The chips are used to monitor body temperature and are pre-loaded in a specially designed needle/syringe device that is inserted subcutaneously between the shoulder blades. Once the chip is placed, the needle is withdrawn and the skin is pinched between 2 fingers for about 10 - 20 seconds to ensure that the chip itself (about the size of a grain of rice) does not dislodge out through the punctured site. If a chip fails, a second chip will be inserted. If necessary, a drop of surgical glue will be placed at the punctured site to ensure that the chip stays in place.

Supportive Care: Antibiotics will be initiated if the absolute neutrophil count (ANC) is< 500 cells/µl and will continue until the NHP ANC reaches >500 cells/µl. The primary antibiotic will be enrofloxacin (Baytril® Bayer HealthCare LLC, Shawnee Mission, KS). The dose will be 5 +/- 0.25 mg/kg administered intramuscularly (im) or subcutaneously (sc) twice a day (BID); or 10 +/- 0.5 mg/kg administered im or iv once daily (QD). If the body temperature is > 103 ºF, ceftiofur (5 mg/kg, sc - lasts 2 days or 20 mg/kg – lasts 7 days) or gentamicin sulfate (GentaMax®, Phoenix Scientific, Inc.) (5 mg/kg, im or iv, QD) will be administered in combination with Baytril, and this treatment will continue for 24 h. If high fever persists, ceftriaxone (Rocephin®, Roche Laboratories Inc., Nutley, NJ) (50 mg/kg, im, every 24 h) will be administered after gentamicin sulfate is discontinued or if microbial resistance is demonstrated to enrofloxacin or gentamicin. If microbial resistance is demonstrated to enrofloxacin, gentamicin and ceftriaxone, an alternative antibiotic to be used under such situation will be clindamycin, 12.5 mg/kg, administered im every 8 h. For this purpose, a bacterial sensitivity culture may be arranged by Veterinary Science Department.

Additional supportive care details: Additional supportive care therapies may be given upon the descretion of an AFRRI veterinarian.

Table. Summary of plan for medical management and medication use

Drug class	Allowed medication or supportive care agents	Indication and/or criterion for administration

Parenteral fluids	Equal volume of Lactated Ringer's Solution (LRS) and LRS with 5% Dextrose; each at 5 ± 2.5 mL/kg body weight via slow IV push; twice daily depending on extent of dehydration; or LRS at 40 ± 5 mL/kg body weight by IV drip over 2 hrs. Fluid administration rates and amounts may be changed at the discretion of AFRRI veterinarian. Pedialyte or Gastrolyte orally 15 ± 5 mL/kg of body weight Bottles containing diluted fruit juice or oral rehydration solutions (Prang™, Bio-Serv)	**Dehydration:** • Mild to moderate dehydration: Ringer's lactate and Ringer's lactate with 5% dextrose via slow IV push. • Severe dehydration: Ringer's lactate by IV drip. • Pedialyte® or Gastrolyte® or similar commercial solutions containing sodium, potassium, and glucose may also be used if IV access is difficult or precluded. **Fever (temperature ≥103 °F)**
Anti-diarrheal	Loperamide hydrochloride (Imodium), Initial dose 0.04 mg/kg QD Diphenoxylate HCl/atropine sulfate (Lomotil), 0.1 mg/kg, (2.5 mg/tablet) will be administered BID, PO. The 2.5 mg tablet first will be dissolved in 5 mL of tap water. Then, 1 mL of the Lomotil solution (0.5 mg/mL) will be added to 5–10 mL tap water, with OralLRS solution or liquid nutrition for 3 days.	**Diarrhea:** • At the first sign of soft to loose stools: Imodium will be administered up to twice daily and should continue for 3 days. It may be stopped earlier than 3 days if the diarrhea resolves. • Severe (diarrhea or if Imodium has been administered for 3 days): Lomotil, up to BID, PO for 3 days. It may be stopped earlier than 3 days if the diarrhea resolves. If the diarrhea does not resolve, the Imodium treatment will be repeated.
Anti-ulcer	Sucralfate (Carafate) 1 g/day, (0.5 g BID) daily from days 5 – 30, PO	For treatment of possible ulcers of the stomach or proximal small intestine
Anti-emetics	Ondansetron (1-2 mg/kg), IM, IV or PO 25-90 minutes prior to irradiation and 30-45 minutes following irradiation to suppress emesis or Granisetron (0.25 mg/kg), PO or IV	• Administered pre-and post-radiation to suppress emesis

Blood products	Whole blood or packed red blood cells will be obtained from a commercial source or obtained from donor animals and blood product irradiated @ 2500 cGy with a source in (b)(4) prior to transfusion Whole blood at 7 – 14 mL/kg or Packed red blood cells (RBC). Note: Repeat blood collection from donor animals will be defined on the total volume collected each time, recovery period and other criteria as described by Diehl et al 2001[5]. A maximum of 12.5% of blood will be collected once every 30 days if needed. Donor animals will get a CBC done prior to donation to confirm they do not have anemia – per consultation with veterinarian.	Whole blood will be transfused if: • PLT counts are <20,000/µL and hemoglobin (Hgb) <7 g/dL or hematocrit (Hct) <20%; • An animal experiences a 5-unit decrease in Hct in a 24-hour period that results in an Hct of ≤ 25%; • An animal that has previously received a transfusion demonstrates continued evidence of bleeding, such as bloody stools and/or any decrease in Hct relative to the most recent result obtained; or • If there is obvious evidence of uncontrolled hemorrhage. • An animal experiences a 7-10 unit decrease in Hct in a 24-hour period; or • An animal's Hct is ≤ 25% for 2 consecutive days and PLT counts are <3,000/µL. Packed RBCs will be administered in preference to whole blood when PLT counts are satisfactory (≥100,000/µL with no clinical bleeding) but the Hgb or Hct remain low (Hgb <7 g/dL or Hct <20 g/dL). • PLT counts are satisfactory (≥100,000/µL with no clinical bleeding) but the Hgb or Hct remain low (Hgb <7 g/dL or Hc <20 g/dL).
Nutritional Support	BIO-SERV Rhesus Liquidiets To facilitate the consumption of food post-irradiation, the primates may be provided with an array of drinking and food products that will heighten their interest. Such items will include kool-aid type drinks, jello and yogurt (as examples of soft type foods), and bananas, sweet potatoes, and celery with peanut butter (as examples of harder type foods). This brief listing is not meant to exclude any drink or food product that will aid in the consumption of diet designated for the animals.	**Weight Loss (Anorexia):** Nutritional support may be administered via oral gastric tube when body weight is <85% of baseline and will be continued as long as the body weigh remains <85% of baseline, and the animal is not eating. In the case where an animal loses its ability to regain weight following irradiation despite actively eating and drinking, nutritional supplementation via oral gastric tube may be foregone in order to avoid daily anesthesia.

V.4.4.8. Tissue Sharing: Brain tissue will be shared with (b)(6) (b)(6) at part of his genome project.

V.4.4.9. Animal By-Products:

Whole blood anti-coagulated with 10% citrate, dextrose phosphate with adenine obtained from healthy animals will be used. The blood will be irradiated prior to use.

V.4.5. Study Endpoint

The primary endpoint used in this study will be mortality. This study is to determine the lethality of ^{60}Co-gamma-radiation using probit curve with various doses of radiation. Such lethality curve is required to know the exact dose for radiation for various levels of lethality (e.g. LD_{30}, LD_{50}, LD_{70}, LD_{90} etc.). Based on lethality estimation in this study, different doses of radiation will be used for evaluating efficacy of radiation countermeasures in future studies. Such lethality information is required for evaluating efficacy against hematopoietic syndrome (LD_{30} or LD_{50}) or gastrointestinal syndrome (LD_{70} or LD_{90}). To develop radiation countermeasures for US Food and Drug Administration approval, one needs to demonstrate that drug significantly increases survival in animals compared to placebo. To demonstrate increase in survivors, end point needs to be mortality. In this study, we are establishing animal model with full supportive care for a future radiation countermeasure study.

Two previous publications have been provided below which have used mortality as an endpoint for studying efficacy of two radiation countermeasures for US Food and Drug Administration approval. Neupogen [9] and Neulasta [13] received US Food and Drug Administration approval based on studies using mortality as an endpoint.

Moribundity will be used as a surrogate for mortality, and euthanasia will be used in order to minimize pain and distress. Necropsy and histopathological analysis will be performed on all euthanized animals. The following parameters will provide the guidelines for moribundity.

1. Weight loss: Significant weight loss (10%) from the baseline (NHPs will be weighed whenever the animal is placed on the restraint chair attached to the scale for blood collection),

2. Inappetance: Complete anorexia for 2 days with deteriorating conditions based on clinical examination,

3. Weakness/inability to obtain feed or water: Inability or extreme reluctance to stand which persists for 1 h,

4. Minimal or absence of response to stimuli (animal does not move when prodded),

5. Core body temperature: Below 96.6º F following a period of febrile neutropenia (such as >103º F and <500 neutrophils/ml),

6. Severe anemia: <13% hematocrit due to acute blood loss or <40 g/L hemoglobin (decision in consultation with AFRRI veterinarians),

7. Severe thrombocytopenia (<10,000 platelets/μl)

8. Other signs of severe organ system dysfunction with a poor prognosis as determined by a veterinarian:

8.1 Respiratory: any dyspnea or severe cyanosis.

8.2 Gastrointestinal: sustained vomiting or diarrhea, obstruction, intussusceptions; peritonitis (transient vomiting and diarrhea are expected results of whole-body gamma irradiation, therefore, as criteria for euthanasia, these symptoms should

be severe and life-threatening per se, i.e., hemorrhagic diarrhea to the point of causing anemia as listed above or severe uncompensated dehydration).

8.3 Urogenital: renal failure based on clinical chemistry parameters (BUN, creatinine) and urinalysis (urine specific gravity).

8.4 Nervous: sustained CNS depression, seizures, paralysis of one or more extremities.

8.5 Integumentary: non-healing wounds, repeated self-trauma, severe skin infections, indicating severe organ system dysfunction with a poor prognosis.

When an animal reaches a state of moribundity (i.e. point of no return) the animal will be euthanized. Any single parameter listed under this section will not lead to euthanasia of the animal, unless in conjunction with the recommendation to euthanize by an AFRRI veterinarian. Moribundity status of the animal will be determined by a team effort between institutional veterinarian, principal investigator, research staff, veterinary technicians and husbandry staff based on the combination of criterions described above.

This full supportive care study includes the administration of anesthetics and analgesics. If the animal reaches a point where it is appears to be in excessive pain, despite the administration of analgesics and other therapeutics, a decision to euthanize will be made in consultation with institute veterinarian.

Surviving animals at the end of the study (60 d post-irradiation) will be euthanized for necropsy and tissue collection as described under section V.4.4.2 Biosamples.

V.4.6. Euthanasia

Animals will be humanely euthanized using the most current American Veterinary Medical Association (2013 AVMA) guidelines. These animals will be given pentobarbital sodium iv (saphenous or cephalic), needle size 20-25 gauge ¾-1" length, (100 mg/kg, 1 - 5 ml). Prior to pentobarbital sodium administration, animal will be sedated using ketamine (5 - 15 mg/kg, im). Intra-cardiac administration will be performed if unable to administer pentobarbital sodium through peripheral veins. The animal will be deeply anesthetized by Isoflurane (1 - 5%) with O_2 at 1 - 4 liters per minute via mask before giving intra-cardiac injection. The animals will be euthanized only under the guidance of a staff veterinarian or a trained technician in consultation with the veterinarian. After pentobarbital sodium administration, the animals will be examined (heart auscultation and pulse) to confirm death.

V.5. Veterinary Care

Animal procedures performed at AFRRI will be in compliance with the *Animal Welfare Act* and the *Guide for the Care and Use of Laboratory Animals.* The AFRRI facility is accredited by Association for Assessment and Accreditation of Laboratory of Animal Care (AAALAC)-International.

V.5.1. Husbandry Considerations

All non-human primates will be housed individually in cages with at least 4.3 square feet of floor space per NHP in accordance with The *Guide for the Care and Use of Laboratory Animals*. In addition, every cage will be equipped with built in perches. Excreta and food waste will be removed from inside each indoor primary enclosure,

once per day, to prevent the primates from becoming soiled, and to reduce disease hazards, insects, pests, and odors. Care will be exercised when washing the primary enclosure so that the animals remain dry at all times. Primary enclosures will be sanitized every two weeks, or longer if it is necessary to decrease stress to the animals during the critical period (displaying clinical signs and symptoms related to acute radiation syndrome). The secondary enclosure (room) will be sanitized once per month. Foraging boards as well as other enrichment devices will follow the same schedule as the primary enclosures of the primate.

Special care will be given to animals that have been irradiated as their natural immunity will be suppressed (more prone to infections). Irradiation boxes will be sanitized after every use or more often as needed.

V.5.1.1. Study Room: Study rooms will be assigned by VSD.

V.5.1.2. Special Husbandry Provisions: None

V.5.1.3. Exceptions: None

V.5.2. Veterinary Medical Care

V.5.2.1. Routine Veterinary Medical Care

All animals will be quarantined for 45 days prior to any experiment. For this study, NHPs will arrive at AFRRI after completing quarantine at supplier's facility. As per Standard Operating Procedures, investigator staff will monitor all animals at least twice daily during morning and afternoon rounds. Any abnormalities will be reported immediately to the on-call veterinarian and PI or PI's staff. In addition, animals will be observed daily by this protocol's research staff. Any sick animal will be observed at least twice a day (early morning and late afternoon/night) by the research staff. When animals become ill or debilitated, a veterinarian will be contacted immediately to assess the animal and provide adequate/emergency care. If the animal becomes moribund, it will be euthanized as outlined in section V.4.6 Euthanasia.

V.5.2.2. Emergency Veterinary Medical Care

The on-call veterinary officer will be available via telephone 24 hours a day. The on-call roster is located outside the VSD conference room (Room (b)(6) on the bulletin board and at the security watch desk. These procedures are in accordance with VSD SOPs.

V.5.3. Environmental Enrichment

V.5.3.1. Enrichment Strategy

In this study, all primates will receive regular enrichment IAW VSD SOP VS0226, Nonhuman Primate Environmental Enrichment. Enrichment provided will include sanitizable toys, contact with husbandry and research staff, and visualization of conspecifics. To facilitate the consumption of food post-irradiation, the primates may be provided with an array of drinking and food products that will heighten their interest. Such items will include kool-aid type drinks, jello and yogurt (as examples of soft type foods), and bananas, sweet potatoes, and celery with peanut butter (as examples of harder type foods). This brief listing is not meant to exclude any drink or food product that will aid in the consumption of diet designated for the animals depending on clinical observations; monthly enrichment can be modified per the veterinarian.

V.5.3.2. Enrichment Restrictions

None

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING

NAME	DEGREE	TRAINING	DATE	PROCEDURES	YRS/MOS EXPERIENCE
(b)(6)				7 (off-hour observation)	(b)(6)
				1,3a,3b,3d,4,5,7 (off-hour observation)	
				1,3a,3b,3d,4,5,7 (off-hour observation)	
				1,7 (off-hour observations)	
				1, 3b, 5	
				7 (off-hour observations)	
				7 (off-hour observations)	
				7 (off-hour observations)	

Procedure and manipulation codes:
Code 1= Animal handling and euthanasia
Code 2= Surgery (aseptic technique) pre- and post-operative care
Code 3= Injections (3a–ip, 3b-sc, 3c-gavage) - can say 3 if trained in all manipulations or add 3d-iv
Code 4= Blood collection under anesthesia (4a-cardiac, 4b-inferior vena cava)
Code 5= Tissue collection (after euthanasia) - doesn't need to be specific
Code 6 = Implantation (provide details)
Code 7 = Others - (provide protocol specific manipulations or procedures for e.g., retro-orbital bleeding, tail vein injection, or drug delivery)

Hands-on training for additional personnel will be provided by study staff designated as trainers by VSD or by VSD technicians using the animals and procedures described in the approved protocol. This will include pole and collar handling of NHPs as well as blood collection and donation, gavage, and injections. The IACUC will be provided with updated records as training is accomplished.

VII. BIOHAZARDS/SAFETY

There is no plan to use any potential biohazard. Standard laboratory safety precautions will be observed throughout this study.

VIII. ENCLOSURES

Form 310

X. ASSURANCES

Protocol Title: Development of a lethality curve with supportive care in the Rhesus macaque (*Macaca mulatta)*

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made every effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with a qualified individual who evaluated the experimental design with respect to the statistical analysis, and that the minimum number of animals needed for scientific validity will be used.

D. Biohazard / Safety: I have taken into consideration and made the proper coordinations regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R", namely, "Responsibility," which the DOD has embraced for implementing animal use alternatives where feasible and conducting humane and lawful research.

G. Scientific Review: This proposed animal use protocol has received appropriate peer scientific review and is consistent with good scientific research practice.

H. Painful Procedure(s): (**I AM**) **AM NOT** (*circle one*) conducting biomedical experiments, which may potentially cause more than momentary or slight pain or distress to animals. If applicable, potential pain and/or distress (**WILL**) **WILL NOT** (*circle one*) be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

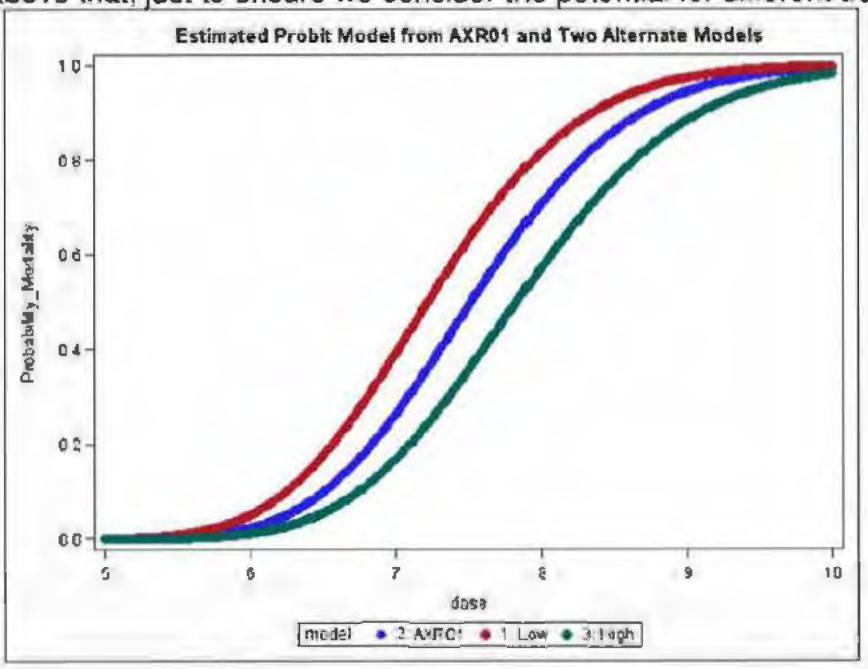
Dear Team,
After our meeting on 10/2/2015, we considered some refinements to the simulations to evaluate the impact of sample size and dosing schedule on the estimation of LD30, LD50, and LD70. Based on the feedback, I estimated the middle 90% of estimates for LD30, LD50, and LD70 in each scenario. Designs with narrower ranges of estimates in my simulations will tend to provide more precise estimates.
I evaluated 4 dosing regimens and 2 total sample sizes (for a total of 8 designs). This evaluation was done for each of three models: a model consistent with AXR01 data, a model with lower lethality curve, and one with higher, to ensure that the results will be robust across a range of possible true curves:

- 4 dosing regimens
  - 8 doses spread uniformly from 6 to 9.5 (6, 6.5, 7, 7.5, 8, 8.5, 9, 9.5)
  - 8 doses spread uniformly from 6.5 to 9 (6.5, 6.86, 7.21,7.57, 7.93, 8.29, 8.64, 9)
  - 6 doses spread uniformly from 6 to 9.5 (6, 6.7, 7.4, 8.1, 8.8, 9.5)
  - 6 doses spread uniformly from 6.5 to 9 (6.5, 7, 7.5, 8, 8.5, 9)
- 36 total animals versus 48 total

Bottom Line: The dosing regimen highlighted above provided the most precise estimates of LD30, LD50, and LD70, regardless of which the three models was true. The advantage of this dosing regimen was relatively modest, but it is the clear winner (because there is no trade-off that I know of). The advantage of using 48 total animals versus 36 was also relatively modest; the sample size decision requires a judgement as it is a trade-off of increased efficiency versus the total cost.
I considered three possible true mortality curves (as shown below) – where the blue curve represents the model from the AXR01 data, and the other curves represent shifts below and above that, just to ensure we consider the potential for different true models



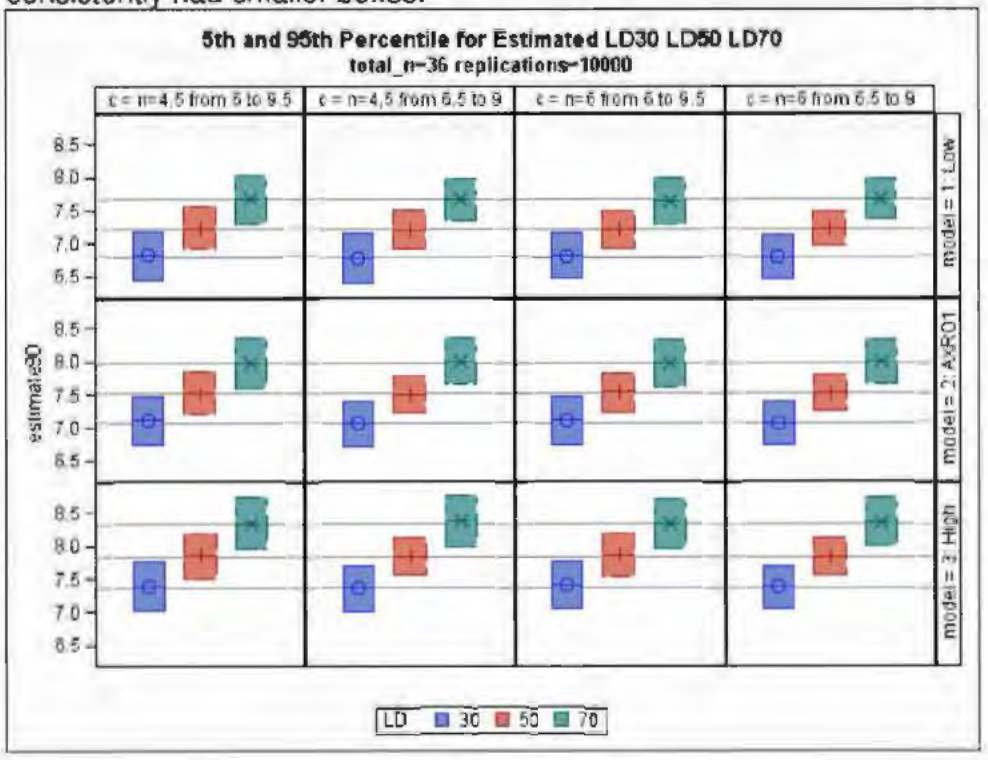
For each of these models, I evaluated 8 different designs. I varied doses (6 or 8), the range of the doses (6 to 9.5 or 6.5 to 9), and the total number of animals studied (36 or 48).

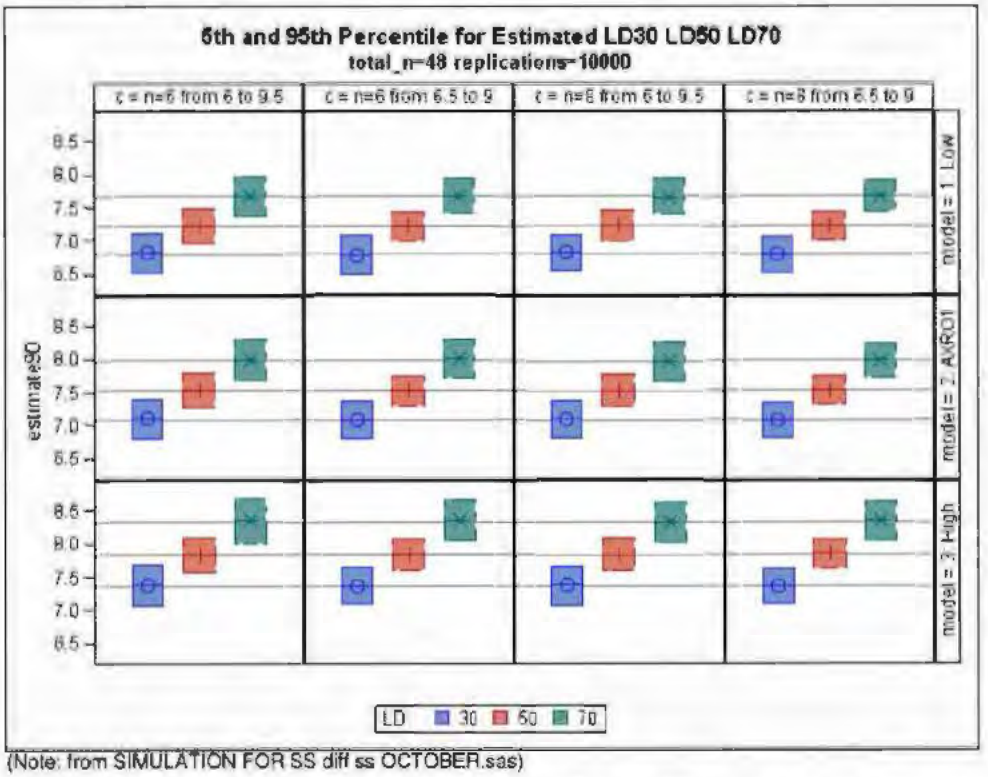
Dosing Regimen		Total N=36	Total N=48
# Doses	Doses Spread Uniformly in this Interval	Animals Per Dose	Animals Per Dose
8	6 to 9.5	Alternate Between 4 & 5*	6
8	6.5 to 9	Alternate Between 4 & 5	6
6	6 to 9.5	6	8
6	6.5 to 9	6	8

* Thus, for example, the doses were 6, 6.5, 7, 7.5, 8, 8.5, 9, 9.5; At Dose=6, there were 4 animals, and at Dose=6.5, there were 5, and Dose=7, there were 4 animals, and so on. This design had 36 animals.

To determine the most efficient dosing regimen I looked across the four columns for each of the 6 rows in the plots below (i.e., 3 rows per total sample size). Each row has the same total sample size and same model, so if any dosing regimen consistently provides increased precision, then it would be the best choice. In every comparison the boxes in the right most row which corresponds to 6 doses from 6.5 to 9 were narrower than the boxes in the other three columns. The differences were modest, but consistent. This dosing regimen corresponds to the highlighted one above. One caveat is that differences in precision between the dosing regimens is not dramatic, so that if there is some other important consideration that favors a different dosing regimen, then it should be considered. Discussion about the total sample size choice follows after the plots.

Results comparing 8 designs under 3 different true mortality models. The gray lines represent the true LD30, LD50, and LD70 under each true model. The fourth column consistently had smaller boxes.





(Note: from SIMULATION FOR SS diff ss OCTOBER.sas)

The choice between total N of 36 versus 48 is a different sort of comparison. By definition, the 48 will give more precise estimates, so it's a trade-off between the increased efficiency versus the additional cost associated with studying more animals. I assume that the above selected dosing regimen with n=36 versus n=48 (i.e., 6 doses between 6.5 and 9 each with 6 animals, versus the same doses with 8 animals) would be used. We look at the same box plots as on the previous page, but narrowing in on the relevant panels. Each row illustrates the results under each of the three models. We see the boxes associated with the larger sample size are clearly smaller, although differences are somewhat modest. Nonetheless, given that the usefulness of future designs depend on the curve being estimated reasonably well, this gain in efficiency may be important.

Subject: This memorandum is for informational purpose for protocol # (b)(6)

We recently conducted a full supportive care (blood transfusions and antibiotic treatments as necessary) NHP experiment in two batches with 6 NHPs each; each NHP received a different dose of radiation (6.5, 7.0, 7.5, 8.0, 8.5, and 9.0 Gy). In the first batch, all study animals received a combination of enrofloxacin and ceftiofur as antibiotic treatments as directed by veterinarian and died by SD 22. In the second batch, enrofloxacin was used as the preferred antibiotic and ceftiofurwas used only as directed by the veterinarian; all but one of our study animals died by SD 15.

Batch 1			Batch 2		
Rad dose (Gy)	Number of transfusions	Euthanasia (SD)	Rad dose (Gy)	Number of transfusions	Euthanasia (SD)
6.5	2	22	6.5	2	12
7.0	2	22	7.0	3	Still alive
7.5	1	15	7.5	0	15
8.0	1	14	8.0	2	14
8.5	3	15	8.5	3	14
9.0	0	10	9.0	2	15

Histopathology results of tissue indicate a large number of cocci bacteria present in the samples from batch 1 (most likely *Streptococcus sp.; Staphylococcus sp.*). Similarly, there were bacterial cocci colonies noted in 4 of the 5 euthanized animals from batch 2. In none of our past studies has such prominent bacterial presence in histopathological findings been noted. Furthermore, batch two animals presented spikes in neutrophil counts at SD-1, perhaps in response to infection.

These results have led us to believe that the increased mortality in these two batches may be due in part to "dormant" antibiotic resistant bacteria within the first batch, which then "bloomed" as a result of radiation-induced immunosuppression; the infection then spread to batch 2, prior to irradiation further compromising their overall health, leading to rapid deterioration of all animals within a short time frame (3 days). Bacterial cultures from the lone survivor of the second batch (b)(4) are under investigation for remaining bacterial presence, if any, and sensitivity. Additionally, a direct correlation could not be demonstrated between mortality and vendor/breeder of multiple studies (4+) done over the course of several years.

A study of this nature is complex with a potential for multiple contributing factors to mortality. Several strategies have been adopted to ensure data integrity of future batches; we will employ more vigorous culture and sensitivity methods to ensure judicious use of antibiotics and take any additional precautions or recommendations by AFRRI veterinarians.

Sincerely,

(b)(6)

Principal Investigator

AFRRI SCIENTIFIC RESEARCH PROTOCOL NUMBER:

I. NON-TECHNICAL SYNOPSIS One of the major missions of Armed Forces Radiobiology Research Institute (AFRRI) is to develop non-toxic, safe, effective and approved radioprotectors for use in victims of an accidental or deliberate radiation exposure. AFRRI is involved in testing various classes of drugs as radiation countermeasure agents under (b)(4) interagency agreement. These drugs can stimulate immunity, remove toxic free radicals and/or activate biological systems to counteract the damage caused by ionizing radiation. In the present protocol, we propose to test new drugs and new formulations for their efficacy in radiation protection under the Intramural Screening Program recently established at AFRRI. In order to establish an optimum dose for radiation countermeasure studies, basic toxicity of various drug formulations will be carried out in mice. The toxicity studies will be followed by basic survival experiments in drug-treated mice using Cobalt-60 gamma radiation at AFRRI. Study endpoint will be thirty days post-irradiation survival. Once a drug shows efficacy either as a prophylactic or therapeutic agent, additional studies which include drug dose optimization, effect of time of drug administration on 30-day survival, and a dose reduction factor to determine the effectiveness of the drugs will be performed.

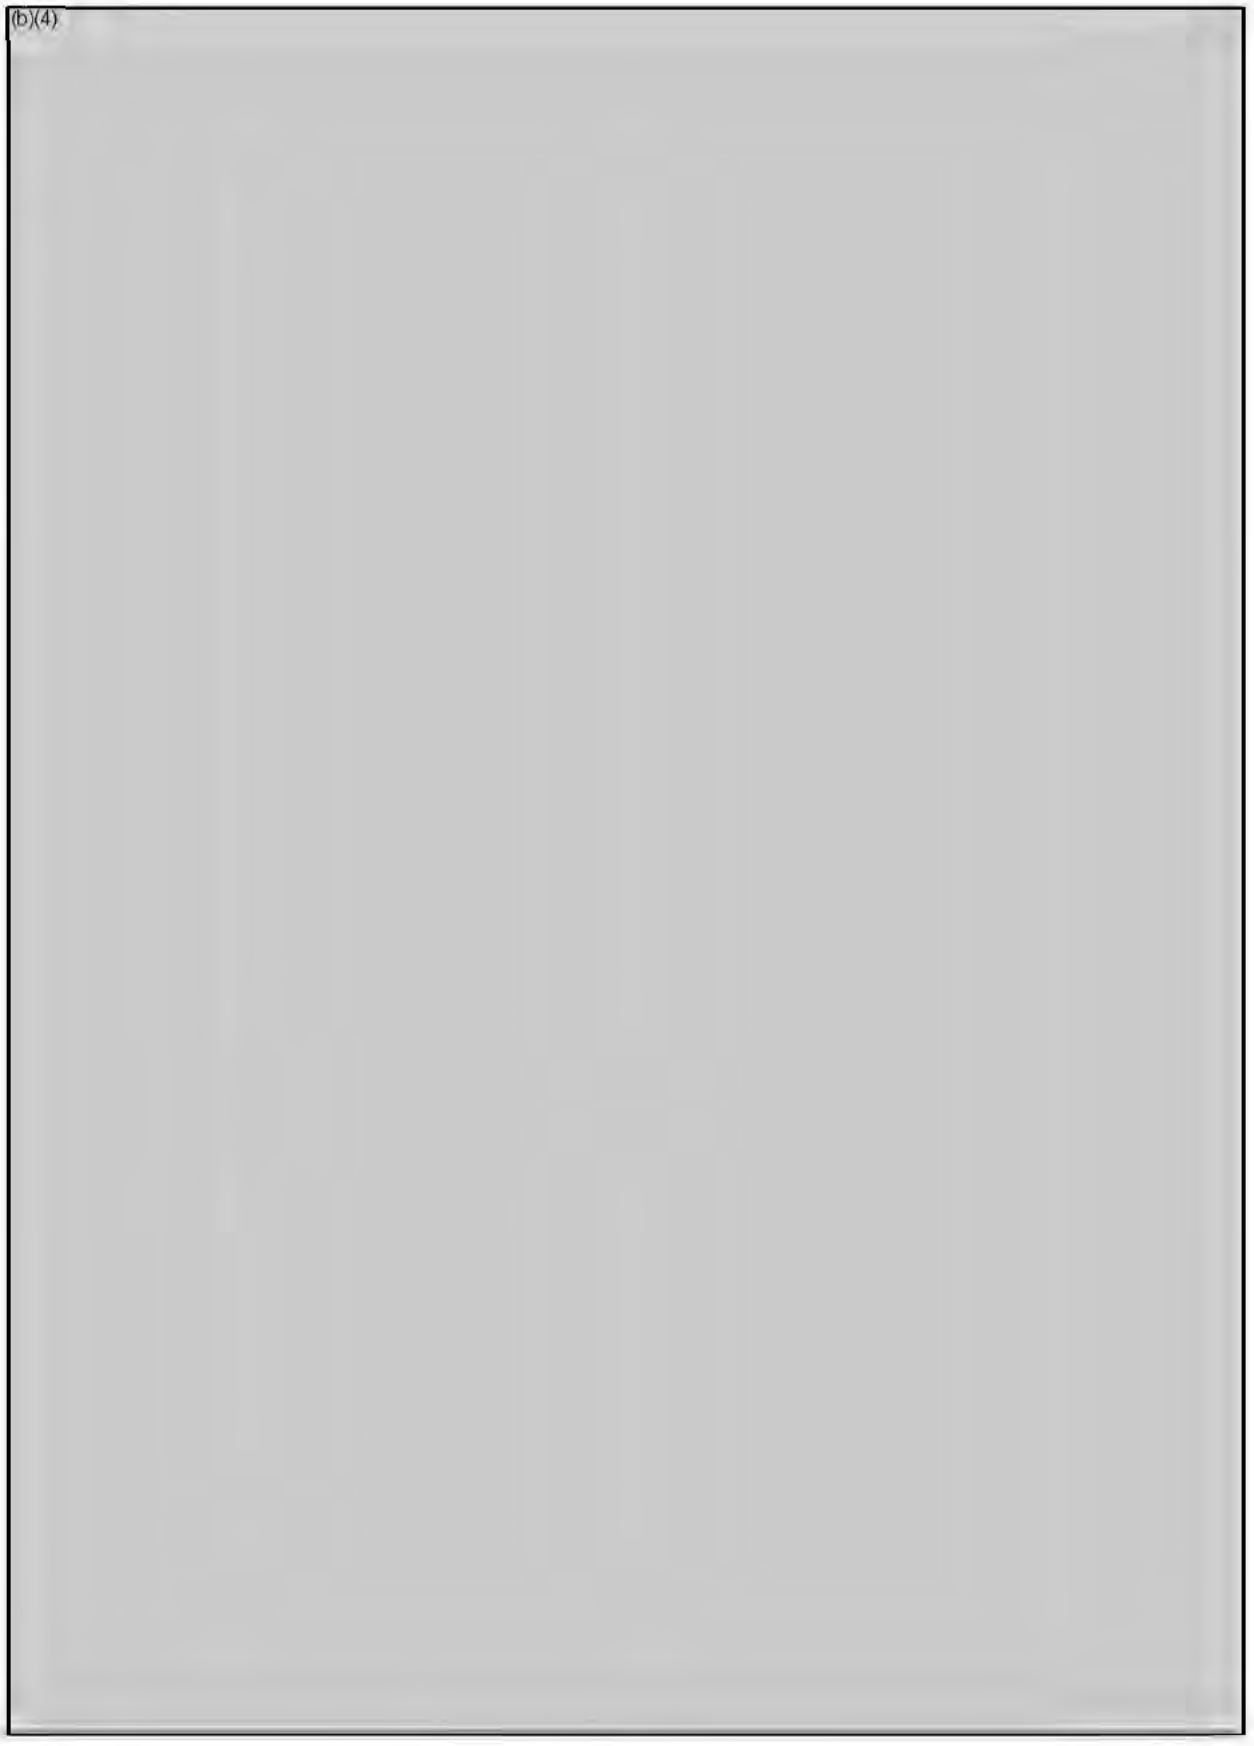
II. BACKGROUND

II.1. Background Radiation exposure can occur in a variety of scenarios [1], including nuclear weapons, accidental exposure in power plants, in nuclear submarines and via terrorist activities using radiological dispersal devices (RDDs) as well as during extended space travel. Acute effects of high-dose radiation include hematopoietic cell loss, immune suppression, mucosal damage (gastrointestinal and oral), and potential injuries to other sites such as lung, kidney and central nervous system (CNS) [2]. As of today, no radiation countermeasure is available for human use except recently approved drugs, Neupogen® and Neulasta®. Since these are of limited use, there is an urgent need to develop safer and more effective radioprotectors for national stockpile to protect emergency first responders and civilians from harmful radiation damage. This is a critical issue for combat commanders in the planning and execution of military operations [2].

Over the years investigators have identified several classes of compounds which act as radioprotectants. These include thiols [3], cytokines [4], steroids (b)(4) prostaglandin analogs, antioxidants (b)(4) and nutraceuticals (b)(4) Early searches for radioprotectors have been dominated by the study of sulphydryl compounds such as amifostine [10]. Despite amifostine being considered a gold standard radioprotector because of its effectiveness in various species in minimizing the deleterious effects of ionizing radiation, it has not been advanced for use during a nuclear event because of its significant performance –degrading characteristics [10,] as well as hypoglycemic (b)(4) response [12]. However, in clinical settings, its cytoprotective characteristics (protection of normal tissue without similar protection of tumor tissue) have been effectively used. It has been approved for clinical use in conjunction with cisplatin and for patients undergoing radiotherapy for head and neck cancer [10]. (b)(4) (b)(4) as a prophylactic radiation countermeasure (b)(4) (b)(4) (b)(4) to evaluate the safety, tolerability and pharmacokinetics of the drug in healthy volunteers (b)(4) (b)(4) (b)(4) Although there are a few compounds in different stages of development, until now only Neupogen® and Neulasta® are approved by FDA for limited use for treating ARS. Therefore, there is an urgent need to develop small molecules/agents/compounds for national stockpile that are less toxic, and efficacious.

AFRRI is involved in testing various classes of drugs as radiation countermeasure agents under (b)(4) interagency agreement. These chemicals/drugs can stimulate immunity, remove toxic free radicals and/or activate biological systems to counteract the damage caused by ionizing radiation. One of AFRRI's missions is to develop non-toxic radioprotectors and therapeutic agents which can be available to our emergency responders and uniformed personnel before deployment to a radiation exposed field. In order to fulfill AFRRI's mission, an Intramural Screening Program (ISP) has recently been established at AFRRI as a core program. Drugs/compounds are brought to the Intramural Screening Program committee (ISPC) by (b)(4) (b)(4) Drugs are reviewed by the ISPC and get approved or disapproved for screening based on available literature/data. We will follow AFRRI's standard protocols used for screening radiation countermeasure drugs under (b)(4) interagency agreement. In order to establish an optimum dose for radiation countermeasure studies, the basic toxicity of various drug formulations will be carried out in mice. Drugs will be tested for radioprotective efficacy (prophylactic and therapeutic) after total body irradiation (Cobalt-60). Mice will be monitored for 30-days as study end point. Further studies (drug dose optimization, time optimization and dose reduction factor determination) will be performed with potential drugs which pass initial efficacy study.

Classification of drugs (for the study):
The new drugs included in the current protocol are subject to legal requirements of confidentiality and material transfer agreement (moderated by the (b)(4) (b)(4)



(b)(4)

(b)(4)

(b)(4)

Positive controls used in the survival study:

1.Gamma-tocotrienol (GT3): Gamma-tocotrienol (GT3), Delta-tocotrienol and (DT3), and tocopherol succinate (TS) are tocols demonstrating radioprotective efficacy against high doses of radiation. These tocols are optimally effective when administered 24 h before irradiation as their radioprotective efficacy can be negated through the administration of antibodies to G-CSF, an essential cytokine playing an important role in protection from ARS. AFRRI researchers have conducted multiple murine studies with CD2F1 mice (male) with several isomers of vitamin E. One of these isomers GT3, has demonstrated strong radioprotection in mice when administered subcutaneously 24 hours prior to total body irradiation (TBI).
GT3 demonstrates almost 100% radioprotective efficacy in mice against the $LD_{90/30}$ dose of radiation (b)(4) Drug reduction factor (DRF) reported for GT3 (200 mg/kg) was1.29 (b)(4) In several mouse studies done at AFRRI, GT3 has shown consistent results of 100% radioprotection at 200 mg/kg body weight.

2. Androstenediol (5-AED): Androstenediol is a direct metabolite of the most abundant steroid produced by the human adrenal cortex, dehydroepiandrosterone (DHEA). It is less androgenic and has been found to stimulate the immune system. Its potential use as a radiation countermeasure was introduced at AFRRI with possible mechanism mainly due to stimulation of production of white blood cells and platelets (b)(4)
5-AED has been used as a positive control (80 – 100% survival when given 24 h prior to irradiation at 30 mg/ kg subcutaneously) in IACUC protocol P# (b)(6)

(b)(6)

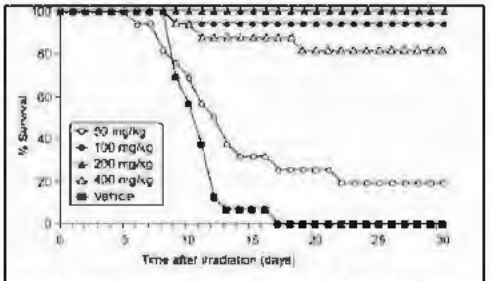


Figure 2. Radioprotection provided by GT3 at 11 Gy. Thirty-day survival of mice (n=16 per group) treated 24 h before receiving 11 Gy of cobalt-60 gamma radiation, with a single SC injection of vehicle (5% Tween 80) or GT3 at doses of 50 to 400 mg/kg body weight. Mice that received a GT3 dose of 100, 200, and 400 mg/kg exhibited a significant increase from vehicle control group ($p<0001$. Chi-square=69.74, df=4).

Representative survival plot has been shown here.

II.2. Literature Search for Duplication

II.2.1. Literature Sources Searched
NIHRePORTER, PUBMED , Embase
II.2.2. Date of Search 11-22-2015 to 12-12-2015
II.2.3. Period of Search The search period extended from 2009-present for NIHReporter, 1970 to present for PubMed, 2006 to present for Embase.

II.2.4. Key Words of Search Each individual term + (radiation), + (radioprotection), + (radioprotection+mice)

II.2.5. Results of Search Table 1. Literature search resulted the following hits as tabulated below:

KEY WORDS	PUBMED	NIHRePORTER	Embase
(b)(4)	5	1	7
(b)(4) + radiation	5	1	5
(b)(4) + radioprotection	2	1	1
(b)(4) +radioprotection+mice	2	1	1
(b)(4)	1644	36	957
(b)(4) + radiation	46	1	33
(b)(4) + radioprotection	2	0	1
(b)(4) + radioprotection+ mice	1	0	0
(b)(4)	6546	116	8140
(b)(4) + radiation	117	6	120
(b)(4) + radioprotection	8	0	4
(b)(4) + radioprotection+ mice	2	0	0

Summary of the Search: Literature for (b)(4) is mostly from the same research group which is providing AFRRI the drug for testing and is specific to radioprotection. However, the proposed study with (b)(4) is not a duplication since the published work was done in (b)(4) (b)(4) and is used to treat urea cycle disorders. It is also a (b)(4) leading respectively to research into its use as an anti-cancer agent and in protein misfolding diseases such as cystic fibrosis. As a result of multiple applications for this class of compounds many literature articles are found in the searches. This study with (b)(4) is not a duplication as the study in the literature has been done in (b)(4) (b)(4) All references available for (b)(4) are either as a dietary supplement or a biomarker.

III. OBJECTIVE / HYPOTHESIS The overall objective of this proposal is to evaluate the prophylactic and therapeutic efficacy of countermeasure agents (b)(4) (b)(4) in mice using a standardized screening protocol. We hypothesize that by screening these compounds, we will be able to identify a countermeasure which can be taken to the next step of evaluation for further development as a radioprotectant and/ or mitigator. Our goal is to develop a drug which is effective in prolonging survival in mice when given either before or after whole body radiation.

IV. MILITARY RELEVANCE The current lack of availability of radioprotectors and therapeutic agents that are non-toxic, effective for use in victims of an accidental or terrorist nuclear event scenario is a major problem in preparing for such an eventuality. Therefore, there is a desperate need to develop effective countermeasures to the pathological impact of ionizing radiation for use by emergency response personnel, military personnel in harm's way prior to deployment, and the general population at risk.

Exposure to whole body irradiation of humans above a dose of about 1 Gy causes depletion of bone marrow progenitor cells, leading to neutropenia and increased susceptibility to infection. Exposure at doses above 2 Gy causes mortality in humans [2]. Our uniformed emergency personnel could be exposed to these levels of ionizing radiation in scenarios involving nuclear detonations or the use of other radiological weapons by international terrorist. One of AFRRI's missions is to develop non-toxic radioprotectors and therapeutic agents which can be made available to our emergency responders and uniformed personnel before deployment to a radiation exposed field. In order to fulfill AFRRI's mission, an Intramural Screening Program (ISP) has recently been established at AFRRI as one of its core activities. In the proposed study we will screen compounds (b)(4)

V. MATERIALS AND METHODS In this study we will test the efficacy of new drugs using either CD2F1 or C57BL/6 mouse model. Reasons for choosing these strains of mice are (i) at AFRRI CD2F1 mice have been used for screening for countermeasures. (ii) In the literature many researchers use C57BL/6 mice in their studies. (iii) In the case where results of the preliminary study are being validated at AFRRI. (iv) efficacy of drugs on varied radio-sensitive strains [27] can be addressed by testing on CD2F1 (LD70/30 = 9.25 Gy) and C57BL/6 (LD70/30 = 8.2 Gy). Drugs will be administered either subcutaneously or by orogastric gavage (see **Section V.4.4**). In case of drugs by orogastric administration, animals will be divided in two groups, with and without fasting. Animals will be fasted for 5-8 h hours before drug administration. Before conducting the efficacy study, we will study the safety of these drugs by conducting a 14-day acute toxicity study.

V.1. Experimental Design

General experimental design: The experimental design for this protocol is divided in to 5 subsections and each subsection covers a specific area:

Section v.1.1.: Basic acute toxicity
Section v.1.2.: Survival studies to test efficacy as an ARS countermeasure
Section v.1.3.: Drug optimization – survival studies
Section v.1.4.: Dose reduction factor - survival studies
Section v.1.5.: Hematological studies - sublethal dose of radiation

Section V.1.1. Basic Acute Toxicity

We will be using the modified toxicity protocol Optimal (non-toxic) Drug Dose for screening (ODDS) which has been used in our previous protocols (b)(6) (b)(6) at AFRRI to determine maximum tolerated dose (MTD). The purpose of using the ODDS method is that it allows testing in one gender and requires fewer animals when compared to the FDA protocol. If the initial drug dose (based on recommendation from the sponsor or literature) doesn't show any signs of basic toxicity (using the clinical signs discussed in modified Policy#10, Appendix 1), then the drug dose will be escalated 2 – 3 fold. However, if toxicity is observed, then the drug dose will be reduced by 2 – 3 fold or as suggested based on the discussion with the company [28]. For either scenario (escalation or reduction 2 – 3 fold), the IACUC will be notified by memorandum. For survival studies we will use 1/4th of the observed non-toxic dose. A maximum of six animals per drug dose will be used to evaluate toxicity, and will be monitored daily for

acute (1 to 4 h and up to 14 days) signs of toxicity after administration of drug. Signs of acute toxicity include decreased activity, squinting eyes, hunching, labored breathing or mortality (see modified Policy#10, Appendix 1). Animals will be euthanized on day 14 and gross necropsy will be carried out by the research staff for any abnormal pathology in all major organs. Research staff will also collect tissues by Pluck method [28].

Serum biochemical and whole blood hematological tests: Whole blood will be collected under anesthesia on day 14 after drug administration (see **section V.4.4.2** for Blood collection) and blood will be transferred to EDTA tubes for hematological analysis. The rest of the blood will be transferred to serum tubes for serum collection for biochemical analysis. Hematological parameters (CBC/differential) will be analyzed using an Advia 2120 hematology system from Siemens Corporation, or replacement analyzer, if necessary. Serum biochemistry will be done using either Vitros 350 (manufactured by Ortho) or Daytona Plus (manufactured by Randox) or any other suitable analyzer.

General Experimental Design: Total no. of animals required

V.1.2. Efficacy of drugs as radiation countermeasures - survival studies (General design)

1) We will use the LD70/30 – LD90/30 radiation dose, a dose that results in 70% - 90% mortality within 30 days following exposure for all drugs we wish to test to preclude additional amendments.

2) There are three major arms to the survival study: one prophylaxis (24 h pre-TBI), and two mitigation (post-irradiation) arms, namely 4 h and 24 h post-TBI.

3) Survival of ≥30% over vehicle is considered the 'pass criteria'.

The efficacy of each drug in enhancing survival of lethally irradiated CD2F1 or C57BL/6 mice will be tested in both the prophylactic and therapeutic regimen (-24 h, +4 h or +24 h after exposure [0 h]) as described below. This regimen could be changed based on the discussions with the company and preliminary data available for a specific drug. A memo will be submitted to IACUC before the study begins.

Each study will consist of 1 positive control (GT3/ 5-AED), 1 negative control (5% tween80®-saline/ PEG400) and 3 groups (Drug, vehicle and Naïve if the vehicle is other than PBS or saline) at 3 regimens (-24 h, +4 and +24 h)

General Experimental Design of Survival Study for 1 drug:

			Total # of animals for 3 drugs	**2004**

Specific experimental designs for 3 drugs described below:

Experimental design for (b)(4)

Based on recommendation from (b)(4),(b)(6) (b)(4) (**Section II, Background**), basic acute toxicity study for (b)(4) will be conducted at 1800 mg/kg administered orally by gavage to fed and fasting (fasted for 5-8 h prior to drug administration) mice. If the drug dose of 1800 mg/kg is found to be toxic, then lower dose (1500 mg/kg) will be tested for toxicity. Maximum tolerated dose (MTD) will be determined from this study.

Toxicity study

Drug	Groups	Route of injection	Diet Condition	# of animals	End point (whole blood)
(b)(4)	Naïve	PO	Fasting	6	CBC/Differential, Serum Biochemistry
	Water			6	
	(b)(4) at 1800 mg/kg			6	
	Naïve	PO	Fed	6	CBC/Differential, Serum Biochemistry
	Water			6	
	(b)(4) at 1800 mg/kg			6	
			Total # of animals	36	

30-day survival study will be carried out at 1/4th of the MTD of (b)(4) (determined in the toxicity study) administered orally by gavage 1 h prior to TBI (Radiation dose LD70/30 determined by the probit curve which will be generated in February 2016, at the rate of 0.6 Gy/min at AFRRI). Survival study will involve two groups of animals – fasting (for 5-8 h prior to administration) and fed mice. (b)(4) will be administered 1 h prior to TBI. Animals will be monitored for 30 days post-TBI. Endpoint of the study is as described in Section **V.4.5. Study Endpoint.**

Survival study

Groups	Administration time point(s)	Route of injection	Diet Condition	# of animals
5% tween80®-saline/ PEG400	-24 h	SC	Fed	10
GT3/ 5-AED	-24 h			10
water	-1 h	PO	Fasting	24
(b)(4)				24
water	-1 h	PO	Fed	24
(b)(4)				24
			Total # of animals	**116**

CD2F1 mice will be used for the **toxicity and survival** study of (b)(4) **The animals for these studies are included in the total animals requested in this protocol.**

Experimental design for (b)(4) : Basic acute toxicity study will be conducted at 100 mg/ kg administered subcutaneously in the nape of the neck of mice. Drug dose determined from the literature information of MTD (b)(4) (**Section II, Background**) . If the dose of PB at 100 mg/kg (sc) is found to be toxic, lower dose (50 mg/kg) will be tested for toxicity. Maximum tolerated dose (MTD) will be determined from this study.

Toxicity study

			Total # of animals	**126**

Radiation dose, drug dose, strain of mice (CD2F1 or C57BL/6) for toxicity and survival studies of (b)(4) will be decided later. **The animals for these studies are included in the total animals requested in this protocol.**

Estimated numbers of animals for toxicity studies:

Drug	# of mice for 2 iterations
(b)(4)	36 x 2 = 72

(b)(4)	18 x 2 = 36
	18 x 2 = 36
Total	**144**

Estimated numbers of animals for survival studies:

Drug	# of mice for 2 iterations
(b)(4)	116 x 2 = 232
	116 x 2 = 232
	126 x 2 = 252
Total	**716**

Section V.1.3. Optimization studies: Optimization studies will be initiated only if any of the drugs tested meets the AFRRI criteria of ≥30% survival than vehicle in the preliminary radiation survival screen. These studies will be conducted in the mouse strain (CD2F1 or C57BL/6) which was used for the survival studies. Assuming that three drugs meet the AFRRI criteria, we request animals to carry out optimization studies and DRF for three drugs.

Drug dose optimization study: 6 groups (Five drug doses determined based of the Survival study + 1 vehicle) x 1 radiation dose x 2 regimen (pre- and post-exposure) x 1 route (*sc* or *po*) x 3 drugs (chosen based on the efficacy (≥30% survival compared to the vehicle group) in the survival study) x 24 animals per group

Subtotal = **864 mice (CD2F1 or C57BL/6)**

Time optimization study: 4 different time points (determined based on Survival study) x 2 groups (1 optimum dose [based on the Drug dose optimization study] + 1 vehicle) x 1 radiation dose (LD70/30) x 1 route (*sc* or *po*) x 3 drugs x 24 animals per group

Subtotal = **576 mice (CD2F1 or C57BL/6)**

Section V.1.4. Dose reduction factor study (DRF):

The dose reduction factor (DRF) studies will use the optimum drug dose and times to evaluate the effectiveness of the drug against a range of radiation doses at the rate of 0.6 Gy/min in CD2F1 / C57BL/6 mice.

6 irradiated vehicle groups (8.5, 9, 9.5, 10, 10.5 and 11 Gy, 0.6 Gy/min)* + 6 irradiated drug groups (8.5, 9, 9.5, 10, 10.5, and 11 Gy)* x 24 mice per group x 3 drugs.

Subtotal = **864 mice (CD2F1 or C57BL/6)**

*These radiation doses are projected based on an earlier probit study and are considered guidance. The appropriate radiation doses will be determined using the new dosimetry map (Feb 2016) and the IACUC will be notified by memorandum.

Section V.1.5. Hematology, clinical chemistry, and bone marrow studies .These studies are anticipated only for those candidates that demonstrate 30% increase in survival.

Data from these studies will form the basis of understanding the mode of action of the drug,
3 groups (Naïve + vehicle + drug) x 7 time-points (0, 1,4,7,10,14 and 30 d post-TBI) x 10 mice per group x 1 route of administration x 2 drugs

Subtotal = 420 mice (CD2F1 or C57BL/6)

2 experimental groups (vehicle-irradiated, Drug-irradiated) x 7 time-points (0, 1,4,7,10,14 and 30 d post-TBI) x 10 mice per group x 1 route of administration x 2 radiation doses x 2 drugs

Subtotal = 560 mice (CD2F1 or C57BL/6)

Grand total no. of mice required in this protocol: Toxicity (324) + Survival (2004) + Optimization (1440) + DRF (864) + Hematology (980) = 5612

V.2. Data Analysis All data will be reported as means with standards errors or percentages where applicable.
Basic Toxicity (ODDS) – This is a qualitative study so no additional statistics will be conducted.
Preliminary survival study - Based on the power analyses, the sample size (n=24) is adequate to provide 80% power required to detect significant difference between two groups, if any. Previously (b)(6) n=24 was used in 30-day survival studies to determine if there is 30% improved survival in the drug group compared to vehicle. Data will be represented as Kaplan-Meier survival curves. Comparison of the survival curves will be made using Log-rank test will be used to compare survival curves. A p value of < 0.05 will be considered significant. Experiments will be repeated once with 24 mice per group, thus providing adequate statistical power for any conclusions in the survival studies. Experiment V.1.4. (Dose Reduction Factor study) probit analysis and estimation of DRF will be done using IBM SPSS Statistics 22 software or any other certified software. In the experiment V.1.5, t-test, Fisher's test or ANOVA will be used to evaluate the outcome and comparisons.

V.3. Laboratory Animals Required and Justification

V.3.1. Non-animal Alternatives Considered Although high throughput screening and computer modeling have advanced significantly in recent years in identification of promising drugs, it would be simplistic to assume that cell systems or artificial intelligence modeling can replace the data that can be generated by using an animal model. Irradiation of animals will result in a cascade of changes including death of stem and progenitor cells in bone marrow, alterations in signal transduction pathways, multiple organ dysfunctions etc. due to differing radiosensitivities of organs. Currently, there are no alternatives in existence that can predict or compute the complexity of the response to total body irradiation. The US FDA recognizes the ethical considerations involved in testing the efficacy of radioprotective drugs in humans. Therefore FDA requires preclinical drug assessments (safety and efficacy) to be performed using both small and large animal models [29] prior to granting approval for safety testing in humans.

V.3.2. Animal Model and Species Justification Recent advances in molecular techniques have allowed significant improvements in understanding the cellular and biochemical processes. These advances are possible only due to whole animal modeling of human ailments. The mouse, in particular, has high sequence homology to humans at a genomic level as well as similar hematological and immunological response to radiation. Mouse models not only confirm primary pathological processes but have also provided a venue for studying basic molecular, cellular, biochemical, and cytological processes. Furthermore, there are extensive data on the mouse for comparison, review and analysis. The practicalities of breeding and housing these small mammals have made the mouse model invaluable. The Principal Investigator's group at AFRRI has significant training and experience in handling mice in radiation countermeasure studies. In this protocol, we will use CD2F1 or C57BL/6 mice. The PI also has used these strains in previous studies.

V.3.3. Laboratory Animals

V.3.3.1. Genus / Species Mouse, *Mus musculus*

V.3.3.2. Strain / Stock CD2F1, C57BL/6

V.3.3.3. Source / Vendor Harlan Inc., Jackson laboratories or any other approved vendors

V.3.3.4. Age (Procurement) 7-8 weeks

V.3.3.5. Weight (delivery) 20-24 grams

V.3.3.6. Sex Males have been used historically and will continue to be used in this study.

V.3.3.7. Special Considerations
Commercially procured animals must be adventitious disease free (see Appendix 2).

V.3.4. Number of Animals Required (by species) Table

Animal (genus, species and common names)	**Study**	**Original**
CD2F1	(b)(4) (Toxicity and survival)	304
CD2F1	(b)(4) (Toxicity and survival)	268
CD2F1 or C57Bl/6	(b)(4) (Toxicity and survival)	288
CD2F1 or C57Bl/6	Future 3 studies	4752
	Total # of animals	**5612**

V.3.5. Refinement, Reduction, Replacement (3 R's)

V.3.5.1. Refinement
PI will take necessary steps for all personnel in the project to be rigorously trained in handling techniques (Tail-tattooing, ear-punch, injections, blood collection, orogastric

gavage and routine cage-side observations) to minimize distress and pain to the animals. Specifically, during capture and restraint of the rodents, care will be taken to ensure that handling does not contribute to distress.

V.3.5.2. Reduction

The protocol will use a tiered approach to reduce the number of animals for testing 3 drugs/ year. Although basic toxicity and survival will be carried out on all the drugs, additional studies will depend on the initial results from survival study. Positive controls and negative controls are used to confirm robustness of experimental conditions and drugs that don't meet our minimal criteria of 30% increased survival over the vehicle control will be eliminated. Based on previous experience, we have proposed that only 3 drugs may be advanced for optimization and dose reduction factor studies (Section V.1.3 and V.1.4). Further, control groups (such as vehicle) will be shared whenever possible between drugs that are dissolved in similar vehicles. In classical toxicology testing, groups of 10-20 mice and both sexes were routinely used; in using the ODDS method (current protocol), we have reduced the number of animals to 6 per group, and use only males, thereby reducing animal numbers significantly. Four drug doses have been proposed for toxicity screening; however, in some cases a smaller number might be selected based on literature search and recommendation by the manufacturers. Similarly, two routes of drug administration have been contemplated in the experimental design; but depending on the existing data and company suggestions, a single and optimal route may be chosen. Wherever possible we have reduced the number of repeats planned for the experiments shown above.

V.3.5.3. Replacement

It is not feasible to use non-animal systems, nor a less-sentient model, in place of the rodent animal models to address the questions in this project.

V.4. Technical Methods

Totals:				5612	5612

V.4.1.2. Pain Relief / Prevention Animals can experience pain and distress. Minimizing and alleviating pain in laboratory animals without compromising the methodological integrity of a research project is important both ethically and legally. Mice often exhibit pain and distress with only subtle changes in their behavior [30]. Potential signs associated with pain and distress in mice includes decreased food and water consumption, weight loss, self-imposed isolation/hiding rapid breathing, open-mouth breathing, abdominal breathing, decreased movement, abnormal posture, muscle rigidity, twitching, trembling, tremor, etc. as included in Appendix 1 (sample scoring sheet for clinical observations with criteria for rodent euthanasia) in modified IACUC policy#10 (Guidelines for establishment of early endpoints in experiments with expected mortality, Appendix 1).

V.4.1.2.1. Anesthesia / Analgesia / Tranquilization
The protocol will not use anesthetics or analgesics during radiation since they will adversely affect the outcome of the experiments or during oral administration of drug. The proposed study is to determine the effects of radiation and countermeasures on the function of the immune and blood forming systems. Use of any analgesics and anesthetics would interfere with the function of the immune system and therefore compromise the interpretation of the results [31]. Topical antibiotics will be applied if wounding occurs via in-cage fighting, under the guidance of the clinical veterinarian in accordance with standard treatment measures.
Anesthesia using standard Isoflurane apparatus under the guidance of the VSD will be carried out in mice for blood collection. All personnel will be extensively trained for efficient administration of the agents as well as to minimize handling stress.
Animals will be placed in the Isoflurane chamber and delivered a metered amount of 3-5% Isoflurane mixed with 100% oxygen (oxygen at the flow rate of 500-1000cc/min) until all voluntary motor movement ceases and the animal is recumbent for approximately 10 seconds. Animal's respiration rate will be closely monitored through the Plexiglas chamber during induction of anesthesia. When animals are recumbent, they will be removed from the chamber and their nose/mouth placed in the anesthesia apparatus breathing/gas administration cone for maintenance of anesthesia at 1-3% Isoflurane and 100% O_2.

V.4.1.2.2. Pre- and Post-procedural Provisions Mice will be housed under standard conditions both before and after radiation procedures in accordance with current VSD rodent husbandry Standard Operating Procedures (see section V.5).

Radiation AND humane	12	0	34

There are no alternatives to irradiation. While radiation itself does not cause pain or distress, it induces a number of changes in the body that alters immune response and destroys hematological tissues, resulting in opportunistic infections, and multi-organ dysfunction leading to death. It is anticipated that animals exposed to high lethal radiation doses will become moribund. Unfortunately, literature clearly demonstrates that use of analgesics alters radiation response and therefore leads to increase in animal number for better statistical results or for iteration of entire experiments. Since the purpose here is to compare the efficacy of the three experimental drugs we will be unable to use analgesics and anesthetics because they may interfere with the innate system [31].

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification
Because exposure to irradiation is potentially lethal or causes debilitating effects in humans, it is ethically impermissible to test the effectiveness of radiation countermeasures on human volunteers. Irradiation compromises the immune and blood forming systems leading to mortality. The radiation-induced mortality and potential percentage increase of survivors over 30 days using potential radiation countermeasures are study endpoints for this protocol. Administration of drugs and analgesics is not an option since it is well documented that they interact with the immune system which will confuse the interpretation [32-34]. Pain relieving measures

are not used because such measures may compromise the experimental integrity of the study. All moribund animals will be euthanized by CO_2 inhalation and confirmatory cervical dislocation (see **Section V.4.6 Euthanasia**).

V.4.2. Prolonged Restraint

The experimental animals will receive radiation at a dose rate 0.6 Gy per/min in the AFRRI Cobalt 60 gamma radiation facility. Animals will be irradiated in Lucite boxes (8 animals/box) and arranged in an array (according to the latest dosimetry map) using plastic racks. Mice will be inserted into the standard radiation boxes just prior to irradiation (~15 min of exposure time) and taken to the cobalt facility for irradiation. Animals will be restrained for no more than 60 min and returned to cages at the end of the irradiation period. They will be monitored daily following modified IACUC policy#10 (Guidelines for establishment of early endpoints in experiments with expected mortality) (at least three times a day during critical period with no more than 10 h interval between late night and morning check and at least twice a day during non-critical period) for 30 days and euthanized at the completion of the observational period.

V.4.3.6.2 Scientific Justification N/A

V.4.4. Animal Manipulations

V.4.4.1 Ear punch:

Three animals/ shoe box for toxicity studies and four animals/ shoe box for survival studies will be housed. They will be identified either by ear punch or tail tattoo.

Procedure for ear-punch

a. Soak the ear punch (Fine Science Tools, Cat# 24212) in a disinfectant (70% ethanol) before use and between animals.

b. Restrain the mouse manually. Place the device on the pinna of the ear (external ear) where the skin is thin avoiding the cartilage. Press firmly to punch a circular hole through the ear

Tattoo procedure: Tattooing will be done either with a machine from Labstamp system following the SOP provided by the company or any other machine certified by VSD. An alphabet followed by two digits will be used as a numbering scheme (e.g. A11).

Irradiation:
These will follow the standard AFRRI protocol with mice placed in restrainers shortly prior to exposure, irradiation at the cobalt facility and return to VSD for further monitoring. Briefly, the experimental animals will receive radiation at a dose rate of 0.6 Gy per/min in the AFRRI Cobalt 60 gamma radiation facility. Exact dose of radiation will be determined based on the probit curve. Animals will be irradiated in Lucite boxes (8 animals/box) and arranged in an array (the latest dosimetry map) using plastic racks. Animals will be restrained for no more than 60 min and returned to cages at the end of the irradiation period. They will be monitored daily following modified IACUC policy#10 (Guidelines for establishment of early endpoints in experiments with expected mortality, Appendix 1) (3-4 times a day during critical period with no more than 10 h interval between late night and morning check and at least twice a day during non-critical period) for 30 days and euthanized at the completion of the observational period.

V.4.4.2. Oral gavage:
Oral administration will be done by orogastric gavage undertaken using 20-24 gauge gavage needle (animal feeding needles, disposable-sterile, non-toxic and nonpyrogenic, 1" length curved gavage needle). Non-disposable, metal ball ended, oral gavage needles of similar gauge and length are included as an alternative to the disposable needles. Drug volume will be 0.1 - 0.2 ml (maximum volume 10 – 50 ml / kg). Drug dosage will vary from one drug to another based on discussions with the company which is providing the drug. The animal will be restrained in a vertical position to align the spine straight. The bulb will be introduced into the mouth horizontally. Using the needle as lever, the syringe will be moved into a vertical position and the needle dropped down the esophagus into the stomach. The needle contents will be administered when the needle hub touches the animal's mouth. All precautions will be taken to ensure that the placement of the needle is properly positioned and that the animal is not in distress. No forceful feeding will be done to prevent perforation of the esophagus.

Injections:
Subcutaneous injections will be given with a 23 - 25 G, 5/8" needle to the nape of the neck of 0.1 ml (maximum volume 1 ml for 25 to 38 g animals). A disposable sterile needle will be used for all sc injections. One needle will be used per cage containing generally 4 animals. Endotoxin testing for all drugs will be completed prior to any animal testing at AFRRI and a report submitted for IACUC/VSD review and approval. The endotoxin tests are conducted by Charles River Laboratories. At the same time, pH will be tested to ensure that it falls in the range (6-8 for sc administration) stipulated by IACUC. It is expected that the osmolality will not be more than AFRRI IACUC's

recommended levels (IACUC Policy#9: Non-pharmaceutical grade experimental drug formulations to be used in experimental animals).

Blood collection:

Mice will be anesthetized as described under section V.4.1.2.1. (Anesthesia). Blood draw for hematology is collected either by cardiac stick or from the inferior vena cava (IVC). The animals will be deeply anesthetized in the rodent anesthesia machine; the tail and the toe will be pinched for reflexive movement, indicative of insufficient anesthesia. If there is no response, the animal will be moved to the station with individual nose cone for continued anesthesia. 70% ethanol will be sprayed on the abdominal area of the animal. An incision will be made on the right side below the abdomen of the animal, closest to the IVC, the vein exposed and blood withdrawn with a 23 - 25 G, 5/8" needle. Similarly, a 23 - 25 G, 5/8" needle will be used to perform cardiac stick while the animal is positioned under nose cone anesthesia. In both cases, the animals will be immediately euthanized on completion of blood draw by cervical dislocation.

V.4.5. Study Endpoint

The time frame for experiment V.1.1 (basic toxicity) will be 14 days after final drug dose administration. The radiation survival studies will span 30 days after radiation exposure (V.1.2).

It is anticipated that the animals involved in these studies may succumb to death either due to a drug administration or radiation or a combination of the two. To maintain a

suitable baseline for humane treatment of the animals while adhering to the study objective, the IACUC recommendations stipulated in IACUC policy#10 (Guidelines for establishment of early endpoints in experiments with expected mortality) with some minor modification (as stated later in the paragraph) will be implemented for judging morbidity and moribundity. The moribund condition is defined as a clinically irreversible condition leading inevitably to death. Signs of morbidity in the mouse include difficulty in breathing, ruffling of hair; drying of lacrimal fluid, fall in body temperature, loss of appetite with/without diarrhea. A modified IACUC policy#10 (Guidelines for establishment of early endpoints in experiments with expected mortality) will be used to record the scoring of clinical signs of pain in animals (attached Appendix 1). PI would like to change the score for the "Changes in breathing" from 3 to 2 and add an in between score of 6 for "Dyspnea / labored breathing" under "Respiratory rate". Description of the score 12 will be "Abdominal breathing/ gasping – open mouth breathing". Previously there was a large jump between a score of 3 (change in breathing) to 12 (abdominal breathing/ gasping – open mouth breathing). From the experience gathered from the studies performed recently, the PI thinks by adding a score of 6 in between 3 and 12 would enhance efficiency of the scoring system giving a fair advantage to the study outcome. PI will seek veterinarian's input for training the staff adequately to learn the suggested scoring system.

a) Body weights will be recorded prior to radiation.

b) Once animals reach a score of 6, concern cards ("green cards") will be put up, weights will be recorded and monitored with each subsequent scoring change.

c) Animals that exceed 35% body weight loss with any other clinical signs are scored at a 12 and will be euthanized immediately.

To adhere to the policy of preventing animal distress, the PI will facilitate the late PM and early AM checks (not more than 10 h apart) in addition to two times a day checks during the critical lethality period (early morning, late morning, and late afternoon and evening). During non-critical periods, we will continue to check animals except late night. All morbid mice will be monitored carefully and their conditions scored for documentation (Appendix 1, revised scoring sheet).

PI will use a scoring card for each animal in the critical period and scored in each observation. Scores below 6 will not be recorded in the scoring sheet. Mice will be euthanized if there is a score of 12 in a single category or a cumulative score of 12 in multiple categories.

No supportive care is proposed, however, moribund animals will be immediately euthanized. VSD veterinarians will be consulted for all matters regarding the animal welfare.

V.4.6. Euthanasia

It is anticipated that at high radiation doses, animals will demonstrate varying degrees of morbidity and moribund, which makes it critical to define the criteria for euthanizing the animals without undermining the study objective.

In toxicity studies, if any animal shows discomfort (hunching, decreased activity, inappetence, separation from cage-mates), that animal will be under careful observation on consultation with the attending VSD veterinarian. Mice found moribund (defined in V.4.5.) or meeting the criteria for euthanasia following a modified IACUC policy#10 (Guidelines for establishment of early endpoints in experiments with expected mortality) (score sheet attached) will be euthanized by CO_2 inhalation plus confirmatory cervical

dislocation by investigator/technician according to the directives of the VSD-SOP (VS0211: Rodent Euthanasia Guidelines) and in accordance with current AVMA Guidelines on Euthanasia [35, 36]. At the conclusion of the experimental time frame, all animals that survived the procedures of irradiation, drug intervention and controls, will be euthanized by CO_2 inhalation plus confirmatory cervical dislocation and their carcasses disposed of according to VSD regulations. An alternate method of euthanasia by cervical dislocation after exsanguination (by cardiac stick or inferior vena cava) under deep isoflurane anesthesia will be applied in experiment V.1.5 (see Section V.4.4.2 Blood collection).

V.5. Veterinary Care

V.5.1. Husbandry Considerations The AFRRI vivarium follows stringent protocols for the housing and care of all animals. The PI and designated team members will adhere to all the policy and guidelines set forth by standard operating protocols of the VSD. The specific requirements for mice housing should meet the following criteria of opportunity for social interaction, opportunity to carry out normal behavior and the opportunity to rest and withdraw from each other [37]. Mice are social animals and hence will be caged together in groups. Nestling pads will be provided in each cage during bedding changes. In cage shelters will also be provided as an enrichment strategy at the discretion of the PI depending on experimental conditions. Animals will receive Harlan Teklad Rodent Diet 8604 and water *ad libitum*. Acidified water (pH 2.5 – 3.0) is routinely provided to AFRRI mice used in radiological experiments. Cages will be regularly changed and cleaned by VSD staff in accordance with Standard Operating Procedure. Animals will have 12 h light/dark cycle. Animals will be habituated to their surroundings and routine procedures prior to experimentation. In the event of procedures that last into the night cycle, care will be taken to minimize exposure to light by using red-lens flashlights.

V.5.1.1. Study Room As assigned by VSD

V.5.1.2. Special Husbandry Provisions N/A

V.5.1.3. Exceptions Mice will be socially (group) housed as described above, except when there is a possibility that during survival studies cage mates may be lost through attrition and for a period of time the sole surviving mouse may remain singly housed until the end of the 30-day study.

V.5.2. Veterinary Medical Care We do not project routine veterinary medical care of animals for injuries/inflammation related to injection site inflammation. In case of minor injuries arising from fighting, topical application of antibiotics is acceptable with consensus from the PI and VSD.

V.5.2.1. Routine Veterinary Medical Care

Experimental animals will be observed daily by either the investigator or technician or both as outlined in the **Section V.4.5. Study Endpoint.**

V.5.2.2. Emergency Veterinary Medical Care Moribund animals as per modified IACUC policy#10 (Guidelines for establishment of early endpoints in experiments with expected mortality, Appendix 1) (gasping, recumbent, non-responsive to mild stimulus) will be euthanized by trained personnel.

V.5.3. Environmental Enrichment:
The husbandry staff provides hutches and nestlets to animals not on active experiments whereas cotton nestlets are provided to animals on active experiments.

V.5.3.1. Enrichment Strategy Nestling pads will be provided in each cage during bedding changes as per AFRRI-VSD SOPs.

V.5.3.2. Enrichment Restrictions N/A

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING

NAME	DEGREE	TRAINING	DATE	PROCEDURES	YRS/MOS EXPERIENCE
(b)(6)				1, 3, 4, 5	(b)(6)
				1, 3, 4, 5	
				1, 3, 4, 5	
				1, 3, 4, 5	
				1,3b,3c,4, 5	
				1, 3, 4	
				1, 3	

Procedure and manipulation codes:
Code 1= Animal handling and euthanasia
Code 2= Surgery (aseptic technique) pre- and post-operative care
Code 3= Injections (3a–ip, 3b-sc, 3c-gavage) - can say 3 if trained in all manipulations or add 3d-iv
Code 4= Blood collection under anesthesia (4a-cardiac, 4b-posterior vena cava)
Code 5= Tissue collection (after euthanasia) - doesn't need to be specific
Code 6 = Implantation (provide details)
Code 7 = Others - (provide protocol specific manipulations or procedures for e.g., retro-orbital bleeding, tail vein injection, or drug delivery)

VII. BIOHAZARDS/SAFETY All personnel working in the protocol have undergone necessary training in handling experimental animals. The amount of drug used will be small and standard safety precautions will be taken while handling them in the laboratory and in the vivarium. All personnel listed in the present protocol have been trained as general radiation users on a regular basis. All investigators and personnel will use appropriate protective gear while in the vivarium as described by the VSD. All listed personnel are current in safety training and medical surveillance.

X. ASSURANCES

Protocol Title:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made every effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with a qualified individual who evaluated the experimental design with respect to the statistical analysis, and that the minimum number of animals needed for scientific validity will be used.

D. Biohazard / Safety: I have taken into consideration and made the proper coordinations regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R", namely, "Responsibility," which the DOD has embraced for implementing animal use alternatives where feasible and conducting humane and lawful research.

G. Scientific Review: This proposed animal use protocol has received appropriate peer scientific review and is consistent with good scientific research practice.

H. Painful Procedure(s): I **AM / AM NOT** conducting biomedical experiments, which may potentially cause more than momentary or slight pain or distress to animals. If applicable, potential pain and/or distress **WILL / WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

Clinical Observations with Criteria for Euthanasia (Rodent)

Criteria:	Description:	Score
Appearance:		
	Normal (smooth coat, clear eyes/nose)	0
	Hunched and/or fluffed	1
	Ocular discharge, and/or edema	3
	Soft stools (fecal matter around anus)	5
	Pale, white mucus membranes/skin	6
	Bloody diarrhea	9
	Blue mucus membranes/skin (cyanosis)*	12
Respiratory Rate:		
	Normal breathing	0
	Change in breathing (an increase or decrease in respiratory rate from normal baseline)	2
	Labored breathing/ Dyspnea	6
	Abdominal breathing (gasping +/- open mouth breathing)/ Diaphragmatic breathing*	12
General Behavior:		
	Normal (based on baseline observations)	0
	Stretching of hind limbs with abdominal motion (writhe) or grimace (App. B and C)	1
	Decreased mobility	2
	Ataxia, wobbly, weak	6
	Inability to stand*	12
Provoked Behavior:		
	Normal (moves when cage is disturbed, runs from hand (mice) or investigates (rat))	0
	Subdued; responds to stimulation (moves away briskly)	1
	Subdued even to stimulation (moves away slowly)	3
	Unresponsive to gentle prodding	6
	Does not right when placed gently on side within 5 seconds*	12
Weight loss		
	0-35% with no other clinical signs	0
	≥35% weight loss	12

*** Regardless of score, immediately euthanize (death is imminent)**

Individual or Cumulative Score:

< 6	Normal
6 - 11	Morbid: See VI.D.2 and VI.D.4 in IACUC Policy #10 for guidelines
≥ 12	Moribund: Notify responsible personnel immediately for euthanasia (if no single criteria is 12*). Any single criteria of 12* euthanize immediately; consider as 'found dead.'

I. NON-TECHNICAL SYNOPSIS

The vast majority of studies on the acute radiation syndrome or sickness (ARS) and biodosimetry have been performed using photon irradiation (gamma and x-rays). Risks for acute mortality from radiation exposure are well known to be influenced by physics-based parameters, such as a radiation quality, low or high linear energy transfer (LET), dose rate, total-body vs. partial body exposure, etc. (Hall and Giarcia, 2011). After an enhanced radiation weapon (ERW) or nuclear device detonation, initial radiation at the time of the nuclear reaction consists of gamma-rays and neutrons (mixed field) produced within the first minute after detonation and its penetration capability, leading to increased damage requiring quality specific biodosimetry as neutrons have different mechanisms of injury to cells and tissues compared to photons, with a higher relative biological effectiveness (RBE).

The present work will evaluate biomarkers for radiation dose-assessment, ARS prognosis, and gender/age effects following mixed-field (gamma-rays and neutrons) using AFRRI TRIGA (Training, Research, Isotope, General Atomic) reactor in a mouse (B6D2F1/J) total-body irradiation (TBI) model. Biomarker measurements will be performed using the Meso Scale Diagnostics (MSD) high-throughput (HT) MULTI-ARRAY plate-format platform and results compared with earlier (b)(4) (b)(4) funded gamma radiation studies.

The proposed efforts supplement an ongoing project to deliver an FDA approved biodosimetry device by potentially expanding the use of its capability for a broader spectrum radiation exposure (mixed neutrons and gamma-rays). This effort is entirely novel. AFRRI is one of a limited number of facilities with the capability to study mixed-field exposures. The proposed studies on radiation biomarker responses to mixed-field irradiation for use with the Meso Scale Diagnostics biodosimetry system is completely new ground. We expect that this project will contribute to bridge a gap that exists in the current capabilities to identify and then rapidly as well as effectively to assess radiation exposure early after a radiation exposure and especially after a mass-casualty radiological incident. In particular, these efforts contribute to validating an early test to distinguish individuals exposed and injured by radiation in order to assist physicians to choose the appropriate medical treatments and hence reducing the adverse acute effects or long-

term risks associated with radiation exposure. The advancement in this type of research might also provide a powerful tool for the accurate assessment of an individual's radiation risk response early after an incident, especially after a mass-casualty radiological incident.

II. BACKGROUND

II.1. Background

A radiological terrorist attack or nuclear accident creates a risk for mass casualties (DiCarlo et al. 2011; Waselenko et al. 2004). The detonation of a nuclear weapon or a nuclear accident represents possible events with significant exposure to mixed-field (neutron + gamma) radiation. The mechanisms of injury of these low linear energy transfer (LET) radiations (pure gamma) are different from those of high-LET radiation such as neutrons or mixed-field, and these differences may affect the radiation dose assessment and countermeasure efficacy. Acute mortality from radiation exposure is well known to be influenced by physics-based parameters such as radiation quality (neutrons or gamma-rays) and dose rate. An enhanced radiation weapon, if detonated, would emit a large portion of neutron radiation with increased radius of exposure and penetration capability, leading to increased damage requiring quality-specific biodosimetry. Currently, a dose of 2 Gy of acute whole-body exposure is thought of as the threshold for medical intervention (Fliedner et al. 2001; Koenig et al. 2005; (b)(4) (b)(4) Moyer 2015). However, absolute reliance on this threshold ignores the impact of radiation quality and is of concern because neutrons are a significant component of the initial radiation released by a fission nuclear device. Hence, there is a current need to accurately determine exposure levels where mixed field combinations of neutrons and gammas are a threat. We have successfully completed four standard gamma only biodosimetry projects funded by (b)(4) (b)(4) (b)(4) the final goal of which is to deliver an FDA-approved hand-held, field deployable point-of-care biodosimetry device, which determines quickly (in few minutes) the radiation dose absorbed by evaluating blood protein biomarker levels after a large-scale radiological or nuclear event (IACUC protocol (b)(6),(b)(4)

Previously established animal (*Mus musculus*, *Macaca mulatta*) total-body irradiation (γ-exposure at a single dose-rate of 0.6 Gy/min) models have evaluated a panel of radiation-responsive proteins that, together with peripheral blood cell counts, to create a multiparametric dose-predictive algorithm with a threshold for detection of ~1 Gy from 1 to 7 d after exposure. The acute radiation syndrome (ARS) severity score systems were also created based on multiple biodosimetric endpoints. The mouse ARS severity score system was created using data collected in individual animals that were identified by IPTT-200, Bio Medic Data System (BMDS) implantable programmable transponders/microchips. Individual tracking of animals via implanted microchips allowed for assessment of criteria based on individuals rather than by group averages. The mouse ARS severity score system created at AFRRI includes the Observational Grading System (currently an IACUC policy #10 [Guidelines for establishment of early

endpoints in experiments with expected mortality]) developed at the AFRRI VSD, survival rate, weight changes, temperature, peripheral blood cell counts and radiation-responsive protein expression profile (Figures 1-3; (b)(6),(b)(4)

(b)(6),(b)(4)

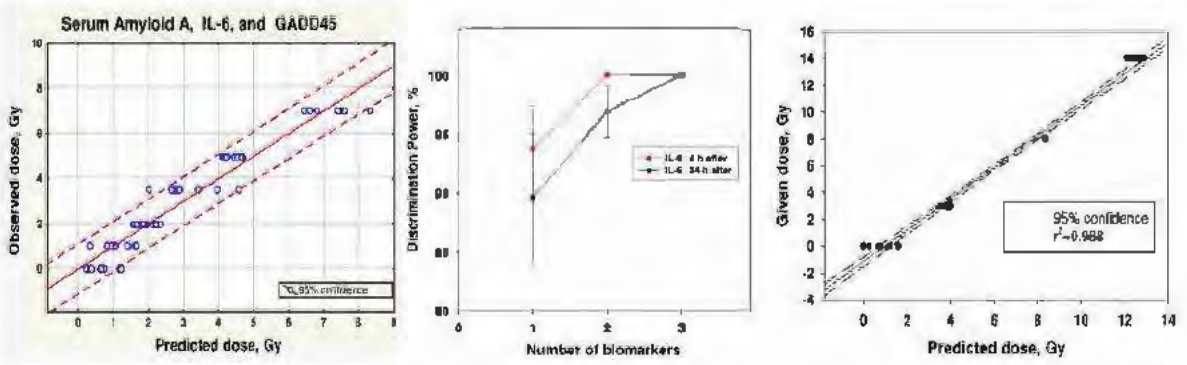

Figure 1. Multiparameter dose-assesment calibration curve (left plot), enhanced discrimination power at radiation dose of 1 Gy (middle plot) and biodosimetry evaluation in "blinded" study (right plot) in mouse TBI model (^{60}Co γ-rays at dose rate of 0.6 Gy/min).

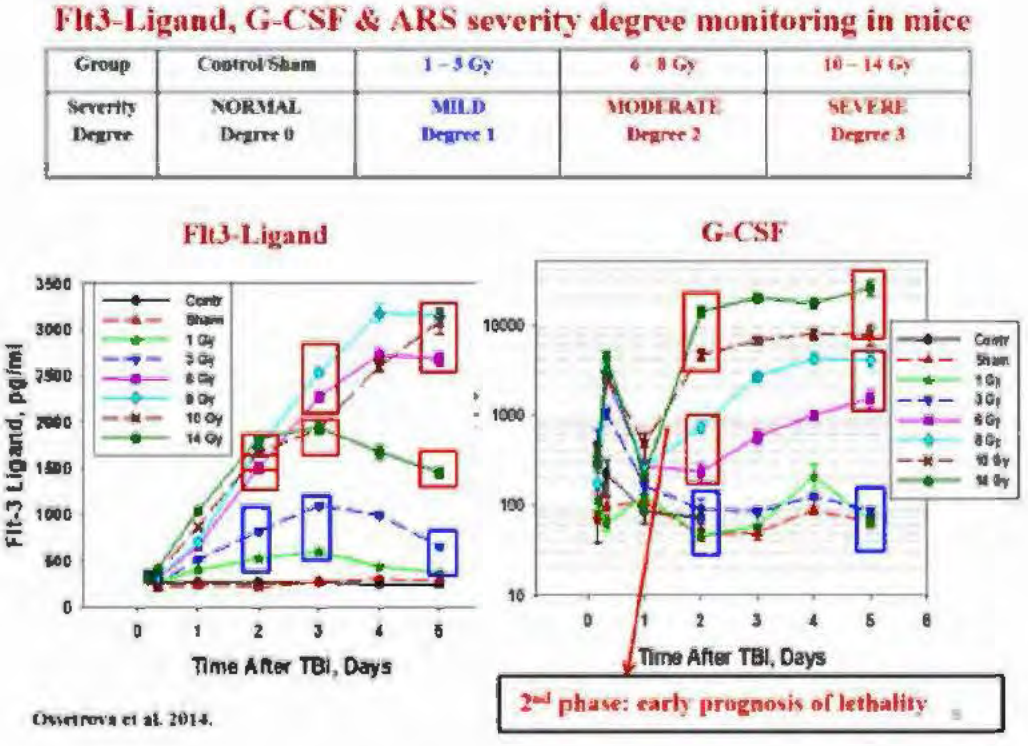

Figure 2. Flt3-Ligand, G-CSF and ARS severity degree monitoring in mouse TBI model (^{60}Co γ-rays at dose rate of 0.6 Gy/min).

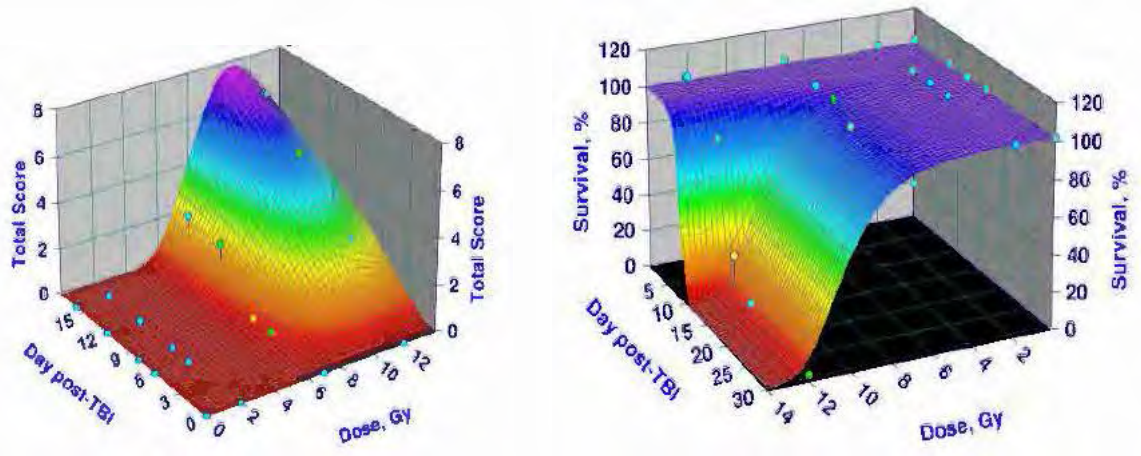

Figure 3. The radition-dose and time-dependent total mean ARS interventional score (left plot) and survival rate (right plot) in mouse TBI model (^{60}Co γ-rays at dose rate of 0.6 Gy/min) that might be used as an early predictive values for ARS prognosis or outcome.

The ARS response category assessment tool was created in order to quantify severity responses for ARS sub-syndromes and determine the criteria and bioindicators for early prognosis of lethality and point of euthanasia. The ARS severity degrees or response categories (RC), defined under the radiation-dose controlled conditions and animal recovery prognosis, were as follows: RC0 (Degree 0) for 0 Gy (control/sham); RC1 (Degree 1) for the dose-range of 1-3 Gy and animal recovery was certain with a low risk of critical phase (mild radiation damage); RC2 (Degree 2) was for the dose-range of 6-8 Gy and animal recovery was likely with a high risk of critical phase (moderate, but reversible damage); RC3 (Degree 3) was for the dose-range of 10-14 Gy and animal recovery was most unlikely (severe, irreversible damage) (Figures 2-3).

Since those studies were performed using only a pure gamma-ray exposure (^{60}Co), the needed dose-assessment modifications for mixed neutron and gamma exposures, a very militarily relevant scenario, remain unknown. There is a current need for biodosimetry and countermeasure drugs to treat ionizing radiation injury, for use in the field by military personnel and emergency responders. Radiation damages blood-forming tissues, resulting in mortality due to infection and hemorrhage (hematopoietic syndrome). (b)(6) (b)(6) assumes that in realistic scenarios, access to medical facilities will be unlikely for some time after a nuclear detonation. Neutrons and photons interact with cells in different ways: photons interact with orbital electrons, and neutrons interact with nuclei. Neutrons have a higher LET compared to photons, and neutron-induced DNA damage is less repairable (an effect not explained solely by frequency of double strand breaks, DSB). Neutrons and photons have different effects depending on the specific cells and tissues being considered. Neutron efficacy in inducing damage is higher than that of photons, i.e., the RBE (dose necessary to cause a degree of injury compared to the photon dose) is greater than one. Tissues and cell types differ in their rate of

accumulation of radiation-induced injury and in their repair capacity. The neutron RBE for GI injury (6 day mortality in mice) is about 3.5, while that for hematopoietic injury (30 day death) is about 2.4 (b)(6),(b)(4) After a nuclear detonation, personnel will be exposed to mixed radiation fields with different neutron to gamma ratios for detonations of concern (from weapons likely to be used by terrorists) (NATO Handbook 1994). In current studies, we have chosen a (33% n + 67% γ) and (67% n + 33% γ) to be representative of the possible fields.

In this protocol, a murine TBI model with a minimal supportive care will be used in order to simulate a catastrophic event involving large number of casualties. In this scenario, there will be limited medical and physical resources. Early and rapid dose assessment is required in radiation disasters that involve a large number of victims and a finite amount of medical resources available to responders and healthcare providers. The goal of this project is to develop biodosimetric assays to permit early and rapid radiation exposure assessment applicable for a forward field application.

Current project approach and aims:

Studies supplement an ongoing efforts to deliver an FDA approved proteomic biodosimetry capability by its expanding to a mixed-field (MF) radiation exposure.

- **Aim 1**: Perform mixed-field (MF, neutron + gamma) radiation validation studies and develop biodosimetry algorithm using hematological and proteomic profiles.
- **Aim 2**: Demonstrate accurate radiological detection, sensitivity and specificity of biomarker combinations to discriminate study groups into tertiles of doses: 0 -1.5 Gy, 1.5 - 3 Gy, 3 - 6 Gy.
- **Aim 3**: Characterize the response category severity score system for ARS prognosis / outcome based on biodosimetry endpoints and survival study results.
- **Aim 4**: Evaluate potential confounding effects of dose-rate and gender on use of proteomic biomarkers for biodosimetry and ARS prognosis / outcome.
- **Aim 5**: Compare MF study results with ones earlier obtained in pure-gamma studies (^{60}Co γ-rays).

II.2.5. Results of Search

There was no duplicative research found for the proposed study evaluating the combined blood based proteomic and hematological approach on biodosimetry endpoints (dose-response relationships for radiation dose assessment, dose-dependent discrimination index of radiation exposure, the response category severity score of the acute radiation syndrome using murine TBI model mixed-field radiation model. The only literature identified (b)(6) and regarding studies done with pure photons (^{60}Co γ-rays and x-rays). Other relevant papers were found reported: (1) measurement of multiple radiation-induced protein expression profiles (using the Luminex system) and chromosome aberrations associated with long-term health risks exposure of astronauts to a mixed-field of space radiation (i.e., protons, high charge and energy ions, neutrons, alpha particles); (2) measurements of dicentrics in peripheral blood lymphocytes and electron paramagnetic resonance (EPR) spectroscopy in tooth enamel for biodosimetry evaluated in pure photon and mixed-field (neutrons and gamma) irradiations; (3) AFRRI papers related to screening of radiation countermeasure against mixed-field (neutrons and gamma) irradiations. None of these studies duplicated the studies proposed in this protocol.

III. OBJECTIVE / HYPOTHESIS

General Hypothesis:

Multiple blood protein and hematological biomarkers along with hematological surrogates will provide enhanced diagnostically useful indices to discriminate between irradiated and non-irradiated (worried well) individuals. A panel of protein biomarkers, each with different radiation responses, coupled with peripheral blood cell counts or hematology surrogates will provide accurate assessment as well as an enhanced discrimination index of radiation exposure.

The proposed mixed-field radiation studies will complement the completed pure-photon mouse TBI studies (IACUC protocol number (b)(6) in terms of (1) develop dose-response relationships for radiation dose assessment; (2) investigate the effect of exposure to different doses of radiation on survival of mice in order to determine associations among protein expression profile, hematology parameters, body weight, and symptoms/signs related to the radiation dose and ARS prediction/outcome.

In addition, studies will evaluate potential confounding effects of dose-rate, age and gender on use of proteomic and hematological biomarkers.

IV. MILITARY RELEVANCE

Radiological terrorist attack or accidental mass-casualty exposures are highly possible. Military personnel responding to such emergencies can be exposed to radiation. Recognizing unpredictable mass casualties, U.S. Department of Defense has given top priority, as stated in the "Defense Technology Objectives (DTO)" to the development of rapid biodosimetry and medical countermeasures to radiation exposure" against both early- and late-arising health effects. In the case of mass casualties, it is difficult to screen out the severely exposed patient from the less exposed or not exposed individuals due to lack of immediate and convenient dose measurement technology.

Proposed studies targeted needs to support radiation diagnostic device (simple, rapid, high-throughput and point-of-care) development efforts based on a multiparametric biomarker-based biodosimetry diagnostic approach to facilitate treatment triage in a mass-casualty situation, and is also essential to the optimal use of scarce therapeutic resources. This strategy addresses the need for developing a high-throughput multiparametric "***Field Radiological Biodosimetry***" system and promotes effective command decisions and force structure planning to ensure mission success. This system should be compatible with military field laboratories, homeland security applications, as well as with radiation therapy centers to assess radiation exposure based on blood protein biomarkers capability. In addition, assessment of a population's exposure to other radiation threats, such as nuclear accidents and terrorism mass casualty scenarios addresses the need for a "***Clinical Radiological Biodosimetry***" system to provide physicians with the ability to triage radiation victims, make appropriate treatment decisions, and reduce uncertainties associated with the variability of individual response to radiation exposure.

V. MATERIALS AND METHODS

V.1. Experimental Design and General Procedures

B6D2F1/J female and male 14-16 wk old mice will be used in experiments. Total-body irradiations (TBI) of mice will be performed at different radiation doses and dose-rates in the AFRRI facilities: TRIGA (Training, Research, Isotope, General Atomic) Mark-F nuclear research reactor is capable of delivering a mixed-LET field of fission neutrons and γ-rays and ^{60}Co (low-LET, pure γ-rays) with reliable and accurate physical dosimetry. Dosimetry for ^{60}Co irradiation was performed using an alanine/electron paramagnetic resonance system, with calibration factors traceable to the National Institute of Standards and Technology and confirmed by an additional check against the national standard ^{60}Co source of the UK National Physics Laboratory. Dosimetry for the reactor-produced radiation fields was performed with paired ionization chambers, as described in AFRRI Technical Report (b)(4) TBI will be given as a single exposure. Mice will be irradiated as outlined in section V.4.4.1.4. Irradiation procedure.

Statistical justification for the number of animals in each experiment is provided in section V.2. Data Analysis. In Experiments 1-4 and 6, blood from mice will be collected by intracardiac puncture or inferior vena cava at sampling time-points 1, 2, 4, and 7d after exposure. Blood for cell counts and differentials (CBC/diff) will be analyzed within several hours after biosampling using a clinical hematology analyzer (Bayer Advia 120, Bayer, Tarrytown, NY) at the AFRRI Veterinary Sciences Department (VSD) facility or sent out to Bioreliance or another approved lab as a backup. The remaining blood will be processed for protein profile (18 biomarkers) measurements in plasma using a Meso Scale Diagnostics (MSD) high-throughput (HT) MULTI-ARRAY plate-format platform as previously described (b)(6),(b)(4) Collected data will be analyzed to create the mixed-field biodosimetry algorithm and ARS prediction outcome. Results will be compared with ones earlier obtained in ^{60}Co γ-rays studies (IACUC protocol number (b)(6),(b)(4)

Summary Table 1 is for all experiments (1-6), detail Tables (2-11) are for each experiment.

Table 1. Summary Table for all experiments (1-6).

V.1.5. Experiment 5

Perform the 30-d survival study after radiation with MF (67% n + 33% γ) to doses of 4, 5, 6, 7 Gy at dose-rate of 0.6 Gy/min) using 14 – 16-wk female old mice to investigate the effect of exposure to different doses of MF in order to find associations between protein expression profile, hematology parameters, body weight, symptoms and signs related to the radiation dose and the ARS severity and create the ARS severity score system. Compare results with ones collected earlier in ^{60}Co γ-rays studies.

Animal survival will be monitored daily for 30 days after irradiation. Based on review by the AFRRI statistician, we plan to use 20-32 mice per treatment group for measurement of animal survival endpoints. Total of 136 mice (124 plus 10% extra) will be used. The extra 10% of mice is needed in order to eliminate the animal body weight outliers. Mice will be individually identified by tattoos performed on their tails as outlined in section V.4.4.1.3 Tattoo Procedures. Observations will be recorded using the Bio Medic Data System (BMDS) electronic data recording system. Mice will be weighed on a Sartoruis ED5201 scale (BMDS data acquisition system) and the weight will be recorded to electronic data files. Clinical observations will be conducted twice daily in noncritical and up to four times per day (including late-night checks) in critical period of ARS (severe pancytopenia). Clinical signs and certain criteria selected to define the morbidity or moribundity in irradiated mice will be scored following the IACUC Policy #10 developed at AFRRI VSD (Appendix 1). The mutiparametric ARS Severity score system following by high-LET (mixed-field, n + γ) irradiations will be created similar to one created earlier in low-LET (^{60}Co γ-rays) studies (b)(6),(b)(4)

V.1.6. Experiment 6

Task 7. Perform the gender-comparison radiation studies with ^{60}Co γ-rays (3, 6, 12 Gy) and mixed-field (67% n + 33% γ) (1.5, 3, and 6 Gy) at 0.6 Gy/min.

V.2. Data Analysis

Number of animals n=8-14 per group (dose, and sampling time-point) is necessary for experiments 1 -4 and 6. It has been determined by AFRRI statistician from similar studies to provide power >90% for two-tailed Student's t-test to get two standard deviations (2 STD) or 95% confidence interval in distinguishing animal groups and less than 10% shifts in biomarker values (reproducibility). Values of $P < 0.05$ will be considered statistically significant. An increase in the number of animals per group up to n=10-14 for TBI doses of ≥3 Gy (TRIGA) and ≥ 6 Gy (^{60}Co) at sampling time-points 4 and 7d is necessary in order to provide the sufficient statistical accuracy because at this dose and later time points there is expected to be potential early morbidity (from 30% to 70% in the 30-d monitoring period) by developing hematopoietic syndrome as well as a broadening of the distribution of radiation responsive biomarkers. Control mice will not be placed into boxes nor transported to the radiation facilities. Comparison of results for sham groups and control groups evaluated any effect of stress induced by handling of mice as it was performed in earlier ^{60}Co studies (b)(6),(b)(4) In 30-day survival study (Experiment 5), we plan to use 20-32 mice per treatment group for measurement of animal survival endpoints. Number of mice will be increased from 20 to 32 due to statistical justification provided below.

The 20 mice per group could have 80% power to detect a significant difference between two groups, given type I error of 5% and a treatment group survival rate of at least 73%, if the control group is 25%. Similar statements would apply, provided the treatment groups display survival of at least 86%, 83%, or 78%, if the respective control groups would be 40%, 35%, and 30%, respectively. Note: power analysis may suggest smaller groups are adequate. However, radiobiologists at AFRRI and elsewhere observe considerable variability from experiment to experiment in mouse survival studies that is not reflected in the power analysis. In fact, some institutions have gone to a group size of 30 in these types of experiments for this reason.

Statistical software, PC SAS, will be used for statistical data analysis (SAS Institute Inc., 2000). Multivariate analysis of variance (MANOVA) Wilks' Lambda statistics will be used when comparing more than two groups and two-sided Student's *t* test will be used when comparing two groups to determine significant differences among observational time-points in radiation biomarkers studies and ARS severity degree categories as previously described (b)(6),(b)(4)

Multiple linear regression analysis will be used to develop dose-response relationships for combination of hematological and protein biomarkers for radiation dose assessment at the 95% confidence level. Multivariate discriminant function analysis of PC SAS will be used to demonstrate accurate radiological detection of the proposed protein and hematological biomarkers from biological samples into tertiles of doses 0-1.5 Gy, 1.5-3 Gy, and 3-6 Gy and also to demonstrate which combinations of proposed protein and hematological biomarkers will better reflect the subgroup differences. Receiver Operating Characteristic curve (or ROC curve) will be used to demonstrate the sensitivity and specificity of the proposed protein and hematological biomarkers to

reflect subgroup (dose and sampling time-point) differences. Results will be shown as a ROC plot of the true positive rate against the false positive rate for the different possible cut-points of a diagnostic test. Kaplan-Meier survival curves will be constructed to determine the survival time probability to estimate the LD30/30, LD50/30, and LD70/30. The Table Curve 3D statistical software will be used to create the dose- and time-dependent fitting equations for ARS scores as prognostic indexes of ARS outcome. Biomarker results and ARS severity score system received in high-LET (mixed-field) experiments will be compared with ones received in irradiations performed with low-LET (^{60}Co γ-rays)[(b)(6),(b)(4)]

V.3. Laboratory Animals Required and Justification

V.3.1. Non-animal Alternatives Considered

Currently, there are no alternatives in existence that can predict or compute the complexity of the response to total body irradiation. Computer modeling and cell cultures are insufficient to determine whether or not a given radiation exposure will result in a characteristic radio-response of molecular changes, protein expression of blood or other tissues. An integrated, functional, computer model of a mammal has not yet been achieved for the purpose of examining intricate physiological interactions among cells, tissues, and organs that occur after exposure to ionizing radiation. The resiliency of organs, such as the hematopoietic system or gastrointestinal system, to ionizing radiation depends on a complex network of interactive signaling systems to sense the magnitude of tissue damage, and to initiate repair, recovery, and other defense processes. The physiology of these interacting networks is altered by radiation in ways that cannot yet be modeled. Alterations of expression of the proteins we propose to measure are influenced by the same complex network of regulatory controls that cannot be duplicated outside of use of living animals.

V.3.2. Animal Model and Species Justification

The mouse model was chosen for this *in vivo* validation study for the following reasons: (1) it is well-defined immunological animal model for this type of research; (2) qualitative similarities exist between human and mouse proliferative tissue including bone marrow (Thompson 1962); (3) molecular responses of mouse and human peripheral blood to gamma radiation are expected to be similar; (4) the ease of use of a mouse model system ensures reliable data collection; (5) median lethal doses (LD50/30) for radiation-induced death for this strains of mice is known (Hendry 1995;[(b)(4)] [(b)(4)] (6) model provides experimental and statistical validity; (7) AFRRI staff has an extensive experience with mice, including B6D2F1 mice, in radiation injury and countermeasure research. In addition, B6D2F1 mice were used in previous studies (^{60}Co γ-rays, protocol number[(b)(6)]

V.3.3. Laboratory Animals

V.3.3.1. Genus / Species

Mice (*Mus musculus)*

V.3.3.2. Strain / Stock
B6D2F1/J

V.3.3.3. Source / Vendor
B6D2F1/J mice: Areas AX-27 or AX-28, The Jackson Laboratory, 600 Main Street, Bar Harbor, Main 04609-1500, Tel: 800-422-MICE or 207-288-5845, Fax: 207-288-6150, www.jax.org <http://www.jax.org/> or any other approved vendors.

V.3.3.4. Age
Age at irradiation from 14 to 16 wks; 11-12 wk of age at purchase, 14-16 wk of age at use.

V.3.3.5. Weight
Approximately 24 to 26 g (20-22 g upon arrival, 23 g or more at the time of experimental manipulation).

V.3.3.6. Sex
Males and females.

V.3.3.7. Special Considerations
Commercially procured animals must be adventitious disease free, including: *Pseudomonas aeruginosa* and *Pasteurella*. All mice need to be free of the following agents: Sendai, Pneumonia Virus of Mice (PVM), Reovirus-3 (Reo 3), Mouse Adenovirus (MAD-1, MAD-2), Mouse Cytomegalovirus Virus (MCMV), Ectromelia, K virus, Lymphocytic Choriomeningitis Virus (LCM), Epidemic Diarrhea of Infant Mice (EDIM), Hantaan virus, Rotavirus, Mouse Parvovirus (MPV), Polyoma Virus, Mouse Minute Virus (MMV), Mouse Thymic Virus (MTV), Theiler's Mouse Encephalomyelitis Virus (TMEV/GDVII), *Encephalitozoon cuniculi*, CAR bacillus, *Mycoplasma pulmonis*, and *Clostridium piliforme.*

V.3.4. Number of Animals Required (by species)
Total number of mice: 1302.

V.3.5. Refinement, Reduction, Replacement (3 R's)

V.3.5.1. Refinement
In this protocol, some radiation doses (≥ 6 Gy) are sublethal, minimizing discomfort due to ARS. Project personnel will take necessary steps to be highly trained in handling techniques (irradiation procedure, tail-tattooing, blood collection, and routine cage-side observations) to minimize distress and pain to the animals. In a survival study, in order to minimize discomfort when animals become morbid, investigators and animal care staff will examine the mice at least twice daily, including the early morning and late afternoon. Number of observations will be increased as mice irradiated to sublethal doses will be in a critical period (pancytopenia). Moribund animals will be considered to have arrived at the study endpoint and will be euthanized as included in Appendix 1

(sample scoring sheet for clinical observations with criteria for rodent euthanasia), an IACUC Policy #10 (Guidelines for establishment of early endpoints in experiments with expected mortality).
Analgesics were considered as a way of minimizing discomfort during the onset of opportunistic infections, which will occur during the survival experiments. However, analgesics and anesthetics are well-known to alter the functional properties of the immune system and resistance to infection (Galley et al. 1997; Elena et al. 1997; Beilin et al. 1996), which would defeat the purpose of the study and results will not be comparable with ones obtained in earlier ^{60}Co studies (IACUC protocol number (b)(6) (b)(6)

V.3.5.2. Reduction
Control groups will be shared between experiments wherever possible. The maximum number of assays will be performed on each tissue sample, minimizing the number of required animals. Tissues from these animals are available for sharing with other investigators. A statistician has reviewed this protocol to ensure that the minimum number of animals will be used to gain statistically significant results. We will collect multiple data from individual animals, providing information on biomarkers and microbiological and hematological endpoints.

V.3.5.3. Replacement
None. It is not feasible to use non-animal systems to address the questions in this project.

V.4. Technical Methods

V.4.1. Pain / Distress Assessment

V.4.1.1. APHIS Form 7023 Information

V.4.1.1.1. Number of Animals: 1302

V.4.1.1.1.1. Column C 372 (# of animals)

V.4.1.1.1.2. Column D 0 (# of animals)

V.4.1.1.1.3. Column E 930 *(# of animals)*

V.4.1.1.1.4. Pain Category Assignments

Exp. #	Experimental/Control Group	C	D	E	Totals
1	TRIGA dose-response: (67% n + 33% γ) @ 0.6 Gy/min	64	0	108	172
2	TRIGA dose-response: (33% n + 67% γ) @ 0.6 Gy/min	64	0	108	172
3	Dose-rate effect: ^{60}Co γ-rays @ 0.6 and 1.9 Gy/min	64	0	138	202
4	Dose-rate effect: TRIGA (67% n + 33% γ) @ 0.6 and 1.9 Gy/min	64	0	156	220
5	Survival study: TRIGA (67% n + 33% γ) @ 0.6 Gy/min	20	0	116	136

Exp. #	Experimental/Control Group	C	D	E	Totals
6	Gender comparison: ^{60}Co γ-rays and TRIGA (67% n + 33% γ) @ 0.6 Gy/min	96	0	304	400
Totals:		**372**	0	**930**	**1302**

E. Justification if animals have been added to "E" category:
There are no alternative procedures for irradiation because its effects cannot be otherwise duplicated. Radiation itself does not cause pain or distress. A number of animals in these experiments will receive either sublethal or near-lethal doses. These dose levels will lead to the clinical syndromes following irradiation, which may lead to distress/pain and moribundity. Moribund animals will be considered to have arrived at the study endpoint and will be euthanized as included in Appendix 1 (sample scoring sheet for clinical observations with criteria for rodent euthanasia), an IACUC Policy#10 (Guidelines for establishment of early endpoints in experiments with expected mortality).

V.4.1.2. Pain Relief / Prevention

V.4.1.2.1. Anesthesia / Analgesia / Tranquilization
In these studies, experiments will be conducted with a minimal supportive care in order to simulate a catastrophic event involving large number of casualties. In this scenario, there will be limited medical and physical resources. Systemic antibiotics, anesthetics or analgesics will not be used as in previous radiation only (not combined injury) studies (IACUC protocol number (b)(6) If wounding occurs via in-cage fighting, topical antibiotics will be applied under the guidance of the veterinarian in accordance with standard treatment measures.

Anesthesia using standard isoflurane rodent anesthesia machine under the guidance of the VSD will be carried out in mice for blood collection. Animals will be placed in the induction chamber and delivered a metered amount of 3-5% isoflurane mixed with 100% oxygen (at the flow rate of 500-1000 cc/min) until all voluntary motor movement ceases and the animal is recumbent for 10 seconds. Animal's respiration rate will be closely monitored through the Plexiglas chamber during induction of anesthesia. The toe pinch response will be used to determine the depth of anesthesia. The tail will be pinched for reflexive movement, indicative of insufficient anesthesia. If there is no response, the animal will be moved to the station with individual nose cone for maintenance of anesthesia at 1-3% isoflurane and 100% oxygen at 500-1000 cc/min to perform blood collection.

V.4.1.2.2. Pre- and Post-procedural Provisions
Mice will be housed and monitored in accordance with VSD standard operating procedures both before and after irradiation procedures (see section V.5. Veterinary Care). For special husbandry considerations post-procedural, see section V.5.1.2.
Project personnel will examine the mice at least twice daily and number of observations will be increased in a critical period of ARS. Moribund animals will be euthanized if criteria will be met as included in Appendix 1 (sample scoring sheet for clinical observations with criteria for rodent euthanasia). Euthanasia will be conducted as outlined in section V.4.6. Euthanasia.

V.4.1.2.3. Paralytics
NA

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures

V.4.1.3.1. Sources Searched
AGRICOLA and PubMed.

V.4.1.3.2. Date of Search
1/12/2016

V.4.1.3.3. Period of Search
AGRICOLA: 2009 - 2016
PubMed: 1995-2016

V.4.1.3.4. Key Words of Search
Ionizing radiation AND pain, neutron AND pain, mixed-field AND pain, alternative, humane, alternative methods to blood collection.

V.4.1.3.5. Results of Search
There are no alternatives to irradiation. Irradiation itself is not a painful process, but it induces various changes in the body, and kills hematopoietic cells. In irradiated animals, the immune response is compromised, and opportunistic infections and multi-organ dysfunction/failure may occur. Results of literature search clearly demonstrate that use of analgesics alters radiation response and therefore leads to increase in animal number for better statistical results or for iteration of entire experiments.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification
Animals irradiated to sub- or lethal doses become immune compromised and might die due to opportunistic infections and /or multi-organ dysfunction/failure. We anticipate that animals exposed to sub- or lethal radiation doses will become moribund. As discussed above, in order to compare results with earlier studies (IACUC protocol number (b)(6) (b)(6) we will not give anesthetic and/or analgesic agents to animals since they are known to interact with the immune system, and would confound the interpretation, resulting in a waste of animals (see references in section V.3.5.1). All moribund animals will be euthanized as outlined in section V.4.6 Euthanasia. As mentioned in section V.4.1.2.1. Anesthesia / Analgesia / Tranquilization, systemic antibiotics, anesthetics or analgesics will not be used. The topical antibiotics will be applied under the guidance of the veterinarian in accordance with standard treatment measures if wounding occurs via in-cage fighting of mice.

V.4.2. Prolonged Restraint
No prolonged restrain.

V.4.3. Surgery

V.4.3.1. Pre-surgical Provisions
NA

V.4.3.2. Procedure(s)

Collection of blood and tissues.
Mice will be deeply anesthetized in the anesthesia machine. The toe pinch response will be used to determine the depth of anesthesia. The tail will be pinched for reflexive movement, indicative of insufficient anesthesia. If there is no response, the animal will be moved to the station with individual nose cone for continued anesthesia. Blood from mice anesthetized by isoflurane inhalation will be drawn by either cardiac stick or from the inferior vena cava using a heparinized 23-25 gauge sterile 5/8" needle attached to 1-3-ml syringe. Typically 0.7-0.9 ml of blood is collected; sometimes more than 1 ml in non-irradiated (sham/control) mice, less blood is available after radiation exposure. After blood collection, animals will be euthanized as outlined in section V.4.6. Euthanasia. Tissues will be made available to other investigators (see also in V.4.4.2. Biosamples).

V.4.4.1.3. Tattoo procedure:

Tattooing of mice in survival study will be done either with a Labstamp machine Labstamp system following the SOP provided by the company or any other machine certified by VSD.

V.4.4.1.4. Irradiation procedure:
Total-body irradiations (TBI) of mice will be performed at different radiation doses and dose-rates in the AFRRI facilities: TRIGA reactor (mixed-field, n + γ) and ^{60}Co (pure γ). TBI will be given as a single exposure. Animal irradiations will be arranged in an array according to the latest dosimetry map provided by the Radiation Sciences Department. For irradiation of mice at the ^{60}Co facility, animals will be placed into well-ventilated Plexiglas boxes and irradiated bilaterally. For irradiation of mice in the reactor, animals will be inserted into aluminum holders placed onto a carousel that rotates the mice within the exposure beam to ensure uniform exposures to all subjects. Sham-irradiated mice will undergo the same procedures as the irradiated mice (transport to radiation facility, placement into Plexiglas box or aluminum cylinder), minus the radiation exposure. In the reactor, non-neutron components of the exposure are controlled by shielding around the carousel. All irradiations will be performed before noon in order to be consistent with studies earlier performed (IACUC protocol (b)(6) It is important because the radiation sensitivity and survival rate varied on time of irradiation (morning, midday, or afternoon) as reported by Plett and colleagues (Plett et al. 2012). Mice will be restrained during the irradiation procedure. They will be inserted into the standard radiation boxes or aluminum holders just prior to irradiation (~15 min of exposure time) and taken to the radiation facilities for irradiation. The restraint time should be less than 60 minutes. After irradiation, mice will be returned to VSD and placed to cages with a fresh bedding/food/water for further monitoring. Mice will be identified by cage cards using VSD SOP Animal Identification and Accountability.

All personnel involved in reactor irradiation experiments will remain current with respect to radiation safety training and will continue to receive annual radiation worker training. They will also undergo all required specialized training provided by Health Physics Department (HPD), and Radiation Sciences Department (RSD), including AFRRI reactor exposure room training given by the reactor facility staff. Appropriate personal dosimeters will be worn at all times when working in reactor area. This includes the standard personal thermoluminescence dosimeter (TLD) along with a self-reading pocket chamber dosimeter to serve as a backup.

All reactor-irradiated mice, their tissues, and their bedding will be considered radioactive unless declared otherwise as a result of HPD surveys. Source accountability and ALARA principles will be adhered to at all times, and the SWIMS procedure will be followed in case of any spills of potentially radioactive materials.

V.4.4.2. Biosamples
Blood (as in the project Statement of Work) and tissues (bone marrow harvested from femurs and legs, spleen, lung, liver, sternums, GI, thymus, and kidney will be shared with other investigators upon request). Biosamples will be collected as outlined in section V.4.3.2. Procedure(s) Collection of blood and tissues. After blood collection, animals will be euthanized as outlined in section V.4.6. Euthanasia.

V.4.4.3. Adjuvants
NA

V.4.4.4. Monoclonal Antibody (MAb) Production
NA

V.4.4.5. Animal Identification
Mice will be housed in groups of 4-6 per cage. They will be identified by cage cards using GLP SOP Rodent Cage Cards. Each card states the investigator's name, protocol number, experiment number, cage number, start date, end date, species, item number (animal lot), birthdate, gender, strain, number of animals in the cage, vendor, arrival date, treatments, and dates of death, including the initials of the staff person who found and removed the dead animals. In addition, mice in Experiment 5 (survival study) will be identified by tattoo for individual tracking (see section V.4.4.1.3).

V.4.4.6. Behavioral Studies
NA

V.4.4.7. Other Procedures
NA

V.4.4.8. Tissue Sharing
Tissues will be made available to other investigators at the time of scheduled euthanasia.

V.4.4.9. Animal By-Products
NA

V.4.5. Study Endpoint
The endpoint of the studies will be euthanasia at the predetermined terminal blood collections (Experiments 1-4 and 6) and based on assessment of moribundity (Experiment 5). Clinical observations for pain and distress in mice will be monitored by project personnel at least twice daily and the number of observations will be increased in a critical period of ARS (pancytopenia). This monitoring schedule includes weekends and holidays. To minimize animal pain or distress, moribund animals will be scored according to sample scoring sheet for clinical observations with criteria for rodent euthanasia (Appendix 1) and euthanized as outlined in section V.4.6. Euthanasia. Mice that survive the 30-d monitoring period after irradiation will be euthanized. Sham mice from survival study may be transferred to another approved protocol.

V.4.6. Euthanasia
In the dose-response study (Experiments 1-4 and 6), for terminal blood sample collections, mice first will be deeply anesthetized with isoflurane and then euthanized by cervical dislocation that will be performed by protocol personnel. In the survival study (Experiment 5), irradiated mice that survived monitoring period (30 days) will be euthanized. Moribund animals that met IACUC Policy #10 euthanasia criteria will be euthanized by VSD staff or protocol personnel. Euthanasia of mice will be performed by

CO_2 inhalation followed by cervical dislocation and their carcasses will be disposed according to VSD SOPs.

V.5. Veterinary Care

V.5.1. Husbandry Considerations

All animals will be housed and maintained in accordance with the "Guide for the Care and Use of Laboratory Animals" and AFRRI VSD Standing Operating Procedures. Mice will be placed in groups of 4 – 6 per cage during experiments. Animals will receive Harlan Teklad Rodent Diet (w) 8604 and water *ad libitum*. Acidified water (pH 2.5 – 3.0) is routinely provided to AFRRI mice used in radiological experiments. Cages will be regularly changed and cleaned by VSD staff and project personnel (see V.5.1.2. Special Husbandry Provisions for mice irradiated with reactor) in accordance with Standard Operating Procedure. Animals will have 12 h light/dark cycle. In the event of procedures that last into the night cycle, care will be taken to minimize exposure to light by using red-lens flashlights.

V.5.1.1. Study Room

As assigned by VSD, study room number will be (b)(6) within the vivarium.

V.5.1.2. Special Husbandry Provisions

Reactor-irradiated animals will be monitored for radiation levels by the Radiation Safety staff. The activated animals will be marked with radiation activity indicator cards that will be removed after natural activity of the isotopes results in levels of radiation not distinguishable from background (estimated to be ~24 hours, judging from past experience of other investigators at AFRRI).

The room (b)(6) housing the irradiated mice will be designated a "radiation room" by RSD and HPD, labeled as such, and access will be restricted to properly trained staff until declared clear by RSD/HPD radiological surveys. Standard radiological room operating procedures will require removal of all PPE before exiting the room and surveying all personnel, equipment, and materials for radioactivity with a Geiger-Müller counter before allowing them to be removed from the room. Following standard operating procedures in sample collections, gloves will be worn at all times when handling the irradiated mice. Finger ring dosimeters will be worn by all personnel handling irradiated mice until they have been declared non-radioactive by HPD. Before mice have been declared non-radioactive by HPD, carcasses and bedding will be disposed by project personnel in the Rad Waste Facility area designated for such material. Irradiated mice remains will be disposed of in the Radiation Safety Storage area designated for such material until the mice can be surveyed for radiation hazard level before final disposal.

V.5.1.3. Exceptions

Mice will be socially (group) housed, except for the possibility that during survival study cagemates may be lost through attrition and for a period of time the sole surviving mouse may remain singly housed until the end of the 30-day study. When this occurs, singly housed animals will be able to view con-specifics in neighboring cages housed on the same rack in the same room.

V.5.2. Veterinary Medical Care

V.5.2.1. Routine Veterinary Medical Care

The animals will be observed daily by protocol personnel. In the critical phase, mice will be monitored three times daily by investigative staff in conjunction with VSD personnel with no more than 10 hours between the late night and early morning check as per IACUC Policy #10. As observations in the Experiment #5 (survival study) also include the weighting of mice, late night, weekend, and holiday checks will be done by investigative staff. Any moribund mice will be euthanized as soon as possible. If needed, a VSD veterinarian will be contacted for decision to euthanize.

V.5.2.2. Emergency Veterinary Medical Care

Emergency veterinary medical care is available 24 hours a day, seven days a week by VSD veterinarians and technicians and will include immediate euthanasia of any moribund mice. The on-call roster is located outside the VSD conference room (b)(6) (b)(6) on the bulletin board and at the security watch desk. These procedures are in accordance with VSD SOP (Duty Roster and Responsibilities of the "On-Call" Veterinary Officer and Veterinary Technician).

V.5.3. Environmental Enrichment

V.5.3.1. Enrichment Strategy

The animals will be housed in standard/conventional rodent caging. Mice will be group-housed, 4 - 6 mice per cage, with cotton bedding nestlets as per AFRRI VSD SOPs. Plastic tubes, hutches etc. will be provided once mice have been declared non-radioactive by SHD.

V.5.3.2. Enrichment Restrictions

Plastic tubes, hutches etc. will be not be provided to use immediately after irradiation to avoid contaminating the enrichment devices, but will be introduced once SHD has declared the mice non-radioactive.

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING

NAME	DEGREE	TRAINING	DATE	PROCEDURES	YRS/MOS EXPERIENCE
(b)(6)				1, 3, 4a, 4b, 6 (micro-chips between shoulder blades), 7 (loading into radiation boxes)	(b)(6)
				1, 3, 4a, 4b, 5, 7 (loading into radiation boxes)	

Procedure and manipulation codes:
Code 1= Animal handling and euthanasia
Code 2= Surgery (aseptic technique) pre- and post-operative care
Code 3= Injections (3a–ip, 3b-sc, 3c-gavage) - can say 3 if trained in all manipulations or add 3d-iv

Code 4= Blood collection under anesthesia (4a-cardiac, 4b-inferior vena cava)
Code 5= Tissue collection (after euthanasia) - doesn't need to be specific
Code 6 = Implantation (provide details)
Code 7 = Others - (provide protocol specific manipulations or procedures for e.g., retro-orbital bleeding, tail vein injection, or drug delivery)

VII. BIOHAZARDS/SAFETY

See V.5.1.2. Special Husbandry Provisions. See also attached AFRRI Form 310.
The primary radiation hazard to workers arises from potential exposure to tissues made radioactive as a result of neutron activation of various elements within those tissues. Activation products of primary concern include Na-24, Cl-38, and P-32, because of their relative abundance in living cells (see AFRRI Form 310).
Those isotopes have a short half-life time (few hours) and were reported to be neutron-activated at the very low residual radioactivity (<0.5 uCi) (Hall DE, 2009. Modeling and Validation of Dosimetry Measurement Assumptions Within The Armed Forces Radiobiology Research Institute TRIGA Mark-F Reactor and associated Exposure Facilities using Monte Carlo Techniques.
All protocol personnel will have a VSD safety training, general radiation users training and additional ones related to irradiations with reactor. Protocols for clean-up of small spills (alcohol, acids, bases, solvents, biological samples, etc.) are maintained in the Biodosimetry Research Group SOP Protocols Binder located in laboratory (b)(6) The reporting of small spills generally includes notification of protocol PI and HPD staff.

VIII. ENCLOSURES

1. AFRRI Form 310

X. ASSURANCES

Protocol Title:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made every effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with a qualified individual who evaluated the experimental design with respect to the statistical analysis, and that the minimum number of animals needed for scientific validity will be used.

D. Biohazard / Safety: I have taken into consideration and made the proper coordinations regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. **Responsibility:** I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R", namely, "Responsibility," which the DOD has embraced for implementing animal use alternatives where feasible and conducting humane and lawful research.

G. **Scientific Review:** This proposed animal use protocol has received appropriate peer scientific review and is consistent with good scientific research practice.

H. **Painful Procedure(s):** I **AM** / **AM NOT** (*circle one*) conducting biomedical experiments, which may potentially cause more than momentary or slight pain or distress to animals. If applicable, potential pain and/or distress **WILL** / **WILL NOT** (*circle one*) be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

Appendix 1
Sample Score Sheet for
Clinical Observations with Criteria for Rodent Euthanasia

DATE:	Time:	Animal ID#	Score
Appearance:			
	Normal (smooth coat, clear eyes/nose)		0
	Hunched and/or fluffed		1
	Ocular discharge, and/or edema		3
	Soft stools (fecal matter around anus)		5
	Pale, white mucus membranes/skin**		6
	Bloody diarrhea		9
	Blue mucus membranes/skin (cyanosis)*		12
Respiratory Rate:			
	Normal breathing		0
	Increased breathing (double normal rate, rapid, shallow)		6
	Abdominal breathing (gasping +/- open mouth breathing)*		12
General Behavior:			
	Normal (based on baseline observations)		0
	Stretching of hind limbs with abdominal motion (writhe) or grimace (App. B and C)		1
	Decreased mobility		2
	Ataxia, wobbly, weak**		6
	Inability to stand*		12
Provoked Behavior:			
	Normal (moves when cage is disturbed, runs from hand (mice) or investigates (rat))		0
	Subdued; responds to stimulation (moves away briskly)		1
	Subdued even to stimulation (moves away slowly)		3
	Unresponsive to gentle prodding **		6
	Does not right when placed gently on side within 5 seconds*		12
Weight Loss: (Only to be used if the total summed score is ≥ 6 in the other four categories. Said weight should not be taken daily, but rather every few days.):			
	Normal < 20%		0
	20-25%		3
	26-30%**		6
	31-34%**		9
	≥35%*		12
TOTAL			_____

**** Regardless of total score, notify appropriate veterinary staff personnel immediately.**

*** Regardless of score, immediately euthanize (death is imminent)**

Total Score:

< 6	Normal
6 - 11	Morbid: See VI.D.2 and VI.D.4 in IACUC Policy #10 for guidelines
≥ 12	Moribund: Notify responsible personnel immediately for euthanasia (if no single criteria is 12*). Any single criteria of 12* euthanize immediately; consider as 'found dead.'

DOD ANIMAL CARE AND USE STANDARDIZED PROTOCOL FORMAT WITH EMBEDDED INSTRUCTIONS (December 2015)

Reference DOD Instruction 3216.01 & AFRRI Instruction 3216.2H

****

Information requested in the following animal use protocol template reflects the requirements of the Animal Welfare Act Regulations (AWAR), the Guide for the Care and Use of Laboratory Animals, and other applicable Federal regulations and DOD instructions.

****

This document is intended to be an aid in the preparation of DOD-sponsored animal use protocols. It is a companion document to an identical protocol template that does not have embedded instructions. Either template may be used to format DOD-sponsored animal research proposals; however, reference to the instructions during protocol preparation is highly recommended. If using the template with instructions, the instructions should be deleted prior to submitting the finished protocol for IACUC review. Please use Arial, regular, size 12, black font to prepare the protocol. With the exception of section headings, all paragraphs require a response. Paragraphs that do not apply should be marked N/A. There is no space limitation for responses to the information requested.

Approved standard operating procedures (SOPs) promulgated by the AFRRI Veterinary Sciences Department (VSD) or similar VSD-validated documents that describe specific procedures may be referenced by SOP number and title in lieu of repeating the details in the protocol. However, it is essential to include general descriptions of all animal manipulations to be carried out under the IACUC-approved protocol and to provide details where no approved references are cited. To do otherwise would constitute a breach of statutory regulations. Manipulations not covered in the originally approved protocol can be initiated only after IACUC approval of a formal amendment adding the new procedures. Additionally, Principal Investigators (PIs), or other delegated research personnel, should maintain accurate experimental records and be able to provide an audit trail of animal expenditures and use that correlates with their approved protocol. Protocol PIs will be required to provide this and other information during annual protocol reviews.

Any supporting information that may be of use to the IACUC during its review may be attached to the completed protocol. Adding subparagraphs within the body of the protocol template is permissible, *provided that the numbering sequence of paragraphs in the original standard format is maintained.* In other words, all of the labeled paragraphs and subparagraphs in this template must be retained, with additional information being presented as sub-numbered paragraphs containing information that supports or complements what is requested.

INTELLECTUAL PROPERTY STATEMENT

Research protocols drafted by Government scientists include intellectual property (e.g., concepts, ideas, experimental approaches, etc.), some of which is innovative or original and therefore considered proprietary to the investigators and/or the sponsoring agency. All Government and non-Government personnel handling this protocol shall exercise EXTREME CARE, to ensure that the information contained herein is NOT DUPLICATED OR DISCLOSED, in whole or part, for any purpose other than to evaluate the protocol, without the written permission of the principal investigator or the sponsoring agency.

AFRRI SCIENTIFIC RESEARCH PROTOCOL NUMBER: (b)(6)

I. NON-TECHNICAL SYNOPSIS

Nuclear attacks and terrorism are serious security threats. Exposure to ionizing radiation (IR) causes rapid hematopoietic, gastrointestinal (GI), skin, and vascular system damage, and can result in acute radiation syndrome (ARS). This multiple organ failure and mortality can result in human and animal death. There is an urgent need in developing effective and non-toxic countermeasures to safeguard military personnel and civilians against the effects of IR exposure. We and others have reported that the vitamin E isomers γ-tocotrienol (GT3) and δ-tocotrienol (DT3) have significant radioprotective effects. Currently, (b)(4) (b)(4) (b)(4) Side by side comparison of the toxicity and survival efficacies of (b)(4) DT3 and GT3 in mice after total-body gamma-radiation will be evaluated in this study. This application is complementary to that effort and will compare mechanisms of efficacy of the three countermeasure candidates. Successful understanding of the effects and mechanisms of tocotrienols on radioprotection and mitigation would increase survival of personnel who are victims of radiation exposure scenarios.

II. BACKGROUND

II.1. Background

Today, nuclear proliferation, terrorist activity, and the distribution of nuclear and radioactive materials make incidents involving radiation injuries of increasing concern. Exposure to IR causes damage to DNA, protein, and lipids in mammalian cells, with subsequent cell cycle checkpoint arrest, apoptosis, and necrosis. Hematopoietic and gastrointestinal (GI) systems are the most radiation sensitive organs. In humans, IR exposures doses above 1 Gy can pose a risk of destruction of the bone marrow (BM) and damage to the hematopoietic system, leading to decreases in blood cell and platelet counts, long-term compromised immune function and increased susceptibility to infection and internal hemorrhage. The acute generalized GI syndrome appears after high-dose (≥ 10 Gy) total-body irradiation (TBI) (*1*, [redacted]) Radiation induces loss of (b)(4),(b)(6) intestinal crypts, damages crypt stem cells, and breakdown of the GI mucosal barrier, which produce symptoms including nausea, vomiting, diarrhea and abdominal cramping (*3*). The number of crypts that survive following radiation damage determines how intact the intestinal mucosa is and, hence, how well an animal can survive the damage. Injury after prompt IR of hematopoietic and GI tissue is due to DNA damage and apoptosis in their cells occurring over a period of hours to days (*4, 5*). The mechanisms of the IR-induced multiple organ cellular and molecule damage and mortality are extremely complex and effective medical countermeasures are lacking(*6*).

Vitamin E is an essential nutrient that includes eight distinct analogs: α-, β-, γ-, and δ-tocopherols; and α-, β-, γ-, and δ-tocotrienols which differ in the number and position of the methyl groups on the chroman ring and differ in the side chain attached to the chroman ring which could be associated with their function. Most previous studies have been conducted with tocopherols, the most commonly used vitamin E supplement and the most abundant vitamin E isoform in human and animal tissue. During the last few decades, tocotrienol research has gained substantial momentum. Tocotrienols have shown neuroprotective, anticancer, anti-oxidative stress and cholesterol-decreasing effects that are often not exhibited by tocopherols (*7, 8*). However, the mechanisms are not understood. Some studies suggested that tocotrienols' anticancer properties were through apoptotic mechanisms and regulation of PI3K/Akt, NFkB, and MAPK signaling (*9, 10*). Further, many research reports revealed that tocotrienols induced apoptosis preferentially in cancer cells but not in normal cells (*11, 12*).

(b)(4)

Pure DT3 and GT3 (desmethyl tocotrienols) are both derived from three most common natural plant sources: palm, rice bran, and annatto seeds (*7, 17*). (b)(4)

The proposed study has no overlapping with published data.

III. OBJECTIVE / HYPOTHESIS:

An approved collaborative study (under the purview of the TT) was commenced in FY15; side by side comparison of the survival efficacies of (b)(4) DT3 and GT3 in mice after TBI will be evaluated (IACUC protocol number (b)(6) This application is complementary to that effort. In the present study, we propose to evaluate and compare the effects of GT3/DT3/(b)(4) on protection (given before irradiation) and mitigation (given post-irradiation) of γ-irradiated hematopoietic and gastrointestinal systems using a mouse model. The proposed study will explore the following hypotheses: (1) (b)(4) may have greater radioprotective and/or mitigative effects than highly purified single T3 candidates alone; (2) radioprotective and mitigative effects of T3s may be through different signal pathways in irradiated mice.

IV. MILITARY RELEVANCE Military personnel are potentially exposed to ionizing radiation in various scenarios. However, no safe and non-toxic radioprotective agent is available for military use to date. Developing countermeasures to radiation exposure is a top priority for the U.S. Department of Defense. We and others have reported that the vitamin E isomers γ-tocotrienol (GT3) and δ-tocotrienol (DT3) have significant radioprotective effects. Currently (b)(4)
(b)(4)

Thus, we propose to conduct a study to further explore, evaluate and compare mechanisms and efficacy of the three countermeasure candidates (GT3, DT3 and (b)(4) on survival of the mouse hematopoietic and gastrointestinal system after different doses of TBI.

V. MATERIALS AND METHODS

V.1. Experimental Design and General Procedures

Mice: Animals will be randomly grouped (criteria-weight within 10% etc.) for different treatments prior to each experiment and re-housed (6-8 to animals per cage).

Drug preparation and administration in mice model: The candidate T3s, highly purified DT3, highly purified GT3, and (b)(4) will be administered at doses of 100 mg/kg as a single subcutaneous (sc) dose to mice 24 h before or 6 h or 24 h after exposure to whole-body gamma radiation as described below. The drugs will be solubilized in saline with 5% Tween-80 that also served as the vehicle control. SC injection will be performed as outlined in section V.4.4.1 Injections. The optimal doses of these T3s were obtained from the aforementioned survival study by AFRRI Tocol Team.

Irradiation: Mice will be placed in ventilated Plexiglas containers and exposed bilaterally to gamma-radiation from the AFRRI cobalt-60 source at doses of 0.0 (sham-irradiation), 7, 8, 9, 10 or 11 Gy at a dose-rate of 0.6 Gy/min. Sham-irradiated mice will be treated exactly the same way as the gamma-irradiated animals, except the cobalt-60 sources will not be raised from shielding water pool.

V.1.1. Experiment 1 Compare the radioprotective and mitigative effects of (b)(4) DT3, and GT3 (b)(4) DT3/GT3) on the mouse hematopoietic system

a) CD2F1 mice (6 animals + 2 phantoms/group) will be placed in ventilated Plexiglas and exposed bilaterally to γ-radiation from the AFRRI cobalt-60 source at doses of 0.0 (sham-irradiation), 7, 8 or 9 Gy (b)(4) DT3/GT3 (100 mg/kg) or vehicle control will be administrated as a single subcutaneous (sc) dose to mice 24 h before or 6 h or 24 h after irradiation. After irradiation, mice will be returned to their specific cages.

b) After TBI, animals will be anesthetized prior to blood collection and then euthanized for tissue collection at indicated time points. For all assays, blood cells, bone marrow (BM), thymus, spleen, and jejunum tissue will be collected from the sham-irradiated and γ-irradiated mice 4 h and 24 h (for groups with drug given 24 h before and/or 6 h after IR), and 3, 7, 14, 21, and 28 days after radiation. Mouse blood will be analyzed in a Siemens ADVIA® 2120 Hematology System. Mouse BM cells will be collected from femurs and humeri. Total myeloid cell numbers and viability from individual mouse BM will be counted after irradiation. Clonogenicity of mouse BM cells will be quantitated. Death and apoptotic markers and cell surface phenotypes will be determined in all collected tissues using BD FACS Calibur flow cytometry (BD Biosciences, San Jose, CA).

c) BM pathological changes in mice treated with (b)(4) DT3/GT3 or vehicle at 1, 3, 7, and/or 14 days post-irradiation will be evaluated by VSD pathologist. Mouse BM structure and cellularity will be examined in HE stained mouse sternum longitudinal sections. BM cellularity especially megakaryocyte restoration will be measured in microscopic fields for each sectioned sternum.

d) Effects of (b)(4) DT3/GT3 on cytokines and chemokines production in mouse serum and cells lyses will be measured by ELISA, cytokine array, and immunoblotting assays.

V.1.2. Experiment 2 Compare the radioprotective effects of (b)(4) DT3/GT3 on the mouse GI tract.

a) CD2F1 mice (6 animal + 2 phantoms/group) will be placed in ventilated Plexiglas and exposed bilaterally to γ-radiation from the AFRRI cobalt-60 source at doses of 0.0 (sham-irradiation), 10 or 11 Gy (b)(4) DT3/GT3 (100 mg/kg) or vehicle will be administrated 24 h before irradiation. After irradiation, animals will be anesthetized prior to blood collection and then euthanized for jejunum tissue collection from γ-irradiated mice 24 h, 3.5 days, 10 days and 14 days after irradiation. Blood and jejunum samples from sham-irradiation will be shared with experiment 1.

b) H&E stained mouse intestinal tissue slides will be examined for intestinal mucosal surface area, crypt cell apoptosis, intestinal crypt colony generation, and villi at 3.5 days after TBI. Surviving crypts will be counted in transverse cross sections.

c) Cytokine release from jejunum mucosa will be measured using ELISA, and compared in different treatment groups. Effects of (b)(4) DT3/GT3 on radiation-induced inflammatory cytokines production in mouse jejunum mucosa will be evaluated.

d) Radiation-induced intestinal bacterial translocation in liver, heart blood and spleen and radiation-induced sepsis will be quantified by bacterial translocation assay. Radiation-induced bacterial translocation starts around day 7 and peaks around 2 weeks after TBI. Analysis of bacterial translocation will be performed on day 10 after exposure to 10 or 11 Gy TBI. The samples collected from euthanized mouse heart blood, liver, and spleen will be cultured for bacteria growth. The single colonies of isolated microorganisms will be observed for their morphological characteristics. Gram stain characteristics will be determined by Gram staining. They can be subcultured and the pure culture will be analyzed by a Vitek 2 Compact automated system to determine the type of bacteria.

V.1.3. Total number of animals: 1900 male CD2F1 mice

Note: The Sham–irradiated mice will be shared between Experiment 1 and Experiment 2.

Sham –irradiated section for Experiment 1 and 2 = 4 groups (vehicle (AO) and DT3, GT3 (b)(4) × 6 animals/group × 7 time points (4 hr and 1, 3, 7, 14, 21, and 28 days) after drug treatment =168 animals

Irradiated section for Experiment 1 = 4 groups (vehicle (AO) and DT3, GT3 (b)(4) × 6 animals/group × 3 drug dosing time (24 h before, 6 h and 24 h post) × 7 sample collection time points (4 hr and 1, 3, 7, 14, 21, and 28 days) after irradiation × 3 radiation doses (7, 8 and 9 Gy) = 1512 animals

Irradiated section for Experiment 2 = 4 groups (vehicle (AO) and DT3, GT3 (b)(4) × 6 animals/group × 2 radiation doses (10 and 11 Gy) × 4 sample collection time points (1, 3.5, 10 and 14 days) after irradiation = 192 animals

Sum of 168+ 1512+192+ 28 (for unforeseen losses or complications) animals = **1900 animals**

V.2. Data Analysis

Statistical software PC SAS will be used for statistical data analysis. Six animals per group will be used to provide statistical power >80% for two-tailed student's t-test. Means and standard deviation (SD) with a significance level at 5% set for each test. We will report the mean ± SD or percentage when applicable. In order to evaluate the hypothesis set forth and establish a comparison of significance of deviation from the hypothesis, Fisher Exact Test can be used. The test can provide the significance and deviation of efficacy of the measures used. The test can provide estimation of changes

as a series of plots of declining magnitude against a sample used to detect difference in the group population.

When inferential statistics is used such as t-test, Fisher's tests, Analysis of Variance (ANOVA) etc, to evaluate the outcome and comparisons, sample size (n) needs to be determined to provide sufficient statistical capability for performance. Based on the power analyses the sample size n=6 for each experiment is sufficient to deliver more than 80%, power to detect a significant difference between two groups if any, given type I error of 5% and delta/sigma has at least 1.03, where the delta is the estimated mean differences between the two groups and sigma is the standard deviation. ANOVA with mixed-effect model will be used when testing one dependent variable and Multivariate analysis of variance (MANOVA) will be used when testing more than one dependent variable to detect if there is significant difference among the groups.
For comparison and effects of survival of γ-irradiated hematopoietic and gastrointestinal systems using a mouse model and data derived from approved study (IACUC protocol # (b)(6) will be used.

V.3. Laboratory Animals Required and Justification

V.3.1. Non-animal Alternatives Considered

Radiation-induced adjustment in cellular tissue homeostasis triggered by various molecular responses related to inter- and intracellular signaling causes both acute and late effects depending upon the interactions in different organs and tissues in animal models. The morphological changes in tissues can only be seen in tissues obtained from the animals. The hematological and cytokine and chemokine measurement can only be performed from blood collected from the animals. Therefore the observation of changes in hematopoietic and GI systems after exposure to radiation will be more meaningful in an *in vivo* model for the proposed study.

V.3.2. Animal Model and Species Justification

The murine model is the most well-defined animal model for research. The mouse was chosen over other animal models because of extensive published data that is readily available for comparison, review and analysis. The mouse model has significant hematological and immunological similarities to higher animals and humans. AFRRI's staff has extensive experience with mice, including male CD2F1 in radiation injury and countermeasure research.

V.3.3. Laboratory Animals

V.3.3.1. Genus / Species Mice (*Mus musculus*)
V.3.3.2. Strain / Stock CD2F1
V.3.3.3. Source / Vendor Envigo (Indianapolis, IN)
V.3.3.4. Age 12-14 weeks
V.3.3.5. Weight 24–30 g
V.3.3.6. Sex Male
V.3.3.7. Special Considerations N/A

V.3.4. Number of Animals Required (by species)

Mice: 1900

V.3.5. Refinement, Reduction, Replacement (3 R's)

V.3.5.1. Refinement

All animal users will be properly trained to ensure minimum stress during animal handling

V.3.5.2. Reduction

We shall make every effort to minimize the use of non-necessary animals. Control groups will be shared between experimental groups. At every stage of the research, plans will be reevaluated in light of incoming data in an attempt to reduce the numbers of experiments and groups.

V.3.5.3. Replacement

It is not feasible to use non-animal systems in place of animal models to address the research questions in this protocol. (See section V.3.1 above.)

V.4. Technical Methods

V.4.1. Pain / Distress Assessment

V.4.1.1. APHIS Form 7023 Information

V.4.1.1.1. Number of Animals

V.4.1.1.1.1. Column C 0 (# of animals)

V.4.1.1.1.2. Column D Sham-irradiated controls 168 for exp-1 and 2 (# of animals). These mice will have drug or vehicle sc. Injection and/or blood collected via cardiac puncture.

V.4.1.1.1.3. Column E All irradiated mice 1732 (# of animals). These mice will be irradiated and will not receive any intervention for pain relief. However, they will be euthanized if found moribund according to AFRRI-IACUC policy # 10.

V.4.1.1.1.4. Pain Category Assignments

Exp. #	Experimental/Control Group	C	D	E	Totals
1	*IR-induced hematopoietic syndrome*		*168*	*1512*	*1680*
2	*IR-induced GI syndrome*			*220*	*220*
Totals:			*168*	1732	1900

V.4.1.2. Pain Relief / Prevention

V.4.1.2.1. Anesthesia / Analgesia / Tranquilization

For blood sample collection, animals will be anesthetized with isoflurane 1-5% in 100% oxygen using the anesthesia machine in the VSD rodent procedure room. Animal respiratory rates will be closely monitored through the Plexiglas chamber during induction of anesthesia. When animals are recumbent and not response to toe/tail pinch, they will be removed from the chamber and their nose/mouth placed in the anesthesia apparatus breathing/gas administration cone for maintenance of anesthesia at 3% Isoflurane and 100% O_2(with the O_2 flow rate at 500 ml/min) during cardiac puncture for blood collection.

V.4.1.2.2. Pre- and Post-procedural Provisions N/A

V.4.1.2.3. Paralytics No paralytic agent will be administered.

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures

V.4.1.3.1. Sources Searched

AGRICOLA

PubMed

V.4.1.3.2. Date of Search December 20-29, 2015

V.4.1.3.3. Period of Search

AGRICOLA – 1976–present

PubMed: includes MEDLINE (1966–present) and OLDMEDLINE (1950–1965)

V.4.1.3.4. Key Words of Search
Irradiation or Pain and Distress or Alternatives or Animal Model; Mouse and Irradiation or Pain or Alternatives; GT3/DT3[b)(4)] or Treatment or Irradiation or Mouse; Blood collection or mouse or cardiac puncture or alternative.

V.4.1.3.5. Results of Search
Irradiation with ionizing radiation is not a painful process but it induces various changes in the body and kills hematopoietic cells and gastrointestinal epithelium. In irradiated animals, the immune response is compromised, and opportunistic infections may ensue. There is no less painful or distressful alternative found that can be used to develop protective and mitigating agents for irradiation. No references were found suggesting any effect of GT3/DT3[b)(4)] or AO (vehicle-control) on pain or distress. There are alternatives for blood collection by cardiac puncture in a mouse, such as tail vein and facial vein blood draw, etc. However, none of these alternatives can provide more than 0.1-0.2 ml of blood but we need 1 ml blood/mouse for experiments. We will use cardiac puncture for blood collection and we will do it while the animal is anesthetized. Therefore, it will not cause more than momentary pain or distress.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification
There is no alternative *in vitro* system and no less painful/distressful *in vivo* system available to test new therapies against acute irradiation syndrome. Thus, we have to use this mouse model to test the protective and mitigative/therapeutic effects of GT3/DT3[b)(4)] on mouse hematopoietic and gastrointestinal systems after different doses of gamma-irradiation.

Furthermore, we will need to collect about 1 ml of blood sample to run all the tests for our experiments in the proposed study. However, there is no other alternative available to obtain 1 ml of blood from a mouse other than cardiac puncture. Therefore, we will be using cardiac puncture for blood collection. The animal will be properly anesthetized during blood collection, so there should not be any pain or distress.

V.4.2. Prolonged Restraint N/A

V.4.3. Surgery
V.4.3.1. Pre-surgical Provisions N/A
V.4.3.2. Procedure(s) N/A
V.4.3.3. Post-surgical Provisions N/A
V.4.3.4. Location N/A
V.4.3.5. Surgeon N/A
V.4.3.6. Multiple Major Survival Operative Procedures N/A
V.4.3.6.1. Procedures N/A
V.4.3.6.2 Scientific Justification N/A

V.4.4. Animal Manipulations

V.4.4.1. Injections

Animal will be manually restrained and subcutaneous (sc) injections will be given with either a 23-25G x ¾ inch to the nape of the neck of 0.1 ml (maximum volume 1 ml for 25 – 38 g animals). Injections will be carried out in VSD animal housing room.

V.4.4.1.1. Pharmaceutical Grade Drugs N/A

V.4.4.1.2. Non-Pharmaceutical Grade Drugs

a) Research grade DT3, GT3, and (b)(4)

(b)(4)

b) The drugs will be solubilized in saline with 5% Tween-80 that also served as the vehicle control.

These experimental formulations were developed by a commercial formulation lab on behalf of (b)(4) and have been tested at AFRRI.

V.4.4.2. Biosamples

Animals will be anesthetized with isoflurane 1-5% in 100% oxygen before blood collection. Blood (0.7-1 ml/mouse) will be drawn by cardiac puncture using 23-25G x ¾ inch needle in anesthetized mice. After blood collection, animals will be euthanized as outlined in section V.4.6 Euthanasia and tissue samples will then be taken. Blood, bone marrow, spleen, and Jejunum tissue will be collected from the sham-irradiated and gamma-irradiated mice.

V.4.4.3. Adjuvants N/A

V.4.4.4. Monoclonal Antibody (MAb) Production N/A

V.4.4.5. Animal Identification

Generally, cage cards will be used to distinguish drug-treated and control groups. Some experiments might necessitate tattoo by personnel to identify individual animals in a cage.

V.4.4.6. Behavioral Studies N/A

V.4.4.7. Other Procedures N/A

V.4.4.8. Tissue Sharing

Tissues will be shared upon availability and request from other Investigators.

V.4.4.9. Animal By-Products N/A

V.4.5. Study Endpoint

In the proposed study, the animals will be kept for maximum of 30 days in Experiment 1 (7, 8 and 9 Gy) and maximum of 14 days in experiment 2 (10 and 11 Gy). We do anticipate the animals to become morbid and moribund in this study. IACUC Policy #10, Guidelines for Establishment of Early Endpoints in Experiments with Expected Mortality will be implemented for judging morbidity and moribundity. Signs of morbidity in the mouse include difficulty in breathing, ruffling of hair, drying of lacrimal fluid, fall in body temperature, loss of appetite with/without diarrhea. No supportive care is proposed, but the morbid mice will be examined at least three times daily, early morning and late afternoon by the research staff (including weekends and holidays) in addition to the

regular VSD health checks. The timing between the late evening and early morning check will not exceed ten hours during the critical period.

The moribund condition is defined as a clinically irreversible condition leading inevitably to death. Animals involved in experiments that may lead to moribundity or death will be monitored daily by personnel experienced in recognizing signs of moribundity (illness, injury, or abnormal behavior) for at least the following: abnormal posture, rough hair coat, head tucked into abdomen, exudates around eyes and/or nose, skin lesions, abnormal breathing, difficulty with ambulation, cyanosis, decreased food or water intake, or self-mutilation (*19*).

Animals will be immediately euthanized when they display abnormal breathing, are recumbent, or unable to respond to mild external stimulus by the research staff and scored as dead on removal. VSD veterinarians will be consulted for all matters regarding animal welfare.

V.4.6. Euthanasia

Animals in experiments involving blood collection will be anesthetized with 1-5% isoflurane before blood collection. After blood collection, cervical dislocation as a secondary method to confirm animal death will be performed while the animal is still anesthetized.

For the non-blood collection groups, before tissue collection or mice found moribund will be euthanized by CO_2 inhalation plus confirmatory cervical dislocation by investigator/technician according to the directives of the VSD-SOP and in accordance with current AVMA Guidelines on Euthanasia. At the conclusion of the experimental time frame, all animals that survived the procedures of irradiation, drug intervention and controls, will be sacrificed by CO_2 inhalation plus confirmatory cervical dislocation and their carcasses disposed of according to VSD regulations.

V.5. Veterinary Care

V.5.1. Husbandry Considerations

Mice are social animals and will be housed together in groups. Nesting material/igloos/tunnels will be provided in each cage. Animals will receive Harlan Teklad Rodent Diet (w) 8604 and water *ad libitum*. Acidified water (pH 2.5–3.0) will be provided. Cages will be regularly changed and cleaned by VSD staff. Animal rooms will be kept on a 12 h/12 h light/dark cycle.

V.5.1.1. Study Room As assigned by VSD

V.5.1.2. Special Husbandry Provisions N/A

V.5.1.3. Exceptions N/A

V.5.2. Veterinary Medical Care

V.5.2.1. Routine Veterinary Medical Care

Routine veterinary care will be provided as per VSD SOPs. This includes am and pm health checks on all the animals by veterinary technicians on weekdays. On holidays and weekends, am checks are done by animal care takers and pm checks by veterinary technicians. In the course of the study, as animals approach morbidity, the research staff observations will be increased to a minimum of three times a day, early morning and late afternoon (includes weekends and holidays). The timing between the late evening and early morning check will not exceed ten hours during the critical period.

There is no supportive therapy contemplated since this would compromise the experimental results (described earlier in the end point and pain category sections).

V.5.2.2. Emergency Veterinary Medical Care
On weekends and holidays, morning rounds will be done by VSD animal care takers and evening rounds will be done by VSD veterinary technicians. Animal care takers and veterinary technicians can contact the on call veterinarian if needed. Our (PI) staff will provide afterhours coverage (outside of the routine veterinary coverage provided by VSD staff) on as needed basis as determined by the VSD veterinarians. Our staff will contact the on call veterinarian if needed.

V.5.3. Environmental Enrichment
V.5.3.1. Enrichment Strategy
Nestling pads, tunnels and/or igloos will be provided in each cage during bedding changes.
V.5.3.2. Enrichment Restrictions N/A

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING

NAME	DEGREE	TRAINING	DATE	PROCEDURES	YRS/MOS EXPERIENCE
(b)(6)				1, 3b, 4a, 5, anesthesia	(b)(6)
				1, 3b, 4a, and 5, anesthesia	

Procedure and manipulation codes:
Code 1= Animal handling and euthanasia
Code 2= Surgery (aseptic technique) pre- and post-operative care
Code 3= Injections (3a-ip, 3b-sc, 3c-gavage) - can say 3 if trained in all manipulations or add 3d-iv
Code 4= Blood collection under anesthesia (4a-cardiac, 4b-inferior vena cava)
Code 5= Tissue collection (after euthanasia) - doesn't need to be specific
Code 6 = Implantation (provide details)
Code 7 = Others - (provide protocol specific manipulations or procedures for e.g., retro-orbital bleeding, tail vein injection, or drug delivery)

VII. BIOHAZARDS/SAFETY
All investigators and personnel will use appropriate protective gear while in the vivarium, as described by the VSD. All listed personnel are current regarding safety training and medical surveillance. All listed personal have completed the Animal Care and Use in Research and Education training (AALAS learning library) courses. Recently they took three refresher courses: Common Compliance Issues, 8th Edition of the Guide for the Care and Use of Laboratory Animals, Pain Recognition and Alleviation in Laboratory Animals and passed the exams.

X. ASSURANCES

Protocol Title: Evaluate the radioprotective and mitigative effects and mechanisms of γ-tocotrienol (GT3), δ-tocotrienol (DT3) and (b)(4) as novel radiation countermeasures in *Mus musculus*

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made every effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with a qualified individual who evaluated the experimental design with respect to the statistical analysis, and that the minimum number of animals needed for scientific validity will be used.

D. Biohazard / Safety: I have taken into consideration and made the proper coordinations regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R", namely, "Responsibility," which the DOD has embraced for implementing animal use alternatives where feasible and conducting humane and lawful research.

G. Scientific Review: This proposed animal use protocol has received appropriate peer scientific review and is consistent with good scientific research practice.

H. Painful Procedure(s): I **AM / AM NOT** (*circle one*) conducting biomedical experiments, which may potentially cause more than momentary or slight pain or distress to animals. If applicable, potential pain and/or distress **WILL / WILL NOT** (*circle one*) be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

DOD ANIMAL CARE AND USE STANDARDIZED PROTOCOL FORMAT WITH EMBEDDED INSTRUCTIONS (April 2015)

Reference DOD Instruction 3216.01 & AFRRI Instruction 3216.2H

****

Information requested in the following animal use protocol template reflects the requirements of the Animal Welfare Act Regulations (AWAR), the Guide for the Care and Use of Laboratory Animals, and other applicable Federal regulations and DOD instructions.

****

This document is intended to be an aid in the preparation of DOD-sponsored animal use protocols. It is a companion document to an identical protocol template that does not have embedded instructions. Either template may be used to format DOD-sponsored animal research proposals; however, reference to the instructions during protocol preparation is highly recommended. If using the template with instructions, the instructions should be deleted prior to submitting the finished protocol for IACUC review. Please use Arial, regular, size 12, black font to prepare the protocol. With the exception of section headings, all paragraphs require a response. Paragraphs that do not apply should be marked N/A. There is no space limitation for responses to the information requested.

Approved standard operating procedures (SOPs) promulgated by the AFRRI Veterinary Sciences Department (VSD) or similar VSD-validated documents that describe specific procedures may be referenced by SOP number and title in lieu of repeating the details in the protocol. However, it is essential to include general descriptions of all animal manipulations to be carried out under the IACUC-approved protocol and to provide details where no approved references are cited. To do otherwise would constitute a breach of statutory regulations. Manipulations not covered in the originally approved protocol can be initiated only after IACUC approval of a formal amendment adding the new procedures. Additionally, Principal Investigators (PIs), or other delegated research personnel, should maintain accurate experimental records and be able to provide an audit trail of animal expenditures and use that correlates with their approved protocol. Protocol PIs will be required to provide this and other information during annual protocol reviews.

Any supporting information that may be of use to the IACUC during its review may be attached to the completed protocol. Adding subparagraphs within the body of the protocol template is permissible, *provided that the numbering sequence of paragraphs in the original standard format is maintained.* In other words, all of the labeled paragraphs and subparagraphs in this template must be retained, with additional information being presented as sub-numbered paragraphs containing information that supports or complements what is requested.

INTELLECTUAL PROPERTY STATEMENT

Research protocols drafted by Government scientists include intellectual property (e.g., concepts, ideas, experimental approaches, etc.), some of which is innovative or original and therefore considered proprietary to the investigators and/or the sponsoring agency. All Government and non-Government personnel handling this protocol shall exercise EXTREME CARE, to ensure that the information contained herein is NOT DUPLICATED OR DISCLOSED, in whole or part, for any purpose other than to evaluate the protocol, without the written permission of the principal investigator or the sponsoring agency.

AFRRI SCIENTIFIC RESEARCH PROTOCOL NUMBER:

I. NON-TECHNICAL SYNOPSIS We are continuing the development of well-characterized minipig models for the gastrointestinal (GI) and hematopoietic (H) Acute Radiation Syndrome (ARS), as surrogate models for the human ARS and for ultimate use by Biomedical Advanced Research and Development Authority (BARDA). The ultimate goal is to evaluate the efficacy of medical countermeasures to mitigate the human H-ARS and GI-ARS, and to support submission of pre-clinical applications to the Food and Drug Administration. This study will fulfill the purpose of providing a well-characterized model for radiation countermeasure testing, as required by the FDA Animal Rule.

II. BACKGROUND

II.1. Background We are continuing the development of well-characterized minipig models for the GI- and H -ARS, as surrogate models for the human ARS and for ultimate use by BARDA. The ultimate goal is to evaluate the efficacy of medical countermeasures to mitigate the human H-ARS and GI-ARS, and to support submission of pre-clinical applications to the Food and Drug Administration. The purpose of this proposal is continue to characterize the natural history of minipigs irradiated at H-ARS and GI-ARS doses, under conditions reproducible at other centers within the BARDA minipig consortium, and to provide probit curves for the testing of radiation medical countermeasures (MCM) under GLP-like conditions, within AFRRI capabilities.

For the H-ARS, we will use a unilateral sequential exposure modality (γ irradiation Cobalt-60 source). The unilateral sequential exposure mimics the rotating plane on which animals are placed for irradiation when a punctiform source of Cobalt-60 is employed, in contrast to AFRRI set up where several rods of radioactive materials are lifted to produce a large field in proximity of the object to be targeted.

Preliminary data using the unilateral sequential exposure suggest that this geometry provides lethality profiles closer to those observed at other sites within the minipig consortium; however data need to be confirmed. In a single experiment done at AFRRI comparing unilateral sequential versus bilateral simultaneous irradiation, under (b)(4) funds, a total of 16 animals were irradiated with 1.85 Gy, using Cobalt 60. Of these, eight were exposed to unilateral sequential irradiation, and eight were exposed to bilateral simultaneous irradiation. Of the animals irradiated bilaterally, two out of eight survived (25%). Of the animals irradiated unilaterally, five out of eight survived (62.5%). Higher counts (thousands per microliter) were seen with unilateral animals for white blood cells (WBC) (3.73 vs. 2.12) and absolute neutrophil counts (ANC) (2.37 vs. 1.66) at day 3 (p 0.001), and for platelets at day 3 (497 vs. 364) and 7 (261 vs. 165), (p 0.001), when comparing complete blood counts (CBC) between animals subjected to different irradiation modalities. Other blood counts did not show major differences. Gross pathology showed hemorrhages in multiple organs (i.e. intestine, heart, lungs) for both groups euthanized due to morbidity before the end of the study. However, petechiae/ecchymoses disappeared around day 23 for unilateral irradiation, but persisted till day 30 (end of study) for bilateral (even though platelet counts were comparable between groups).

Since the gastrointestinal syndrome is 100% lethal after total body irradiation (TBI) in the absence of treatment, for the GI-ARS we will use a linear accelerator (LINAC Elekta) to irradiate only the GI and the bottom half of the animal while sparing thoracic cavities, upper limbs and head, in alignment with dosimetry protocols used at other centers using minipigs and sponsored by (b)(4) We have previously shown that doses of 2 to 5 Gy are associated with an accelerated hematopoietic syndrome, characterized by villus blunting and fusion, the beginning of sepsis, and a mild transient reduction in plasma citrulline concentration (b)(4),(b)(5) At higher doses, the Göttingen minipig exposed to γ radiation of 5 to 12 Gy demonstrates a dose-dependent occurrence of all parameters classically associated with acute GI-ARS. Our results suggested that the Göttingen minipig is a suitable model for studying GI-ARS after total body irradiation (b)(4),(b)(5) However the use of supportive care and/or partial body shielding to extend survival beyond 10 days for characterizing overlapping H-ARS, as expected in humans, is strongly recommended. Unlike total body irradiation, partial body irradiation (PBI) exposure is expected to allow survival at gastrointestinal doses that are otherwise lethal because of concomitant underlying hematological-acute radiation syndrome, gastrointestinal and pulmonary complications. Furthermore, non-uniform or partial body exposure leading to some bone marrow shielding is likely to be the most common modality of exposure in case of a radiation accident. This approach will provide a specific and reproducible GI and hematopoietic injury. The natural history of GI and bone marrow damage will be characterized in terms of general indicators of animal health, as well as by apoptotic and mitotic activity in GI tissues, structure and function of the GI, hematological depression and recovery of the bone marrow.

The Göttingen minipig has demonstrated marked sensitivity to the development of coagulation anomalies and vascular leakage after exposure to irradiation, leading to bleeding, multi-organ dysfunction, and death. Animals that succumb to lethal doses of radiation, starting at hematopoietic doses, are

characterized by widespread hemorrhages, edema, deposition of fibrin, and blood clots. The effect of radiation on blood coagulation is an area that has been largely neglected, although much evidence of induction of coagulation disorders is found among individuals exposed to irradiation from clinical, accidental and malicious exposures. The molecular mechanisms behind species variations in sensitivity to radiation are unknown. Krigsfeld et al (2014a) report that disseminated intravascular coagulation (DIC) may play an integral role in death at the LD50 dose of either gamma or solar particle event (SPE)-like proton radiation. In pigs and ferrets, DIC was characterized by impaired whole blood clotting as measured by thromboelastometry alterations, decreased platelet counts, elevated d-dimer concentrations in the blood, hemorrhaging, and deposition of fibrin in tissues (Krigsfeld, 2014a; Krigsfeld, 2014b). Inflammation, hemostasis and hemodynamics are intimately linked, with each process propagating the other, creating a vicious cycle of thrombogenesis, inflammation and hypo-perfusion, leading to coagulopathies and multi-organ dysfunction. Coagulopathy may derive from thrombocytopenia and reduced levels or absence of clotting factors, or through stimulation of pro-coagulant activities, dysregulation of the thrombomodulin pathway, and inflammation (through increase in levels of fibrinogen, and CRP-induced complement activation). As part of animal model development, we propose to evaluate the dose dependent occurrence of radiation-induced coagulopathies in the Göttingen minipig. This study will fulfill the purpose of providing a well-characterized model for radiation countermeasure testing, as required by the FDA Animal Rule.

II.2.5. Results of Search

BRD The database is no longer available.

RePORTER: The search with swine and radiation gave 117 results. Among these results, the term "radiation" was used mainly within the context of medical devices (i.e. X-rays, MRI, laser) or for local therapy targeting the eyes, local tumors, or for surgical applications. The project most relevant to this proposal consisted in engineering transgenic pigs to enable the study of adult stem cells following diseases/injuries, including cancer, and regenerative responses resulting from radiation/chemotherapeutic or viral/ bacterial damage. When the term coagulation or intestine were added to the search, the results consisted of projects evaluating interventional techniques (intravascular imaging, MRI, spectra CT, laparoscopy, etc), immune response to specific coagulation factors, blood flow regulation in glaucoma, and the research on genetically engineered transgenic pigs. There were no studies addressing the consequences of acute radiation injury on coagulation parameters or intestinal function.

PubMed: The search with minipig OR swine and radiation gave over 5000 results. Most "hits" were not pertinent to acute radiation, as it is in the case of this proposal. The most relevant publications using acute radiation as search terms were our own (see section on "References" at the end of the protocol), and a few publications on the radiation-induced gastrointestinal syndrome in the Göttingen minipig and its application in clinical research (Shim et al, Rad Res, 2014; Wang et al, PLoS ONE, 2013). In our previous studies we have not investigated intestinal function or the role of coagulation in the etiology of the ARS. The work by Shim et al (2014) uses the approach of ileo-cutaneous anastomosis to gain a "window" over the intestine of irradiated animals which allow the investigators to follow morphological changes overtime following abdominal irradiation. No assays addressing intestinal function were done in that study. The work by Wang et al (2013) suggests that radiation can reduce the energy metabolism, as measured by levels of adenosine-triphosphate (ATP), adenosine-diphosphate (ADP), adenosine-monophosphate (AMP), total adenine nucleotides (TAN), and presence of aberrant mitochondria in Tibetan minipigs.
Of the 178 "hits" found when searching for swine, radiation and coagulation, only one result was relevant to coagulopathies resulting from total body, acute irradiation as in the case of this study. Radiation-induced coagulopathies were assessed using the Yucatan minipig irradiated acutely with total body using solar particle event (SPE)-like proton (Krigsfeld et al, Life Sci Space Res, 2014), or following skin thermal injury after laser irradiation. Other studies were done using laser pulses, ultrasounds, UV, X-rays and neutron scattering. All studies found completely differ from our proposal, in the quality of radiation and endpoints evaluated.

III. OBJECTIVE / HYPOTHESIS Our objectives are:

(i) To establish the dose dependent natural history of animals exposed at H-ARS doses to unilateral sequential (Cobalt-60) irradiation, and to follow the development of radiation-induced coagulopathies.
(ii) To establish the relationship between radiation-induced intestinal bleeding and function of the GI tract, and to evaluate biomarkers of GI structure and function under PBI.
(iii) To establish a radiation dose dependent injury profile for GI-ARS in animals irradiated under PBI.

Experimental details are reported in Section V Materials and Methods.

IV. MILITARY RELEVANCE

Both early and late health effects of radiation exposure are major concerns for the military. Developing countermeasures to radiation exposure is a top priority for the US Department of Defense. Effective countermeasures would expand the options available to field commanders operating Ionizing Radiation (here defined as IR) threat environments, and improve the morale of personnel at risk of exposure to IR. DoD Defense Technology Objective MD.18 states: "Effective mitigation of health consequences [of IR] will (1) reduce casualty load at medical treatment facilities, (2) sustain a more effective operational force after a radiation exposure event, (3) allow commanders to conduct operations in radiation field environments without undue risk of decremented performance of personnel due to acute tissue injury, and (4) reduce the negative psychological impact on personnel tasked to operate in contaminated environments."
An important barrier to advanced development of radiation countermeasures is the paucity of large, long-lived, non-rodent animal models of radiation injury. The only choices at present are nonhuman primates (NHPs) and canines. The higher sentient status of NHPs, their expense and occupational health hazards, are also disadvantages of working with NHPs. Canines are notoriously sensitive to NSAID and vomiting, therefore providing oral medication may be an issue (Swindle et al. 2012). The addition of miniature swine as a large animal radiation injury model would facilitate development of promising countermeasures for both military and civilian use that could be used for prophylactic, mitigator and therapeutic use.

V. MATERIALS AND METHODS

V.1. Experimental Design and General Procedures

Male Göttingen minipigs will be obtained from Marshall BioResources, North Rose, NY, at age of 4-6 months, and at a weight 7-13 kg (see section V.3.). Minipigs may be group-housed during quarantine (see section V.5.1). Age and weight will be strictly controlled, which will avoid possible complications related to increasing weight and fatty mass (see section V.5.1.2).

Animals will be irradiated at an age of approximately 5 months. Minipigs will be single-housed but kept in visual contact with each other, and fed twice a day according to their weight, following recommendations from the vendor (Marshall Bioresources), and as described in section V.5. Veterinary care. After the required period of quarantine/acclimation (see Section V.5.1.), animals will be sedated as described in section V.4.1.2.1. Anesthesia / Analgesia / Tranquilization, transported to the radiation facility, placed on a sling or a table, irradiated and returned to their quarters, where they will be monitored until full recovery. A LINAC with field definition determined by a multi-leaf collimator, or a Cobalt-60 source with unilateral sequential exposure, will be used to irradiate the animals, depending on the experiment. A representative figure of a LINAC Elekta is reported in Figure 1.

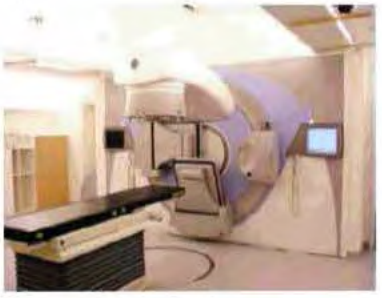

Figure 1: Example of LINAC Elekta with table.

All animals will receive preventative minimum supportive care, according to section V.4.1.2.2.

Survival will be monitored for 30-60 days, depending on the experiment; appropriate biomarkers to support the natural history of ARS will be collected at periodic time points. Blood for CBC/differential and plasma will be collected before irradiation and at several time points after irradiation, as described in the individual experiments and in section V.4.4.2 Biosamples. Time points may be shifted by 24 – 48 hour, or dropped in case of unforeseen circumstances. Additional blood draws may be taken, per veterinarian request, if needed to assess health of the animal. Blood will be collected from either a Vascular Access Port, or an externalized catheter, or from peripheral veins (V.4.3.2. Procedure(s) and V.4.4.2. Biosamples).

Moribund animals will be euthanized according to pre-established euthanasia criteria (section V.4.5. Study Endpoints); animals completing the survival study will be euthanized within 3 days from the completion of the observation period. Euthanasia will be carried out according to section V.4.6. Euthanasia. Tissues and blood samples may be collected for further analysis and tissue sharing, as outlined in section Tissue Sharing V.4.4.8.

Primary data-points of the study will depend on the Experimental Aims.

V.1.1. Experiment 1. To establish the dose dependent natural history of animals exposed at H-ARS doses to unilateral sequential (Cobalt-60), and to follow the development of radiation-induced coagulopathies.

Minipigs will be exposed to hematopoietic total body doses of radiation using unilateral sequential Cobalt-60 exposure. We will irradiate animals with four doses, between 1.6 Gy and 3.0 Gy, based on historical data from the (b)(4) corresponding to expected LD20/45, LD40/45, LD60/45 and LD80/45. Final doses will be provided to the IACUC via memo prior to commencement of the experiment. Survival will be monitored for 45 days after exposure. Simultaneously, we will follow the development of radiation-induced coagulopathies. Blood will be collected twice before irradiation, and, with day 0 the day of irradiation, at days +1, 3, 7, 10, 14, 17, 20, 23, 27, 30, 35, 40 and 45. Time points of blood collection may be subjected to change by up to +/- 24 hours. Blood volume will be within allowed guidelines: up to 1% of total blood will be drawn in a single day, and no more than 7% of total blood volume in a week (Diehl et al, 2001) (see V.4.4.2).

Coagulation assays are sensitive to dilution parameters. As part of Experiment 1, we will use control sham animals to optimize protocols and dilution factors for swine samples, and to obtain baseline values and measures of assay reliability.

Primary experimental endpoints

The primary endpoints will be 45-day survival, blood cell counts, general indicators of animal health, gross and histopathology (H&E) of major organs (heart, lung, small intestine, liver, spleen, kidney, lymph nodes).

Secondary experimental endpoints

We will assess clotting factors (i.e. AT, APTT, fibrinogen), thrombomodulin (TM)-protein C system, acute phase proteins, fibrin deposition/clots (i.e. PTAH), complement activation (i.e. C5a) and hemostasis molecular assays (i.e. soluble fibrin, D-dimer, TA complex, F1+2, anti-thrombin, angiotensin-converting enzyme, clot formation).

Number of animals for Experiment 1: 12 animals x 4 radiation doses (expected LD20 to LD80) + 3 animals (for pilot coagulation evaluation studies and GI function studies) = 51

V.1.2. Experiment 2. To establish the relationship between radiation-induced intestinal bleeding and function of the GI tract, and to evaluate biomarkers of GI structure and function

Minipigs will be exposed to irradiation geometries that will spare approximately 40-50% (head, forelimbs and thorax shielded) of bone marrow, using a LINAC at 0.5-0.6 Gy/min, and GI structure and function will

be followed by scheduled necropsy points out for 30 days. Necropsy will occur at day 6 (n=3 animals/dose), day 9 (n=3 animals/dose), day 15 (n=3 animals/dose), and day 30 (n=3 animals/dose). Animals will be exposed to either one of two doses, a lower one, between 8-12 Gy, or a higher one, between 13-16 Gy. Final doses will be established based on BARDA data from other minipig-funded studies; a memo will be submitted with the final radiation doses. In addition, we will use 3 sham-irradiated animals to optimize the procedures for the GI function assays (measuring metabolic mucosa function, protein digestibility and absorption of sugars) and to collect data from normal, un-irradiated animals, to compare to those obtained from irradiated animals

Metabolic mucosa function, protein digestibility, amino acid absorption test and xylose absorption test will be measured using tracers according to Engelen et al. (2013). Tracer is a substance (not naturally found in the system) added to the system to trace out a metabolic pathway (i.e. L-[ureido-13C-4,4,5,5-2 H5]-citrulline); the tracee is the native substrate being traced (citrulline).

Tracers for metabolic mucosa function, protein digestibility, amino acid absorption test and xylose absorption test will be administered as described in section V.4.4.7. Other Procedures – Administration of tracers and samples will be collected according to section V.4.4.2. Biosamples. Metabolic mucosa function and protein digestibility will be measured using a modified protocol with NON-radioactive stable isotopes of tracer amounts of the following macro-nutrients: L-[ureido-13C-4,4,5,5-2H5]-citrulline,15N-labeled spirulina protein and L-[1-13C]-Phenylalanine. Amino Acid absorption will be measured with tracer amounts of the NON-radioactive stable isotopes of the following inert amino acids: L-[13C6]-allo-isoleucine AND L-[D10-15N] - allo-isoleucine. Sugar absorption will be done using the standard D-xylose test.

Epithelial intestinal cell proliferation index will be measured using in vivo labeling with BrdU. BrdU will be administered according to section V.4.4.7 Other Procedures, and samples will be collected according to section V.4.4.2. Biosamples.

Timeline for the collection of CBC, plasma, and tissues for the GI function assays described above will be done according to Table 1.

Table 1

Exp2: time line and endpoints

A = complete blood counts B= Spirulina, D-Xylose, Citrulline C = Brdu, Euthanasia, Tissue Collection

Blood samples volume At the time of blood collection, animals will be restrained, according to Section V.4.2. Prolonged Restraint. On the days when intestinal function is tested (labelled as B in Table 1), we will exceed the 1% daily (1% of 65 ml/kg) allowed total blood volume (Diehl et al, 2001). On those days, there will be 14 blood collections, for a total of approximately 25 ml of blood (14 time points x 1.7 ml + 0.5 ml for CBC). The 1.7 ml include initial 0.7 ml of fluid (blood mixed with saline or heparin used to lock the catheter) to be discarded. With the exception of experimental groups Sham and cohort 1, we will not exceed the 7% allowed in a one-week period. With regards to experimental groups Sham and cohort 1 we may exceed the 7% allowed in a one-week period (depending on the weight of the animal). For Sham and cohort 1 groups we will be collecting multiple blood samples on 3 different instances within 1-week time period. However, the animals will be euthanized within 1-4 days after the last blood collection.

Blood sample time points Blood samples for measuring citrulline will be taken before the single dose of citrulline, in a post absorptive state (16-18 hours overnight fasting), and again at 2, 5, 10, 20, 30, 60, 90, 120 min after administration of the single dose of citrulline (Figure 2). Time 0 (T=0min) starts at administration of citrulline.

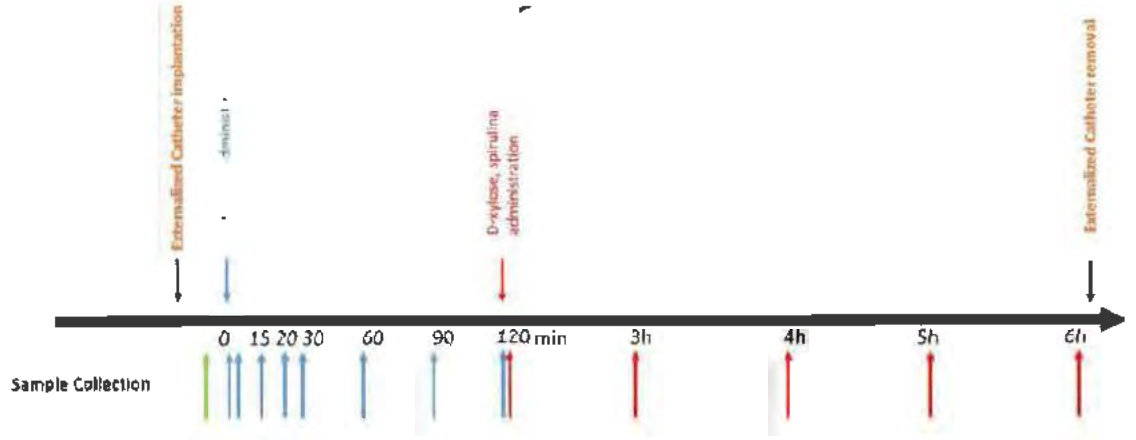

Figure 2: schematic of reagents administration and sample collection. Green: baseline sample before treatment. Blue: administration and plasma samples for citrulline kinetics. Red: D-xylose, spirulina, phenylalanine and allo-isoleucine administration and plasma samples for D-xylose, spirulina, phenylalanine and isoleucine kinetics. Black arrows bracket the entire duration of the experimental procedure, approximately 7 hours.

For the nutritional supplement with tracers, time zero is the time of oral administration of standard meal containing the tracers (15N-labeled spirulina, L-[1-13C]-phenylalanine, L-[13C6]-allo-isoleucine and D-xylose), and the simultaneous single dose administration of L-[D10-15N]- allo-isoleucine through the infusion set. This time corresponds to the 120th minute (T=120min) after administration of citrulline. Afterwards, blood sampling will continue on hourly basis, over the course of four hours. The first collection of these series will be 2 minutes after tracer's administration (five blood samples total per animal) (Figure 2). Blood samples (1 ml aliquots) will be put in Lithium-heparinized tubes, immediately placed on ice, processed to obtain plasma, divided in aliquots, and immediately frozen at -80 °C until further analysis.

At the time of scheduled euthanasia (day 6, 9, 15 and 30), animals will be infused with BrdU (see section V.4.4.7 Other Procedures),approximately one hour prior to humane euthanasia . Parts of GI tract (jejunum, duodenum, and ileum) will be fixed and analyzed for proliferative markers. Table 1 reports the timeline for sample collection and type of assay. Sham irradiation will be done before irradiation with Cobalt, in order to perfect techniques and assays prior to dealing with irradiated animals. For each of the two radiation doses, we will irradiate 12 animals during the same day. No more than 12 animals will be irradiated in one day. For each radiation dose, four cohorts, consisting of three animals each, will be followed over time; each cohort will be euthanized at either day 6 or 9 or 15 or 30.

Primary experimental endpoints. The primary experimental endpoints of the study will be structure and function of the GI, as measured by histological slides, percentage protein digestibility (Engelen et al. 2013), production rate of citrulline (Engelen et al. 2013), plasma concentration of D-xylose, and 30-day survival.

Secondary experimental endpoints. Repair of GI will be determined by BrdU labeling, as well as Ki67 and TUNEL assay.

Number of animals for Experiment 2: 3 animals x 4 time points x 2 doses TBD (8-12 Gy, and 13-16 Gy) + 3 control animals = 27

V.1.3. Experiment 3. To establish a radiation dose dependent injury profile for GI-ARS in animals irradiated under PBI using LINAC.

We will irradiate fifty-six animals under 40-50% bone marrow sparing, as described in Experiment 2 (head, forelimbs and thorax shielded). Animals irradiated at GI doses (5 12 Gy) show extensive hemorrhages and necrosis of the GI tract, in addition to villar blunting/fusion and loss of crypts, which may contribute to impaired absorption of nutrients. We will use histological measures as well as metabolomics technology to assess expression of biomarkers in the plasma of animals irradiated at GI doses, and to gain insights into the molecular pathways possibly involved in loss of GI function. Final doses are to be determined in consultation with (b)(4) a memo will be submitted with the final radiation doses. Survival will be monitored for 45 days after exposure. Blood will be collected twice before irradiation, and, with day 0 the day of irradiation, at days +1, 3, 7, 10, 14, 17, 20, 23, 27, 30, 35, 40 and 45. Time points of blood collection may be subjected to change by up to +/- 24 hours. Samples will not exceed the 7% total blood volume within one week time period (see V.4.4.2 Biosamples).

Primary experimental endpoints. The primary experimental endpoint of the study will be natural history of GI function over 45 days, metabolomics, and correlation with histological features.

Secondary experimental endpoints. The secondary experimental endpoint will be blood cell counts, and general indicators of animal health.

Number of animals for Experiment 3: 8 animals x 7 doses = 56 animals

V.2. Data Analysis

Experiment 1 and 2: the number of animal requested is the minimum necessary to allow for analysis of all proposed biomarkers and replication of results. This is a pilot study, therefore we cannot make any assumptions in terms of expected size effects or difference in means. Differences in means between groups will be assessed using Student's T-test or ANOVA (or corresponding non-parametric tests). Strength and direction of association between variables will be estimated using the Pearson Product-Moment correlation coefficient or the Spearman coefficient or the Kendall rank correlation (experiments 1-3).

Experiment 3: Kaplan Meyer curves and a preliminary probit will be calculated using 8 doses and 7 animals per dose, for the PBI-GI irradiation. Probit curves are usually constructed using a minimum 5 doses/6 animals per dose; 8 doses and 7 animals per dose will increase the power of analysis, and narrow the confidence intervals, increasing the overall predictive ability of the probit curve

V.3. Laboratory Animals Required and Justification

V.3.1. Non-animal Alternatives Considered The purpose of this project is to determine the effect of radiation on survival, GI function and coagulation. There is no computer model or tissue culture that can mimic the effect of radiation on the whole organism and predict lethality. Survival and organ function depend on an intricate network of organ cross-talks and cellular microenvironment that cannot be recreated *in vitro*. We do not know all of the cell types and tissues involved in radiation injury or how radiation injury causes cell and tissue damage. The concept of multi-organ failure has been suggested, but how the injured organs affect each other's vital functions is unknown. The present state of the art of tissue culture is still incapable of reproducing the *in vivo* relationships. Computer modeling is similarly limited by lack of full characterization of the biological elements and interactions under study.

These considerations are consistent with the FDA requirement ("Animal Rule') for preclinical research in both small and large mammals before granting approval for drug testing in humans.

V.3.2. Animal Model and Species Justification Large, long-lived, non-rodent animal models are required for drug studies submitted to the FDA for licensure applications. The close similarity to humans in anatomy and physiology of organs such as the liver, pancreas, kidney and heart has made the pig the primary species of interest as organ donors for xenographic procedures. Minipigs are routinely used for toxicity testing. As such, further and rapid characterization at physiological, molecular and genetic level of the minipig is likely to occur, thus increasing acceptance of this model and facilitating advanced drug development. We have been developing the Göttingen minipig as an additional large animal model for the study of the ARS and advanced development of radiation countermeasures. The current study will help to further characterize the model in terms of natural history of GI- and H-ARS, and to understand the reasons behind organ dysfunction. Studies on the Sinclair minipig will increase the choice of animal model available to mimic the condition in humans, overall increasing the chances of obtaining a FDA approved drug for the mitigation and treatment of the ARS and eventually decreasing the number of animals required for research. Our previous studies on H-ARS and GI-ARS have utilized male Göttingen minipigs to develop probit curves. Since we are using our own historical data as terms of comparison, we will continue to use male minipigs for this study.

V.3.3. Laboratory Animals Swine

V.3.3.1. Genus / Species *Sus scrofa domestica*

V.3.3.2. Strain / Stock Göttingen miniature swine

V.3.5. Refinement, Reduction, Replacement (3 R's)

V.3.5.1. Refinement

The study data-points currently mandated by the FDA for approval of radiation countermeasures under the Animal Efficacy Rule is mortality. Hence the primary study data-point in our development of Göttingen minipigs as a model for ARS is survival. Moribundity will be used as a surrogate for mortality, and euthanasia will be used in order to minimize pain and distress, using an extensive set of criteria (see animal endpoints, paragraph V.4.5 – Lethargy, weight loss, temperature, respiratory distress, food intake, bleeding *etc.*). Animal care and use procedures will only be performed by trained personnel. We have considerable experience in the care and handling of minipigs. Extensive human interaction every weekday will reduce stress in the animals. Use of slings, supportive care, topical anesthetics, and injectable or inhalation anesthetics will minimize distress during blood collections and irradiation. For instance, topical lidocaine will be used for blood collection from VAPs and isoflurane anesthesia will be used for blood collection from peripheral veins. Animals are acclimated to the sling during the incoming physicals at which time we use positive reinforcement by offering them treats at the end of the physical exam. VAP design and the blood collection have been refined during multiple iterations of previous studies to minimize discomfort to the animals.

V.3.5.2. Reduction

Blood samples obtained from minipigs before irradiation will serve as controls, thus reducing the number of animals required for this study.

V.3.5.3. Replacement None

Exp. #	Experimental/Control Group	C	D	E	Totals
1	To establish the dose dependent natural history of animals exposed at H-ARS doses to unilateral sequential (Cobalt-60), and to follow the development of radiation-induced coagulopathies.		3	48	51
2	To establish the relationship between radiation-induced intestinal bleeding and function of the GI tract, and to evaluate biomarkers of GI structure and function		3	24	27
3	To establish a radiation dose dependent injury profile for GI-ARS in animals irradiated under PBI.			56	56
Totals:			6	128	134

V.4.1.2. Pain Relief / Prevention

V.4.1.2.1. Anesthesia / Analgesia / Tranquilization

We are planning to use anesthesia/sedation at the time of blood sampling (if necessary), prior to irradiation, surgery (if applicable), and prior to euthanasia. Midazolam and Acepromazine may be used to sedate large and fractious animals prior to blood collection for the ease of handling and alleviating stress to the animals as well as handlers. Anesthesia/sedation regimen for the animal procedures is outlined in Table 2. Drug dose, frequency, route, site of injection, and needle/catheter size are outlined in Table 3 in

section V.4.4.1. Injections. Atropine will be added for any procedure that requires intubation. Cetacaine topical spray may be used to facilitate intubation

Table 2

*Anesthesia/sedation regimen**

Blood sampling, emergency medical care	i	Midazolam or Acepromazine, with or without isoflurane 1-5% (face mask or endotracheal tube)
		OR
	ii	Xylazine + Telazol or Telazol with or without isoflurane1-5% (face mask or endotracheal tube)
		OR
	iii	Isoflurane 1-5% (face mask or endotracheal tube)
		OR
	iv	Telazol + dexmedtomidine or ketamine + xylazine with or without isoflurane 1-5% (face mask or endotracheal tube)
Irradiation, Surgery, Euthanasia	v	Telazol with or without isoflurane 1-5% (face mask or endotracheal tube), Atropine (when intubated)
		OR
	viii	Telazol + dexmedtomidine or ketamine with or without isoflurane 1-5% (face mask or endotracheal tube), Atropine (when intubated)
		OR
	ix	Xylazine + Telazol with or without isoflurane 1-5% (face mask or endotracheal tube), Atropine (when intubated)

*Agents will be selected and doses may be refined based on veterinarian's discretion.

At the end of the irradiation procedure or surgery, once the animals are back in their cages, dexmedetomidine can be reversed by atipamezole *i.m.* (same volume as dexmedotmidine) to facilitate recovery.

V.4.1.2.2. Pre- and Post-procedural Provisions

Body weights and health check status

Body weights and standard animal health check status (hydration status, hair coat, skin quality, vitals) will be determined at least once prior to irradiation, and on days of blood collection. Data will be recorded on the Animals' Clinical Observation at Blood Collection Form (c) (see Section VIII Enclosures). Animals will be monitored daily for general indicators of animal health (activity, posture, stool, vomit, respiratory activity, respiratory rate, anorexia and temperature). Monitoring will occur at least once in the morning (am) and once the afternoon (pm) throughout the duration of the study. Monitoring in the critical period of sick animals will be performed with increased frequency, as described in V.5.2.1. Routine Veterinary Medical Care. Daily observations will be recorded on study specific form, Animals' Daily Observations Form (d) (see Section VIII Enclosures).

Supportive care

We will administer prophylactic empirical antibiotic regimen to reduce the risk of infection to all animals in the protocol between day 3-30 post irradiation. For the animals to be used for pilot coagulation evaluation studies (Experiment 1), we will administer the supportive care prior to initiation of the experimental procedures. Supportive care will be provided in the form of antibiotics (Gentamicin and Amoxicillin), antipyretic/anti-inflammatory (Carprofen), and gastrointestinal protectant (sucralfate) as per the dose and route outlined in the Table 3 in section V.4.4.1. Injections. Dietary supplementation and oral hydration will be offered in the form of moistened/liquid food, Metamucil, pumpkin mash, Pedialyte, and apple sauce. This supportive care was proven to improve survival in Göttingen minipigs irradiated with total body irradiation (Cobalt-60).

Preventative supportive care will follow a population based regimen, which will provide care to all animals on a fixed schedule, regardless of blood counts and body temperature values, starting 3 days after irradiation, and continuing through day-30. Emergency care on an individual basis may be added per veterinarian requirement

V.4.1.2.3. Paralytics NA

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures

V.4.1.3.1. Sources Searched Altweb, AGRICOLA and Pubmed

V.4.1.3.2. Date of Search 12/2/2015

V.4.1.3.3. Period of Search 2000 - 2015

V.4.1.3.4. Key Words of Search swine, total body irradiation, partial body irradiation, ARS, sequelae, pain, distress, death as an endpoint, alternatives

V.4.1.3.5. Results of Search

Alternatives to toxicity testing in five animals have been proposed in the form of cell and tissue culture, which are not feasible for the purpose of this study where the cross-talk among organs and strain sensitivity is being investigated in relationship to survival after acute irradiation. Additionally, bioinformatics or *in silico* approaches applied to life science might be created ad hoc to validate studies; however these approaches cannot be adopted to model the complexity of multi-organ failure in a large animal, because the mechanisms of radiation injury are still for the most part unknown. Alternatives to irradiation to study the ARS (total body or partial body) do not exist. We will however provide anesthetics and analgesics for pain management at the time of VAP and catheter implantation (See VAP or externalized catheter placement under section **V.4.3.2. Procedure (s)**), as well as during the days that follow surgery, to alleviate the pain produced by the procedures.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification

Irradiation itself is not a painful procedure. Pain and distress are associated with the immune suppression, GI injury and bone marrow suppression post TBI. At equivalent TBI doses, pain and distress after PBI are expected to be less intense, because of the residual, spared, bone marrow which is still capable of producing blood cells. These animals may not have acute effects of irradiation (bleeding, infection *etc.*). Depending upon the irradiation dose, irradiated animals die due to compromised immune responses and opportunistic infections. The percentage of surviving animals is the indicator of the efficacy of a countermeasure. We cannot give systemic anesthetic agents to animals after the irradiation procedures, since they are known to interact with the immune system (see references in Jacobsen, K. O., V. Villa, V. L. Miner, and M. H. Whitnall. 2004. Effects of anesthesia and vehicle injection on circulating blood elements in C3H/HeN male mice. *Contemp Top Lab Anim Sci* 43:8-12.), and would confound the correlation of radiation dose with incidence of moribundity, resulting in a waste of animals. However, we are providing supportive care in terms of analgesics, antibiotics, and oral fluids/ nutritional support. Use of supportive care is expected to mitigate the pain associated to the sequelae of irradiation.

V.4.2. Prolonged Restraint

Only short periods of restraint in the sling (<30 minutes) will be necessary for irradiation (in Cobalt facility) procedure, physical examination and blood collections. To minimize discomfort, we have designed a new type of sling that uses softer, elastic material to support the animal, and utilizes a more efficient restraint design that maintains the animal in place while reducing manipulation by technicians and consequently stress to the animals. During the acclimation period, slings are used for physical examination. At the time of physical examination, animals are acclimated to the sling for 5-10 minutes. Acclimation to the sling is

very rapid and non-stressful; animals are petted and gently spoken to while restrained. It has been our experience that resting on the sling does not agitate the animal at all.
Animals are anesthetized/sedated and transported to the Cobalt Facility or LINAC holding area prior to irradiation (<20 minutes). Animals will be kept under continuous observation while anesthetized.
For Experiment 2, animals may be restrained for a maximum of 6 hours in cages with limited space (based upon the experimental design), that allow the minipig to sit or stand, but not turn around, or in the sling. The choice between cage or sling (or a combination of both) will depend upon animal's individual preference, based on vocalization and motion. Animals will be at first placed on the sling, for the samples to be taken in the first 1-2 hours. During restraint, animals will be under continuous monitoring.

V.4.3. Surgery

V.4.3.1. Pre-surgical Provisions

Animals will be fasted overnight (approximately 16 – 18 h) prior to VAP implantation surgery. For antibiotic, one dose of Cefazolin sodium or ampicillin sodium will be given just prior to the surgery, or intra-operatively, for prophylaxis. A single dose of Pre- or intra-operative buprenorphine or Carprofen will be provided for analgesia. Drug doses, frequency, route of administration, site of injection, and needle/catheter size are outlined in Table 3 in section V.4.4.1. Injections. Cetacaine topical spray will be used to facilitate intubation.

V.4.3.2. Procedure(s)

VAP implantation. VAP catheters (SoloPort subcutaneous access port, either PMID or MID model; Instech Solomon, PA) will be surgically implanted in the right external jugular veins under general anesthesia according to the principles of aseptic surgery. Animals will be lying either in dorsal or lateral recumbency; vital signs such as heart rate, respiration rate, and blood pressure will be taken at every 5 min, whereas, temperature and percent oxygen saturation will be measured at every 15 min by vet techs. The catheter tip will be introduced through a 2-3 mm incision in the right jugular vein and advanced to the junction of the external jugular vein and vena cava. Prior to insertion, the VAP catheter will be flushed with locking solution (heparin lock flush solution, 100 IU/ml). Prior to securing the VAP catheter within the vein, 1 preplaced 2-0 or 3-0 Vicryl (polyglactin 910) suture (Ethicon, Somerville, NJ) will be used to ligate the vessel just cranial to the insertion point of the catheter tip. A second and third vicryl ligature will be placed around the caudal portion of the vessel containing the VAP catheter and retention beads, with 1 ligature on either side of one of the beads. The port will be secured within the scapular or mid-dorsal incision site to the underlying musculature by use of 2-0 or 3-0 poldioxanone (PDS) (Ethicon, Somerville, NJ) or 2-0 or 3-0 Monocryl (poliglecaprone 25) at a minimum of 2 of the 5 anchor holes on the port. Catheter function will be confirmed intraoperatively through aspiration of heparinized saline and withdrawal of a blood sample via the septum. If the aspiration of a blood sample is not successful, or there are air bubbles indicating incomplete seal, another ligature around one of the beads will be added and catheter function will be re-checked. The port reservoir and catheter will be flushed again with saline

and locked with a heparin lock flush solution (100 IU/ml). All subsequent lock solutions will be heparin (100 IU/ml).

During closure of the surgical sites, special attention will be given to eliminating dead space around the port and around the catheter loop on the neck. The muscle and subcutaneous layers will be closed with 2-0 or 3-0 PDS II (polydioxanone suture; Ethicon) or 2-0 or 3-0 Monocryl (poliglecaprone 25) using a simple continuous pattern. Skin incisions will be closed with 2-0 PDS II (Ethicon) or 2-0 or 3-0 Monocryl (poliglecaprone 25) in a continuous intradermal pattern. Tissue glue (VetBond, 3M, St Paul, MN) may be used to help seal surgical sites as necessary to help prevent contamination.

Externalized catheter implantation. An externalized catheter (7 Fr, Polyurethane single or triple lumen catheter, approx. 60-70 cm) may be used in place of the VAP in the external jugular vein as described above in the VAP catheter placement. However, in this case, the catheter will be tunneled to an exit site on the dorsum of the animal without a VAP. A coil of the catheter will be left underneath the skin and a subcutaneous purse-string suture will be placed around the catheter to secure it at the exit site. Skin will be closed using 2-0 PDS or 2-0 or 3-0 Monocryl (poliglecaprone 25).

V.4.3.3. Post-surgical Provisions

VAP surgery or externalized catheter surgery. Animals will continue to be monitored until fully recovered from anesthesia; they will be returned to their home cage when ambulatory. Supplemental heat may be provided in the home cage post-operatively (e.g. Bair Hugger warm air blanket, heating pads).Additional post-operative analgesia will be given with oral Carprofen for three days starting the day after surgery, or using sustained release buprenorphine as recommended by an AFRRI veterinarian in consultation with the PI. Trimethoprim-sulfa will be given for 5 days or more as determined by veterinarian to lessen the risk of post-op infection. Alternatively, enrofloxacin can be given every 24 hrs for 3-5 days or more if needed as determined by the veterinarian. Excede (Ceftiofur) may be used as an antibiotic as determined by the veterinarian. The advantage of this antibiotic is that the single injection provides protection against the bacterial infection for seven days. Drug doses, frequency, route of administration, site of injection, and needle/catheter size are outlined in Table 3 in section V.4.4.1. Injections.

Postsurgical recovery and pain will be monitored twice daily by visual examination of the incisions and overall conditions of the animals. Parameters monitored will be food intake, activity, alertness, vocalization, guarding, and response to human contact. Topical antibiotic ointment may be applied at the surgical site. Animals will be allowed to fully recover from the surgery before irradiation is done. The recovery period may last for 2-4 weeks.

V.4.3.4. Location

VSD surgical suite

V.4.3.5. Surgeon

Surgeons will be AFRRI/HJF veterinarians.

V.4.4.1.1. Pharmaceutical Grade Drugs

Lidocaine (5%), topical

Telazol®

Xylazine

Ketamine

Atropine sulfate

Cefazolin sodium

Ampicillin sodium

Heparin lock, IV

Saline

Buprenorphine

Carprofen

Metamucil

Enroflaxacin

Amoxicillin

Gentamicin

Midazolam

Acepromazine

Cetacaine topical spray

Atipamezole (Antisedan, Pfizer)

Dexmedetomidine (Dexdomitor, Pfizer)

Excede (Ceftiofur)

Isoflurane

Euthasol (sodium pentobarbital)

All the drugs listed above are ordered from veterinary product distributors by VSD or USUHS pharmacy, and they all are pharmaceutical grade drugs.

V.4.4.1.2. Non-Pharmaceutical Grade Drugs

BrdU (Sigma Aldrich)

L-[ureido-13C-4,4,5,5-2H5]-citrulline (Cambridge Isotopic Laboratories, Andover, MA)

15N-labeled spirulina protein (Cambridge Isotopic Laboratories, Andover, MA)

L-[1-13C]-Phenylalanine (Cambridge Isotopic Laboratories, Andover, MA)

L-[13C6]-allo-isoleucine (Cambridge Isotopic Laboratories, Andover, MA)

L-[D10-15N] - allo-isoleucine (Cambridge Isotopic Laboratories, Andover, MA)

D-xylose (Sigma Aldrich)

V.4.4.2. Biosamples We will collect blood samples throughout the duration of the study, as well as tissue samples at necropsy, for use in our laboratory and for sharing with collaborators. Time points of

blood collection are subjected to change by up to +/- 24 hours. Blood will be used for CBC counts and isolation of plasma/serum for laboratory assays. Tissues will be used for histology as well as molecular laboratory techniques as applicable (*i.e.* Western blot, PCR, ELISA, *etc.*). Tissue samples, to include organs ((heart, lung, small intestine, liver, spleen, kidney, lymph nodes), blood and hair may be taken at the time of euthanasia for tissue blocks and for frozen tissue repository.

Mean blood volume for minipigs is 61-68 ml/kg. Up to 1% of total blood will be drawn in a single day, and no more than 7% of total blood volume in a week (Diehl, 2001), unless as otherwise specified in Experiment 2.

Collection of blood samples. We will obtain blood samples from externalized catheter (if applicable), or from VAPs (if applicable), or from peripheral veins namely cephalic, saphenous, auricular, epigastric, and/or femoral. Blood collection will be performed using same needle and catheter size as used for i.v. injections as indicated in Table 3 in section V.4.4.1. Injections.

Blood draw from VAP. Lidocaine (5%) cream may be applied topically to the site of venipuncture to minimize discomfort to the animals about 15 minutes before starting the procedure; site will be cleaned with 70% alcohol and povidone iodine or Chlorhexidine as described below.
The port will be accessed using a gripper portal access needle/Huber needle with or without infusion set. For Experiment 2, the needle (or infusion set) may be capped and left in place for up to 7 hours, to facilitate multiple blood draws separated by short time intervals and/or administration of multiple tracers. The needle will be maintained in place using clear skin patches (i.e. Tegaderm) or tape. Otherwise, a jacket/tether system may be used.

Before placement of a non-coring needle, the port injection site will be scrubbed with povidone iodine or Chlorhexidine and alternating with 70% isopropyl alcohol until all gross debris is removed (3 to 5 scrubs each). To collect a single sample, approximately 1 ml fluid will be withdrawn from the catheter and port until blood no longer appears to be mixed with saline. This fluid will be discarded. The blood sample will be collected into a new syringe and placed in appropriate vials for analysis. Next, 3 ml heparin lock flush solution (100 IU/ml) will be infused into the port and catheter as a locking solution.

When collecting multiple samples within the same day, the catheter will be flushed with 1 ml of saline solution and locked with 0.5 ml of heparin lock. At the time of blood collection, we will discard the first 0.7 ml of fluid (blood mixed with heparin) prior to collecting the blood sample.

A standard protocol will be followed for obtaining a sample from a problematic catheter. First, external pressure will be applied to the non-coring needle where it entered the port to ensure the tip of the needle is all the way through the septum and into the reservoir. Second, high-pressure turbulent flushing will be attempted with a change in the animal's position. This may result in the use of a higher volume of saline

flush (more than 5 ml). A second person will be needed to extend the neck of the animal by raising it or flexing it away from the side that contains the VAP (in case the VAP has been secured at the scapular incision). Third, the non-coring needle will be replaced; at times the blood may be clotted inside the lumen of the needle. Fourth, if the described series of interventions fail to return the VAP to functioning, the sample will be collected from accessible peripheral vessels (cephalic, saphenous, auricular, and/or femoral) using one of the anesthesia regimens as described in section V.4.1.2.1. (With the exception of Experiment 3 (time point 120 min) where anesthesia cannot be used.

Blood draw from externalized catheter. If an externalized catheter is implanted in the external jugular vein (section V.4.3.2) and used for blood collection, the catheter will be flushed with 1-5 ml saline and the first 0.5 ml of blood will be discarded. Blood samples will be collected using a new syringe. After blood collection, catheter will be flushed again and locked with 1-3 ml of heparin lock (100 IU/ml). When collecting multiple samples within the same day, the catheter will be flushed with 1 ml of saline solution and locked with 0.5 ml of heparin lock. At the time of blood collection, we will discard the first 0.7 ml of fluid (blood mixed with heparin) prior to collecting the blood sample.

Blood draw from peripheral veins. Alternatively, we will collect blood from peripheral veins such as auricular, femoral, cephalic, epigastric, and/or saphenous veins. An i.v. catheter may be placed in one of the peripheral veins. Animals may be sedated at the time of blood sampling according to section V.4.1.2.1 Anesthesia/Analgesia/Tranquilization, if necessary. All procedures will be entered into the experimental record. At blood collection, site will be cleaned with 70% alcohol.
Collection of samples will be performed with the minipig restrained in a sling or on a minipig in the cage; at the same time, we will take vitals. The entire procedure takes less than 30 min. After blood draw, animals will be returned to their cages and checked to ensure that the needle puncture wound is closed and the blood has clotted.

V.4.4.3. Adjuvants NA

V.4.4.4. Monoclonal Antibody (MAb) Production NA

V.4.4.5. Animal Identification Tattoos or ear tags and cage cards/tags

V.4.4.6. Behavioral Studies NA

V.4.4.7. Other Procedures

Temperature transponder. At the time of irradiation, VAP surgery, or catheter implantation, while the animal is anesthetized, a temperature microtransponder (Implantable Electronic ID Transponder IPPT-

300, Bio Medic Data Systems, Seaford, DE), will be implanted subcutaneously behind the neck, over the shoulder to facilitate body temperature measurements. Alternatively, body temperature will be measured using a minimally-invasive ear probe or a rectal probe.

Dosimetry. Animals will be sedated, and taken in covered transporting cages to the Cobalt or LINAC facility, where they will be placed on a sling or a table and body measurements will be taken. Additional sedation will be administered as appropriate.

Administration of tracers (L-[ureido-13C-4,4,5,5-2H2]-cit, L-[D10-15N]- allo-isoleucine, 15N-Spirulina, L-[1-13C]-Phenylalanine, L-[13C6]-allo-isoleucine, D-xylose)

All test substances and solutions will be freshly prepared. For i.v. administration the solutions will be sterile (by 0.22 µm filtration/or autoclaving) and isotonic. All solutions must be at room temperature prior to dosing. Animals will be fasted overnight (16 -18 hours). The catheter will be flushed with 5 times the dead volume immediately after the injection of a tracer. This may result in the use of a higher volume of saline flush (more than 5 ml). The dead volume of the VAP includes port plus internal catheter, and will be measured at the time of VAP implantation. The dead volume of the catheter or the infusion set will be measured prior tracer administration/blood collection, by ejecting the liquid into an Eppendorf tube and measuring with a pipette.

1) T=0min: citrulline NON-radioactive stable isotope (L-[ureido-13C-4,4,5,5-2H2]-cit, Cambridge Isotopic Laboratories, Andover, MA) will be delivered intravenously through the VAP (using a gripper portal access needle/Huber needle) or peripheral veins or central venous catheter or a peripheral intravenous catheter @1.28 µmol/kg, in a volume of 0.7 ml/kg. The needle and catheter sizes, and site of injection are outlined in Table 3 in section V.4.4.1. Injections.
2) T=120min (i.v. administration): L-[D10-15N]- allo-isoleucine NON-radioactive stable isotope (Cambridge Isotopic Laboratories, Andover, MA) will be delivered intravenously through the VAP (using a gripper portal access needle/Huber needle) or peripheral veins or central venous catheter or a peripheral intravenous catheter @ 3.86 µmol/kg in a volume of 0.7 ml/kg. The needle and catheter sizes and site of injection are outlined in Table 3 in section V.4.4.1. Injections.

   T=120min (oral administration): the following tracers will be administered orally in ENSURE: 15N-Spirulina, NON-radioactive stable isotope (Cambridge Isotopic Laboratories, Andover, MA) + L-[1-13C]-Phenylalanine, NON-radioactive stable isotope, (Cambridge Isotopic Laboratories, Andover, MA) + L-[13C6]-allo-isoleucine, NON-radioactive stable isotope, (Cambridge Isotopic Laboratories, Andover, MA) (all isotopes at 3.86 µmol/kg in a volume of 0.7 ml/kg) + D-xylose.

BrdU. BrdU is a synthetic analog of thymidine. BrdU is selectively incorporated into the newly synthesized DNA of replicating cells during the S phase of the cell cycle, and it is commonly used in the

detection of proliferating cells. Antibodies specific for BrdU can then be used in cells and in frozen or formalin-fixed paraffin embedded tissues to detect levels of BrdU and identifying actively replicating cells. BrdU has cytotoxic, teratogenic, and mutagenic properties; accidental exposure presents potential health and safety hazards to laboratory staff, animal handlers and other personnel. Primary routes of occupational exposure to BrdU include aerosol exposure, ingestion, accidental injection, and tissue absorption. Biosamples and anything that has been in contact with BrdU injected animals is considered hazardous to humans for 72 hours from the time of injection. A standard operating procedure for working with BrdU in minipigs at AFRRI has been developed and is attached as part of this amendment (see Appendix 1), together with the approved Safety Form 310.
VSD staff will be notified of the intention of using BrdU two weeks prior to the beginning of the experiment (see section V.5.1.Husbandry Consideration). Rooms will be posted and the SOP will be made available outside the animal room. At all time when handling animals injected with BrdU, personnel will have to wear proper PPE (see BrdU SOP in Appendix 1 and section V.5.1. Husbandry Considerations).

BrdU will be injected in sedated animals, according to the procedure attached in Appendix 1. This protocol has been optimized for the Göttingen minipig under (b)(6) Briefly, animals will be anesthetized (as described in V.4.1.2.1. Anesthesia / Analgesia / Tranquilization) and restrained on the sling. BrdU (150mg/kg) will be infused through the VAP (using a gripper portal access needle/Huber needle) or externalized central venous catheter or intravenous catheter. See Table 3 for needle and catheter size. Possible veins to be accessed will be peripheral veins (cephalic, auricular, saphenous, epigastric, and femoral), vena cava, or external jugular vein.
Central venous cut down may be performed in case percutaneous access is not possible. The site will be aseptically prepared and a 1-2 cm incision will be made under sterile conditions. Manual pressure will be applied on the vein for hemostasis after injection is made. Incision will be closed using either absorbable suture material (2-0 or 3-0 PDS) or staples. Buprenorphine (dose, route, site of injection, and needle size specified in Table 3 in section V.4.4.1. Injections) may be given as needed for pain management. BrdU will be injected at the rate of up to 5 ml/kg body weight through the cut-down vein. Needle size is specified in Table 3 in section V.4.4.1. Injections.

V.4.4.8. Tissue Sharing Bio-samples (as described in section **V.4.4.2. Biosamples**) will be collected, to be used for CBC counts, plasma/serum isolation, histo-chemistry/protein/molecular assays among others, and to be shared with collaborators upon request and as experiments permit.

V.4.4.9. Animal By-Products NA

V.4.5. Study Endpoints Moribundity will be used as a surrogate for mortality, and euthanasia will be used in order to minimize pain and distress. The determination of the moribundity must be made in consultation with a veterinarian.

Euthanasia will be carried out either after completion of the observation period (30 day for experiment 2, or 120 day for experiment 3), or when the animal(s) shows at least one of the absolute criteria for moribundity, or a combination of four criteria for non-absolute moribundity. Absolute criteria will be lack of responsiveness (lying down, no effort to get up when people enter the cage, no ability to stand without support), continuous prolonged dyspnea (>30 minutes), body weight loss (loss of greater than 20% of expected weight), hypothermia (<36°C) and anorexia (skip 3 consecutive meals, even if eating enrichment), Non-absolute criteria will be hyperthermia (>40°C), anemia/pallor, petechiae/ecchymosis, vomiting/diarrhea, lethargy, seizures or vestibular signs, and prolonged hemorrhage. Attainment of 4 non-absolute criteria will qualify for immediate euthanasia. Euthanasia of the animal with less than 4 non-absolute criteria will be made upon consultation and/or discretion of a veterinarian.

Absolute	
1	Non responsive, assuming the animal has recovered from anesthesia
2	Dyspnea (fast respiration rate, shallow breathing, labored breathing), continuous, prolonged >30 minutes)
3	Loss of 20% of expected weight**
4	Hypothermia (<36°C) (rectal temperature)
5	Complete anorexia (skip 3 consecutive meals – pig chow)
Non-absolute	
1	Hyperthermia (>40°C) (rectal temperature)
2	Anemia/pallor, CRT > 2 seconds.
3	Vomiting/diarrhea
4	Lethargy
5	Seizures or vestibular signs (falling, circling or head tilt, paddling)
6	Partial anorexia
7	Prolonged hemorrhage (hemorrhage = any sign of internal or external bleeding, including presence of petechiae/ecchymosis, bleeding from snout, eye, mouth, anus; presence of blood in the cage; presence of blood in the stool. Hemorrhaging can be also determined by drop in HCT %).
*Attainment of 4 non-absolute criteria will qualify for immediate euthanasia	
**Based on Marshall Bio-resources growth chart –weight versus age	

Animals will be euthanized according to current American Veterinary Medical Association (AVMA) guidelines.

V.4.6. Euthanasia Animals will be euthanized according to current American Veterinary Medical Association (AVMA) guidelines. Animals will be anesthetized with Telazol® or ketamine/xylazine or 1-5% isoflurane via mask (with 1-3 L/min O_2 flow rate) or any one of the combinations described in section V.4.1.2.1. Animals will then be euthanized with Euthasol® (sodium pentobarbital) or another commercial euthanasia solution. Animals will be deeply anesthetized with 1-5% isoflurane (via face mask) in addition to the injectable anesthesia during intra-cardiac injection of Euthasol. Drug doses, site of injection, route of administration, and needle/catheter size are specified in Table 3 in section V.4.4.1. Injections. In the rare event that a moribund animal is not responsive and necessitating of immediate euthanasia, Euthasol may be injected intravenous or intracardiac under 1-5% isoflurane without prior injectable anesthesia. Death will be confirmed by AFRRI veterinarian or veterinary technician via auscultation of the heart, with cessation of sounds for at least 2 minutes or longer as per current SOP. See item V.4.5 for euthanasia criteria before the end of the study.

V.5. Veterinary Care

V.5.1. Husbandry Considerations Minipigs will be housed in stainless steel cages/runs, in tactile, visual and olfactory contact with adjacent animals. During quarantine/acclimation period, up to day of surgery, minipigs may be group-housed. After surgery, they will be singly housed to prevent damage to the VAPs and to allow individual assessment of feed consumption and fecal/urine/blood production. Rooms will be maintained on a 12:12 h light (0600 to 1800) dark cycle with the temperature set to 27 to 29°C and 30% to 70% relative humidity. Commercial diet (Mini-Swine Diet 8753, Harlan Teklad Diets, Madison, WI) will be provided. Water will be provided ad libitum.

Handling and housing of animals administered with BrdU. Generally, special care has to be taken when handling animals and animal excreta for the 72 hours subsequent to BrdU administration. Cages must be lined with plastic sheets, and sheets must be covered with low-dust animal bedding. No change in bedding and no cage hosing is done for the 72 hours following BrdU administration. Drains are temporarily sealed during those 72 hours. After 72 hours, the bedding and the underlining plastic liners are collected in hazard waste bags, and picked up as hazardous waste by USUHS waste pick-up, as per SOP. Cages are rinsed and sent through cage wash. We plan to maintain the animals in the necropsy room (b)(6) after administration of BrdU, until euthanasia (approximately 1 hour after BrdU administration). If, in case of emergency, animals need to be returned to their home cages, housing will be performed according to instructions above.

V.5.1.1. Study Room

Minipigs will be located at AFRRI for the duration of the study. They will either be in a VSD surgical suite for VAP implantation, in transit to and from the cobalt /LINAC facility in a covered transport cage, in slings for irradiation in the cobalt/LINAC facility, or in their housing cage or a VSD prep room for blood collections or euthanasia. They will be housed in stainless-steel cages in an environmentally controlled and continuously monitored animal room as described in Section V.5.1. For BrdU injections, animals will be injected in VSD (b)(6) next to an eye wash station for protection of personnel.

V.5.1.2. Special Husbandry Provisions Tap water will be provided ad libitum. Diet will be controlled in accordance with vendor's recommendations so as to prevent excessive weight gain. Pumpkin mash will be provided starting at day 3 after irradiation to all animals. Liquid food (i.e. ProMod Liquid Protein) and/or moistened pellet will be offered if observed that the sick animal prefers it to dry food. No treats in the form of marshmallow, peanut butter, crackers will be offered to this animal, since they are on a calorie-restricted diet. Instead, fresh fruits, vegetables, and/or yogurt will be offered daily (excluding weekends and holidays).

V.5.1.3. Exceptions NA

V.5.2. Veterinary Medical Care

V.5.2.1. Routine Veterinary Medical Care Animals will be acclimated for at least 1 week prior to any procedure. Each animal will be observed at least twice daily for evidence of pain or distress, stool consistency, left-over food, demeanor and overall animal appearance. Body weights will be determined at least once prior to irradiation and on days of blood collection.
Animals will be qualitatively assessed at least twice daily (a.m. and p.m.) for general behavioral status and food consumption by VSD techs and/or research techs. Daily observations will be annotated on the Animals' Daily Observation Form (d). The heart rate will be measured at the time of each blood collection. If animals look dehydrated, supplemental oral fluids (Pedialyte, etc.) will be provided. Diarrhea has not been observed in minipigs irradiated at doses <8 Gy. Appropriate standard operating procedures will be followed by staff veterinarians in the event of pain or distress.

The critical period (period of time when animals show signs of ARS and experience increased morbidity and mortality) is defined as day 14-30 post-irradiation for animals irradiated at H-ARS, and day 5-10 post-irradiation for animals irradiated at GI-ARS doses (bilateral, total body irradiation). The window of the critical period may change for partially irradiated animals and for animals irradiated with unilateral sequential geometry.

Monitoring of sick animals will be performed with increased frequency during this time to include: an early morning check (before 9 a.m.), a mid-morning check (between 9 a.m. and noon), an afternoon check (between 1 p.m. and 3 p.m.), and a late afternoon check (between 4 p.m. and 6 p.m.).

If animal conditions are deteriorating rapidly during the day, an additional evening check (after 8 p.m.) will be done, followed by an early morning check at <10 hours apart. Rapidly deteriorating conditions are defined as follows: activity score of 2, >1°C change of body temperature per hour, respiratory activity of 1 with continuous dyspnea for more than 10 consecutive minutes, complete anorexia for more than 12 hours, single instance of vomiting/diarrhea, single instance of seizure or vestibular signs, mild hemorrhaging for longer than 6 hours.

Scoring Criteria

i.	Activity score: 0- Normal bright alert and responsive (BAR), 1-Periods of inactivity, quiet, alert and responsive (QAR), 2-Laying down, gets up with stimulus, 3- Non-responsive
ii.	Posture/Movement Score: 0- Normal gait and posture, 1- hunched appearance or slower movement, 2-sternal recumbency without dog sitting posture, 3-lateral recumbency, 4-dog-sitting posture, shoulders forward, 5-ataxia or uncoordinated movement
iii.	Stools: Y=1, N=0
iv.	Stool Consistency Score: 0 =Normal Formed Stool, 1- Formed Hard Stool, 2-Loose stool, 3- Diarrhea
v.	Vomit: Y=1, N=0
vi.	Respiratory Activity Score: 0- Normal Respiration, 1- Labored breathing, or intermittent cough 2- gasping, open mouth breathing, or persistent cough
vii.	Respiratory rate (RR): breaths per minute
viii.	Food (left in the cage): Y=1, N=0, partial =0.5
ix.	Temp: °C

V.5.2.2. Emergency Veterinary Medical Care Emergency veterinary medical care is available 24/7. The on-call veterinary officer will be available via telephone 24 hours a day. The VSD on-call roster will be located outside the VSD conference room (b)(6) on the bulletin board and at the security watch desk. Additionally, the on-call roster for the research staff will be located outside (b)(6)

V.5.3. Environmental Enrichment

V.5.3.1. Enrichment Strategy

Physical and occupational enrichment will be done as per the VSD minipig enrichment SOP, except single housing after catheter/VAP implantation if applicable, and irradiation. Dietary enrichment will be done as per section V.5.1.2.

V.5.3.2. Enrichment Restrictions Minipigs will be single-housed after surgery (if applicable) and after irradiation until completion of the study, to avoid mechanical and infectious complications related to implanted catheters and irradiation, but they will be in visual, olfactory and auditory contact with other minipigs in the same room. Animals may be group-housed during quarantine.

X. ASSURANCES

Protocol Title: A STRAIN COMPARISON STUDY ON SURVIVAL, VASCULAR DAMAGE, AND LONG TERM HEALTH EFFECTS IN IRRADIATED MINIPIGS (*Sus scrofa domestica*)

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made every effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with a qualified individual who evaluated the experimental design with respect to the statistical analysis, and that the minimum number of animals needed for scientific validity will be used.

D. Biohazard / Safety: I have taken into consideration and made the proper coordinations regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R", namely, "Responsibility," which the DOD has embraced for implementing animal use alternatives where feasible and conducting humane and lawful research.

G. Scientific Review: This proposed animal use protocol has received appropriate peer scientific review and is consistent with good scientific research practice.

H. Painful Procedure(s): I **AM / AM NOT** conducting biomedical experiments, which may potentially cause more than momentary or slight pain or distress to animals. If applicable, potential pain and/or distress **WILL / WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

Rapidly deteriorating conditions are defined as: activity score of 2, >1°C change of body temperature per hour, respiratory activity of 1 with continuous dyspnea for more than 10 consecutive minutes, complete anorexia for more than 12 hours, single instance of vomiting/diarrhea, single instance of seizure or vestibular signs, mild hemorrhaging for longer than 6 hours).

Appendix 1

PROTOCOL: in vivo labeling of 5-Bromo-2'-deoxyuridine (BrdU)

GENERAL PROCEDURE

1- Preparation and mixing of BrdU (final concentration 31 mg/ml in PBS)

Preparation and mixing of BrdU will be performed ONLY in a fume hood. Any work with BrdU needs to be done over disposable absorbent bench top spill pads. Any laboratory equipment or surfaces that have come in contact with BrdU will be disposed of or decontaminated. This can be done by wiping them down with soap and water and paper towels. Keep a copy of BrdU safety form and MSDS close by.

- Order 5-Bromo-2'-deoxyuridine from SIGMA (cat. No. B5002, 5 grams, ≥99% pure by HPLC); BrdU can be stored at -20°C as powder or in solution.
- PPE: Disposable lab coat; two pairs of powder-free, disposable nitrile gloves, with the outer one covering the gown cuff whenever there is risk of exposure to hazardous chemicals; eyewear providing chemical splash protection; appropriate lab attire (full-length pants, closed toe shoes, etc.)
- Notify the Open Lab (b)(6) in advance (by email) for the days we will be using the hood for mixing BrdU and that BrdU is a potential carcinogen. Reserve the hood on the day of use.
- Prepare the fume hood by covering the surface with disposable absorbent bench top spill pads. Place inside the hood a stirrer/hot plate, one pipetman, 10 mL pipettes, paper towels, sterile syringes with Luer-Lock™ fittings, sterile syringe

caps, one Nalgene filter unit with 0.2 microns filter (Nalgene® vacuum filtration system (250ml), from Sigma cat no. Z370606), 2 ziplock bags (gallon size), aluminum foil cut in 8x8" pieces for wrapping syringes. The hood will be posted with a sign "CAUTION - CANCER SUSPECT AGENT".

- BrdU stock (powder) is stored at -20ºC. Place one bottle (5 grams) in a ziplock bag, contained inside a polystyrene box covered with absorbent material and sufficiently large to contain a 500 mL beaker. Transport the box to the hood. Place box inside hood.
- Prepare a beaker (250 ml) by adding 160 mL of sterile PBS and a disposable stirring bar. Place a thermometer inside the beaker.
- Place the beaker on the hot plate. The temperature should reach between 40º-50ºC.
- Open the container of BrdU; aspirate about 5 ml of warm PBS from the beaker and add it to the bottle of BrdU (careful not to spill!). Try to mix – the Brdu powder will clog the tip of the pipette. Return the pipette to the beaker, and immerge the tip into the warm PBS. Expel any content and mix by pipetting up and down a couple of time. Again, aspirate about 5 ml of warm PBS from the beaker and add it to the bottle of BrdU and repeat the procedure described above until all the BrdU is dissolved.
- Once the BrdU is completely dissolved, connect the filter unit to the vacuum. Close the empty bottle of BrdU and place in an empty ziplock. Place the filter unit inside the polystyrene box. Carefully, pour the BrdU solution into the filter unit and open the vacuum. Once all the solution has been filtered, close the vacuum,

remove the top portion of the filter unit and discard in the ziplock bag together with the empty BrdU bottle.

- When loading the syringes, first un-wrap one syringe and one cap for each reiteration. Load the syringe with the required volume (i.e. 5 syringes with 10 ml + 1 syringe with 5 mL), recap the syringe, wrap in aluminum foil, and place in a clean ziplock bag.
- Discard empty receiving unit of the Nalgene filter unit in the ziplock with the empty BrdU bottle. Place ziplock with syringes in the polystyrene box. Place box on a cart and wheel to VSD.
- To clean the hood: immediately dispose of all contaminated supplies in a biohazard box (triple-bag). Wipe down surface with 10% bleach. Fill the beaker with 10% bleach, let it sit a few minutes, and rinse with soap and water. Immediately close biohazard box, label with "caution carcinogen suspect agent and "incineration only". Send it for incineration.

2- In vivo labeling – 150 mg/kg final concentration

VSD staff will be notified of the intention of using BrdU two weeks prior to the beginning of the experiment. Rooms will be posted with: CAUTION - CANCER SUSPECT AGENT, AUTHORIZED PERSONNEL ONLY. The SOP will be made available outside the animal room. At all time when handling animals injected with BrdU, personnel will have to wear proper PPE.

3- Required PPE

To prevent skin exposure, appropriate personal protective equipment (PPE) will be worn when handling any amount of BrdU. Ensure that all exposed skin is covered.

- Tyvek coveralls
- Double-nitrile gloves. Use two pairs of powder-free, disposable nitrile gloves, with the outer one covering the gown cuff whenever there is risk of exposure to hazardous chemicals
- Face shield for protective eyewear that provides chemical splash protection
- Appropriate lab attire (scrubs, closed toe shoes, etc.)
- Face mask
- Two pairs of shoe covers. One can be discarded inside the animal room

4- Animal room set up and handling

- Animals will be NPO for BrdU injections. Post a NPO sign outside the room door day before the injections.
- The animal room will be set up with twice as many cages as animals. One half of the cages will be set on one side of the room, and will be used during the days preceding the experiment. The remaining half will be set up on the other side of the room as described below to house animal after BrdU injection.
- Underneath each animal cage set up for BrdU experiment, plastic lined sheets (Custom-cut Diamond TEK liners, dimensions: 24" by 32", Harlan Laboratories Inc., Indianapolis, IN) will be put on the floor first, and then the sheets will be covered with low-dust animal bedding (Product #7092, 1/8" corn cob, Harlan Laboratories Inc., Indianapolis, IN). Also, some bedding will be put on the floor all around the cage to absorb any potential fluid draining from the cage. Additional corn husk bedding may be added during the 72 h period as needed.
- Special care will have to be taken when handling animals and animal excreta for the 72 h subsequent to BrdU administration. Animal room will have an MPW (medical pathological waste) box lined with two biohazard plastic bags to discard used PPE.

- There will be no change in bedding and no cage hosing for the 72 h following BrdU administration. Drains will be temporarily sealed during those 72 h. The weekend caretaker will need to arrive early during the weekend to feed the animals when they are in the first 72 hours period from injection, since VSD personnel is not trained for that. After 72h, the bedding and the underlining plastic liners will be collected in triple bagged biohazard boxes. Each box will be labelled appropriately by identifying the hazard (BrdU animal waste – biohazard/chemical hazard), date, and investigator's name. Put two "Incinerate Only" stickers on the box (one at the top and one at the side), and store the box into VSD (b)(6) cold room for pick up.
- The boxes will be picked up as hazardous waste by USUHS waste pick-up. The regular pick-up schedule is every Wednesday. Pick up services can be contacted at (b)(6) if needed.

5- Necropsy Room set up

Necropsy room will be set up for BrdU injection and to perform necropsy after euthanasia.

Materials:

- Materials required for physical, and injection of telazol, BrdU, and euthasol will be as follow:

  Animal records books, thermometer, timer, clock, syringes and needles, heavy duty packaging tape for biohazard boxes and sharps container, surgical tape for securing the catheter, saline flush, alcohol swab, externalized catheters, disposable 18 Micron filters (Homo-Nate® filter, P/N 50783, Utah Medical Products, Inc., Midvale, UT), telazol, euthasol, isoflurane anesthesia machine with appropriate sized mask, stethoscope, sling, plastic backed absorbent sheets, sharps container, and waste boxes lined with three biohazard plastic bags (01waste box and 01 sharp container for each injection day, and 02 waste boxes and 01 sharp container for each necropsy day).
- For necropsy, materials needed will be: 1 bucket filled with 3 liters of formalin labeled (Animal ID, Species, BrdU, (b)(6) Date, Protocol (b)(4)

(b)(4) scissors, scalpels, forceps, blades. Place "Formalin Caution" stickers on the bucket

6- Procedure for BrdU injection

- Animal will be transported from the animal room to the necropsy room using animal transport cage.
- Once in the necropsy room, animal will be put and secured on the sling.
- The physical will be performed by doing the overall assessment, and taking vital signs.
- If collecting blood prior BrdU injection, animal will be sedated with isoflurane. Blood will be collected from peripheral vein, and then telazol will be injected using dose, route, site of injection and needle size as outlined in Table 3 in section V.4.4.1. Injections.
- If blood is not going to be collected, telazol will be injected after the physical examination. Once animal is completely sedated, catheter and filter will be placed on the animal ear's vein, the flush syringe will be attached to the catheter to check for patency of the vessel.
- If the vein is patent, catheter will be secured by using pieces of surgical tape and BrdU (150 mg/kg) will be injected through the filter. The starting and ending time for BrdU injection will be recorded in the animal record book.
- In case of non-terminal BrdU injection, the catheter will be removed from the ear and animal will be returned back in the room using transport cage. Once in the animal room, animal will be transferred into its cage set up for BrdU experiment (with liners and bedding on the floor) and will be monitored until complete recovery.
- In case of terminal BrdU injection (one hour prior to euthanasia), catheter on the ear will be left in place, animal will be moved from the sling to a transport cage during the one-hour period. Animal will be closely observed during this period. Towels will be used to provide thermoregulation in case animal is hypothermic. Either telazol bump (approximately 0.1 ml) or isoflurane will be given if animal begins to gain consciousness. After one hour, animal will be humanely euthanized as outlined in section V.4.6. Euthanasia.

- Five minutes after injection, auscultate for cessation of heart sounds, and check mucous membrane for cyanosis.

7- Procedure for Necropsy

- Before starting necropsy, wear a PAPR (Powered Air Purifying Respirator) in addition to PPE listed above.
- Put the bucket with formalin for tissue sample collection into the fume hood and turn the air flow on.
- Move the animal from the transport cage to the necropsy table. The table will be covered entirely with the spill absorbent pads.
- Animal is placed in dorsal recumbency. A ventral midline incision is made extending from the manubrium to the pelvic canal. Skin and underlying musculature is reflected to the side. A small incision is made into the peritoneum and abdominal cavity is opened. About 20 cm long section of jejunum is snipped from the small intestine coils on the right side of the abdomen using straight Mayo scissors. The section is laid on the cutting board and cut into two halves. On one half, small horizontal incisions at a distance of 10-20 mm are made along the length using curved metzenbaum scissors and the tissue is dropped into formalin by holding it from the mesentery with thumb forceps (bucket labelled as "short"). The remaining section is opened along the entire length and dropped into formalin. Duodenum and ileum are collected in similar fashion. However, the total length of duodenum collected is about 10-12 cm and therefore one section that is cut open along entire length is approximately 6-8 cm and shorter one with horizontal incisions along the length is about 4 cm. Intestinal contents from the sections that are opened along the entire length are removed gently without touching the mucosae before putting them in formalin.
- Following small intestine tissue collection, sternum is collected using Mayo scissors.
- The tissues collected will stay in fixative for 48 hours at room temperature.
- The sternum is taken out of formalin after 48 hours, as with the other tissues. Then, the sternum is placed in Immunocal (Formic Acid bone decalcifier) solution for 24-48 hours. Finally, it is placed on the tissue processor

overnight, embedded, cut and stained. So, it takes a slightly longer time (3-4 days) to produce the sternum slides compared to lungs and small intestines.

- After necropsy is completed, discard carcass in triple bagged biohazard box, and store into VSD cold room. The box will be appropriately labelled by identifying the hazard (BrdU carcass – biohazard/chemical hazard), date, species, and investigator's name. 02 "Incinerate Only" stickers will be put on the box (one at the top and one at the side).
- Tissues will be ready for immunostaining a week following the necropsy. Submit the tissues (FFPE blocks) for immunostaining.
- Immunostaining - Blocks will be sent out to HISTOSERV, INC., 19526 Amaranth Drive, Germantown, MD 20874, PHONE (301) 972-2600, FAX (301)972-2627, Email: histoserv@histoservinc.com

8- Sanitizing Animal Room and Necropsy Room after BrdU Procedure

Materials needed: scrub brush, 10% bleach, sterilant solution (i.e. Vindicator), miltex instrument cleaner, miltex instrument lubricant, hose and sprayer

For the animal room, cages will be pre-washed with sterilant solution and rinsed using hose and sprayer before sending to cage wash.

For the necropsy room, all materials used for necropsy will first be soaked into 10% bleach, then rinsed. They will be soaked again into water with miltex instrument cleaner added (Alimed Inc., Dedham, MA), and will be allowed to sit for at least 15 min. Following the pre-soak, instruments will be scrubbed and rinsed with water. The clean instruments will be spread out on an absorbent sheet and miltex instrument lubricant (Alimed Inc., Dedham, MA) will be evenly sprayed.

All walls and floor will be pre-sprayed with 10% bleach than scrubbed through using a scrub brush, and rinsed. Then, walls and floor will be sprayed for the second time with sterilant solution that will be allowed to sit on the surfaces for at least 10 minutes. Using the hose and sprayer, all walls and floor will be rinsed and excess water will be squeegeed down the drain.

MEMORANDUM FOR DR. (b)(6) DEPARTMENT OF ANESTHESIOLOGY

SUBJECT: IACUC Approval of Protocol - Initial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on April 15, 2015:

Animal Protocol Title: "Serotonin Targeted Biomarker and Therapeutic Approach in the Treatment of Traumatic Brain Injury (blast) and Posttraumatic Stress Disorder"

USUHS Protocol Number: (b)(6)

Expiration Date: April 14, 2018

Supporting Grant(s) Number: TBD

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. NON-TECHNICAL SYNOPSIS:

Taken together, a critical factor in blast-induced traumatic brain injury (bTBI) and posttraumatic stress disorder (PTSD) lies with the association of cognitive deficits and mitochondrial metabolic integrity in the brain. Serotonin is one of the key neurotransmitter, which is affected by depression and anxiety (Gardner & Boles, 2011). How serotonin levels modulate the stress following bTBI or PTSD is entirely unknown. Our **long-term goal** is to identify the blood-based brain specific protein biomarkers of brain injury progression and to determine the potential targets for safe and effective therapeutic strategies. **The objectives** of this current proposal are to **a)** understand the relationship of serum serotonin levels, psychological, and biological effects of pre-existing stress on the severity of blast injury, and **b)** examine the potential intervention of sodium pyruvate that help to prevent, attenuate, and treat the effects of bTBI and PTSD. The work outlined below will test the **hypothesis** that low serum serotonin levels are associated with the severity of stress-related symptoms following recurrent bTBI and PTSD, which can be improved by increasing the serotonin level with pyruvate treatment.

II. BACKGROUND

II.1. Background:

Disturbances in the neurotransmitter system regulated by the hypothalamic–pituitary–adrenal (HPA) axis constitute a leading cause of neurophysiologic long-term sequelae after traumatic brain injury (TBI; J. Llompart-Pou et al., 2008; McIntosh, 1993). These are the same regions implicated in the etiology of PTSD, suggesting that although the initiating events of brain injury may differ, there may be a common etiological pathway resulting in the overlapping their clinical symptoms (Sumpter & McMillan, 2006).

Part of the problem in the effective treatment of bTBI is the lack of biomarkers to distinguish between PTSD and bTBI due to their overlapping impaired cognitive symptoms. We will compare the serum serotonin, cognitive behavior, and neuropathological markers of bTBI in rats with stress alone, or combined pre-existing stress with bTBI followed by pyruvate treatment to address the questions: **1)** If low serum serotonin can be used as a biomarker of cognitive deficit related to PTSD; **2)** If combined pre-existing stress and TBI also affect serum serotonin levels; and **3)** What is the efficacy of pyruvate treatment in PTSD-like symptoms following stress or stress+bTBI?

In our preliminary study, we found that low serum serotonin is associated with increased anxiety and depression in stressed rats. It is not known if stress associated with blast may also be affected by decreased serotonin levels. Experiments proposed will address the questions: (1) can serum serotonin be used as a biomarker of bTBI, and (2) what is the efficacy of pyruvate treatment in bTBI?

Our published results also suggest a protective role of pyruvate in ischemic astrocytes through the mitochondrial mechanism (Sharma, Karian, Sharma, Liu, & Mongan, 2003; Sharma, Walsh, Kerr-Knott, Karaian, & Mongan, 2005). These neuroprotective properties of pyruvate may be attributable to pyruvate's role in improving neuronal energy via intracellular calcium buffering (Villalba et al., 1994).

Serotonin (5-hydroxytryptamine; 5HT) is a monoaminergic neurotransmitter, produced by its precursor tryptophan. However, the exact origin of serotonin levels around the injured brain area is not known because about 90% of the body's serotonin resides in intestine, blood platelets and pre synaptic endings (Da Prada & Picotti, 1979). Serotonin exerts its multiple physiological actions by its recycling mechanisms through a variety of receptors in brain (5-HT2A, 5-HT3, 5-HT5A and 5-HT7; Barnes & Sharp, 1999).

It is widely believed that brain serotonin deficiency plays a role in depression. Brain serotonin levels in humans can be measured by conventional method of positron emission tomography (PET; Visser et al., 2011). The disadvantage of this method is that tracer used in PET imaging can enter into the kynurenine pathway under inflammatory conditions and thus provide a false signal. In rats, in-vivo serotonin levels can also be measured by voltametery with carbon fiber microelectrodes implanted into the brain. This is used frequently to monitor sub-second dopamine release in freely moving and anesthetized rats (Hashemi et al., 2009). This technique has its own technical difficulties such as electrode deterioration and increased sensitivity to 5-HT measurement. Using commercial ELISA kit, we have recently demonstrated that compared with control animals, low serum serotonin levels in rats are associated with increased anxiety and damaged brain mitochondria in stressed animals with or without mTBI (using fluid percussion). We don't know if serotonin blood levels reflect the brain's level of serotonin. Also, researchers don't know whether the dip in serotonin causes the depression or the depression causes serotonin levels to drop. Therefore, *in this current proposal, we will measure serotonin levels in plasma, CSF, and brain from rats subjected to stress alone, bTBI alone, or stress+bTBI (compared to controls).*

The most common drugs to treat depression are SSRIs (selective serotonin reuptake inhibitors) such as Celexa, Lexapro, Prozac, Paxil and Zoloft. However, serious side effects (dizziness, nausea, lethargy, headache, anxiety, and agitation) have

been reported after the withdrawal of prolonged SSRI treatment. This discontinuation syndrome results from neurophysiologic readjustment in the central nervous system to compensate for the pharmacologic activity of the SSRI (Visser et al., 2011; Bond, 2005). *Now the question is, are there any alternatives that are effective but safer than SSRI?* Based on our preliminary data about the protective effects of pyruvate in increasing the serum serotonin and in reducing the depressive symptoms in PTSD rats, we plan to extend our study on pyruvate effects in bTBI and PTSD on serotonin, cognitive deficits and neuropathology.

Pyruvate: Glucose is an obligatory metabolic fuel for brain. The metabolism of glucose by brain cells requires several coordinated steps involving different cell types and different cellular compartments, either of which may be markedly disrupted by the time a head injured patient is able to recognize the consequences of his/her TBI. Furthermore, experience with the precarious use of glucose to treat head injured patients necessitates the development of a more targeted metabolic and anti-inflammatory treatment strategy (Desagher, Glowinski, & Premont, 1997; Matsumoto, Yamada, Kohmura, Kinoshita, & Hayakawa, 1994).

A decrease brain serotonin following TBI and PTSD is also known to cause reduced cellular metabolism through impaired mitochondrial oxidative phosphorylation, increased inflammation and oxidative stress (Gardner & Boles, 2011). Therefore, in this proposed study; use of sodium pyruvate in the treatment of bTBI and PTSD to elevate the brain serotonin levels through its mitochondrial mechanisms, anti-oxidative and anti-inflammatory property is a novel avenue (Lee, Kim, & Koh, 2001; Matsumoto et al., 1994; Mongan, Capacchione, Fontana, West, & Bunger, 2001; Mongan, Karaian, Van Der Schuur, Via, & Sharma, 2003; Moro, Ghavim, Hovda, & Sutton, 2011; Neigh, Bowers, Pyter, Gatien, & Nelson, 2004; O'Connell et al., 2005; O'Donnell-Tormey, Nathan, Lanks, DeBoer, & de la Harpe, 1987; Sharma, Benford, Li, & Ling, 2009; Sharma et al., 2003; Sharma & Mongan, 2009; Vilau, Pascu, & Kitulescu, 1967). Ours is the first study to examine the effects of pyruvate on serum and brain serotonin levels, cognitive deficits and neuropathology in response to bTBI with/out pre-existing stress.

II.2. Literature Search for Duplication

II.2.1. Literature Source(s) Searched: Medline (PubMed), PsycInfo, F1000Biology (and electronic journal review service), BRD, and RePORT

II.2.2. Date of Search: December, 2014

II.2.3. Period of Search: No Period Restriction

II.2.4. Key Words and Search Strategy: Traumatic brain injury, BOP (blast overpressure), PTSD (post-traumatic stress disorder), rats, age differences, locomotion, activity, anxiety, depression, serotonin, pyruvate (words are entered separately and in combination; rat is entered with each term) have been searched in data base searches. We also read electronic and paper journals regularly and search for phrases, titles, and abstracts relevant to our work.

II.2.5. Results of Search: There has been extensive work on traumatic brain injury, and the various behavioral measures included in our work. However, there has been little work combining these variables with our rat stress model of "Warrior Stress Paradigm" and blast TBI. Overall, literature searches on the topics to be covered in our experiments indicate the value of our approaches, and have not revealed existing

literature or data that would supersede our experiments on blood based biomarkers of brain injury severity in response to repeat blast TBI with/out pre-existing stress and pyruvate treatment.

III. OBJECTIVE\HYPOTHESIS:

The objectives of this current research proposal are: a) Understand the spectrum of changes in serum serotonin levels, psychological and neuro-pathological effects of pre-existing stress on the severity of blast TBI, and b) Examine the potential effects of sodium pyruvate that may prevent, attenuate and treat the effects of repeat blast on TBI and PTSD. The work outlined in this proposal will test the **hypothesis** *that low serum serotonin levels are associated with the severity of stress related symptoms following recurrent bTBI and PTSD, which can be improved by increasing the serotonin level with pyruvate treatment.*

IV. MILITARY RELEVANCE:

The use of improvised explosive devices (IEDs) during the recent Iraq and Afghanistan wars has led to an injury, which is different from that in previous US wars (Traumatic Brain Injury in the United States: A Report to Congress. Emergency Department Visits, Hospitalization, and Deaths, 2002-2006, Atlanta, 2010, CDC report 2010). The Department of Defense and the Defense and Veteran's Brain Injury Center estimate that 22% of all combat casualties from the recent Afghanistan and Iraq conflicts are brain injuries (Hoge et al., 2008).

It is likely that the mild TBI and cognitive impairments observed among many of the troops returning from OIF and OEF result from repeated exposures to blast overpressure (Belanger, Kretzmer, Yoash-Gantz, Pickett, & Tupler, 2009; Sayer et al., 2008; Traumatic Brain Injury in the United States: A Report to Congress. Emergency Department Visits, Hospitalization, and Deaths, 2002-2006, Atlanta, 2010, CDC report 2010). While there are some reports to suggest that PTSD like symptoms in our troops might be due to the war related exposure to psychological trauma (Belanger, Kretzmer, Vanderploeg, & French, 2010; Vanderploeg, Belanger, & Curtiss, 2009). The intriguing questions is "why not all soldiers with mTBI have PTSD?" The diagnostic dilemma and ineffective treatment of mTBI and PTSD offer a great challenge to the clinicians due to the overlapping neurobehavioral symptoms such as insomnia, irritability, social withdrawal, impaired concentration and short-term memory deficit and complex metabolic and biochemical manifestations. If not diagnosed and treated promptly, PTSD quickly manifests itself into a socio-economic burden on society. Hence, it is very important to identify the blood -based biomarkers of TBI and PTSD.

V. MATERIALS AND METHODS

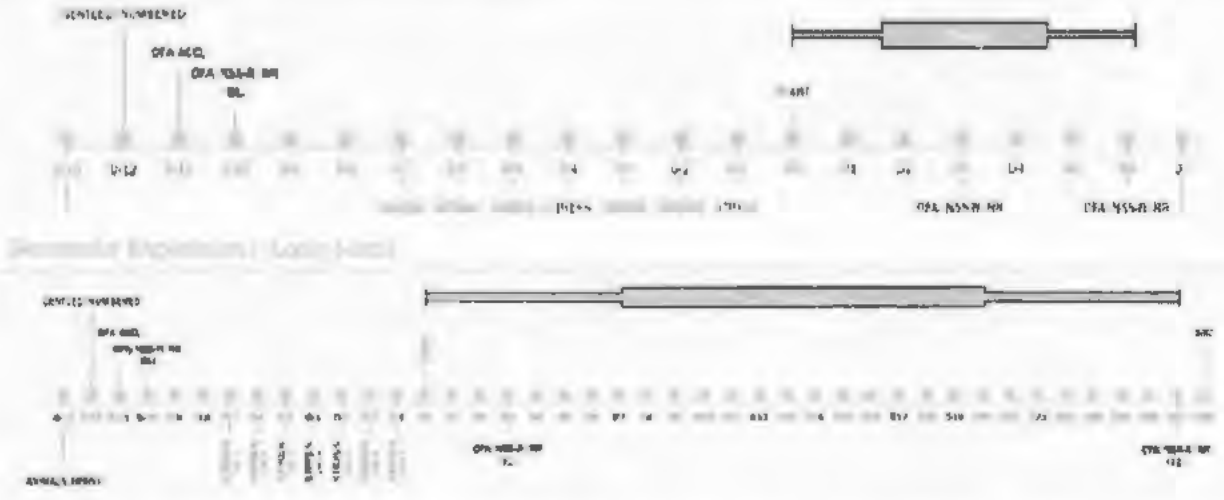
V.1. Experimental Design and General Procedures:

The experimental design for the 2 experiments is: 2 (no blast, blast) x 2 (no stress, stress) x 2 (no pyruvate, pyruvate) x 2 (short-term [7 days], long-term [28 days]) yielding 16 "cells" each of which will include 12 rats (10-12 rats are required for appropriate statistical power, so 12 rats are planned for each cell in case of loss of data due to equipment failures or unforeseen problems). In addition, animals are necessary for

training and piloting procedures (additional 20 rats). Therefore, this protocol requests authorization of 212 rats (see section V.3.4).

Group	Explanation
1	No blast, No Stress, No Drug
2	No blast, No Stress, Drug
3	No blast, Stress, No Drug
4	No blast, Stress, Drug
5	Blast, No Stress, No Drug
6	Blast, No Stress, Drug
7	Blast, Stress, No Drug
8	Blast, Stress, Drug

Both aims will be run simultaneously in counter-balanced cohorts to minimize experimental error. Please see below Tables for timelines of the biological and behavioral data collection. The behavioral test will include 1. Open field activity (OFA)- This test is a measure of motor performance, anxiety and general health of the animal, 2. Neurological severity Score- Revised (NSS-R)- These measures include observation of a righting response, leg flexion, balance, and sensory responses to mild stimuli (e.g., touching ear with cotton-tipped stick, response to light). These measures are similar to those described in CNRM SOP #2, and 3. Rotarod (RR)- The rotarod test measures an animal's fatigue and ability to maintain balance by coordinating the movement of all four feet and making the necessary postural adjustments. It also measures the animal's ability to improve on these skills with practice.



V.2. Data Analysis: Samples sizes for each experiment were based on two strategies: (1) sample sizes of previous experiments in our laboratory and in the published literature that have yielded statistically significant findings; and (2) power analyses of the dependent measures based on data from ongoing experiments and

data reported in the relevant literature following the procedures of (Cohen, 1988; Keppel, 1991; Keppel, Saufley, & Tokunaga, 1992). Estimates of effect size in the population were determined by calculating an estimated omega squared. Phi statistics then were calculated to determine the ratio of treatment variance to error variance for a given sample size. Using phi and power tables, the necessary sample size to achieve 0.80 power was determined. Sample sizes of 12 are appropriate for the behavioral and biological measures. The data will be analyzed by ANOVA or MANOVA (with and without covariates). Tukey HSD post hoc tests or Dunnett's t will be used to compare differences between conditions. All analyses will be two-tailed with alpha = 0.05.

V.3. Laboratory Animals Required and Justification

V.3.1. Non-animal Alternatives Considered: This research project relies on biological and behavioral responses in living organisms. Rats are subjects in this study because their responses are similar and predictive of human responses. Non-animal alternatives such as computer modeling and cell cultures were considered but are not suitable to assess biology and behaviors in organisms.

V.3.2. Animal Model and Species Justification:

Rats were chosen as subjects because they provide a valid and reliable model for the questions under study. There is extensive similarity between rodents and humans at the genetic level and there exists an extensive research literature using rats in animal models of a variety of human conditions including stress and mental and physical health. In addition, rodents are commonly used in investigations of TBI.

Dr. (b)(6) laboratory has used rats, mice, other rodents, and primates in their research over the past 30 years. Their findings with rats have been reliable (in their laboratory and in other laboratories) and have proven to be valid predicting effects in human subjects and human populations with regard to the topics that we study. Dr. (b)(6) has also been using rats in her laboratory for over 18 years and has found reliable results.

V.3.3. Laboratory Animals: All animals that will visit the Army Institute of Research (WRAIR) vivarium as part of collaborative studies must be shown to meet WRAIR Veterinary Services Program (VSP) health criteria IAW *UWN-501, Quality Control of Rodents and Rabbits* and/or *UWN-015, Receipt and Quarantine* prior to arrival. Diagnostic results, sentinel data, health certificates and prior notification and coordination with VSP will be required as applicable. The attending veterinarian will deny receipt of animals that do not meet required entry criteria.

		Species #1	Species #2
V.3.3.1.	Genus & Species:	*Rattus norvegicus* (Rat)	
V.3.3.2.	Strain/Stock:	Sprague-Dawley	
V.3.3.3.	Source/Vendor:	Charles River	
V.3.3.4.	Age:	Young adult/ adolescents (about 55 days)	
V.3.3.5.	Weight:	250– 300 g	
V.3.3.6.	Sex:	Males	
V.3.3.7.	Special	N/A	

Considerations:

V.3.4. Number of Animals Required (by Species) 212

V.3.5. Refinement, Reduction, Replacement (3 Rs)

V.3.5.1. Refinement: Animals are carefully monitored to limit or avoid pain and distress. Animals are observed daily for any behavioral signs of distress, including vocalizations, weight loss/gain will be evaluated by periodic weighing every alternate day, changes in food consumption, changes in reactivity, and any signs of injury. If there are any indications of pain or distress, then the LAM staff is consulted. With regard to logistical and technical refinements, many of the behavioral assessments use automated equipment interfaced with computers to allow for the collection of many parameters simultaneously and non-invasively. The use of sophisticated software and computerized technologies allows us to collect fine-grained and complete data sets for every animal included in the experiment, eliminating the need for additional studies that might otherwise have been necessary. Dr. (b)(6) many years of behavioral investigations regarding stress and various drugs also have allowed us to minimize the sample sizes as we have refined testing to be sensitive and reliable.

V.3.5.2. Reduction: The sample sizes for the proposed work were derived from power analyses of pilot data and past work in our laboratory and in other laboratories. These samples sizes therefore constitute the minimum number of animals necessary to obtain meaningful results and represent a useful application of knowledge of statistical effect size and the concept of power. In addition, in each experiment multiple dependent variables are measured. Measurement of many variables in the same animals markedly reduces the total number of experiments conducted. This strategy is used to reduce the number of subjects as much as possible without compromising the science.

V.3.5.3. Replacement: There are no appropriate replacement methods for the proposed work. See CNRM SOP #1 for additional information indicating that replacements are not available for this type of project.

V.4. Technical Methods

V.4.1. Pain / Distress Assessment:

Animals will be anesthetized during brain injury. Animals will be observed daily by investigators and by LAM staff to check their health and well-being and to insure that there is no undue pain or distress based on behaviors (e.g., excessive grooming, shivering, or other unusual motor behaviors) and vocalizations (e.g., squealing or excessive squeaking). Any indications of pain or distress will be dealt with by alleviating the cause of the problem (with the exception of experimentally-induced behavioral distress) or by contacting LAM personnel for assistance and guidance.

V.4.1.1. APHIS Form 7023 Information

V.4.1.1.1.	**Number of Animals:**	**Species #1**	**Species #2**
V.4.1.1.1.1.	**Column C:**	48	
V.4.1.1.1.2.	**Column D:**	68	
V.4.1.1.1.3.	**Column E:**	96	

The number of animals in each category has been broken down as follows (please refer to table in Section V.1. for group assignments):

Category C:

- Animals that no not receive blast, stress (Groups 1, 2)

Category D:

- Animals that receive blast but no stress (Groups 5, 6)
- Pilot animals are included in this group to teach techniques

Category E:

- Animals that receive stress (Groups 3, 4, 7, 8)

V.4.1.2. Pain Relief / Prevention

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization:

Rats will be anesthetized by inhalation with 5% Isoflurane mixed with compressed medical air (21% O2) at 1 liter/min for 2 minutes prior to TBI using an induction chamber. The inhalant anesthesia does provide sufficient anesthesia while in the blast tube. Animals are placed directly from the induction chamber, into the blast tube, blast occurs, and animal is placed back in home cage. The time it takes once the animal is anesthetized to the time to blast is less than 2 minutes and all animals remain anesthetized. If they wake up too early, they are placed back in the anesthesia.

After 2 min, the rat is tested for consciousness by pinching its tail. If the rat responds to the tail pinch, anesthesia is continued for an additional minute. If the rat does not respond, the anesthetized rat is transferred and secured in the rat holder and secured in the blast tube. Further details regarding this procedure appear in (Yarnell et al., 2013).

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions:

The non-surgical procedures that may induce momentary discomfort (e.g., tail pinch) are included for scientific purposes and are short in duration (see time course listed for each dependent variable; Section V.4.4.6). Animals are observed daily by investigators and by LAM staff to check on their health and well-being and to assure that there is no undue pain or distress. Animals also are carefully monitored during behavioral testing procedures. In addition, animals are closely monitored during all procedures that involve any pain or potential distress (e.g., during and after minor surgery; during and after injections). Pain/distress is assessed based on behaviors and vocalizations. Any indications of pain or distress are dealt with by alleviating the cause of the problem (with the exception of experimentally-induced behavioral distress) or by contacting LAM personnel for assistance and guidance.

Repeat Blast exposure: Blast exposures will be conducted in the morning; animals will be exposed to 3 blasts (at 75 kPa each) with 30 minutes in between each blast. Animals will be monitored continuously, by the PI and/or authorized staff member for an additional three hours post-blast or until they are fully recovered from anesthesia at WRAIR. After recovery, animals will be brought back to USUHS. After blast exposure day they will be monitored at least twice daily, by the research staff and LAM staff, until the study endpoint for that animal is reached.

Pain Assessment Score Sheet (please see attachment): This instrument will be used for all post blast evaluations to ensure that pain symptoms are assessed in a

relatively objective manner. If the pain assessment score sheet indicates, the attending veterinarian at WRAIR will be contacted promptly to provide their clinical opinion and consult with PI and/or authorized research staff to determine disposition. If an animal is euthanized as a result of this process, the appropriate pain category numbers will be reported to the IACUC. We typically do not observe signs of pain or distress post-blast – especially at the blast intensity specified.

Rat stress model: We developed a non-painful "Warrior Stress Paradigm" to model impending threat of attack in novel environments based on previous studies, many of which were conducted in our laboratory (Yarnell, 2013). Briefly, in this stress paradigm, predator stress is manipulated by introducing a cotton ball with commercially purchased synthetic fox urine into a test cage with the rat. Unpredictable, non-painful stressors include noise, flashing light, and cage shaking. The animal is transferred from its home cage to the stress cage with lid. The fox urine (10mL) is absorbed by a large cotton ball and placed in varying spots in the stress cage. The procedure is conducted in a room separate from the housing room and the behavioral rooms. A bright fluorescent overhead light remains on during the procedure. This procedure lasts 20 minutes. The stimuli are presented for 7 days in a manner designed to minimize habituation of the response. Each manipulation occurs no more than once per day. A combination of these stimuli avoids habituation of the response.

Pyruvate administration: Sodium pyruvate (1g/kg) will be started within 30 min after the completion of injury/stress protocol (on day 0), and then it will be administered every 24h until the end of the experiment, by oral gavage in 2 ml sterile distilled water. At the same time, control animals will receive the similar volume of distilled water.

V.4.1.2.3. Paralytics: N/A

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures

V.4.1.3.1. Sources Searched: Medline (PubMed), PsycInfo, and F1000 Biology, BRD, RePORT.

V.4.1.3.2. Date of Search: December, 2014

V.4.1.3.3. Period of Search: All years available on each database are searched (from recent work up to 20 years in the past)

V.4.1.3.4. Key Words of Search: brain injury, brain injury model, blast injury, pain, rat, anesthesia (these words are searched in carious combinations)

V.4.1.3.5. Results of Search: No alternatives are available to avoid using live animals for the assessment of biological and behavioral effects of brain injury and in intact rats and the procedures that are followed. The blast overpressure procedure (See section V.4.4.7) is described in detail in a recent paper (Yarnell, et al., 2013). This paradigm is considered to be the best animal model for exposure to improvised explosive devices. Animals are monitored closely for > 1 hour after brain injury and are monitored daily during each behavioral measure as well as during daily rounds by investigators.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification:

This study is designed to examine and treat the effects of pre-existing stress on blast TBI in terms of neuropatholical and neurobehavioral parameters. Yes, our stress

procedure will cause temporary distress during animal exposure to light, sound, and predator scent. But this non-painful stress procedure will cause less disstress than other existing stress protocols such as "repeat tail shock or animal exposure to the close vicinity of live predators". Our proposed stress model of "**Warrior Stress Paradigm**" is to simulate the impending threat of attack in novel military environments.

V.4.2. Prolonged Restraint: N/A

V.4.3. Surgery N/A
V.4.3.1. Pre-surgical Provisions: N/A
V.4.3.2. Procedure: N/A
V.4.3.3. Post-surgical Provisions: N/A
V.4.3.4. Location: N/A
V.4.3.5. Surgeon: N/A
V.4.3.6. Multiple Major Survival Operative Procedures: N/A
V.4.3.6.1. Procedures: N/A
V.4.3.6.2. Scientific Justification: N/A

V.4.4. Animal Manipulations
V.4.4.1. Injections: N/A
V.4.4.2. Biosamples:

Blood for biochemical analysis: Just prior to the beginning (day -10) and at the termination of the experiments, using a 22 Gauge BD Vacutainer® Eclipse™ blood collection needle, 100-150 µl blood will be drawn from the tail vein into an anticoagulant-free (red top) Vacutainer®. 50 uL of blood will be immediately used for ISAT machine for determination of blood gases, acid-base parameters, glucose, lactate and pyruvate. We will allow the remaining blood to clot for 15-20 minutes at room temperature. We will centrifuge the Vacutainers® for 10 minutes at 2,500-2,800 revolutions per minute (rpm) (1,500-2,000 x g) to separate the plasma.

Collection of CSF for brain injury evaluation: Just before the termination of experiment, rats anesthetized with isoflurane will be secured in a stereotactic frame in such a way as to allow the head to move up and down but not to move side-to-side. The back of the head and neck will be shaved clean of fur, and wiped with alcohol swabs. The head will be flexed in order to clearly display the occipital protuberance in the neck. After making a skin incision on the midline above the cervical vertebrae and the occipital protuberance, the atlantooccipital membrane will be evidenced by blunt dissection. A 25G needle will be used to puncture the membrane and collect the cerebrospinal fluid. The fluid will be cleared by centrifugation and the supernatant saved at -80°C.

Collection of brain parts for molecular biology, enzyme assays and serotonin measurements: Deeply anesthetized animals (8 rats/group) will be decapitated and brains will be quickly removed and placed on ice; the frontal cortex, amygdala, and the dorsal and ventral hippocampus will be dissected, weighed, flash frozen, and stored at -80C until use. Brain regions will be processed individually for protein extraction. In addition to the brain, we will also collect intestine, lungs, and spleen for further studies to examine the impact of blast exposure and stress on serotonin levels.

Collection of whole brain tissue for histology: Deeply anesthetized animals (4 rats/group) will be transcardially perfused with normal saline, followed by 4% paraformaldehyde in phosphate buffered saline (PBS) into the left ventricle. Following fixation, immediately thereafter, the brain, spinal cord, lungs, spleen, and intestine will be removed, and post-fixed for further evaluation. Organs will be post-fixed in 4% paraformaldehyde and 10% sucrose in PBS overnight at 4°C. The next day, brains will be transferred to 30% sucrose solution to complete the cryoprotection; after 24 hours or when organs no longer floats, they will be stored at -80°C.

V.4.4.3. **Adjuvants**: N/A

V.4.4.4. **Monoclonal Antibody (MAbs) Production**: N/A

V.4.4.5. **Animal Identification**: Cages are numbered corresponding to the animals in that cage and rat tails are coded with a marker using a stripe system that corresponds to units of hundreds, tens, or ones, depending on the location of the mark on the tail.

V.4.4.6. **Behavioral Studies**: Behavioral testing of rats will be performed in Laboratory for Animal Research (LAM) at USUHS. All rats will undergo the following neurobehavioral tests to determine 1) what kinds of behaviors are affected by the brain injury and/or stress; and 2) the outcomes of various treatments to see if there is an improvement after the treatment. Data from tests that utilize categorical (non-continuous) scoring (e.g., 5-point scales) should be analyzed by a non-parametric statistical method that does not make any assumptions concerning the normality of data distribution. All behavioral measures will occur on the same day and will occur directly after the previous one is complete (wait times of approximately 15-45 min will occur while equipment is being cleaned and while other animals are being tested).

1) **Open field activity (OFA)**. OFA is a collection of sensitive unconditioned behaviors that occur when an animal moves in its environment. These measures have been used in rat studies in Dr (b)(6) laboratory for many years (including recent studies of single blast-induced and other brain injuries) and have provided reliable and valuable data (Bowen, Eury, & Grunberg, 1986; Elliott, Faraday, Phillips, & Grunberg, 2004; Elliott & Grunberg, 2005; Faraday, Elliott, Phillips, & Grunberg, 2003; Faraday, O'Donoghue, & Grunberg, 2003; Faraday, Scheufele, Rahman, & Grunberg, 1999; Grunberg & Bowen, 1985; Morse et al., 1997). Horizontal activity provides information about gross motor performance and general health; center time provides an index of anxiety-related behavior (with an inverse relationship between center time and anxiety); vertical activity provides an index of depression-related behavior (with escape behaviors inversely related to depression). Locomotor activity is measured using an Accuscan Electronics infrared photocell system (Accuscan Electronics, Columbus, OH), located in a dedicated room within the animal facility. This room is constructed of cinderblock walls, acoustic tile ceiling and steel doors so that sound is kept to a minimum. One-hour activity measurements will be obtained during animals' active or dark cycle. Animals will be placed singly in a 40 x 40 x 30 cm clear Plexiglas arena and a Plexiglas lid with multiple holes to allow air flow. The lid ensures that subjects have adequate ventilation but cannot escape during data collection. A photocell array measures horizontal

locomotor activity and vertical activity. Data will be automatically gathered and transmitted to a computer equipped with "Fusion" software (from Accuscan Electronics). Once subjects are placed in the test areas, the experimenter turns off the lights and leaves the room. Chambers are cleaned between subjects with a clidox-s solution. Duration, frequency of repetition, and number of test days: The duration of locomotor activity testing is a maximum of 60 min per day. Animals will be acclimated to the equipment and then tested prior to blast exposure (baseline), 3 days, and either 6 or 27 days post exposure. OFA will be performed around the same time at each time point.

2) **Neurobehavioral observation.** Observations will be made and recorded using the Neurobehavioral Severity Scale-Revised (NSS-R) that was developed in the PI's laboratory (Grunberg, Yarnell, Chwa, Hutchison, & Barry, 2011) and based on neurological severity scales in the literature (Hamm, 2001; Shohami, Novikov, & Bass, 1995) using a Likert-format scoring system. These measures include observation of a righting response, leg flexion, balance, and sensory responses to mild stimuli (e.g., touching ear with cotton-tipped stick, response to light). The measures are similar to those described in CNRM SOP #2.
The NSS-R is a specific, continuous sequence of behavioral tests and observations based on the Neurological Severity Score (NSS). The 10 tasks assess reflex suppression, general movement, and postural adjustments in response to a challenge. The tests are ordered to ensure that subsequent measures are not affected by the preceding measure. Each task is scored using a three-point Likert scale, in which a normal, healthy response is assigned a "0," a partial or compromised response is assigned a "1," and the absence of a response is assigned a "2." Scores are totaled (max score of 20; where higher scores reflect greater extent of injury) and analyzed. Duration, frequency of repetition, and number of test days: The duration of neurobehavioral testing is a maximum of 5 min per day. Animals will be tested prior to blast exposure (baseline), 3 days, and either 6 or 27 days post exposure. Neurobehavioral observations will be performed around the same time at each time point.

3) **Rotarod.** The rotarod test measures an animal's fatigue and ability to maintain balance by coordinating the movement of all four feet and making the necessary postural adjustments. It also measures the animal's ability to improve on these skills with practice. Each Rota-Rod treadmill consists of a motor-driven drum with constant speed or accelerating speed modes of operation. The drum (7.0 cm diameter) allows each animal to maintain a suitable grip. It is divided into four test zones (8.9 cm wide) so that up to four animals may be tested at the same time. The device consists of a smooth hard plastic cylinder with concentric circular plastic sides (39.7 cm diameter) attached to prevent the rat from climbing off the cylinder laterally. The cylinder is connected to a variable speed reversible motor, allowing the speed and direction of rotation of the cylinder to be changed.
An accelerated rotarod task will be used with a Med Associates rat rotarod (Med Associates, Inc, St. Albans, VT). The equipment consists of a metal frame with polyvinyl chloride (PVC) dividers. Rats will be placed on the device facing the wall with the rod rotating in the direction opposite from the animal (so that the rat has to use its

paws to pace forwards to avoid falling off the rod). When a rat falls of the rotating drum (height of 26.7 cm), it breaks a photobeam, stopping the timer associated with that chamber. Once all four photobeams have been broken, the drum will cease rotating. Rats will be tested 3 times/time point on this device. In each trial, the speed of rotation will be slowly increased from 0 revolutions per minute (rpm) to 35 rpm for a maximum of 5 min. The mean duration on the device, expressed in seconds will be recorded for scoring each rat. Each animal's performance will be evaluated, including time spent on the rotarod at each rotation speed. The procedures will be consistent with other reports in the literature (e.g. McPhee, et al., 2005; Rustay et al., 2003).
Duration, frequency of repetition, and number of test days: The duration of neurobehavioral testing is a maximum of 15 min per day. Animals will be tested prior to blast exposure (baseline), 3 days, and either 6 or 27 days post exposure. Neurobehavioral observations will be performed around the same time at each time point.

V.4.4.7. Other Procedures:

For blast over pressure (BOP), rats will be transported to WRAIR and back to USUHS in a closed van provided by WRAIR and driven by an insured WRAIR driver. Rats will be housed in transportation cages. Cages will be secured from sliding and room temperature will be maintained. The vehicle will be cleaned before and after transport. WRAIR requires that we use their van and driver (this procedure of animal transport to WRAIR is similar with our current ongoing studies).

For BOP, there will be no surgery. Exposure to BOP will be conducted at WRAIR under the direction of Dr. (b)(6) following procedures described by our research group (Yarnell et al., 2013). The blast tube consists of a 2.5 ft long compression chamber separated from a 15 ft long expansion chamber (both of 1 ft diameter) by a polyester Mylar sheet (Du Pont, Wilmington DE). Anesthetized rats will be placed singly in a secured holder within the mouth of the blast tube. Using an air compressor, the pressure is then increased in the compression chamber until it reaches a critical value determined by the thickness of the Mylar sheet at which point the Mylar ruptures, causing a blast pressure wave to pass down the expansion tube. Available membranes will be calibrated to rupture at a compression pressure generating an exposure pressure of ~ 75 kPa. This level of blast exposure produces a mild traumatic brain injury. Rats will be exposed to three consecutive blasts with about 30 minutes in between each blast (three blast exposures in one day). After injury the rats will be returned to their home cages and monitored until consciousness is regained. They will be observed at WRAIR for at least 30 min after exposure to BOP. Rats will be kept at WRAIR for less than 12 hours.

The temperature of the transport vehicle will be maintained between 68-72°F. Once rats have received their blast exposure, they will be monitored for 30 minutes after they have recovered righting reflexes and will be examined to determine that they are not showing any signs of severe stress in excess of the symptoms expected for recovery from anesthesia before they are transported back to USU. An approved member on the protocol will accompany the rats at all times at WRAIR and monitor the rats for any signs of severe stress. If any signs of severe stress occur while the animals are away from USU, the accompanying investigator will euthanize the animal within the

WRAIR facilities.

BOP injuries will be conducted at WRAIR, Forest Glen. Behavioral measures will be conducted in the laboratories of Dr. (b)(6) in LAM at USUHS.

V.4.4.8. **Tissue Sharing**: N/A

V.4.5. Study Endpoint:

The study endpoint is euthanasia in each experiment. Rats will be euthanized on either 7 or 28 days after injury (injury day = day 0 [i.e., all animals including sham will be euthanized on days 7 or 28]; depending on if they are in the short- or long-term injury group). If any animals show evidence of pain or distress at any time, then LAM staff will be consulted regarding the most appropriate treatment or procedures. If the condition is not ameliorated in the judgment of a LAM veterinarian, then the rat will be euthanized after consultation with the PI.

V.4.6. Euthanasia:

Subjects will be euthanized by increasing dose of isoflurane followed by necropsy for organ harvesting. For transcardial perfusion, deeply anesthetized animals will be transcardially perfused with normal saline first followed by 4% paraformaldehyde in phosphate buffered saline (PBS) into the left ventricle.

If any signs of severe stress occur while the animals are away from USU, the accompanying investigator will euthanize the animal within the WRAIR facilities. WRAIR has a similar setup for euthanizing animals, as USU and the same procedures will be followed.

V.5. Veterinary Care

The WRAIR IACUC Collaboration Protocol Signature Sheet (UWZ-1001 Processing, Reviewing and Maintenance of Extramural and Collaborative Proposals) must be signed by the Institute PI, the Business Office, the Joint Safety and Environment Office (JSEO) and the Attending Veterinarian or designee prior to protocol approval. This form indicates the responsible parties have reviewed and can support the collaborative proposal.

V.5.1. Husbandry Considerations:

Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol.

V.5.1.1. **Study Room:**

Building(s) LAM facility (b)(6) Room Number(s) (b)(6)

(b)(6) (b)(6)

V.5.1.2.

Special Husbandry Provisions:

Food Restriction:	Yes	_____	No	X
Fluid Restriction:	Yes	_____	No	X

V.5.1.3. **Exceptions**: None

V.5.2. Veterinary Medical Care

V.5.2.1. Routine Veterinary Medical Care:

Animals will be observed and cared for by the Center for LAM veterinary technicians and veterinarians according to USUHS Center for LAM SOPs.

V.5.2.2. Emergency Veterinary Medical Care:

All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays.

V.5.3. Environmental Enrichment

V.5.3.1. Enrichment Strategy:

Except as indicated below, all animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents.

V.5.3.2. Enrichment Restrictions: N/A

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Name of person performing activity	Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
(b)(6) **Ph.D.**	Animal Handling	18+ years' experience with rat surgery	USUHS Investigator Training and Animal Handling courses (Several sessions, including session in 2000). CITI tarininh 2014
	Oral gavage	18+ years	
	Anesthesia	18+ years	
	Blood collection	18+ years	
(b)(6) **Ph.D.**	Animal Handling	30+ years experience with rats and other rodents	USUHS Investigator Training and Animal Handling courses (several sessions, including sessions in fall, 1980 and again in fall, 1990); NIH/NIMH training courses (several in fall, 1981-4)
	Oral gavage	30+ years experience with rats and other rodents	USUHS Investigator Training and Animal Handling courses, 1980,1990; NIH/NIMH training

			courses 1980s
	Behavioral Measures	30+ years experience with rats and other rodents	NIH/NIMH training courses1980s
	Biological sample collection	30+ years experience with rats and other rodents	NIH/NIMH training courses 1980s
	Anesthetized Decapitation	30+ years experience with rats; 1000+ decapitations performed	NIH/NIMH training courses1980s
	Blast tube procedures	5 years experience	WRAIR collaboration 2009 - present

VII. BIOHAZARDS/SAFETY: During animal handling, all personnel will wear personal protective equipment including lab coats, gloves and face- mask to minimize the exposure to rat allergens. All personnel included in this protocol will also annually visit the USUHS health nurse to discuss their needs and suggestions regarding their safety.

All animal perfusions with formaldehyde will be performed in fume hood or a ventilated table in LAM necropsy room to avoid inhalation of toxic fumes from formaldehyde. In addition, all protocol members will wear appropriate protective equipment.

VIII. ENCLOSURES:

1. See attached letter of support for access to the BOP tube at WRAIR from Dr. (b)(6)
2. See attachment for WRAIR's pain assessment score sheet that is used after BOP procedure to determine the level of animal discomfort.

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

(b)(6) 02 | 18 | 2015

Principal Investigator Signature Date

G. Training: The following personnel will attend the next USUHS Investigator/Animal User Training Course:

TBD

H. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely, "Responsibility" for implementing

animal use alternatives where feasible and conducting humane and lawful research.

(b)(6) [redacted]

02 | 18 | 2015

Principal Investigator Signature Date

I. Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress WILL or WILL NOT be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

X. **PROTOCOL ABSTRACT:**

A. **Animal Protocol Number:**

B. **Animal Protocol Title:** Serotonin Targeted Biomarker and Therapeutic Approach in the Treatment of Traumatic Brain Injury (blast) and Posttraumatic Stress Disorder

C. **Principal Investigator:** (b)(6) PhD

D. **Performing Organization:** Uniformed Services University of the Health Sciences

E. **Funding:** DARPA

F. **Objective and Approach:** Taken together, a critical factor in blast-induced mTBI and PTSD lies with the association of cognitive deficits and mitochondrial metabolic integrity in the brain. Serotonin is one of the key neurotransmitter, which is affected by depression and anxiety (Gardner & Boles, 2011). How serotonin levels modulate the stress following bTBI or PTSD is entirely unknown. Our **long-term goal** is to identify the blood-based brain specific protein biomarkers of brain injury progression and to determine the potential targets for safe and effective therapeutic strategies. **The objectives** of this current proposal are to **a)** understand the relationship of serum serotonin levels, psychological, and biological effects of pre-existing stress on the severity of blast injury, and **b)** examine the potential intervention of sodium pyruvate that help to prevent, attenuate, and treat the effects of bTBI and PTSD. The work outlined below will test the **hypothesis** that low serum serotonin levels are associated with the severity of stress-related symptoms following recurrent bTBI and PTSD, which can be improved by increasing the serotonin level with pyruvate treatment.

G. **Indexing Terms (Descriptors):** traumatic brain injury (TBI), post-traumatic stress disorder (PTSD), stress, blast overpressure (BOP), serotonin, pyruvate, behavioral/biological responses of rats to TBI/PTSD/stress

MEMORANDUM FOR DR. (b)(6) DEPARTMENT OF ANATOMY, PHYSIOLOGY, AND GENETICS

SUBJECT: IACUC Approval of Protocol - Triennial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via designated member review on April 3, 2012:

Animal Protocol Title: (b)(4)
(b)(4)

USUHS Protocol Number: (b)(6)

Expiration Date: April 2, 2015

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. NON-TECHNICAL SYNOPSIS: (b)(4)
(b)(4)

II. BACKGROUND:

II.1. Background:

The effects (b)(4)

The possibility of a terrorist attack against civilians, or military troops deployed overseas is at present in the minds of both citizens and government officials. Mass casualties can be inflicted with chemical or biological toxins/weapons. Nerve agents are lethal chemical weapons that have been used in war and in terrorist attacks, with devastating consequences. Organophosphate nerve agents display a very high affinity for brain acetylcholinesterase (AChE) (9, 10, 11, 63). Inhibition of AChE by OPs and the resulting accumulation of acetylcholine can initiate seizures by activating nicotinic and muscarinic receptors, which are widely distributed throughout the brain. These receptors are present not only at postsynaptic sites in cholinergic synapses, but also on presynaptic terminals of both excitatory and inhibitory synapses, regulating the release of glutamate and gamma-aminobutyric acid (GABA) (37, 108). Therefore, it is conceivable that OP-induced inhibition of AChE can tilt the balance between the two major excitatory and inhibitory neurotransmitter systems—glutamatergic and GABAergic, respectively (38, 55). One of the clinical manifestations of exposure to nerve agents is seizure activity and status epilepticus (SE), which can lead to death or brain damage, with long-term cognitive and other behavioral consequences (8, 35, 56, 91, 99) (b)(4)
(b)(4)
(b)(4) Current medical countermeasures against nerve agent

poisoning are not adequately effective in preventing seizure-induced brain damage (57, 89, 96). (b)(4)

(b)(4)

(b)(4) This is very important because in an emergency situation there is no opportunity for pretreatment. Our ultimate goal is to develop a medical countermeasure against nerve agents that will effectively stop seizures and protect from brain damage and the resulting behavioral deficits, and do so without significant acute and/or long-term adverse effects. (b)(4)

(b)(4)

The necessity to study immature, aged, and female rats

Having demonstrated the effectiveness of the (b)(4)

(b)(4) we now propose to test if these compounds are equally effective in young and aged rats, as well as in female rats. Are there reasons to expect age- and/or gender-related differences in the (b)(4)

(b)(4) First, let us examine if the existing literature suggests differential propensity for seizure generation, and, thereby, differential susceptibility to seizurogenic agents between genders and in different ages. It is well documented that young animals and humans are more prone to generating seizures than adults, but the neuropathology induced by seizure activity is less severe and more transient in the developing brains (41, 42, 67). It is particularly relevant to mention that pilocarpine-induced SE causes inflammation and epileptogenesis in rats, but not in infant rats (64). Aged humans (45, 58) and animals (68,110) are more susceptible to both seizures and the associated neuropathology compared to adults. Gender-related differences in seizure susceptibility exist in animals and humans (47), but more research is needed to clarify and categorize these differences. For example, in humans, males have a greater susceptibility to SE, but females have a higher incidence of idiopathic epilepsies (23, 74). In animals, male rats also are more susceptible to limbic seizures and SE than female rats (94, 83), but aged female mice are more sensitive to kainic acid-induced seizures (113). There are only few studies on the age- and gender-dependency of the susceptibility to nerve agent toxicity. In guinea pigs, the lethal potencies of VX and sarin are significantly higher in the adult males than in any other age or in females (30). In rats, the lethal potency of soman is greater in 5 day-old rats than in 30 day-old rats (106), and in the young (up to 30 days) and the aged males, compared to the adults (101,106), suggesting that the toxicity of soman during an animal's life span approximates a U-shaped curve (101). Our proposed studies will yield data on the age- and gender-related susceptibility to soman toxicity and lethality. Based on the limited information available, as reviewed above, our working hypothesis is that the LD50 will be lower in the immature and aged rats (greater susceptibility/lethality to

soman), greater in female rats or similar to the LD50 in males, but the soman-induced neuropathology –which will be examined at multiple points, 24 hours, 1 week, 1 month, and 3 months after soman exposure– will be lower in the immature rats, and the recovery of the damage will be faster (the reverse will probably be true in the aged rats). It is also possible, however, that the soman-induced SE in the early postnatal rats will produce disruption in the normal brain development, which will become evident in the behavioral studies proposed here.

(b)(4)

(b)(4) On an acute basis, GABA agonists in developing rats can facilitate instead of suppressing seizures (82). In response to metabotropic glutamate receptor-anticonvulsants, different responses have been observed even in a narrow range of young ages (7 to 25 day-old rats) (66), and, in general, young rats are more responsive to NMDA and non-NMDA receptor antagonists used as anticonvulsants compared to adult rats (67). Aged animals and humans also differ from other age groups in their responses to anticonvulsants, one reason being the different pharmacokinetics in the aged organism (45, 58, 68, 110). (b)(4)

(b)(4)

Significance of studying the protection of the amygdala, the hippocampus, and the prefrontal cortex

(b)(4)

(b)(4) There are two reasons that we choose to study these structures. First, the amygdala and the hippocampus are seizure-prone structures that play a central role in temporal lobe epilepsy, which is the most common form of epilepsy, the (5, 6, 7, 76, 85). It is not surprising therefore that the amygdala and the hippocampus also appear to play a central role in the generation of seizures induced by nerve agents (4), as suggested by the rapid increases in extracellular glutamate in these brain regions after nerve agent exposure (52, 53, 54), and the profound damage these structures suffer by exposure to nerve agents (2, 4, 12, 35, 40, 46, 80, 102, 103, 104, 111). (b)(4)

(b)(4)

(b)(4)

(b)(4) The second reason is that the amygdala, the hippocampus and the prefrontal cortex are the most important brain regions in affective and cognitive functions. The amygdala is best known for its central role in emotional behavior, being a key component of the brain's neuronal network that determines the emotional significance of external events (26, 29, 61). Many emotional/psychiatric disorders are associated with pathophysiological changes in the amygdala (21, 28, 88, 109). In addition, both the amygdala and the hippocampus play a pivotal role in mediating or modulating cognitive functions (26, 61). The amygdala modulates memory acquisition and consolidation, decision-making, and interpretation of the emotional significance of external and internal events via extensive, reciprocal connections with the prefrontal cortex (36, 84) (the brain area considered to be the center for cognitive functions) and the hippocampus (76). Long-term memory storage is thought to occur in neocortical areas, but the amygdala appears to be the site for storage of fear-memory (29, 65), whereas the hippocampus is the storage site of short-term memory and the gateway for consolidation of long-term memory in neocortex (20, 33, 60). Therefore, damage to these regions is likely to be significantly responsible for the long-term cognitive and behavioral deficits that follow nerve agent exposure, in both animals (9, 50, 51, 69, 70, 71, 72, 73) and humans (18, 27, 77, 81, 97). For these reasons it is important to determine the neuropathological and pathophysiological changes induced in the amygdala, hippocampus and prefrontal cortex by soman. (b)(4)

III. OBJECTIVE\HYPOTHESIS: (b)(4)

(b)(4)

female rats. The 16-20 month category is designated as "aged" by the supplier, and even 8 month-old male rats have been shown to be more sensitive to soman than immature or adult rats (101). After exposure to soman, the animals will be euthanized at 24 hours, 1 week, 1 month, or 3 months to evaluate nerve agent-induced pathology. Neuronal loss, using design-based stereology, and neurodegeneration, using Fluoro-Jade-C staining will be studied in the amygdala, hippocampus, and prefrontal cortex, at 24 hours, 1 week, 1 month, and 3 months after soman exposure.

In specific aim 3 we will determine whether treatment of immature (7 to 14 days-old) and adult (50 to 70 days-old) male and female rats with (b)(4) protects the animals against the behavioral alterations that are observed after (b)(4) (b)(4) At 1 month and 3 months after soman exposure, we will perform a comprehensive neurobehavioral evaluation in these animals. These tests will evaluate motor, cognitive, mnemonic and emotional abnormalities known to be associated with (b)(4) Motor performance will be evaluated using the roto-rod test; performance on this test has been shown to be reduced in rats following soman exposure (32). Cognitive impairment will be determined using tests for novelty preference in the open field, and mnemonic cognitive processes will be evaluated using the t-maze test, performance in which has also been shown to be affected by soman exposure (32, 78). Finally, emotional behavior will be evaluated by measuring the acoustic startle response/pre-pulse inhibition, and with tests of unconditioned fear (light/dark boxes, elevated plus-maze); increases in these responses have been seen following exposure to soman in rats (25).

In specific aim 3 we will also determine whether treatment of immature (7 to 14 days-old) and adult (50 to 70 days-old) male and female rats with (b)(4) protects the animals against alterations in synaptic plasticity and neuronal excitability that are observed after (b)(4)
(b)(4)

Behavioral and pathophysiological studies will be performed in both the immature and the adult male and female rats, but not in the aged animals, where variability among rats in cognitive/behavioral and physiological functions may be very high even in the control group, making it difficult to determine the deficits resulting from the (b)(4)
(b)(4)

IV. MILITARY RELEVANCE: (b)(4)
(b)(4)

(b)(4)

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures:

(b)(4)

(b)(4)

V.1.1. Experiment 1:

(b)(4)

(b)(4) (7 to 14 days old), adult (50 to 70 days old), and aged (16 to 20 months old) male rats.

(b)(4)

(b)(4)

A week prior to the experiments, 50% of the adult and aged, male and female rats in experiment 1 will be implanted with cortical electrodes for electroencephalogram (EEG) recordings. These EEG recordings will be used to confirm the onset and intensity of behavioral convulsions observed in the rest of the animals. For the EEG recordings, along with behavioral observations, the timing (time to onset and duration) and the intensity of seizures will be measured via continuous EEG monitoring. Animals will be placed in individual recording chambers, and a baseline EEG will be obtained before administration of any drug.

The immature rats will not be implanted with cortical electrodes and the timing (time to onset and duration) and the intensity of seizures will be measured via behavioral observations.

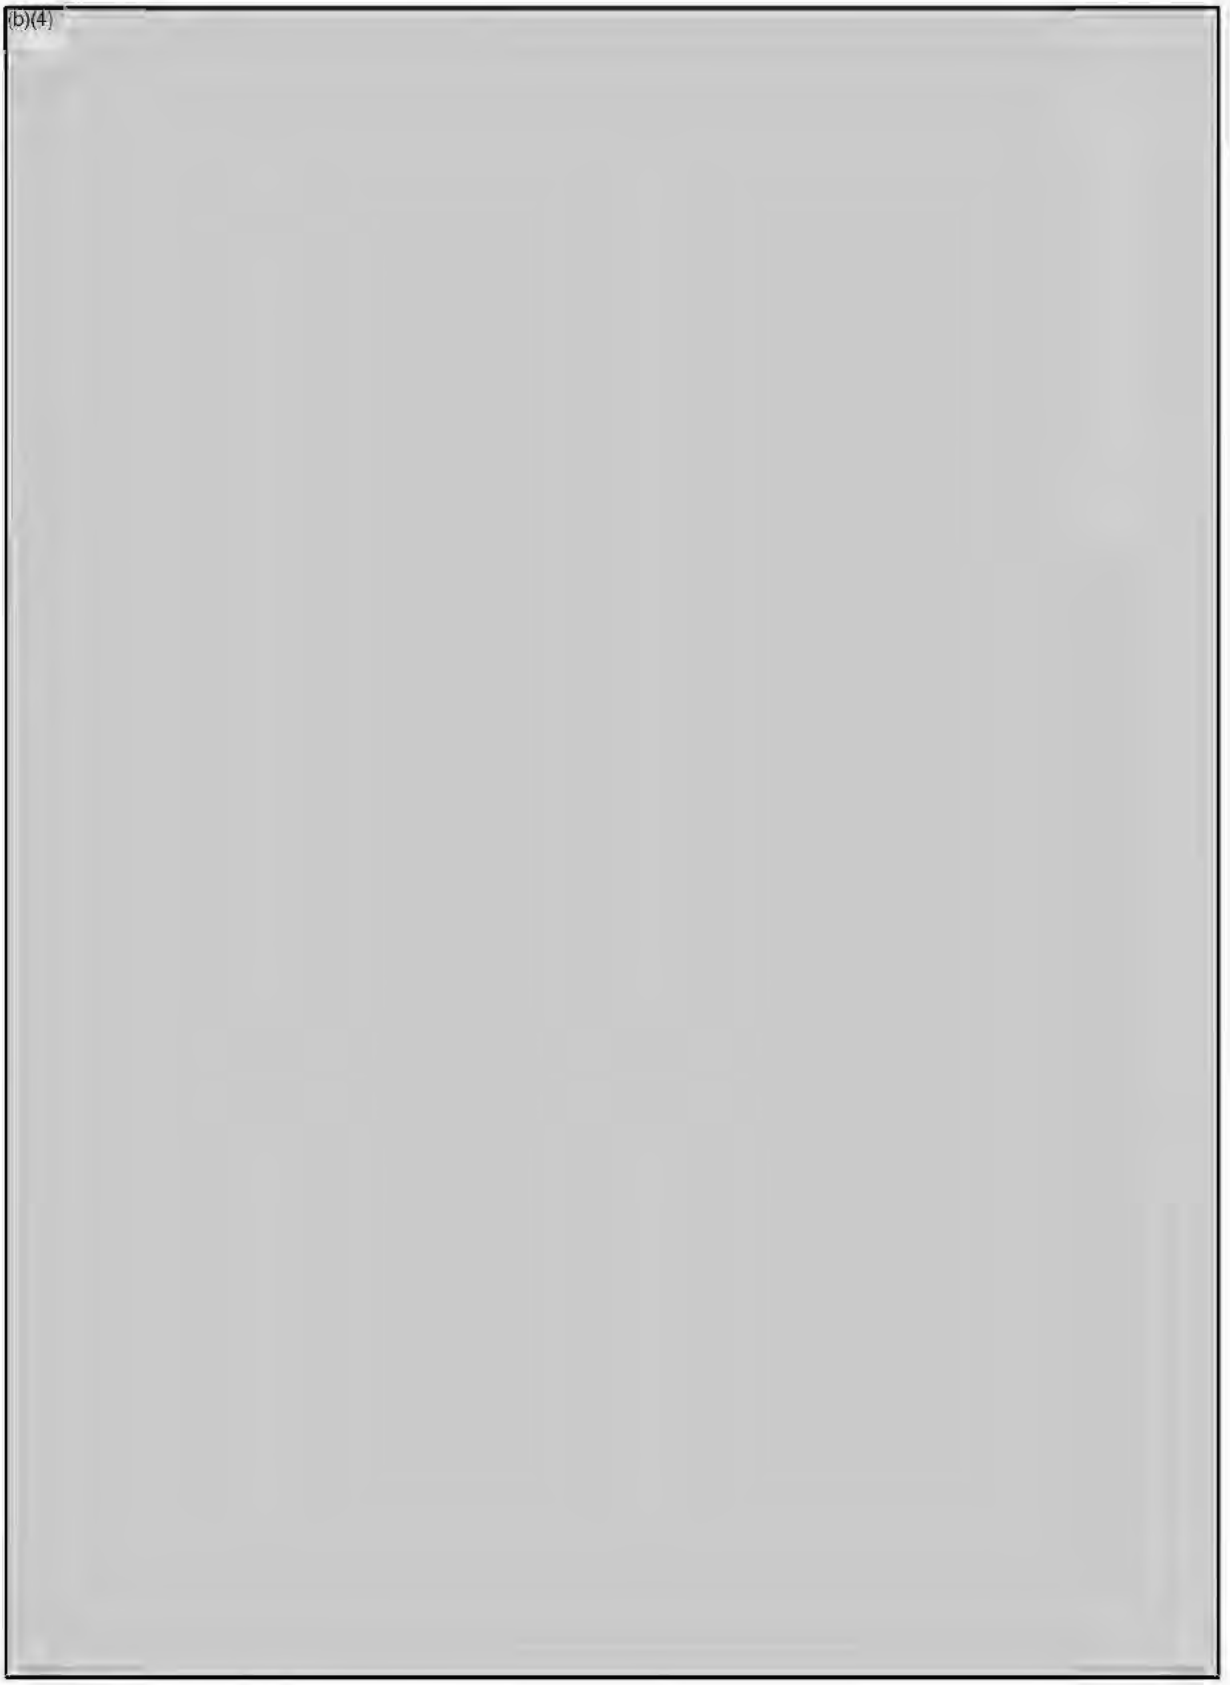
(b)(4)

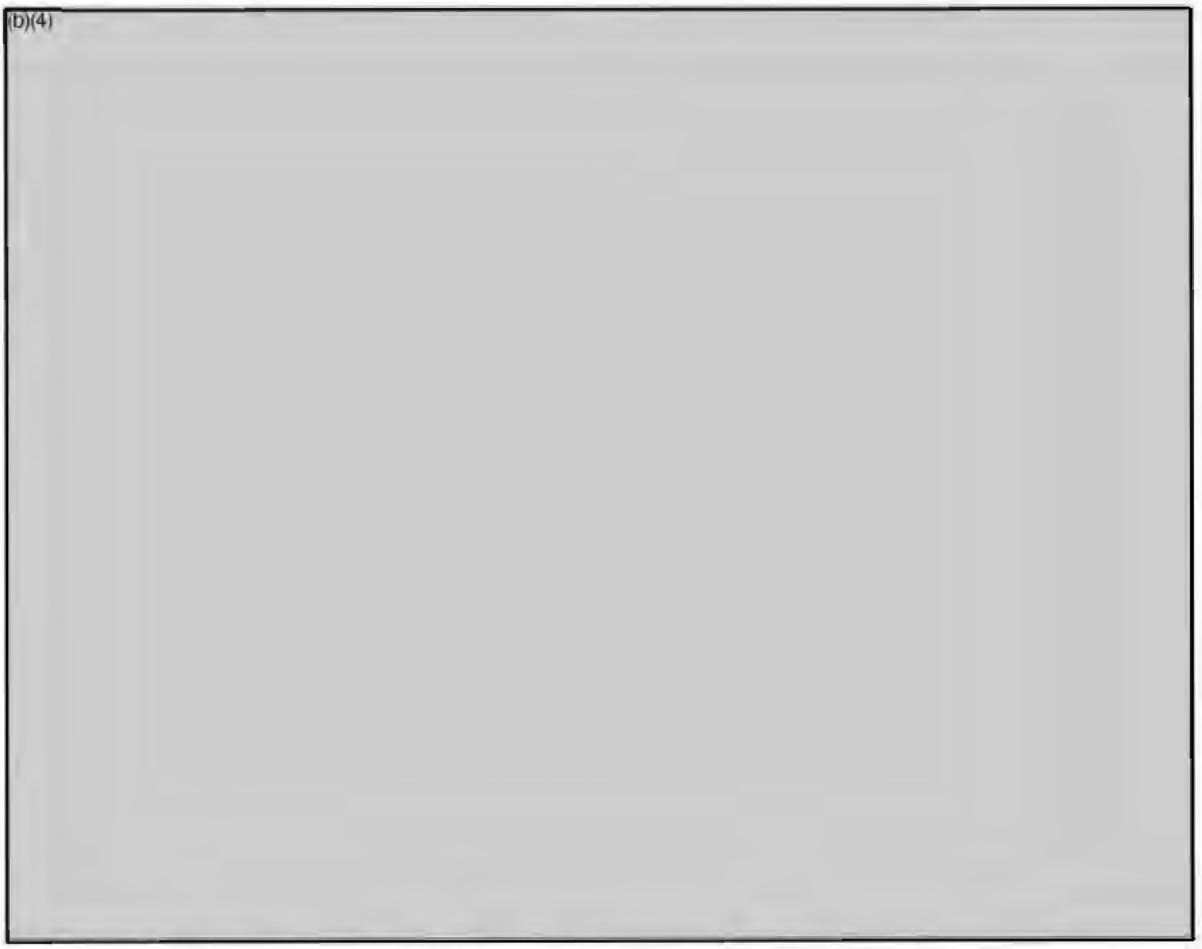
(b)(4) The determination to classify a seizure as being terminated will be the progressive diminution and eventual elimination of repetitive high amplitude spikes or sharp waves in the EEG and the absence of obvious signs of clonic convulsive behaviors. For a seizure to be considered terminated the EEG will have to be free of repetitive high amplitude spikes or sharp waves within the 3-hour EEG recording period on the day of exposure and during the 30-min EEG sample obtained 24 hours after exposure.

The following dependent measures will be used to establish the effectiveness of the drug treatments: the speed (latency) at which the EEG "normalizes" following drug treatment, the overnight change in body weight and the extent of the neuropathological damage at 24 hours, 1 week, 1 month, and 3 months after soman exposure. With the drug treatment protocol described above, we expect a very high survival rate. However,

(b)(4)

(b)(4)





Considerations regarding Experiment 1:

1) In a previous protocol we have obtained neuropathology data for adult male rats at 24 hours and 1 week after soman (b)(4) exposure, but not at 1 month and 3 months after exposure. In this study we will perform additional experiments in adult male rats at 24 hours and 1 week after soman, which are necessary for comparisons with other ages and the females.

2) The age we chose for the immature rats (7 to 14 days old at which time they open their eyes) coincides with the rapid developmental changes in the brain. The gender of the immature rats may not be possible to determine at the time of soman exposure, but it will be determined at 1 week, 1 month and 3 months after soman exposure, when neuropathology and behavioral studies will be carried out. The same issue applies to the (nominally female) immature rats in Experiment 2, and it is expected that the numbers of male and female animals will even out between the 2 experiments. If not, additional animals will be ordered.

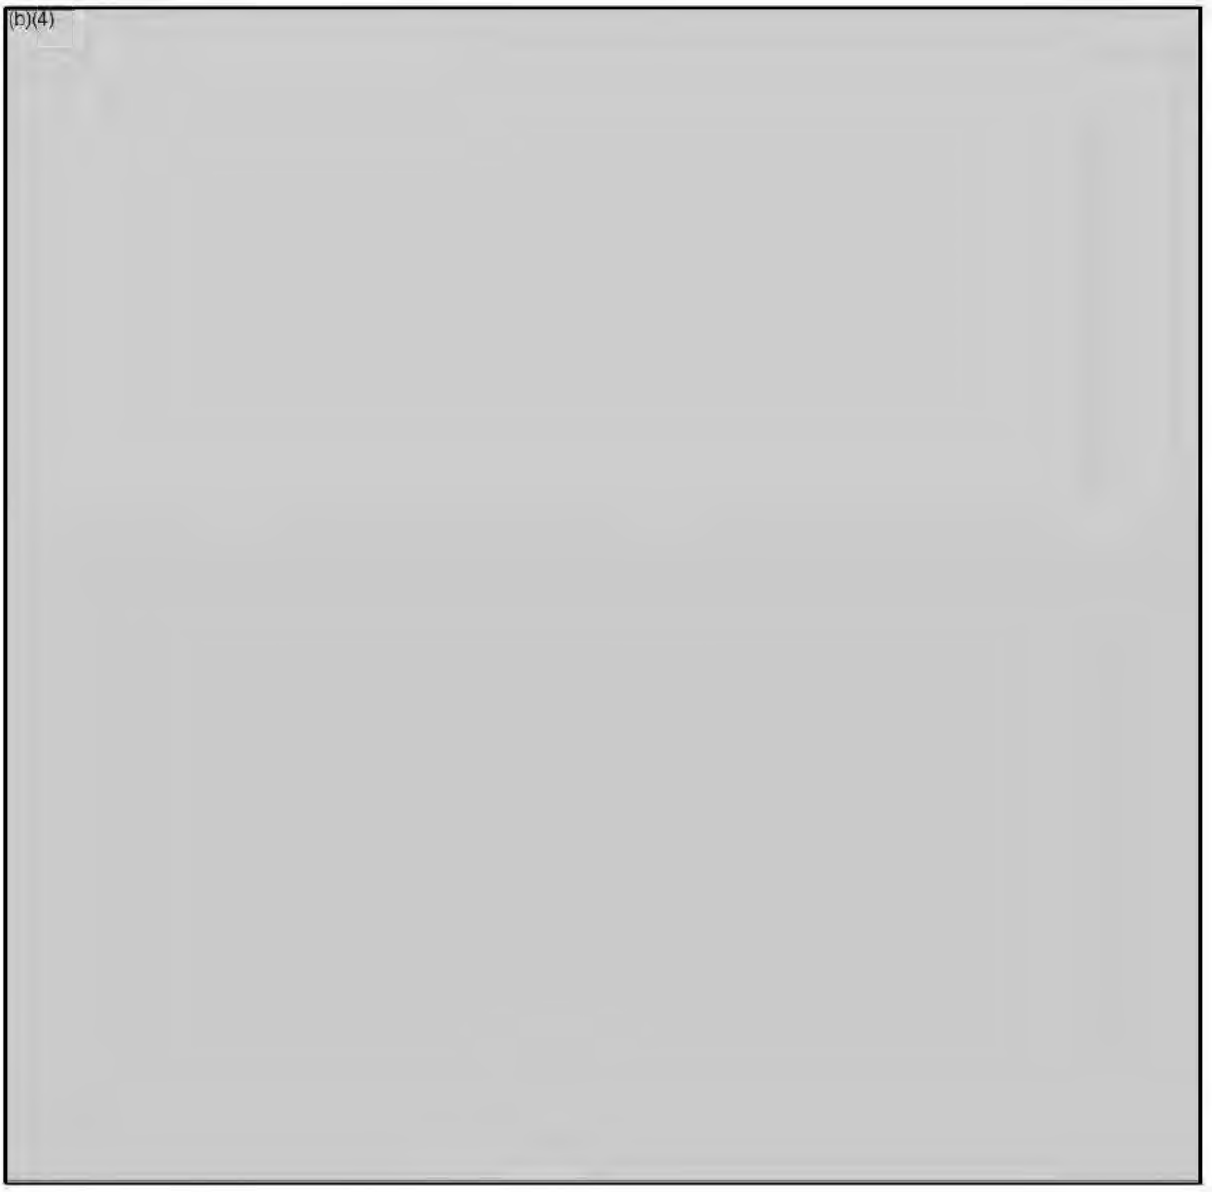
V.1.2. Experiment 2:

The experimental design of Experiment 2 is exactly the same as described in Experiment 1 with the exception of the use of **female** rats.

(b)(4)

Immature, adult, and aged **female** rats will be randomly assigned to groups per Tables 4, 5, and 6 below:

(b)(4)



Considerations regarding Experiment 2:

1) The age we chose for the immature rats (7 to 14 days old at which time they open their eyes) coincides with the rapid developmental changes in the brain. The gender of the immature rats may not be possible to determine at the time of soman exposure, but it will be determined at 1 week, 1 month and 3 months after soman exposure, when neuropathology studies will be carried out.

2) In the female rats, the estrous cycle will be monitored, and if the results show that it influences the variables under study (susceptibility to the soman-induced SE and behavior in particular), then the estrous cycle will be taken into account in the analysis and presentation of the results.

V.1.3. Experiment 3:

In specific aim 3 we will determine whether treatment of immature (7 to 14 days old) and adult (50 to 70 days old) male and female rats with (b)(4) protects the animals against the behavioral alterations that are observed after nerve agent exposure (**Experiment 3A**). At 1 month and 3 months after soman exposure, we will perform a comprehensive neurobehavioral evaluation in these animals. These tests will evaluate motor, cognitive, mnemonic and emotional abnormalities known to be associated with exposure to soman and other organophosphates. Motor performance will be evaluated using the roto-rod test; performance on this test has been shown to be reduced in rats following soman exposure (32). Cognitive impairment will be determined using tests for novelty preference in the open field, and mnemonic cognitive processes will be evaluated using the t-maze test, performance in which has also been shown to be affected by soman exposure (32, 78). Finally, emotional behavior will be evaluated by measuring the acoustic startle response/pre-pulse inhibition, and with tests of unconditioned fear (light/dark boxes, elevated plus-maze); increases in these responses have been seen following exposure to soman in rats (25).

In specific aim 3 we will also perform electrophysiological experiments to determine whether treatment of immature (7 to 14 days old) and adult (50 to 70 days old) male and female rats with (b)(4) protects the animals against alterations in synaptic plasticity and neuronal excitability that are observed after nerve agent exposure (**Experiment 3B**). At 1 month and 3 months after soman exposure, rats will be euthanized, and brain slices containing the amygdala, hippocampus and prefrontal cortex will be prepared. Alterations in neuronal excitability and synaptic plasticity (long-term potentiation) in these three brain regions will be performed using both whole-cell recordings and extracellular, field potential recording techniques.

Behavioral and electrophysiological experiments will be conducted in both immature and adult male and female rats, but not in aged animals. Variability among aged rats in cognitive/behavioral and physiological properties may be very high even in the control group, making it difficult to determine the functional deficits resulting from the exposure to soman and the protection conferred by the (b)(4)

(b)(4)

Experiment 3A: To determine whether treatment of immature (7 to 14 days old) and adult (50 to 70 days old) **male and female** rats with (b)(4) protects the animals against the behavioral alterations that are observed after nerve agent exposure.

(b)(4)

(b)(4)

A week prior to the experiments, 50% of the adult and aged, male and female rats in experiment 1 will be implanted with cortical electrodes for electroencephalogram (EEG) recordings. These EEG recordings will be used to confirm the onset and intensity of behavioral convulsions observed in the rest of the animals. For the EEG recordings, along with behavioral observations, the timing (time to onset and duration) and the intensity of seizures will be measured via continuous EEG monitoring. Animals will be placed in individual recording chambers, and a baseline EEG will be obtained before administration of any drug.

The immature rats will not be implanted with cortical electrodes and the timing (time to onset and duration) and the intensity of seizures will be measured via behavioral observations.

(b)(4)

(b)(4) The determination to classify a seizure as being terminated will be the progressive diminution and eventual elimination of repetitive high amplitude spikes or sharp waves in the EEG and the absence of obvious signs of clonic convulsive behaviors. For a seizure to be considered terminated the EEG will have to be free of repetitive high amplitude spikes or sharp waves within the 3-hour EEG recording period on the day of exposure and during the 30-min EEG sample obtained 24 hours after exposure.

(b)(4)

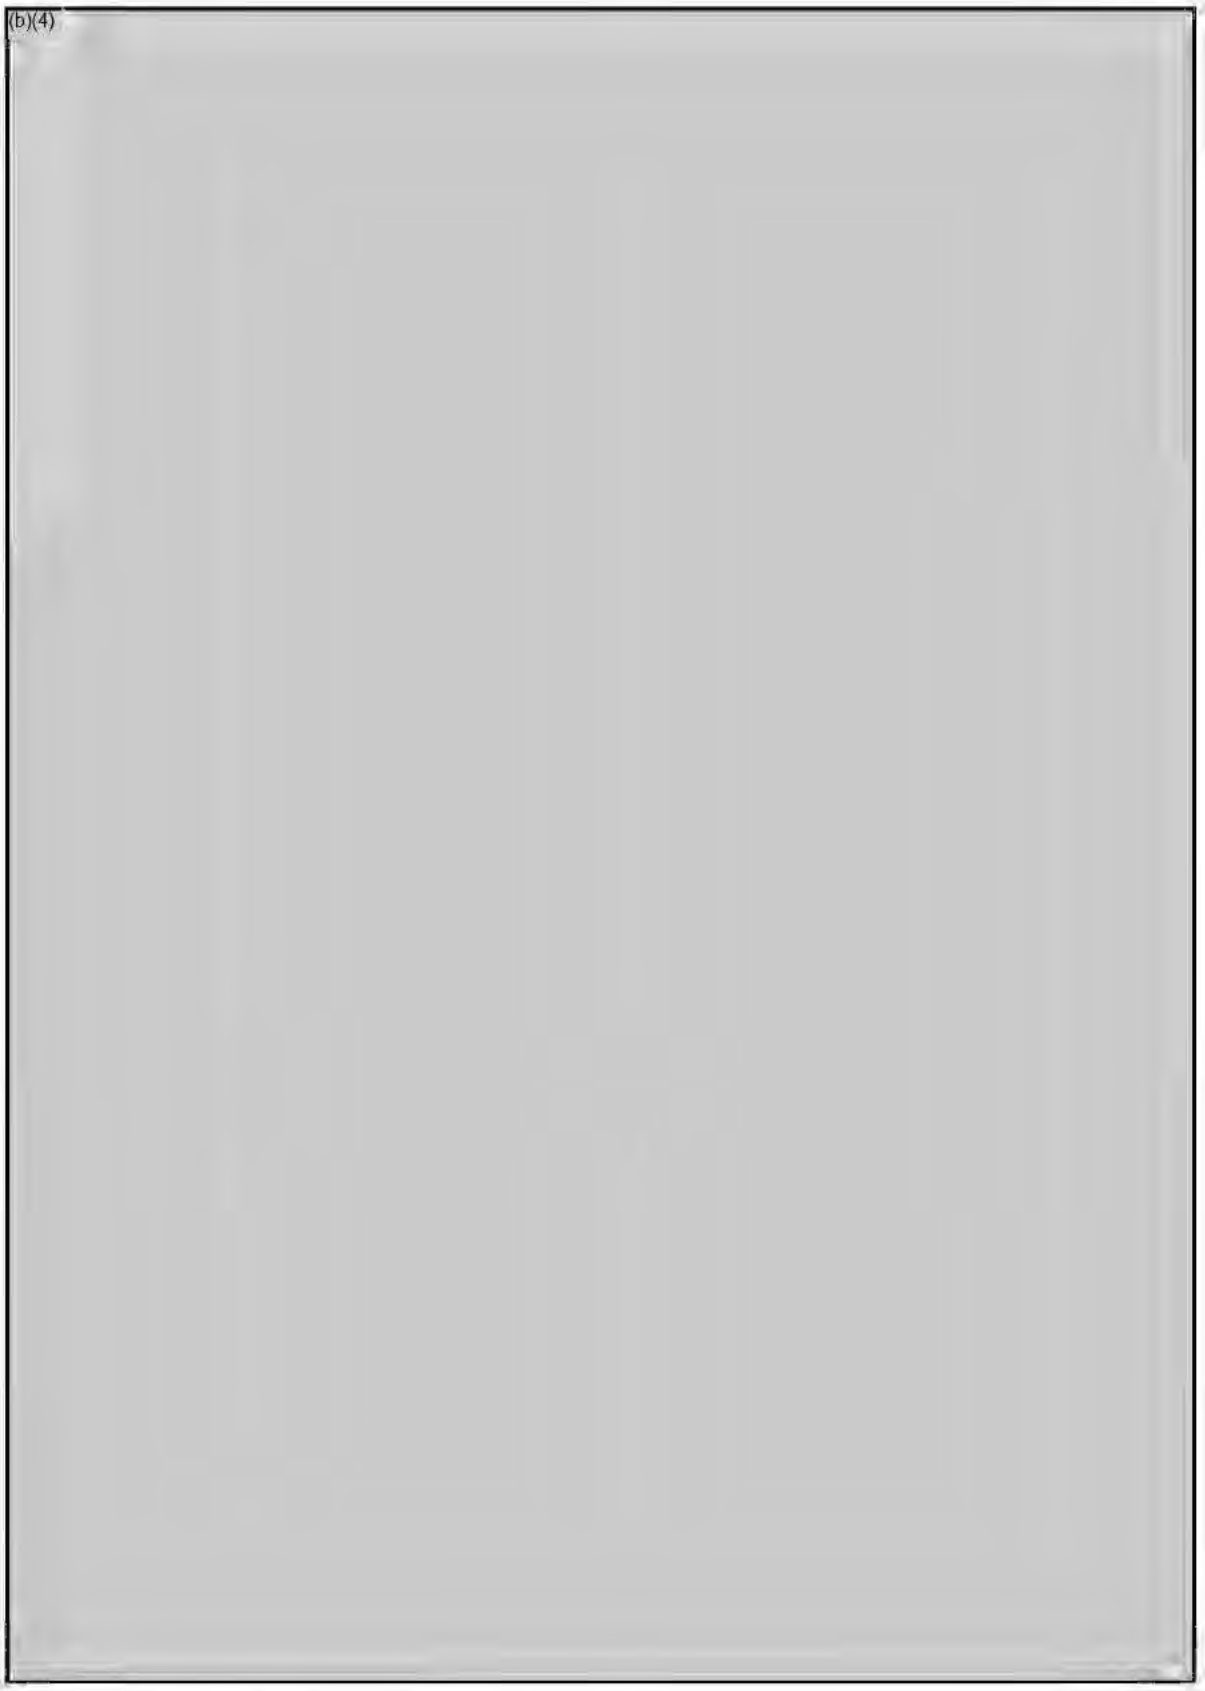
We will perform a comprehensive battery of behavioral and neurological tests (see Section V.4.4.6. Behavioral Studies) on the (b)(4) rats, the (b)(4) (b)(4) 1 month and 3 months after soman exposure. These tests will evaluate motor, cognitive, mnemonic and emotional abnormalities known to be associated with (b)(4) (b)(4) Motor performance will be evaluated using the roto-rod test; performance on this test has been shown to be reduced in rats following (b)(4) (b)(4) Cognitive impairment will be determined using tests for novelty preference in the open field, and mnemonic cognitive processes will be evaluated using the t-maze test, performance in which has also been shown to be affected by (b)(4) (b)(4) Finally, emotional behavior will be evaluated by measuring the acoustic startle response/pre-pulse inhibition, and with tests of unconditioned fear (light/dark boxes, elevated plus-maze); increases in these responses have been seen following (b)(4) in rats (25).

(b)(4)

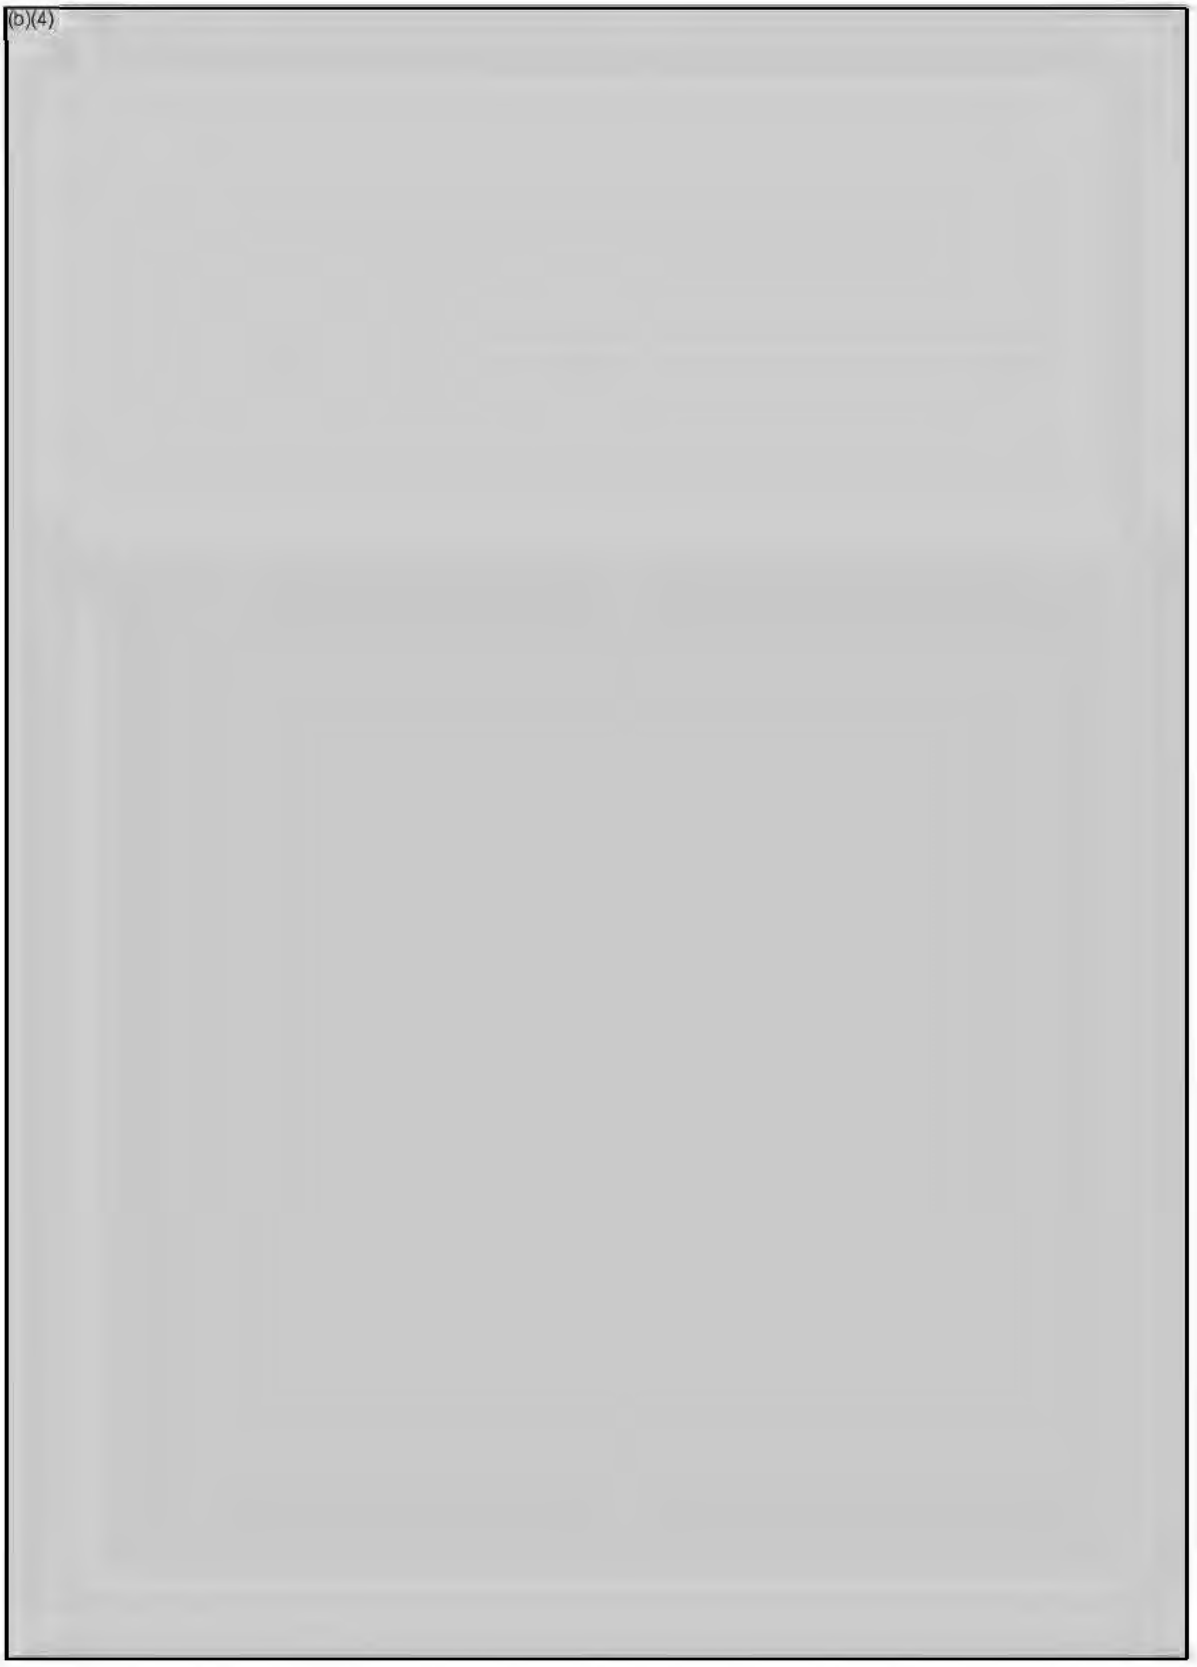
Immature and adult male and female rats will be randomly assigned to groups per Tables 7, 8, 9, 10, 11, and 12 below:

(b)(4)

(b)(4)



(b)(4)



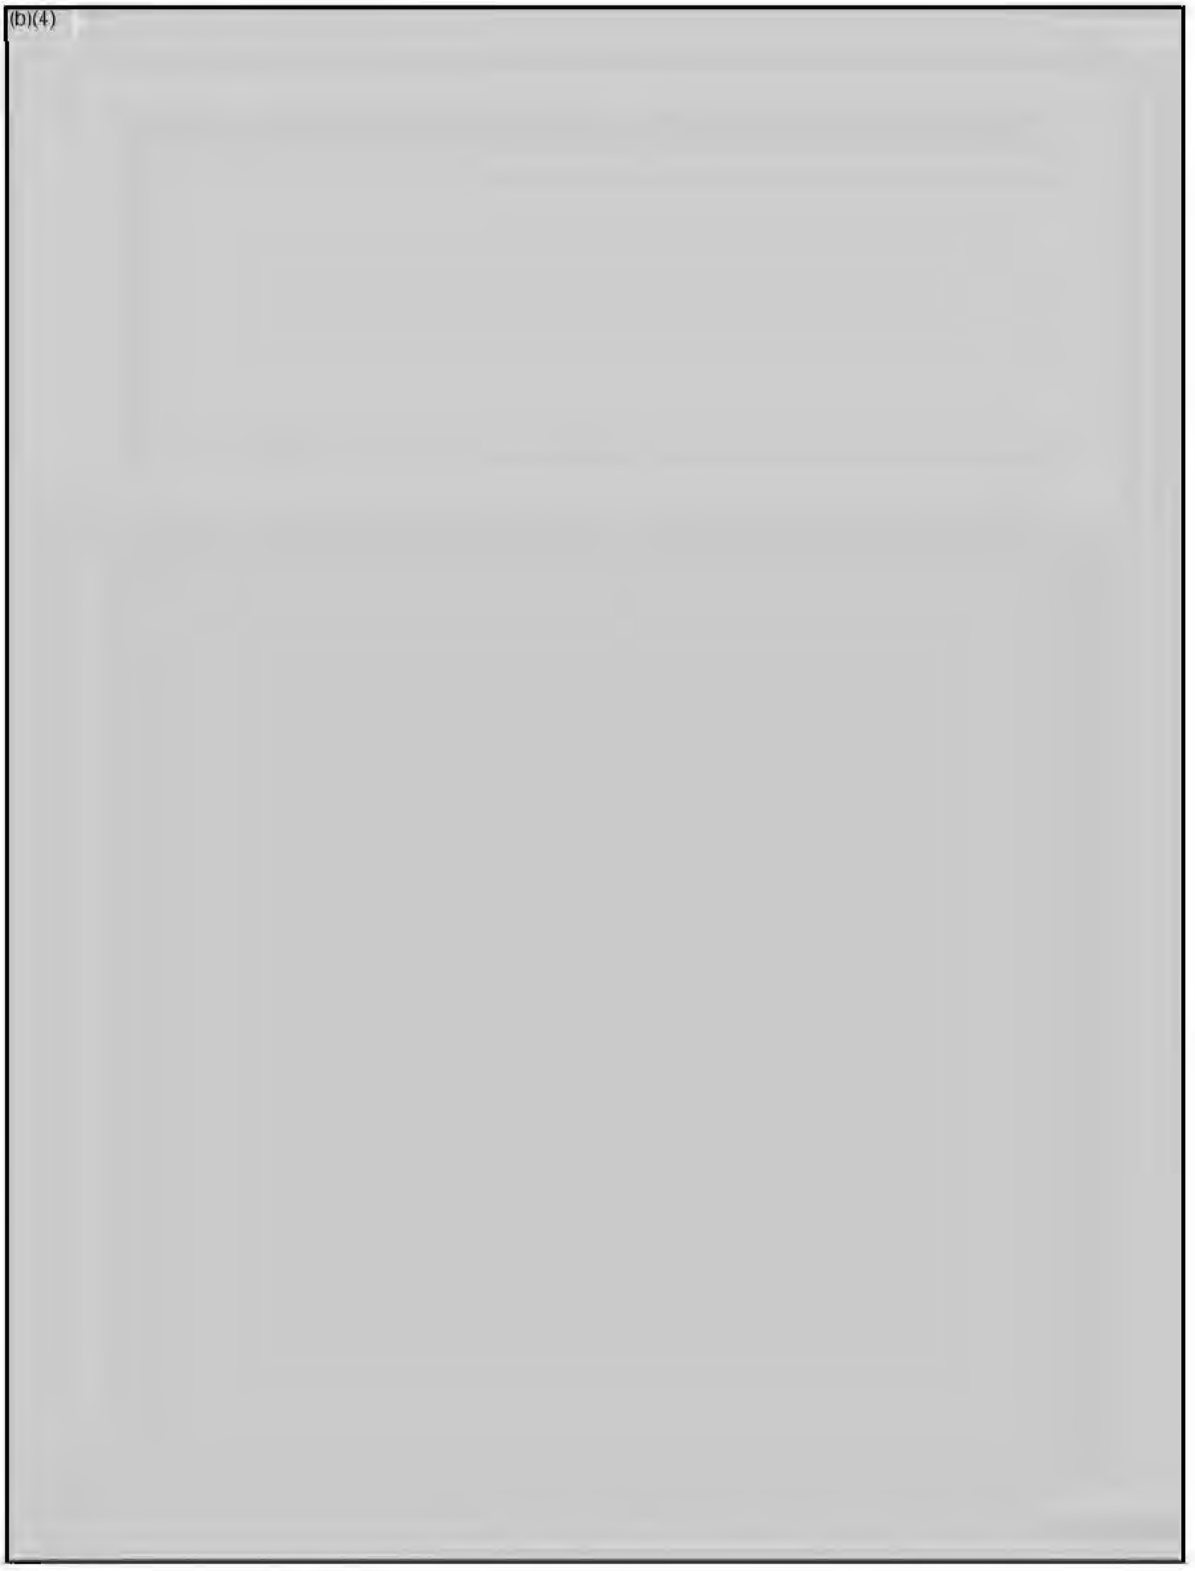
(b)(4)

Immature (7 to 14 days old), and adult (50 to 70 days old) **male and female rats** will be (b)(4) One month or three months after (b)(4) electrophysiological experiments will be conducted in the (b)(4)

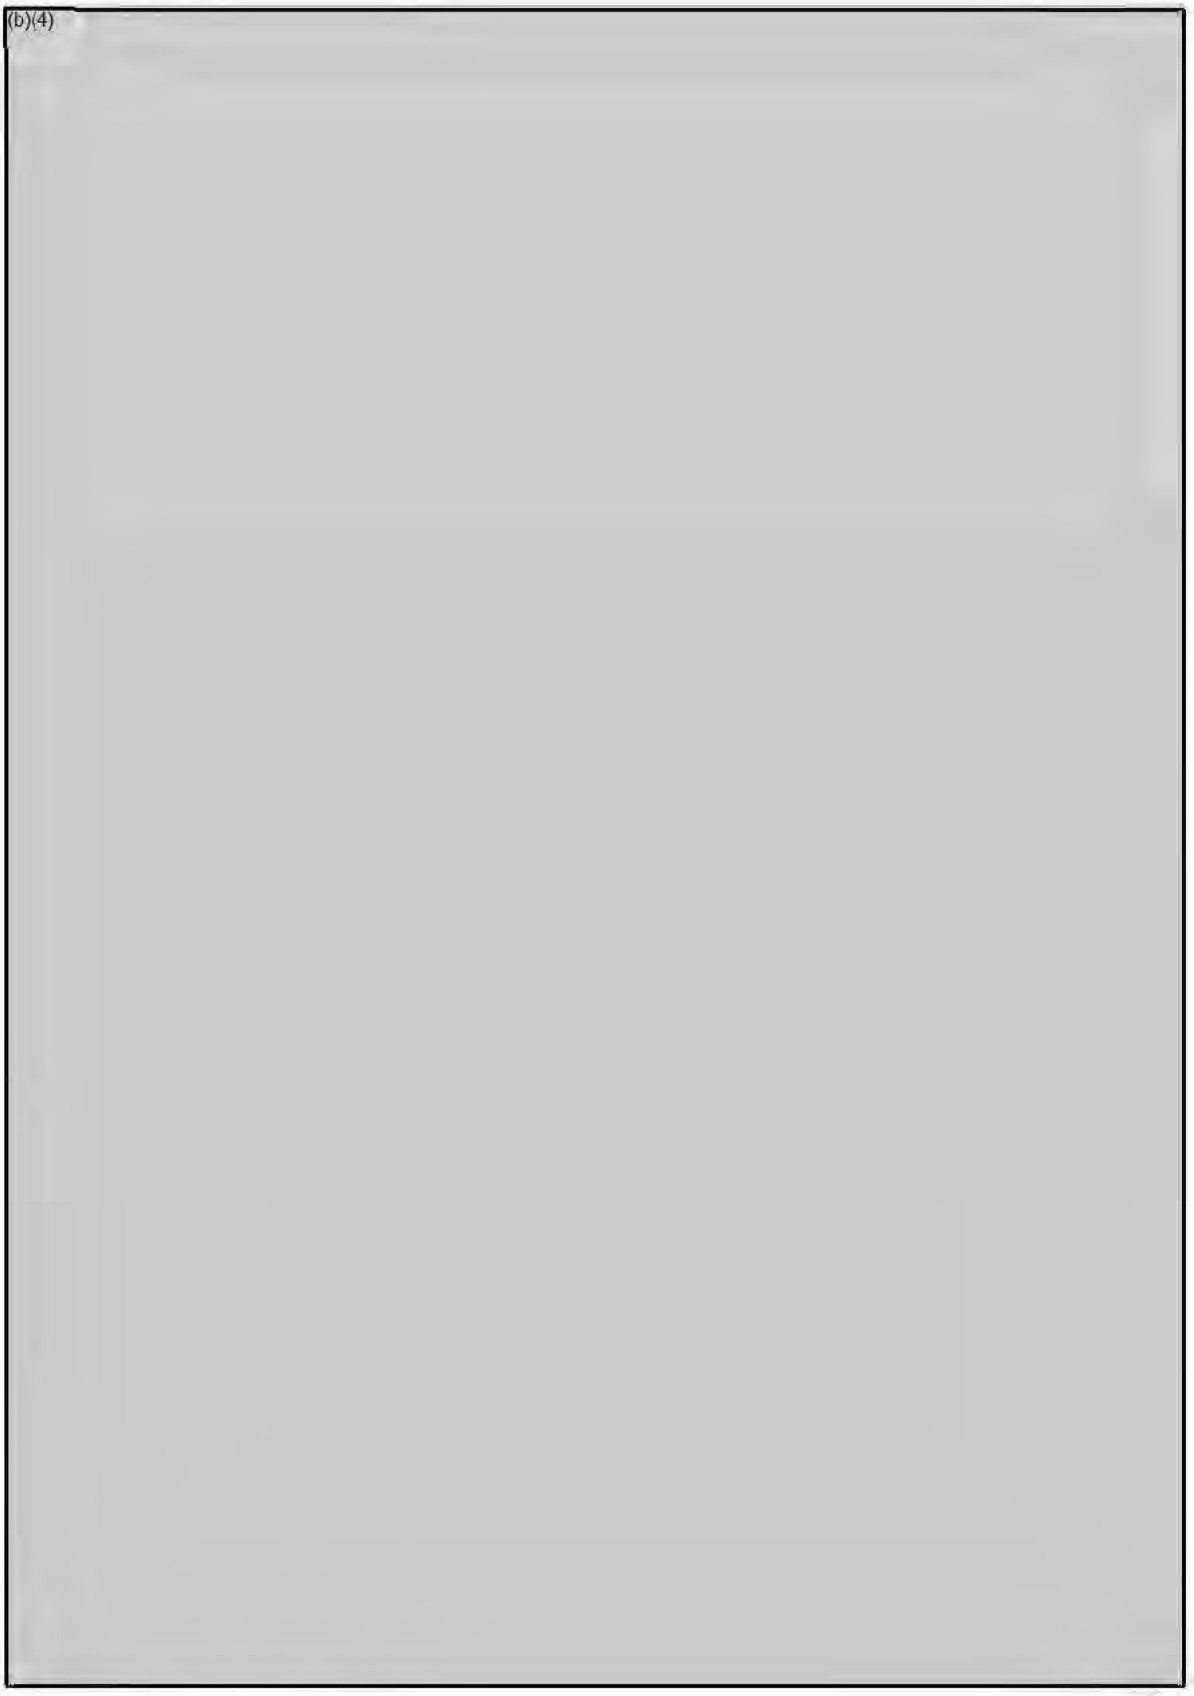
Pathophysiological alterations will be studied in *in vitro* brain slices containing the amygdala and hippocampus and in slices from the prefrontal cortex. These studies will be performed using both extracellular, field potential recording techniques and whole-cell recordings.

(b)(4)

(b)(4)



(b)(4)



(b)(4)

vivo, information obtained using non-animal models may not accurately reflect a drug's action in a whole animal.

V.3.2. **Animal Model and Species Justification**: Immature (7 to 14 days old), adult (50 to 70 days old), and aged (16 to 20 months old) Male and Female Sprague-Dawley (SD) rats (*Rattus norvegicus*) will be used for these experiments. SD rats have been chosen as a suitable species and animal model for this research because they have been extensively used in nerve agent research to evaluate new medical countermeasures. Also, the SD rat is a primary model used in studying the pathophysiology of the amygdala, hippocampus, and prefrontal cortex. Consequently, it is helpful to use the same animal to make comparisons with the literature. Rats can provide up to eight 400-µm thick brain slices per animal. By using the SD rats, we can produce high quality slices and thus facilitate and expedite the acquisition of data. The rat brain slice preparation allows stable whole-cell patch clamping recording and various pharmacological manipulations under controlled conditions. Thinner slices can easily be prepared for morphological staining. Lactating surrogate mothers will be required to accompany the rat pups that have not yet been weaned.

V.3.3. **Laboratory Animals:** Note that all animals used in Experiments 1, 2 and 3A and B will be purchased and received by the principal investigator (b)(6) at USUHS.

		Species #1	Species #2
V.3.3.1.	**Genus & Species:**	*Rattus norvegicus*	
V.3.3.2.	**Strain/Stock:**	Sprague-Dawley (b)(4)	
V.3.3.3.	**Source/Vendor:**	(b)(4)	
V.3.3.4.	**Age:**	7-14 days (males and females) 50-70 days (males and females) 16-20 months (males and females) Adult lactating retired breeders (age to be determined by vendor)	
V.3.3.5.	**Weight:**	Appropriate for age at time of delivery	
V.3.3.6.	**Sex:**	Male and Females for experimental animals Female for lactating surrogate mothers	
V.3.3.7.	**Special Considerations:**	Lactating surrogate mothers (retired breeders	

from the supplier) will be required to travel with the immature rats that have not yet been weaned and to be housed with pups at USUHS. Single housing is required after EEG surgery on adult and aged rats to prevent animals from interfering with implant healing. Single housing is also required after agent exposure when animals may still be sick or debilitated. Animals may be pair-housed until the day of surgery, after which they must be singly housed.

V.3.4. Number of Animals Required (by Species):

(b)(4)

V.3.5. Refinement, Reduction, Replacement (3 Rs):

V.3.5.1. Refinement:
Rats will be anesthetized with isoflurane and reach a surgical plane of anesthesia for restraint purposes before decapitation for preparation of brain slices. All EEG surgery will be performed under appropriate anesthesia and pre-and post-surgical analgesics will be used to relieve pain. Any rat exhibiting signs of pain or impairment beyond that from this model will be euthanized at an early endpoint per paragraph V.4.5.

V.3.5.2. Reduction:
Use of an *in vitro* brain slice preparation in Experiments 3B allows the harvest of multiple brain slices per rat, thus significantly reducing the number of animals needed to obtain the proposed data. Power calculations have been performed to determine the minimum number of rats needed to reach statistical significance for each experiment. If the first 6 animals in *in vivo* treatment groups (Experiments 1, 2 and 3A and B) survive, the remaining 4 animals will not be ordered.

V.3.5.3. Replacement:
Biological response to drug treatment is highly complex; no alternative to animal experimentation is available or practical. We are using a rodent model (rat) versus a

the first 6 animals in *in vivo* treatment groups (Experiments 1, 2 and 3A and B) survive, the remaining 4 animals will not be ordered.

V.3.5.3. Replacement:
Biological response to drug treatment is highly complex; no alternative to animal experimentation is available or practical. We are using a rodent model (rat) versus a nonhuman primate model. The rat model is the least sentient and smallest animal model we could use for this study and still obtain acceptable results. In addition, we will perform a series of morphological measurements that require a sufficiently large animal to assure that there is sufficient brain mass for multiple samplings. Mice would not be sufficient.

V.4. Technical Methods:

V.4.1. Pain / Distress Assessment:

V.4.1.1. APHIS Form 7023 Information:

In this protocol 288 lactating mothers from Experiments 1, 2, and 3A and B will be available for transfer for training or experimental purposes, or euthanized if they cannot be used (Column B). Six hundred eight (608) male SD rats from Experiment 1 and 3A and B and 608 female SD rats from Experiment 2 and 3A and B will receive an injection of saline instead of nerve agent in combination with (b)(4) and therefore will experience no pain (Column C). Eight hundred (800) male SD rats from Experiment 1 and 3A and B and 800 female SD rats from Experiment 2 and 3A and B will be injected with nerve agent and experience intense seizures. While the drugs/treatments under investigation may reverse some of these signs during certain phases of these experiments, these animals will experience some level of seizure or physical stress and discomfort for some period of time during the experiments and will be included in Column E (Non-alleviated pain).

V.4.1.1.1. Number of Animals:

	Species #1	Species #2
V.4.1.1.1.1. Column C:	(b)(4)	
V.4.1.1.1.2. Column D:	0	
V.4.1.1.1.3. Column E:	(b)(4)	

V.4.1.2. Pain Relief / Prevention:

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization:
For surgical implantation of cortical electrodes for EEG recordings in Experiment 3, animals will receive one dose of buprenorphine (0.05 mg/kg s.c.) before any incisions are made. The animals will be anesthetized with isoflurane (3% for induction, 2.0-2.5% for maintenance; with oxygen). Anesthesia will be induced by isoflurane vapor in 100% oxygen in a commercially available induction chamber. Once anesthesia is induced,

animals will be transferred to the designated surgery area and anesthesia will be maintained via nose cone. To monitor the depth of anesthesia (including during surgery time) we will test whether the animal has lost its toe pinch (pedal withdrawal) reflex. Prior to incision, animals will receive bupivicaine at electrode placement sites (infusion of surrounding tissue), at a maximum of 0.2 ml within any one animal, and buprenorphine HCl (0.05 mg/kg, s.c.) to assist in post-operative pain management.

Following surgery for implantation of cortical electrodes, animals will receive buprenorphine HCl (0.05 mg/kg, s.c.), which will be given at a minimum one time at the end of the day of surgery, just before close of business. This is in addition to the preemptive dose given prior to surgery. All surgeries should be performed in the AM. Additional doses may be given every 8-12 hours, up to 3 days after the surgery as needed, in consultation with the attending veterinarian.

The buprenorphine dose may be increased, up to a dose of 0.25 mg/kg i.m. or s.c. at each buprenorphine dosing time point, depending on the pain status of the animal. Dose will not be adjusted without approval of the attending veterinarian.

For brain pathology studies, the animals will be anesthetized with 75-100 mg/kg, i.p., sodium pentobarbital prior to euthanasia.

For amygdalo-hippocampal and prefrontal cortex slice preparations, rats will be anesthetized by isoflurane inhalation under a hood until they are non-responsive to toe-pinch, (b)(4)

(b)(4)

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions:

(b)(4)

V.4.1.2.3. Paralytics: N/A

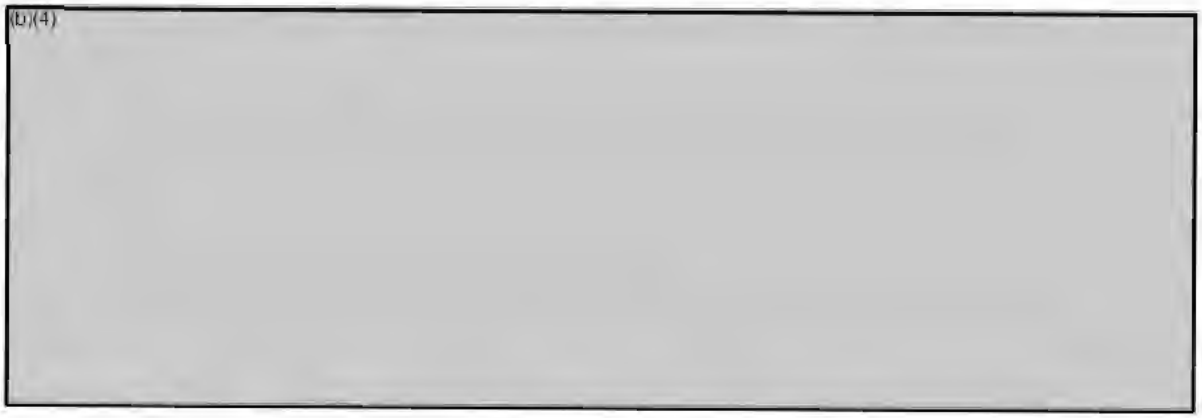
*Duplicate citations removed in PubMed/Web of Science bibliography

The references found in this search cited the use of several *in vitro* models, including primary neuronal cultures and acute and organotypic hippocampal slices. The cited studies investigated protection from neurotoxicity, release or uptake of neurotransmitters, gene expression, and electrophysiological effects of ACh stimulation. We will use hippocampal, amygdala, and prefrontal cortex slices in this protocol. None of the other models offer any advantage over the slice preparations we propose to use. None are able to duplicate the behavioral convulsions, electrographic seizures, or brain damage produced in an *in vivo* animal model, which are necessary to evaluate anticonvulsant and neuroprotective drugs.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification:
There is no alternative for inducing brain damage in rats that mimics the damage caused by nerve agents to determine whether a compound is neuroprotective. The only way to determine the neuroprotective efficacy of a putative drug is to cause actual status epilepticus in an animal model to induce damage prior to administration of the neuroprotective compound and to determine the number of surviving neurons.

(b)(4)

(b)(4)



V.4.2. Prolonged Restraint: N/A

V.4.3. Surgery:

V.4.3.1. Pre-surgical Provisions:
A week prior to the experiments, 50% of the adult and aged, male and female rats in experiment 1 will be implanted with cortical electrodes for electroencephalogram (EEG) recordings. These EEG recordings will be used to confirm the onset and intensity of behavioral convulsions observed in the rest of the animals. For the EEG recordings, along with behavioral observations, the timing (time to onset and duration) and the intensity of seizures will be measured via continuous EEG monitoring. Animals will be placed in individual recording chambers, and a baseline EEG will be obtained before administration of any drug.

The immature rats will not be implanted with cortical electrodes and the timing (time to onset and duration) and the intensity of seizures will be measured via behavioral observations.

The surgical procedures will be performed aseptically following the guidelines of the SOP from USUHS (VSD SOP 22-300). Animals will receive one dose of buprenorphine (0.05 mg/kg s.c.) before any incisions are made. Anesthesia will be induced by isoflurane vapor in 100% oxygen in a commercially available induction chamber. Once anesthesia is induced, animals will be transferred to the designated surgery area and anesthesia will be maintained via nose cone. See Section V.4.1.2.1 Anesthesia/Analgesia/Tranquilization for details.

When the animal is anesthetized, its head will be shaved with a hair clipper. The head will be cleaned with betadine and alcohol, each repeated 3 times alternately. Then the animal will be placed into a stereotaxic frame (appropriate frame size will be used for rats) after treating its pressure points such as ears and nose with lidocaine jelly. A heated pad with thermister-controlled feedback will be put between the animal's body and the base of the stereotaxic frame. Ophthalmic ointment will be applied to the eyes to prevent dryness. The body will be covered with a sterile drape with an opening to expose the head. Prior to incision, animals will receive bupivicaine at electrode placement sites (infusion of surrounding tissue) to assist in pain management. The

injection volume will be limited to the minimum required for pain control, to minimize health risks. Care will be taken to avoid systemic effects.

V.4.3.2. Procedure:

The skin will be incised longitudinally along the midline from eye level to the neck level and retracted to the sides with hemostats. The periosteum will be scraped off from the skull. Five stainless steel machine screws (the smallest possible size that provide adequate anchoring) will be used as electrode contact and simultaneous anchoring points for the headpiece that will be built from acrylic cement to secure the female electrode connector in place. The screws will be manually positioned in the frontal or parietal bone plates and one over the cerebellum. The screws will be partially screwed in manually without penetrating the dura mater.

V.4.3.3. Post-surgical Provisions:

Excess cement will be removed from the headpiece to make its edges smooth. If necessary, skin will be sutured at both ends of the incision line. The sutures (suture thread - non-absorbable nylon) will be performed with the help of atraumatic needles with suture size #0. The animal will be released from the stereotaxic frame and placed in a recovery cage on a chemical pocket warmer wrapped in cloth or paper until the animal fully recovers from anesthesia. Alternatively, the animals may be placed in a forced-air recovery chamber warmed to 34 °C. Once fully awake and performing purposeful movements, the animal will be moved back to the holding area. At least 7 days will be allowed for recovery after surgery before any experimentation. Removal of stitches will occur 7 days after surgery.

Only the rats that maintain good health following the surgery will be used for experiments. This decision will be jointly made by the animal-care personnel and the investigators. All efforts will be made to provide all animals with the best care possible. Each animal will be individually monitored throughout the study by experienced personnel from our laboratory. We will also closely work with the veterinarian and animal-care staff of the animal facility to ensure that adequate treatment is provided in a timely manner should it be deemed necessary.
After surgery, the animals will be placed in a clean cage provided with a recirculating warm-water veterinary heating pad or in a forced-air recovery chamber warmed to 34 °C to maintain proper body temperature. After recovery from anesthesia (evidence of righting reflex and purposeful movements) the animal will be given at least one dose of an analgesic, buprenorphine HCl (0.05 mg/kg s.c.), for post-operative analgesia, which will be given every 8-12 hours up to 3 days after the surgery. The medication will be administered by the by PI or by qualified PI staff. If necessary, based on consultation with the attending veterinarian, additional buprenorphine may be given as needed.

Additional doses of buprenorphine will be given if required, based on assessment of PI and attending veterinarian of animal's condition, which will include assessment of the presence of the following signs of pain/distress: hunching, abnormal gait, abnormal attitude (increased or decreased aggression), inability to move to food/water, excessive porphyrin staining of eyes/nose, shuddering or twitching, unkempt appearance, and vocalization when handled.

Following at least 1 hour on the warming pad or in a forced-air recovery chamber, upon full recovery in which the animal can maintain an upright posture and is ambulatory, the animal will be returned to its holding room cage. Laboratory personnel will provide the care of the animal until full recovery if it has not already occurred. All animals will be checked at least once 30 minutes after return to home cage, to ensure recovery is continuing, and at least once again just prior to the end of the work day to ensure animals are recovering normally. Animals will be examined at least once daily by the PI staff for one week post-surgery to ensure that no complications occur. Observations will be recorded for each animal in a place that is accessible to the animal care staff (post-surgery cage cards may be used for this purpose). PI staff observations will be separate from routine observations conducted by the animal care staff.

V.4.3.4. Location:
Surgeries (implantation of electrodes) will be performed at USUHS in LAM, Room (b)(6) Euthanasia and perfusions will be performed in room (b)(6) at USUHS. Euthanization will occur in chemical hoods in (b)(6)

It is anticipated that all of the EEG surgery will be performed at USUHS (LAM).

(b)(4)

(b)(4)

V.4.4.3. Adjuvants: N/A

V.4.4.4. Monoclonal Antibody (MAbs) Production: N/A

V.4.4.5. Animal Identification:
Cage cards, headpieces numbered with nontoxic ink. This will be the responsibility of the USUHS research team.

V.4.4.6. Behavioral Studies:
The following procedures will be performed at the USUHS:

Rotarod test: It measures an animal's ability to maintain balance by coordinating movement and making postural adjustments. It also measures the ability to improve these skills with practice. Each rat rotarod treadmill consists of a motor-driven drum with constant speed or accelerating speed modes of operation. The drum (7.0 cm diameter) allows each animal to maintain a suitable grip. It is divided into four test zones (8.9 cm wide) so that up to four animals may be tested at the same time. The device consists of a smooth hard plastic cylinder with concentric circular plastic sides (39.7 cm diameter) to prevent the rat from laterally climbing off the cylinder. Rats are placed on the device facing the wall with the rod rotating in the direction opposite from the animal (so that the rat uses its paws to pace forward and avoid falling off the rod). When a rat falls off the rotating drum (height of 26.7 cm), it breaks a photobeam, stopping the timer associated with that zone. In each trial, the speed of rotation is increased from 0 revolutions per minute (rpm) to 35 rpm for a maximum of 3 or 5 min. The mean duration on the device (based on 3 consecutive trials) is recorded.

Preference for Novelty (Open Field): Testing will be performed in a Plexiglas cage (56cm x 34cm x 20cm) with the floor divided in 18 equal squares. Three identical aluminum cubes will be evenly distributed in the cage in fixed positions. Three other cubes will make up the novel objects. One novel object will be similar to the neutral cubes in that its top will be uneven with tracks making up a square pattern (tactile stimuli). One novel object will be identical with the neutral objects except that a slight smear of cheese will be placed on the side facing the experimenter (olfactory stimuli). The third object will be similar to the neutral blocks except that it will be slightly smaller with uneven sides (visual stimuli). Locomotor activity will be measured using an Omnitech Electronics Digiscan infrared photocell system. One-hour activity measurements are obtained during animals' active or dark cycle.

T-maze: The task is based on the premise that animals have evolved an optimal strategy to explore their environment and obtain food with a minimum amount of effort. The T-maze apparatus is made of white Perspex. The runway of the maze is 80 cm long and its side arms are 30 cm long. The width of the maze is 10 cm and the walls are

10 cm high. A guillotine door is used to open the start box and two additional doors are used to block access to the arms, as necessary. Distinctive extra-maze cues are placed in the surrounding walls. Habituation sessions will be performed during 2 consecutive days, allowing free exploration of the maze for 15 min each day. Each rat will receive 10 precision pellets of food, scattered evenly throughout the maze, on each of the habituation sessions. During training each trial consists of a sample run and a test run. In the sample run, rats will be placed at the start position and required to make a forced choice by blocking the access to one of the arms. Two pellets will be positioned at the end of the open arm. The rats will be allowed to eat the pellets and will be immediately placed in a holding cage for 10 s before being returned to the maze for the test run. In the matching-to-place (MTP) and the non-matching-to-place (NMTP) versions of the task the reinforced choice in the test run is either the previously visited arm (MTP) or the arm opposite (NMTP). Each rat will perform 1 block of 10 trials each day. The sequence of arm visits (sample runs) will be randomized for each experimental subject.

Acoustic Startle Response: ASR testing will be conducted with a Startle Response Acoustic Test System (Coulbourn Instruments, PA). This system consists of a weight-sensitive platform in a sound-attenuated chamber. The animals' movements in response to stimuli will be measured as a voltage change by a strain gauge inside each platform and will be converted to grams of body-weight change following analog to digital conversion. These changes will be recorded by an interfaced computer as the maximum response occurring within 200 ms of the onset of the startle-eliciting stimulus. All acoustic stimuli will be administered by an amplified speaker mounted 24 cm above the test cage. During testing, animals will be individually placed in holding cages (14.5 × 7 × 6.5 cm) that are small enough to restrict extensive locomotion, but large enough to allow the subjects to turn around and make other small movements. These will then be placed on the weight-sensitive platform. Following placement of the animal into the chamber, the chamber lid will be closed, leaving the subject in darkness. A three-minute adaptation period occurs in which no startle stimuli is presented. Startle stimuli consist of 120 dB Sound Pressure Level (unweighted scale; re: 0.0002 dynes/cm2) noise bursts of 20 msec duration. In addition to the 120 dB stimuli, the 110 dB level will also be used for comparison to insure that the 120 dB stimulus level not only will meet a response threshold but also will not reach a leveling out of the maximum response. Thus confirmed, results will be given for the 120 dB level only. Decibel levels will be verified by a Radio Shack Sound Pressure Machine Model 2800 (Provo, UT). Each stimulus will have a 2-ms rise and decay time such that onset and offset will be abrupt, which is a primary criterion for startle. Each trial type (120 dB, 110 dB, or no stimulus) will be presented eight times. Trial types will be presented at random to avoid order effects and habituation. Inter-trial intervals will range randomly from 15 to 25 s.

Light-Dark Task/Open Field Behavior: Assessment of Anxiety and Locomotor Response to Novelty. The light-dark task will be performed in Hamilton-Kinder activity monitors (40 x 40 x 40 cm) fitted with "dark" inserts which make half the volume of the box dark (0-2 lux). The rest of the chamber is open to ambient lighting (85-125 lux). A small arch-shaped opening allows the rats to move freely between the two sides. The floor of both halves of the box is covered with corncob bedding. Infrared beams surrounding each box detect the animals' positions. Infrared beam breakages are then converted into distance and position by Hamilton-Kinder software running on a personal

computer. The test session begins when the rat is placed gently in the light side of the chamber. Rats are allowed to move freely about the chamber for 15 min. The following measures are scored 1. Total distance traveled (cm). Distances in the light and dark halves are summed to obtain "total distance," which is a measure of locomotor activity. 2. Time spent in the light half of the chamber(s). This is one of two indicators of anxiety in this task. Rats that spend less time in the light are deemed to be more anxious. 3. Emergence from the dark (emergence interval; s). This is a second measure of anxiety. Rats that take longer to emerge from the dark after their first entry are deemed to be more anxious.

V.4.4.7. Other Procedures:
On the day of exposure to the nerve agent, the animals will be connected to recording leads via the connection plug on their heads. Brain EEG activity will be recorded while they are in cylindrical plastic recording chambers, 16" in diameter and 26" high with Iso-pad bedding on the floor, where they are free to move about. The period of confinement in the recording chambers will not exceed 3 hours on the experimental day or 1 hour on the day after.

The following 5 procedures will be performed at the USUHS:

Histology: Twenty-four hours, 1 week, 1 month, or 3 months after soman exposure, the animals will be deeply anesthetized with 75-100 mg/kg, i.p., sodium pentobarbital, until a surgical plane of anesthesia is reached (non-response to strong toe-pinch) and then exsanguinated via perfusion with normal saline followed by 10% neutral buffered formalin. The brains will be removed and post-fixed overnight at 4° C, then transferred to a solution of 30% sucrose in PBS for 72 hours, and frozen with dry ice before storage at –80° C until sectioning. Sections containing the rostro-caudal extent of the BLA, the hippocampus, and the prefrontal cortex will be cut at 40 µm on a sliding microtome. One series of sections will be mounted on slides (Superfrost Plus; Daigger, Vernon Hills, IL) in PBS for Nissl staining with cresyl violet. An adjacent series of sections will also be mounted on slides for Fluoro-Jade C staining.

Fluoro-Jade C staining (Histo-Chem, Jefferson, AR) will be used to identify irreversibly degenerating neurons in the amygdala, the hippocampus, and the prefrontal cortex. Mounted sections will be air-dried overnight and then immersed in a solution of 1% sodium hydroxide in 80% ethanol for 5 min. The slides will then be rinsed for 2 min in 70% ethanol and 2 min in deionized water (dH20), and incubated in 0.06% potassium permanganate solution for 10 min. After a 2-min rinse in dH20, the slides will be transferred to a 0.0001% solution of Fluoro-Jade C dissolved in 0.1% acetic acid for 10 min. Following three 1-min rinses in dH20, the slides will be dried on a slide warmer, cleared in xylene for at least 1 min and coverslipped with DPX (Sigma). Fluoro-Jade C stained sections undergo tissue shrinkage, so they cannot be used for stereological quantification.

Stereological quantification: Design-based stereology will be used to quantify the total number of neurons on Nissl-stained and GAD67-stained sections. Sections will be viewed with a Zeiss Axioplan 2ie (Oberkochen, Germany) fluorescent microscope with a motorized stage, interfaced with a computer running StereoInvestigator 7.5

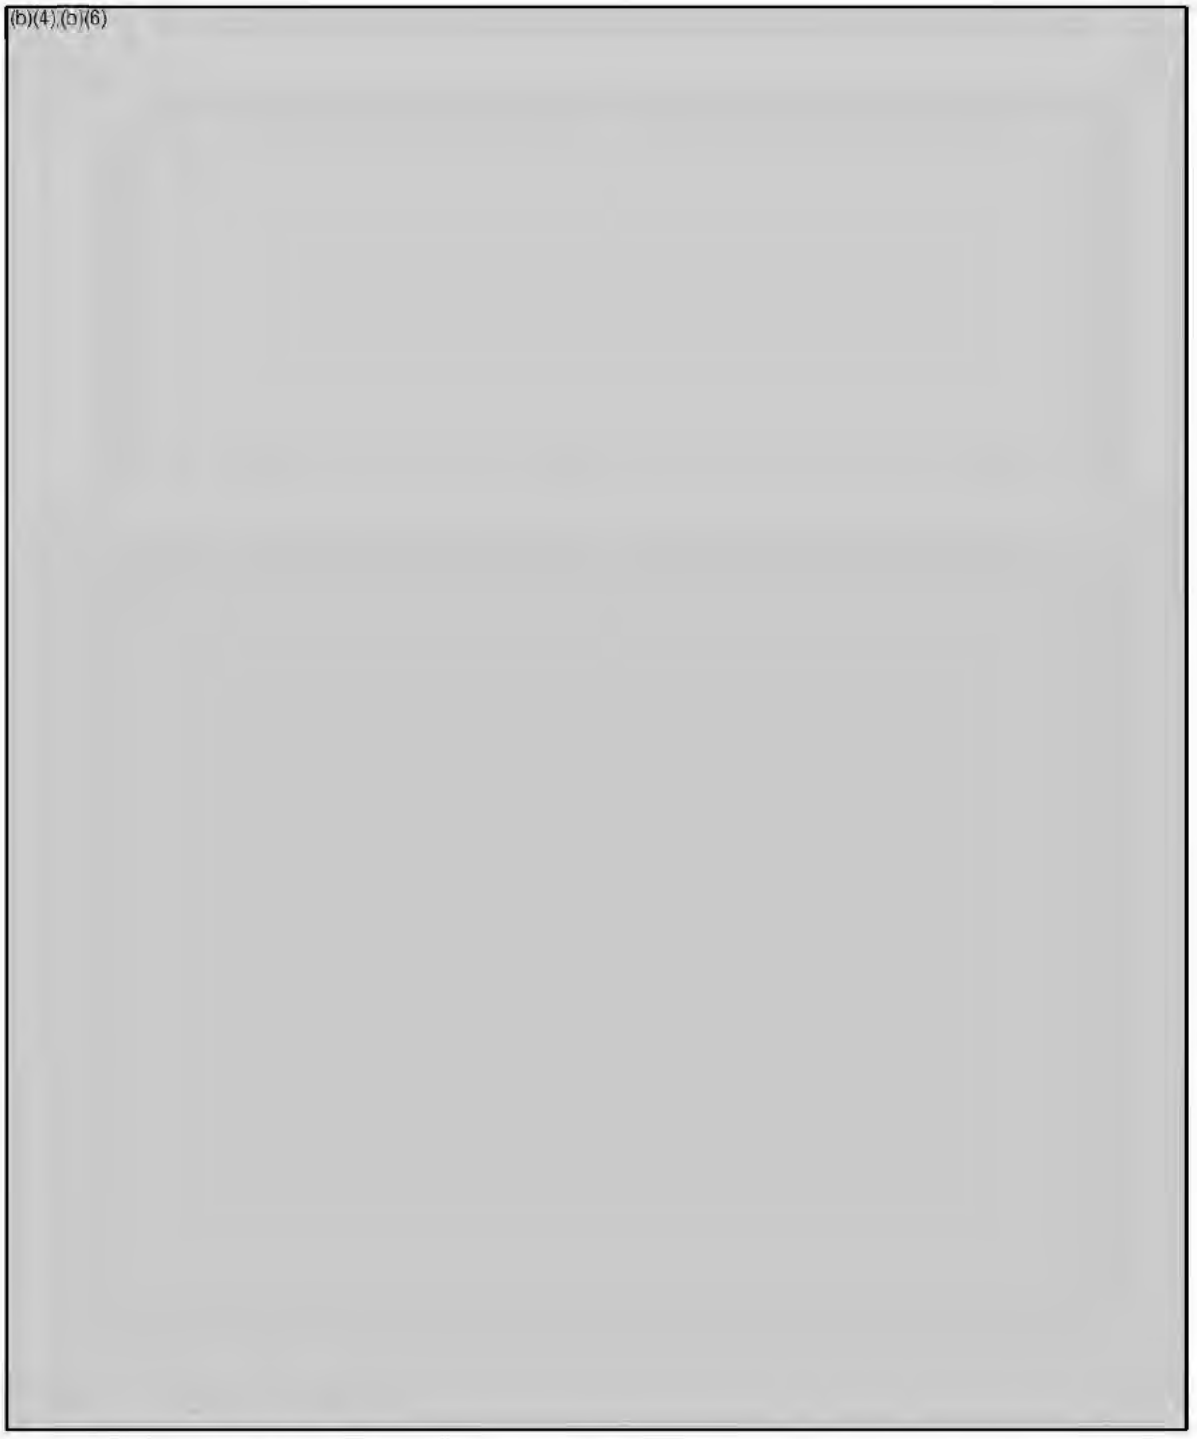
(MicroBrightField, Williston, VT). Estimated totals will be determined using the fractionator probe, and all sampling will be done under a 63× oil immersion objective.

Glutamic acid decarboxylase-67 (GAD67) immunohistochemistry. Our previous studies have demonstrated delayed loss of GABAergic interneurons in the BLA (31, 86). To determine what proportion of the lost neurons are GABAergic interneurons, we will combine stereological quantification with GAD67 immunohistochemistry. To label GAD67-immunoreactive neurons, a I-in-5 series of free-floating sections will be collected from the cryoprotectant solution, washed three times for 5 min each in 0.1 M phosphate buffered saline (PBS), then incubated in a blocking solution containing 10% normal goat serum (NGS; Chemicon, Billerica, MA) and 0.5% Triton X-100 in PBS for one hour at room temperature. The sections will then be incubated with mouse anti-GAD67 serum (1:1000, MAB5406; Chemicon), 5% NGS, 0.3% Triton X-100, and 1% bovine serum albumin, overnight at 4°C. After rinsing three times in 0.1% Triton X-100 in PBS, the sections will be incubated with Cy3-conjugated goat anti-mouse antibody (1:1000; Jackson ImmunoResearch, West Grove, PA) and 0.0001% DAPI (Sigma-Aldrich, St. Louis, MO) in PBS for one hour at room temperature. After a final rinse in PBS, sections will be mounted on slides, air dried for 30 min, then coverslipped with ProLong Gold antifade reagent (Invitrogen, Grand Island, NY).

Brain slice electrophysiology: Coronal slices containing the amygdala and the hippocampus, and slices containing the prefrontal cortex will be prepared from experimental and control rats, 1 month and 3 months after soman exposure. The rats will be anesthetized with isoflurane and then decapitated. The brain will be rapidly removed and placed in ice-cold artificial cerebrospinal fluid (ACSF) composed of (in mM) 125 NaCl, 2.5 KCl, 2.0 $CaCl_2$, 2.0 $MgCl_2$, 25 $NaHCO_3$, 1.25 NaH_2PO_4, and 22 glucose, bubbled with 95% O_2 and 5% CO_2 to maintain a pH of 7.4. Coronal slices containing both the hippocampus and the amygdala, and coronal slices containing the prefrontal cortex will be cut at 400 µm with a Vibratome (Series 1000; Leica Microsystems, Bannockburn, IL). Slices will be kept in a holding chamber containing oxygenated ACSF at room temperature, and recordings will be initiated ≥1 hr after slice preparation. For whole-cell recordings, slices will be transferred to a submersion-type recording chamber, where they will be continuously perfused with oxygenated ACSF, at a rate of 3–4 ml/min. Neurons will be visualized with an upright microscope (Nikon Eclipse E600fn; Nikon, Tokyo, Japan) using Nomarski-type differential interference optics through a 60× water immersion objective. Tight-seal (>1 GΩ) whole-cell recordings will be obtained from the cell body of pyramidal-shaped neurons in the BLA region, the pyramidal layer in the CA1 hippocampal area, and the layer III and V pyramidal cells of the prefrontal cortex. Patch electrodes will be fabricated from borosilicate glass to have a resistance of 1.5–5.0 MΩ when filled with a solution containing (in mM) 135 Cs-gluconate, 10 $MgCl_2$, 0.1 $CaCl_2$, 1 EGTA, 10 HEPES, 2 Na-ATP, 0.2 Na3GTP, pH 7.3 (285–290 mOsm). Neurons will be voltage-clamped using an Axopatch 200B amplifier (Molecular Devices, Sunnyvale, CA); some recordings will be obtained in the current-clamp mode. Access resistance (5–24 MΩ) will be regularly monitored during recordings, and cells will be rejected if resistance changes by >15% during the experiment. The signals will be filtered at 2 kHz, digitized (Digidata 1322A; Molecular Devices), and stored on a computer using pClamp9 software (Molecular Devices). Analysis of recorded currents will be performed using pClamp9 software and

the Mini Analysis Program (Synaptosoft, Inc., Leonia, NJ). Extracellular field potentials will be obtained from the BLA, while stimulus pulses are applied to the external capsule, the CA1 hippocampal area, while stimulation is applied to the Schaffer collaterals, and layer III and V of the prefrontal cortex slices, while stimulation is applied to the subcortical white matter. Recording electrodes will be filled with ACSF (resistance: 4 to 7 MΩ). To determine alterations in neuronal and network excitability, whole-cell recordings will be performed in the current-clamp mode to determine changes in the intrinsic excitability parameters of pyramidal cells in the BLA region of the amygdala, the CA1 hippocampal area, and layers III and V of the prefrontal cortex, in slices obtained from the experimental and control groups, at 1 and 3 months following exposure to soman (or saline, for the controls). The following parameters will be measured: resting membrane potential, neuronal input resistance, action potential threshold, action potential characteristics, spontaneous firing, and firing characteristics in response to depolarizing current pulses passed via the recording electrode. Whole-cell recordings in the voltage-clamp mode will also be performed to determine differences, among experimental and control groups, in spontaneous GABAergic and glutamatergic activity in the BLA region of the amygdala, the CA1 hippocampal area, and layers III and V of the prefrontal cortex. These experiments will provide an insight into soman-induced alterations in the intrinsic excitability of pyramidal neurons in the BLA, the CA1 region, and the prefrontal cortex, as well as alterations in the basal, spontaneous activity of the two major neurotransmitter systems that control neuronal network excitability (the GABAergic and the glutamatergic system), and the extent to which the (b)(4) (b)(4) administered 30 or 60 min after soman exposure prevent these alterations. For alterations in synaptic plasticity, we will test the hypothesis that soman-induced seizures and the resulting neuronal damage alter synaptic plasticity in the amygdala, the hippocampus, and the prefrontal cortex, and that termination of the seizures by administration of the (b)(4) will minimize these alterations. Synaptic plasticity will be studied by investigating the characteristics of long-term potentiation (LTP) of synaptic transmission, as we have done previously in both amygdala slices (3) and cerebral cortex slices (2a). In brain slices obtained from rats from experimental and control groups, sacrificed 1 or 3 months after exposure to soman (or saline, for the control groups), field potentials and compound EPSCs will be recorded in the BLA, the CA1 area, and in the prefrontal cortex in response to electric stimulation of the external capsule, the Schaffer collateral/commisural pathway, and the subcortical white matter, respectively. Because LTP is considered to be the cellular mechanism underlying learning and memory, these experiments may provide an explanation for the memory impairment and other cognitive deficits that result from exposure to nerve agents, and will determine if the (b)(4) can prevent alterations in synaptic plasticity by soman.

(b)(4)



V.4.4.8. Tissue Sharing:
Tissues not used in this study may be made available to other investigators as required. Lactating mothers will be available for transfer for training or experimental purposes, or euthanized if they cannot be used. Every effort will be made to transfer these animals to another protocol.

V.4.5. Study Endpoint:

For **Experiments 1, 2, and 3A and B** the endpoint is euthanasia of the male and female rats for neuropathological studies, preparation of brain slices, or at the end of the behavioral experiments, within 4 months of receipt at USUHS. The study endpoint for the surrogate mothers is the time when the pups are weaned or removed for experiments.

(b)(4)

Early Endpoint: Any of the following will represent a reason for early euthanasia: inability to ambulate or reach food or water, persistent seizures (development of continuous (>10 sec) rhythmic spike and/or sharp wave activity at least 2X greater than the baseline amplitude and that lasts more than 30 min), persistent tremors, self mutilation, continuous circling, or persistent labored respiration or gasping, loss of 20% of weight below baseline, prostration/inactivity for up to 24 hours, or a significant decline in vital signs. These signs, if observed by animal facility personnel and no study personnel can be reached, may be taken by the veterinarian as cause for euthanasia. Some behavioral changes may be caused by nerve agent-induced seizures and will not represent early endpoints: lethargy, weakness, inability to walk straight and uncertain ambulation (as long as it does not interfere with the animal's ability to eat and drink), intermittent abnormal breathing pattern. The enclosed Pain/Distress Criteria scoring sheet may be used as a guide.

V.4.6. Euthanasia:

If any of the experimental animals develop serious complications due to the agent exposure and/or associated treatments while at USAMRICD, the animal may be euthanized early with an overdose of pentobarbital (>75 mg/kg, IP) or carbon dioxide administered from a cylinder upon consultation between the PI and the facility veterinarian.

For brain pathology studies, at USUHS the animals will be anesthetized with 75-100 mg/kg, i.p., sodium pentobarbital, until a surgical plane of anesthesia is reached (non-response to strong toe-pinch) and then exsanguinated via perfusion with normal saline followed by 10% neutral buffered formalin.

For brain slice preparations, rats will be anesthetized with isoflurane inhalation under a chemical fume hood and euthanized by decapitation. Isoflurane will be administered via a precision vaporizer. When the animal has lost its toe pinch (pedal withdrawal) reflex and eyelid blink (palpebral) reflex, and is immobilized, it will be removed from the vaporizer and decapitated with a guillotine.

Following the collection of tissues the remaining carcass will be disposed of IAW the most recent version of VMSB SOP VM-08-301 (114), "Animal Euthanasia."

Comments on the use of decapitation: The guillotine will be maintained in a sharpened condition to ensure rapid and clean decapitation. In the past, one guillotine has been effective for approximately 200 rat decapitations without sharpening. Commercial sharpening will be performed after every 200 procedures or sooner if needed to ensure continued sharpness. The PI has utilized guillotines in two other protocols as co-investigator and three as PI and is proficient in their use. Any other personnel on this protocol will not assist until they have been trained in the use and safety considerations by the PI and are proficient. Decapitation is preferred over other euthanasia procedures because it minimizes residual medications that might affect neuronal responses to stimulation.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol.

The rats will be maintained under an AAALAC accredited animal care and use program. They will be acclimated upon arrival for 5 days. Animals will be housed in an approved animal holding room after release from acclimation. They may be pair-housed but must be individually housed post-surgery to ensure no interference with the surgical sites. Food and water will be freely available except during the exposure period. The veterinary staff will provide daily checks of general health and provisions of food and water.

(b)(4)

V.5.1.1. Study Room:

Building(s): (b)(6) Room Number(s): (b)(6)

V.5.1.2. Special Husbandry Provisions:

Food Restriction: Yes _____ No X

Fluid Restriction: Yes _____ No X

V.5.1.3. Exceptions: (b)(4)

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care:
The PI or research staff will observe the rats at least twice a day following all procedural manipulations. The veterinary staff will observe the rats at least once a day for general health and husbandry condition. Any rat displaying any other signs of pain, distress or illness will be evaluated by the PI and/or attending veterinarian and, if necessary, euthanized as previously described.

Animal monitoring: Animals will be examined after return to their home cage, approximately 30 minutes after return, and once again that day near end of the work day by the USUHS research team. Animals will be checked at least twice daily for one week post-exposure by the USUHS PI and staff. Observations will be recorded somewhere accessible to animal care staff. USUHS PI and staff observations for specific signs related to surgery will be in addition to routine observations conducted by the animal care staff.

V.5.2.2. Emergency Veterinary Medical Care: All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays.

If any rat experiences non-study related distress or pain prior to the study, the PI or co-PI will consult the attending veterinarian. If necessary, the rat will be treated or euthanized as directed by the attending veterinarian. Euthanized rats will not be entered into the study and additional rats may be requested as replacements.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: Except as indicated below, all animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets for rodents; balls, toys and food enrichment treats for rodent species.

V.5.3.2. Enrichment Restrictions: N/A

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
Animal handling, agent handling, injections, anesthesia, EEG surgery, guillotine usage, euthanasia, electrophysiology	(b)(6)	PhD in neuroscience. 20+ yr rodent handling, surgery, tissue dissection, electrophysiological experimentation. Over 200 rats euthanized via guillotine. 6 years performing EEG electrode surgery in rodents.	Investigator training Dr. (b)(6) has performed hundreds of surgeries, euthanasia, and anesthesia.
Animal handling, agent handling, injections, anesthesia, EEG surgery, guillotine usage, euthanasia, electrophysiology		PhD in physiology 30+ yr animal handling, injections, surgery, tissue dissection, electrophysiological experimentation. Over 200 rats euthanized via guillotine.	Investigator training Small animal handling workshop 30+ years experience and on-the-job training
Animal handling, anesthesia, EEG surgery, guillotine usage, euthanasia, perfusions, electrophysiology		PhD in neuroscience. 20+ yr rodent handling, surgery, tissue dissection, and electrophysiological experimentation. Over 200 rats euthanized via guillotine	Dr (b)(6) was retrained as an animal investigator at USUHS in 2007. 20+ years experience and on-the-job training, anesthesia, euthanasia, tissue samples, small animal surgery, perfusions, electrophysiological experimentation.
Animal handling, injections, EEG		PhD in neuroscience More	Investigator training in small animal

surgery, perfusion, histological preparation, neuropathology	(b)(6)	than 15 years of experience in small animal handling, injections, perfusion, histological techniques, and assessment of neuropathological damage	handling and experimentation, including behavioral tests.
Animal handling, injections, EEG surgery and recordings		Ph.D. student at USUHS. Two+ years experience in handling small laboratory animals, tissue samples and small animal surgery including EEG and osmotic minipumps.	Investigator training and small animal handling workshop to be completed. Extensive experience and on-the-job training
Animal handling, injections, EEG surgery and recording		Lab Technician, Ms. (b)(6) has one year of on-the-job training in animal experimental procedures, Rats perfusions and surgery.	Investigator training Small Animal Handling Workshop.
Animal handling, agent handling, injections, anesthesia, EEG surgery, guillotine usage, euthanasia, electrophysiology		PhD in physiology 20+ yr animal handling, injections, surgery, tissue dissection, electrophysiological experimentation. Over 200 rats euthanized via guillotine.	Investigator training Small animal handling workshop 20+ years experience and on-the-job training

VII. BIOHAZARDS/SAFETY:

XCSM agent, decontaminated XCSM agent waste, chemicals, and hazardous waste used in this protocol will be handled in accordance with all applicable state and federal guidelines, regulations, and standing operating procedures.

Use of XCSM: The laboratories follow the standard operating procedures for the use and disposal of XCSM agents, as described IAW the latest version of SOP# 87-201-RS-

01, SOP# 87-335-VA-12, and APGR 200-60. These include initial and quarterly monitoring, as well as daily checks, of hood safety.

Use of formalin: All operators using formalin must wear proper personal protection equipment, i.e., gloves, safety glasses, lab coat, and they will also use a portable chemical hood. Exposure to 10% neutral buffered formalin solution for perfusion is limited to no more than 400 mL/day. The 10% neutral buffered formalin waste (mixed with blood) will be disposed of down the sink in rm 6, bldg E-3244, and documented in a sink waste log.

Minimal PPE for animal handling includes nitrile gloves, mask worn in the slung position or readily available, safety glasses with sideshields or goggles, and fully buttoned lab coat. Double gloves will be worn during agent exposure. All agent work will be done in a certified chemical fume hood in a laboratory that has been appropriately permitted IAW USAMRICD Memorandum 385-6.

Waste anesthetic gas (isoflurane) will be scavenged either by evacuation into a chemical fume hood or by extraction with a filter system in a recirculating air cleaning device (Extract-All system, VetEquip Inc., Pleasanton, CA).

VIII. ENCLOSURES:

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Tra

MEMORANDUM FOR DR (b)(6) DEPARTMENT OF ANATOMY, PHYSIOLOGY, AND GENETICS

SUBJECT: IACUC Approval of Protocol – Initial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on September 7, 2012:

Animal Protocol Title: "Epigenetic biomarkers of post-traumatic stress disorder in mouse model in constant pressure environment."

USUHS Protocol Number: (b)(6)

Expiration Date: September 6, 2015

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. NON-TECHNICAL SYNOPSIS:

At present, there is no definitive treatment and no cure for post-traumatic stress disorder (PTSD). Brain function of PTSD victims is strongly impacted especially with changes in how neurons in the brain communicate between each other. In this proposal we will continue to use mice as an animal model to address an important challenge facing clinical research in its quest to help PTSD victims. This proposal is building on the previous proposal (Animal Study Proposal/ USUHS IACUC (b)(6) where we have investigated one of the epigenetic mechanisms: microRNAs (miRNAs) expression in mice subjected to various levels of stress conditions. Epigenetic mechanisms are not related to mutations in DNA but they affect DNA encoded read-outs, which include messenger- and micro- RNAs and therefore translation into proteins. As miRNAs are complementary to one or more mRNA molecules they can interfere with expression of a number of target genes and influence gene regulatory networks and therefore affect signaling pathways underlying pathophysiology and behavior changes caused by PTSD. Because complex epigenetic changes may underlie diverse phenotypes of PTSD and contribute to PTSD pathophysiology, a novel more complete approach than has been used previously is needed. This novel approach has to take into account individual variations between subjects because different life experiences and epigenetic modifiers affect mice during their development and impact their behavioral characteristics. In our PTSD model, we will expose mice to one of several stress levels: no stress, 3 hours of restraint stress, or 3 hours of restraint stress plus intermittent tail shock. US Air Force personnel may face intermittent changes in atmospheric pressure when performing their mission therefore our model will include (b)(4) chamber, where mice will be under controlled pressure environment for determined time period.

We hypothesis that epigenetic characteristics play a major role in the communication between neurons after a stressful environmental or psychological insult by regulating mechanisms underlying activity dependent molecular processes. Epigenetic signatures in the central nervous system appear critical for controlling cell identity and play an important role in the development of brain function. Some of the end targets of epigenetic regulation include signaling proteins that play important roles in communication between neurons, brain function and respective behavior. Abnormalities in the epigenetic modifications will result in the disruption of the translation of mRNAs affecting proteins that mediate brain function and alert neuronal communication. Therefore understanding the way the epigenetic profiles impact the brain and influence PTSD will allow for therapeutic intervention. We believe that in the future we will be able to develop

therapeutic applications for the reversal of brain malfunction caused by stress. This will enable a reduction of anxiety episodes in military and/or civilians associated with PTSD and exposure to (b)(4) pressures associated with (b)(4)

II. BACKGROUND:

II.1. Background:

Interactions between an individual's genetic make-up and environmental exposure results in differential disease outcomes in response to the same environmental insults. One such example is post-traumatic stress disorder (PTSD) where individuals exposed to trauma display heterogeneous responses, including the development of diverse psychological symptoms and differential rates of recovery. This heterogeneous breakdown of neurocognitive systems is one of the most important indicators of the involvement of gene-environmental interaction in the etiology of PTSD.

Environment can interact with the genome in non-mutagenic manner to produce gene expression changes caused by epigenetic mechanisms during development and adulthood. Epigenetic factors including histone modifications, DNA methylation and microRNA (miRNA) expression can dynamically change genome function under acute and chronic environmental influence, thereby impacting neuroplasticity, learning and memory [4, 5]. Chromatin modifications and miRNA interference emerges as fundamental molecular mechanisms for the altered transcriptional regulation involved in brain injury, neurodegenerative and stress related disorders [6-8]. Stress, infectious agents, environmental toxins and "harsh" environmental conditions are well recognized chromatin modifiers that may alter the PTSD outcome and the efficacy of treatment [9]. Recent years brought growing evidence supporting the specific impact of environmental toxins on chromatin [10, 11].

During deployments/operations, US Air Force (USAF) personnel are exposed to extreme environmental conditions including low-oxygen, low-ambient air pressure, environmental toxins, etc. Most, or perhaps all individuals develop a spectrum of (b)(4) symptoms known as acute or chronic mountain sickness, including the more severe conditions of cerebral and lung edema [12]. In addition, deployment and other rescue operations can lead to PTSD among USAF personnel as depicted from the recently reported increase in the incidence of PTSD among USAF personnel after deployment to Iraq/Afghanistan [1]. Furthermore, the environmentally induced PTSD symptoms have also been observed in active-duty USAF noncombatants [13, 14]. Thus the deployment to any war zone in combination with extreme environmental conditions can cause increased mental health problems. Differential PTSD outcomes and treatment response among the USAF personnel occurs due to the underlying complex gene-environmental interactions. The understanding of how genes and environmental factors interact to cause disease states will thus lead to novel strategies for the diagnosis, treatment and prevention of complex human disorders.

A number of association studies that have been performed to date clearly support our hypotheses on the polygenic nature with strong environmental component as the underlying causes for the etiology of (b)(4) sickness and adaptation [15]. Recent genome-wide association studies designed to identify genetic contributions to human adaptation a(b)(4) have revealed a subset of genes related to the HIF (b)(4) nducible factor) pathway [16]. HIF, the key regulator of oxygen homeostasis, constitutes a set of heterodimeric transcription factors (HIF1, HIF2, HIF3) comprised of different alpha and beta subunits [17]. HIFα subunits are

stabilized by (b)(4) thereby regulating the expression of variety of genes that control a switch from oxidative to glycolytic metabolism, cause inhibition of cellular proliferation, elicit an increase in the production of red blood cells & hemoglobin in blood, and stimulate oxygen delivery through erythropoiesis and angiogenesis [18, 19]. It is interesting to note that hematological response (higher hemoglobin concentration, increased hematocrit values, erthyocytosis etc.) caused by acute exposure or adaptation to (b)(4) vary significantly among endemic/ethnic populations suggesting genetic component (b)(4) and possible environmental factors (b)(4) [20, 21]. Under (b)(4) conditions, HIF1 activates the transcription of Jumonji domain containing histone demethylase enzymes (JMJD1A- demethylates H3K9, JMJD2B- demethylates H3K36, JMJD2C, PLU-1), thereby affecting the downstream expression of their target genes [22, 23]. SIRT1 (deacetylates H3K9) and SIRT6 (deacetylates lysine residues) are also known to inactivate HIF1α under (b)(4) [24, 25]. A recent study has shown (b)(4) mediated upregulation of histone methyl transferase - G9a and histone deacetylases [26]. HIF transcription factors also affect the expression of miRNAs (considered a part of epigenome), which are short ~22 nucleotide RNA sequences that bind to complementary sequences in the 3' UTR of multiple target mRNAs mostly resulting in their silencing [27, 28]. In cancer cell lines (b)(4) triggers a specific pattern of miRNAs expression, suggesting a (b)(4) impact on epigenome in the tumor cells [29]. Also in non-proliferating cells, HIF1α/ HIF1β induction alter miR-101 expression, which in turn downregulates the expression of EZH2, a polycomb protein that catalyzes H3K27 trimethylation [30]. All these studies support the combinatorial role of epigenetic mechanisms and HIF factors in regulating (b)(4) stress response. In addition to HIF-mediated pathways, expression of genes linked to (b)(4) sickness is also epigenetically regulated in a tissue specific manner [15, 16, 31].

We hypothesize that physiological conditions caused by (b)(4) such as (b) air pressure and low oxygen, trigger epigenetic modifications in various organs that are comorbid to stressful deployment activity. We will implement an integrated approach using molecular epigenetics and behavioral techniques to unravel the underlying role of epigenetic modifications, which affect brain function, neuronal circuitries, hematological and pulmonary functions and behaviors associated with PTSD after exposure to (b)(4) insults. Behavioral phenotyping of mice is critical in order to identify biomarkers of stress under (b)(4) conditions in relation to subject specific response to stress and traumatic events. (b)(4) (b)(4) Building upon our previous experience, we will categorize the mouse behavioral phenotypes using the results of their performance in rotarod, fear conditioning and acoustic startle response tests. Comprehensive genome-wide epigenetic profiling (ChIP-Seq for histone modifications, RRBS-Seq for DNA methylation, miRNA-Seq) and expression profiling (RNA-Seq) will be implemented via next-generation sequencing approach, that yields unprecedented quality sequencing data with the highest signal to noise ratio. We will build our approach based on our experience gained during yet to be completed project focused on the epigenetic signature of (b)(4) (b)(4) we generated PTSD mouse model by exposing mice to two stress levels: 3 hours of restraint stress plus intermittent tail shock (severe stress level) or 3 hours of restraint stress (low stress level). Based on the acoustic startle response, we have categorized these mice into three behavioral groups (consistent, frozen and hyperactive). Interestingly, among these miRNAs, which are deregulated in response to stress, miR-106a is predicted to inhibit HIF-1α expression. The miR-199a-5p, with observed down-regulation in restraint + shock mice, has been experimentally proven to inhibit HIF-1α expression [33]. In the study proposed here, we will build on these findings by employing the same PTSD mouse model, and

exposing animals to (b)(4) conditions in a chamber mimicking the (b)(4) environment.

In the proposed project, we will establish a genome wide list of targets affected by exposure to (b)(4) conditions alone and in combination with stress. We will perform bioinformatics functional pathway analysis to unravel signaling pathways involved and propose future treatment targets for PTSD. In the follow-up study, we plan to determine epigenetic markers altered in blood samples from PTSD USAF personnel post- and pre-deployment and compare them with the best hits from animal studies; and validate therapeutic options based on the outcome of these studies.

II.2.5. Results of Search:

Investigations of epigenetic modifications resulting in physiological adaptation to (b)(4) environments and their corresponding interactions with PTSD susceptibility have yet to be investigated. A search for (b)(4) and "epigenetics" in PubMed returned one article that is a perspectives paper suggesting that epigenetic studies would be valuable in assessing adaptation mechanisms. A search for (b)(4) and "PTSD" in PubMed also returned a single paper. This study investigated the use of (b)(4) exposure in desensitization therapies for flying phobias. Searching (b)(4) and "microRNA" returned two manuscripts that examined the impact of (b)(4) on cells grown in culture and variations in (b)(4) related transcription factors in the yak. Changing the search term (b)(4) returned a few additional papers with respect to PTSD. Both examined the potential anxyolytic effects of (b)(4) exposure in rats. Thus, no currently published research indicates a duplication of studies proposed in our experiments.

With respect to ongoing funded projects, examination of NIH RePORTER and the Department of Defense Biomedical Research Database revealed only a single study combining (b)(4) or (b)(4) conditions with epigenetic modifications. This study is investigating mechanisms contributing to vasculature blockage in patients with sickle cell disease. No funded research was found that examines the epigenetic changes induced by (b)(4) environments or its contributions to PTSD onset.

III. OBJECTIVE\HYPOTHESIS:

In the proposed project, we will establish a genome wide list of targets affected by exposure to (b)(4) conditions alone and in combination with stress. We will perform bioinformatics functional pathway analysis to unravel the signaling pathways involved and propose future treatment targets for PTSD. We propose the following Specific Aims:

Specific Aim 1 - Test the impact of differential time course of (b)(4) exposure on mouse behavioral phenotypes as well as hematological, pulmonary and central nervous system pathologies.

Specific Aim 2 - Determine genome-wide epigenetic profile in mouse brain, blood and lung tissues exposed to (b)(4) pressure/oxygen conditions.

Specific Aim 3 - Identify genome-wide epigenetic profile in brain, blood and lung tissues of PTSD mouse exposed to (b)(4) pressure/oxygen conditions.

IV. MILITARY RELEVANCE:

Understanding the interaction between a demanding environment and the dynamic human genome is one of the most challenging and pressing areas of military and clinical research that in the long run should help to alleviate the debilitating consequences of military activity resulting from interactions between harsh environment, demand for high achievement and enduring stress. Recent reports found increasing rates of PTSD among those serving in the harsh and stressful

environments of Iraq and Afghanistan [1]. The proposed project aims to determine epigenetic marks or novel regulatory pathways affected by (b)(4) environment and stress, which may further help to identify individuals at risk for PTSD, assess mental health readiness among those who remain active in service and also enable targeted treatment for a wide spectrum of PTSD cases.

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures:
FLOW CHART OF EXPERIMENTAL PROCEDURES:

V.1.1. Specific Aim 1

Experiment 1.1: Pilot experiment to assess proper chamber ventilation during (b)(4) exposure.

In all experiments covered by this protocol we will utilize the compact (b)(4) chamber developed by (b)(4) (b)(4) They have extensive experience in creating research level chambers designed for small animals such as mice that enable proper monitoring of animal health during experimental conditions. Our chamber will be used in combination with a pressure controlled purge system to mimic (b)(4) conditions. We are working closely with the company to ensure our chamber is capable of achieving our experimental goals while maintaining the most naturalistic living environment the mice (beyond those variables related to (b)(4) environments). The final design will be discussed with (b)(6) to ensure the safety and well-being of the mice and if required further modification of this protocol will be submitted.

The (b)(4) Research Chamber- Modified Vickers Special to be used will be supplied by (b)(4) and is equipped with the vacuum source. The chamber was originally built as a medical (b)(4) chamber for (b)(4) oxygen therapy by Vickers and has 23" inch inside diameter with an approximately 6'8" interior length. The overall length is about 7 feet. A removable full-length tray can be used to support 2-3 normal mouse cages within the chamber. The tray is designed to slide out onto a removable dolly. (The dolly is needed only if the tray is to be pulled out more than 1/3 of its length.) A control panel enables continuous ventilation at known controlled rates with system panel to monitor pressure and temperature inside the chamber. Within the chamber we will maintain the (b)(4) using constant volume fraction air removal by the vacuum pump. We will maintain the constant air flow to maintain the adequate ventilation. The system is able to provide ventilation upto 300 l/min if necessary (usually 240 l/min for human exposure). We will monitor the build-up of condensation-moisture and during these preliminary experiments we will also monitor CO2 levels. Based on the experience of the renowned expert in pulmonary rodent physiology our consultant/collaborator Dr. (b)(6) (b)(6) we estimate that 15 mice will produce 1700 ml per hour of CO2, which should be easily compensated by appropriate ventilation flow.

Upper limit of CO2 production rate: 0.075 ml/g per minute or 4.5 ml/g per hour [42]. Thus, for 15 mice weighing 25g each, a high estimation for the rate of CO2 production will be: (15 mice) x (30g/mouse) x (4.5ml/g per hour) = 1700 ml per hour. During the active dark cycle oxygen consumption in C57Bl6 mice is 160 (ml/kg per min) (PMID: 22653990) [43]. This equals 9.6 ml/g per hour or approximately twice the rate of CO2 production. Thus, based on high

activity consumption rates, adequate ventilation can be achieved with an exchange rate of 4 liters per hour.

The pilot experiment will have 2 phases (short 15 min and 3 hour duration). During the first 15 min two mice will be exposed to (b)(4) psia pressure respectively and MouseOx Pulse Oximeter/Physiological Hub (Starr Life Sciences, Oakmont, PA) will be used to record non-invasively vital signs (arterial oxygen saturation, heart and breath frequencies (f_h & f_b), and motion status) periodically throughout the duration of the experiment. Mice vitals will be monitored continuously for 15 min at the normal pressure (baseline), during ascent and at the designated pressure and then during descent (the rate of ascent and descent to reach specified simulated (b)(4) condition will be performed at a rate of 200m/min, and for 1500 m this will take ~8 min and for 5000m this will take ~25 min respectively). After reaching normal pressure we will continue monitoring vitals for another 15 min. Based on previous experience of experts in pressurized chamber physiology CAPT (b)(6) (b)(6) Walter Reed National Military Medical Center Pulmonary/Critical Care Medicine, Silver Spring) and Dr. (b)(6) (Duke University) we do not expect any problems with mouse physiological processes during these experiments. We also do not expect bigger than 1% changes in CO2 level during these experiments. In order to minimize potential gasses build up over time conventional cages with the filter covers removed will be used. NH4 levels will be monitored inside the chamber using portable NH4 monitor and then indicator paper positioned inside the cage will be used immediately before cage changes during the longer than 24 hours exposure time. This cage level monitoring will continue throughout the duration of the project if the buildup is significant, otherwise it will be terminated after pilot experiments, and after approval from the veterinarian.

In the second phase of pilot experiment we will verified the accuracy of calculated ventilation flow with 3 cages (5 mice per cage) in the chamber, when the mice will be visually monitored constantly by (b)(6) for 3 hours under (b)(4) psia pressures respectively.

Once in the chamber mice will be monitored for sign of distress (such as hyper or hypoactivity, inner ear discomfort indicated by excessive grooming or scratching, vocalizations, self-trauma, unkempt appearance, respiratory distress, reduced food and water intake, head tilting or shaking) and we will consult with Veterinarian staff if any sign of abnormal behavior is noted. If abnormal breathing is noted mice will be descended to normoxic pressure. The chamber is transparent and therefore monitoring will be easy to achieve. As in the 15 min exposure experiments we also do not expect any problems with mice behavior, accumulation of moisture and CO2 level during these 3-hour exposure experiments.

The final design of the Reimers Systems modified chamber will be discussed with Dr. (b)(6) and the Veterinarian staff and if required modification of this protocol will be submitted for IACUC approval.

This experiment uses a total of 15 mice. Two mice will be exposed for 15 minutes to each pressure (normoxic, (b)(4) psi) every 24 hours therefore we can monitor well-being of mice the day of exposure and the day afterwards. Then same mice plus the thirteen will be exposed for three hours at three pressures every 24 hours so we can monitor well-being of mice the day of exposure and the day afterwards.

In summary, we will wait at least 24 hours between exposures and will not re-expose mice who display the symptoms of distress outlined in section V.4.5. Study Endpoint.

Total mice number will be 15 and mice will be used in these pilot experiments. There will be at least 2 one day interval between different exposure pressures.

Experiment 1.2: Impact of (b)(4) exposure on mouse behavioral motor phenotypes as well as hematological, pulmonary and central nervous system pathologies.

In these experiments we will implement the (b)(4) chamber with parameters determined in the pilot experiments (Exp.1.1). C57BL/6J (B6) mice will be exposed to simulated atmospheric pressure of (b)(4) psia corresponding to (b)(4) sea level. Atmospheric pressure of (b)(4) psia (equivalent to sea level) will be applied as normobaric normoxic environment. The rate of ascent and descent to reach specified simulated altitude and sea level condition will be performed at a rate of 200m/min. Mice will be exposed to (b)(4) for 3 hrs, 6 hrs, 24 hrs, 1 week and three weeks. 15 mice per group each for three diverse pressure levels and 5 different exposure periods will be used. Total mice number will be 15x 3 pressure levels (b)(4) (b)(4) x 5 exposure periods (3 hrs, 6 hrs, 24 hrs, 1 week and 3 weeks) = 225 total mice.

Behavioral impact of (b)(4) conditions will be determined using the rotarod performance test, where the mouse will be placed on a rotating cylindrical rod and subjected to forced motor activity. The time period for which the given mouse stays on this rotating rod is a measure of its balance, coordination, physical condition, and motor-planning. The limited supply of oxygen at (b)(4) could result in a potential loss of coordination and balance.

For rotarod performance test, baseline line values will he recorded 24 hrs prior to the (b)(4) (b)(4) exposure and final test values will be measured immediately at the end of exposure at normoxic pressure.

Brain, blood and lung tissues collected from the mice after (b)(4) exposure for different time points, will be processed using standard histopathological, hematological and immunohistological techniques to determine the pathological effects of (b)(4) environment as compared to sea level in coordination with the AFRI veterinarian pathologist, Dr. (b)(6) MAJ, U.S. Army Veterinary Corps. Particular attention will be paid to histological signs of pulmonary edema (see our recent study [28]), pulmonary fibrosis, hemopoietic abnormalities, morphological changes in carotid body and brain vasculature in order to identify the underlying pathological effects of low-pressure. If necessary our long-term collaborator Dr (b)(6) will be consulted for the outcome of behavioral studies.

Time period of exposure that showed the most significant alterations (in terms of behavioral, pathological and hematological) in response to (b)(6) conditions during the minimal time will he then used in Specific Aim 2. We expect that 1 week of exposure will be a sufficient time period.

Organ and blood isolation: Mice male (8-10 week old) will be anesthetized. Under anesthesia mice will be cervically dislocated, decapitated with scissors and then the brain and lung will be removed and then fixed with 4% of paraformaldebyde (10 mice for each group). For hematological evaluation the blood will be removed from tail or if required for more extensive hematological analysis using cardiac puncture.

Justification and rational for mice number see above.

V.1.2. Specific Aim 2

Experiment 2.1: Genome-wide epigenetic profile in mouse brain, blood and lung tissues exposed to (b)(4) conditions.

C57BL/6J (B6) and Balb/cJ (Balb) male mice will be exposed to (b)(4) psia corresponding to (b)(4) or normobaric normoxia for a time period that showed the most significant alterations (in terms of behavioral, pathological and hematological) in response to (b)(4) conditions, as evaluated in Specific Aim 1. We will use 80 mice per strain each for 2 different pressure levels (b)(4). Total # mice will be 2 strains x 2 conditions x 80 = 320 mice

We selected these two inbred strains as previous comparative studies show their large differential susceptibility to (b)(4) and environmental challenges [35, 36]. Specifically, ventilatory response to acute (b)(4) challenge is significantly greater in Balb compared with B6 mice due to a greater increase in (b)(4) breath frequency (fb) [35] and changes in lung structures between these strains [36]. In addition, B6 mice show a greater exercise tolerance in (b)(4) compared to Balb mice, suggesting that mechanisms of altitude adaptation favored acclimation in B6 mice [37]. In collaboration with our consultant/collaborator Dr. (b)(6) total body plethysmography will be performed to measure breathing tidal volume (VT) and inspiratory time (T_I) in mice [35]. Minute ventilation (VE)= f_b*VT, and mean inspiratory flow (VT/TI) as a surrogate of neural activity in breathing regulation will be calculated. Metabolic data will also be measured by assessing O_2 consumption (VO_2) and CO_2 production (VCO_2) using indirect open circuit calorimetric system (provided by Dr (b)(6) in-line with the barometric chambers. Reference gas measurements will be obtained intermittently to correct for sensor drift, and VO_2 and VCO_2 data will be normalized to standard temperature and pressure conditions, and to the body weight of each animal. The baseline VE will be referenced to VO_2 and VCO_2 to assess the coupling between ventilation and metabolic rate. Increased VE/VO_2 indicates greater ventilation for a given level on O_2 delivery, suggesting that gas exchange in the lung is impaired. Total body plethysmography will be performed before mice enter the (b)(4) chamber, and then immediately after exposure period. Animals will be placed in the plethysmography chamber (17cm x 6cm x 6cm; ~600 cm^3) situated close to (b)(4) chamber and will be allowed to acclimate to the chamber (exploration, and self-grooming is expected) for at least 30 min and only after the animal became quiescent the breathing frequency, tidal volume, and inspiratory time will be recorded. The total recording time in chamber is not expected to exceed 30 min and then animals will be weighed afterwards.

Behavioral phenotyping will be done using the rotarod test as specified in Specific Aim 1 at 24 hours before the beginning of exposure and then immediately after total body plethysmography.

Tissue collection:
Tissue samples will be collected from each group of mice. Briefly, mice will be anesthetized with isoflurane placed in a transparent desiccator jar under a perforated floor in order to separate the mouse from the isoflurane. This will be done in a fume hood present in our lab (b)(6)

(b)(6) Once the mouse is adequately anesthetized, demonstrated by lack of the pedal withdrawal reflex, the live mouse will be removed from the desiccator jar. Alternatively, IP injection of anesthetic will be administrated with 25 - 30 gauge needles in the caudal abdomen with sodium pentobarbital 50 mg/kg (1.5 mg per 30 g mouse) (or, if sodium pentobarbital creates interference with signaling pathways, a mixture of ketamine 100mg/kg and xylazine 20mg/kg will be used) before perfusion. The level of anesthesia will be assessed by toe pinching. Following anesthesia, the mouse chest will be cut open with scissors to expose the beating heart and then perfused through the left ventricle of the heart with heparinized phospbate-buffered saline (10% v/v) for 5 min. Once perfusion is complete, tissues will be dissected out. Tissue samples will be immediately fixed in 10% formalin and would be handed over to AFFRI, veterinary pathologist (10 mice for each group).

The tissue samples from the remaining 60 animals from each group will be collected to perform epigenetic studies. We will quantify histone H3/H4 acetylation and histone H3-Serine10 phosphorylation or other relevant epigenetic targets by quantitative Western blot, chromatin immunoprecipitation (ChIP) assays or genome-wide ChIP-sequencing. Quantitative real time PCR will be used to verify significant findings of high-throughput approach. We will also measure methylation differences by RRBS and changes in miRNA profiles in response to (b)(4) exposure. The brain (cortex, hippocampus), blood and lung tissues will be collected from these mice will be utilized to perform whole genome epigenetic profiling. Histone modifications will be determined through chromatin immunoprecipitation assays (ChIP-Seq) [38] using anti-acetyl histone H3, anti trimethyl histone H3K4, anti trimethyl histone H3K27, anti acetyl histone H3K18 and normal rabbit IgG antibodies. Genome-wide DNA methylation will be determined using reduced representation bisulphite sequencing (RRBS-Seq) approach, a bisulfite-based protocol that enriches CG-rich parts of the genome particularly the gene promoters [39]. For hematological evaluation 10 mice in each group the blood will be removed using cardiac puncture. Whole-genome profiling for miRNA (miRNA-Seq) and mRNA (RNA-Seq) will be performed with RNA isolated from brain, blood and lung tissues. Bioinformatics pipelines to statistically analyze these results have already been developed in (b)(6) Top hits from chromatin/expression and methylation profiling will be validated using quantitative real-time PCR/RTPCR and pyrosequencing respectively.

We plan to establish genome wide list of targets affected by exposure to (b)(4) conditions that are epigenetic biomarkers for (b)(4) condition,

Mice total per group per strain= 80 = 10 for pathology evaluation + 60 for CNS and lung epigenetic evaluation and 10 for blood epigenetic evaluation.

We have 2 pressure groups (sea level + 5000m) and 2 strains = total 320 mice

V.1.3. Specific Aim 3

Experiment 3.1 - Identify genome-wide epigenetic profile in brain, blood and lung tissues of PTSD mouse exposed to (b)(4) pressure/oxygen conditions.

To generate the PTSD mouse model, we will expose C57BL mice to 2 stress levels: 3 hours of restraint stress plus intermittent tail shock (severe stress), 3 hours of restraint stress (lower level stress), and naïve-control (putatively unstressed) (for details of stress protocol see below). This will be carried out before exposure of mice to the (b)(4) conditions (b)(4) corresponding to (b)(4) or normobaric normoxia. The period of (b)(4) exposure post stress will be same as specified in Specific Aim 1. We will use 60 mice for each three different levels of stress and two diverse pressure values (b)(4) (total number is = 60x 3x 2= 360 mice). Acoustic startle (ASR) and fear conditioning behavioral tests will be performed with

PTSD mice exposed to stress before and immediately after exposure to (b)(4) or normobaric condition. ASR system consists of weight-sensitive platform inside sound-attenuated chamber, where mouse movements in response to stimuli (sound) are measured as a voltage change by a strain gauge. ASR baseline line values will be recorded 24 hrs prior to the (b)(4) exposure and final test values will be measured immediately at the end of exposure. Brain (cortex, hippocampus), blood and lung tissues dissected from the PTSD and naïve control mice exposed to (b)(4) or normobaric conditions will be utilized to perform whole genome epigenetic profiling (ChIP-Seq, RRBS-Seq, miRNA-Seq) and RNA-Seq similar to Specific Aim 2. Comprehensive blood analysis and pathological assessment of each PTSD mouse model subjected to (b)(4) conditions will also be performed. Top hits from chromatin/expression and methylation profiling will be validated using quantitative real-time PCR/RTPCR and pyrosequencing respectively. In addition, top hits will be also verified in amygdala, a brain region implicated in response to (b)(4) and stress. Whole genome approach cannot be applied to RNA/DNA extracted from amygdala because of its relative small size and therefore a small yield of RNA/DNA. In general we plan to establish comprehensive genome wide list of targets affected by exposure to (b)(4) conditions alone and in combination with stress that are epigenetic biomarkers for stress under (b)(4) environment
This should help us to unravel signaling pathways involved and propose future treatment targets for PTSD.

Stress protocol in the mice and perform acoustic startle response (ASR) testing in order to determine the impact of the stressing procedures on behavioral phenotype.

Stress model:

Male mice 5-6 week old will be exposed to immobilization and tail shocked for 2 h per day for 3 consecutive days. This procedure will be done during the dark phase of the light–dark cycle (adapted for mice from [54]. Mice will be restrained but wrapped in a cloth jacket and immobilized in a ventilated plexiglass tube to avoid increase in the intrinsic temperature of mouse. In addition the room where the stress will be applied will be well ventilated. (b)(4) electric shocks (b)(4) GrassS88 stimulator, [59]) will be delivered to their tails at semi-random intervals of 150 to 210 s. This stress protocol is based on the helplessness paradigm in which animals undertake an aversive experience without possible adaptive response ([56,57], see [54]). The duration of stress is based on previous demonstrations that repeated stress sessions for 3 days are more effective than a single stress session in producing lasting physiological and behavioral abnormalities, such as elevations in basal plasma corticosterone levels, exaggerated acoustic startle responses and reduced body weight [55,59]. Stress sessions lasting beyond 3 days do not appear to produce greater physiological and/or behavioral changes [55,59]. The weight of mice will be monitored for stressed and control groups.

ASR testing will be conducted with a Startle Response Acoustic Test System (Coulbourn Instruments, PA). The system is computer-based and all stimulus parameters are specified by entries in Windows based software with protocols saved to disk files. The audio source module placed above the test cage is used to provide acoustic stimuli. The software allows the use of either stimulus type (tone or noise). For tone stimuli, amplitude, frequency and duration, and for white noise stimulus duration of noise bursts is computer controlled.

Two days before the stress protocol mice will be placed in ACS chamber with no sound applied for 15 min in order to acclimate them to the equipment. Then one day before exposure to

stress protocol, mice will be placed on the weight-sensitive platform in a sound-attenuated chamber and after chamber lid is closed, mouse will be left in darkness for 3-5 min adaptation period (without startle stimuli). Then startle stimuli will be applied (100 &110 dB) as a noise bursts of 20 ms duration, preceded or not by 100-150 ms pre-pulse with 68 dB intensity. Sound intensities will be verified by a sound meter. Six types of stimulus will be applied: 100 &110 dB alone, with pre-pulse, pre-pulse alone and no stimulus. Each trial type will be presented eight times. Trial types will be presented in random order to avoid order effects and habituation. Inter-trial intervals range randomly from 15 to 25 s. The mice movements in response to stimuli will be measured as a voltage change inside platform and then will be converted to grams of body weight change after analog-digital conversion. These changes will be recorded as the maximum response occurring within 100-200 ms of the onset of the startle-eliciting stimulus. All acoustic stimuli will be administered by an amplified speaker placed above the test cage. Mice will spend not more than 15 minutes in the chamber. The chamber used to ASR experiments will be sanitized with soap, water and then alcohol after each animal.

All animals will be tested 1 day following the final day of the stress procedure and then the same day after the results will be compared to reaction that startle stimuli evoked before exposure to stress. During an experimental session, the software displays both numeric and response waveform data. A post-hoc viewer is included for critical examination trial-by-trial response data.

Rational for number of mice

This proposal constitutes our initial award on exposure to (b)(4) conditions therefore limited or no preliminary data are available. Based on our experience in areas hippocampal signaling pathways and electrophysiology, and our previous and then published results on stress by Dr. (b)(6) and on brain microRNA [46,47] we used following criteria to estimate group size.

The tissue samples from the remaining x animals from each group will be collected to perform epigenetic studies as mentioned in our previously approved protocols. We will quantify histone H3/H4 acetylation and histone H3-Serine10 phosphorylation or other relevant epigenetic targets by quantitative Western blot, chromatin immunoprecipitation (ChIP) assays or genome-wide CHIP-sequencing. Quantitative real time PCR will be used to verify significant findings of high-throughput approach. We will also measure methylation differences in response to exposure to (b)(4) conditions. The animal number is determined by the requirement to provide sufficient amount of tissue required for *in-vitro* analysis (ChIP experiment required many animals due to small sample amount obtained per animals). The group size is based on results of previous experiments, published literature and an effect size and power analysis calculation previously performed [41].

The data generated from the above experiments will be analyzed by ANOVA and differences with $P< 0.05$ will be considered statistically significant. All data will be subjected to statistical analysis to determine significant differences between control and various metal treated tissues. For direct comparison of 2 samples, students T-test will be used. For quantitative analysis of Western blots, optical intensity of bands will be evaluated with MultiGuage. Gel loading variation will be normalized with total H2A. Unpaired T-test will be used to detect changes in histone modifications in metal exposed tissues as compared to controls. If there are any queries about the statistics and data used, then Dr (b)(6) (biostatistician) will be consulted.

V.1.4. Table

Expt	Treatment	Organs and blood	Analysis	Number
1	(b)(4) chamber	Lung,CNS, blood	Pathological evaluation, motor test (rotarod)	15
2	chamber	Lung,CNS, blood	Pathological evaluation, motor test (rotarod)	225
3a	chamber C57BL	Lung, CNS, blood	ChIPSeq, RNA-Seq,mi-RNA profiling, RRBS, motor test (rotarod), total body plethysmography	160
3b	(b)(4) chamber Balb/cJ	Lung, CNS, blood	ChIPSeq, RNA-Seq,mi-RNA profiling, RRBS, motor test (rotarod), total body plethysmography,	160
4	Sham/Stressed C57BL	Hippocampus & Cortex	acoustic startle response ChIPSeq, RNA-Seq, mi-RNA profiling, RRBS, motor test (rotarod),	360
			Total	920

V.2. Data Analysis:

For quantitative analysis of Western blot, image analysis will be performed [60]. Data will be compared across sham and/or stressed mice. All data will be subjected to statistical analysis to determine significant differences between various treatments for stressed and sham mice. For direct comparison of 2 samples, Student's T-test will be used. If several parameters are being compared then ANOVA will be run. The significance will be determined at a probability level of $P < 0.05$. If there are any queries about the statistics and data used, then Dr. (b)(6) (biostatistician) will be consulted.

For behavioral experiments, 15 animals per group are sufficient to detect a difference of 1.1 standard deviations between groups with 80% power, based on a 2-group t test with a 5%, two-sided significance level. Previous behavioral studies with similar outcomes have observed differences in this range [30].

We will assess differences between different groups of mice in several different parameters.

The software program a statistical package Sigma Stat from Jandel Scientific and GraphPadInStat from GraphPad will be used for statistical analysis. Significance will be defined as $P < 0.05$.

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered:

The physiological effects of stress (PTSD) are best understood in the context of the whole organ. Cell lines do not provide a good model for PTSD because neuronal/glia and neuron/neuron connectivity has undergone extensive rearrangement during the stress. Computer models are not a viable alternative since the complexity of CNS can be model only at the levels of small neuronal networks with simplified electrophysiological characteristics and without taken into account metabolic and signaling pathways. Tissue culture cannot model stress responses that are related to complex interactions of sensory and motor systems. Cell and tissue cultures with permanently transfected receptors were considered, but these systems lack the complex cellular interactions and physiologic responses found in whole organisms and needed to answer our experimental questions.

We have not come across any other non-animal alternatives that would mirror complexity of the whole animals and could model expression of mRNAs, micro-RNAs, epigenetic modification of respective promoter networks and its subtle interactions with neuronal networks, neuronal channel and receptors and signaling pathways.

V.3.2. Animal Model and Species Justification:

Mice have been successfully used to model complex human neurological pathology and genetic conditions (for comprehensive review see book by Crawley, What's wrong with my mouse?; 2nd edition, publisher John Wiley and Sons 2007). We also considered rats as an alternative model, which Drs (b)(6) used in their study of PTSD, however the potential of obtaining knockout or transgenic mice in the future targeting molecules involved in synaptic plasticity was a decisive factor in selection of mouse vs. rat. Our laboratory has extensive experience with murine models. (b)(4) (b)(4) In addition extensive comparative data are available for studies of C57Bl mouse (see e.g. Crawley 2007 pages 19-29 and 188-191, www.jax.org). In order to avoid a potential confounding effect of estrous cycle male mice will be used. In the future studies females will be used for more complete evaluation.

V.3.3. Laboratory Animals

	Species #1	Species #2
V.3.3.1. Genus & Species:	Mus musculus	Mus musculus
V.3.3.2. Strain/Stock:	C57Bl	Balb/cJ (Balb)
V.3.3.3. Source/Vendor:	(b)(4)	

V.3.3.4.	**Age:**	4-6 weeks	4-6 weeks
V.3.3.5.	**Weight:**	20-40 g	20-40 g
V.3.3.6.	**Sex:**	Males	Males
V.3.3.7.	**Special Considerations:**	N/A	

V.3.4. Number of Animals Required (by Species):
Total 160 Balb/cJ and 760 C57Bl mice will be used under this protocol see Table in V.1.4 for details.

V.3.5. Refinement, Reduction, Replacement (3 Rs):

V.3.5.1. Refinement: Novel tailshock delivery device incorporating coiled wire electrodes embedded in soft agar and affixed with flexible parafilm wrap will be employed (following suggestions of Dr. (b)(6) [54]). This would allow us to avoid the traditional "alligator clip" and reduce injury to animal with increasing efficacy of shocks delivered.

Mice may display different behaviors to indicate pain or distress. These include hyper- or hypoactivity, inner ear discomfort indicated by excessive grooming or scratching, vocalizations, self-trauma, unkempt appearance, respiratory distress, reduced food and water intake, head tilting or shaking. No distress is expected beyond the temporary discomfort during the tail shock and restraint periods (PTSD model). Mice that display distress behaviors that induce overt injuries (self-mutilation or aggression injury) will be euthanized. Mice that signs of respiratory distress will be monitored until symptoms improve or euthanized after 8 hours if distress persists. Mice with unkempt appearance or abnormal activity levels (including head tilting or shaking) will be referred to veterinary staff for assessment if the condition persists for more than 8 hours. When possible, treatment options will be pursued before euthanization.

V.3.5.2. Reduction: If possible, tissue from each mouse will be used in more than one Western Blot/mi-RNA profiling, qPCR test thereby reducing the overall number of animals required. In order to optimize RNA/ChIP(DNA) yield different brain regions (like cortex) will be considered in testing. Statistical tests will be constantly applied to the data generated, to ensure that the minimal number of animals necessary to obtain significant data is used. No other reduction alternatives were considered.

V.3.5.3. Replacement:

V.4. Technical Methods:

V.4.1. Pain / Distress Assessment:

V.4.1.1. APHIS Form 7023 Information:

V.4.1.1.1. Number of Animals:

	Species #1	Species #2
V.4.1.1.1.1. **Column C**:	520	160
V.4.1.1.1.2. **Column D**:	0	
V.4.1.1.1.3. **Column E**:	240	

V.4.1.2. Pain Relief / Prevention:

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization: Mice will be anesthetized with isoflurane before euthanasia using the drop method in a transparent bell chamber. Once the mouse is adequately anesthetized, demonstrated by lack of the pedal withdrawal reflex, the live mouse will be removed from the desiccator and cervically dislocated. Although isoflurane is our preferred method of anesthesia, it has been noted that isoflurane may influence the quality of neuronal survival in acute slices. Therefore if micro-RNA yield is affected we will anesthetize mice by IP injection of anesthetic administrated with 22-25 gauge needles in the caudal abdomen with sodium pentobarbital 50 mg/kg (1.5 mg per 30 g mouse) (or if sodium pentobarbital creates interference with signaling pathways mixture of ketamine 100mg/kg/ and xylazine 20mg/kg or other anesthetics recommended by Veterinarian will be used). This procedure will be performed by Drs (b)(4) (or personnel trained and supervised by them) and the level of anesthesia will be assessed by toe pinching.

Mice will be anesthetized prior to transcardial perfusion or brain removal by one of the following methods: overdose of isoflurane anesthesia in a "open drop" bell jar with a perforated floor to separate the mouse from the liquid anesthetic or 4% isoflurane/pure oxygen in an induction chamber; IP injection of sodium pentobarbital 50 mg/kg (1.5 mg per 30 g mouse); or a mixture of ketamine 100mg/kg and xylazine 20mg/kg. IP injections will be administered with 25 to 30 gauge needles and in a volume less than 0.5 cc. This procedure will be performed by Drs. (b)(4) (or personnel trained and supervised by him) and the level of anesthesia will be assessed by toe pinching (lack of a pedal withdrawal reflex). For *in vivo* experiments, mice will remain anesthetized with either isoflurane, or ketamine/xylazine throughout the recording session. Anesthesia will be supplemented as needed to maintain unresponsiveness to noxious stimuli (toe pinch to check pedal withdrawal reflex). Mice will be euthanized by anesthetic overdose at the end of the experiment (in the case of isoflurane, 4% in oxygen will be administered until breathing ceases) followed by cervical dislocation.

Although we do not anticipate any more than momentary pain or distress from any of the procedures, topical anesthetics will be applied to the tips of tails after tissue sampling if the animal appears to be in pain. A topical anesthetic spray (such as ethyl chloride spray) will be applied to the tail tip, followed by a small amount of EMLA anesthetic cream applied to the distal end of the tail. This will be repeated if the mice continue to exhibit signs of discomfort.

For general inhalation anesthesia during recovery procedures (blood spotting), oxygen will be mixed with isoflurane delivered via precision vaporizer using a rodent anesthesia machine. Mice will be placed in an induction chamber and exposed to a mixture of O2 and isoflurane (2-4%) to induce general anesthesia. Following induction, mice will be removed from the chamber and maintained on 0.25-2% isoflurane administered by nose cone. We will monitor the depth of anesthesia by noting response to toe pinch (pedal withdrawal reflex), mucus membrane color, and rate and quality of respirations. Tail snip procedures will begin once there is no pedal reflex.

Waste anesthetic gases will be actively scavenged through the central vacuum system or passively scavenged using a charcoal canister.

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions: Pre-stress Provision: We will identify the mice that will be used in our stress protocol and we will request LAM staff for additional information with regard to their behavior and appearance (e.g. skin lesions and external pathological changes). Mice that exhibit any sign of excessive aggressive behavior or any visible pathological changes will be excluded from studies. Mice will be handled and exposed to behavioral equipment for few minutes one day prior to experiments to minimize any stress effects that might result from routine handling during the behavioral testing and novel environment stress effects.

Post-stress Provision: After stress procedure,, mice will be clearly identified and LAM personnel will be notified and arrangements made so that stressed mice will be checked at least twice a day by LAM personnel and lab personnel to observe signs of excessive pain and severe distress. These signs include self-mutilation, gnawing at limbs, abnormal breathing, unkempt appearance, self-imposed isolation, abnormal posture, muscle rigidity or lack of muscle tone, and twitching/trembling/tremor. Mice that loose weight 20% and show signs of excessive distress will be removed from the study and euthanized. While inside the (b)(4) chamber where weight measurements are not possible, we will use the body condition scoring technique described Ullman-Culleré and Foltz (Body Condition Scoring: A Rapid and Accurate Method for Assessing Health Status in Mice, (1999) *LAS 49(3)319-23*). We will consult veterinary staff for mice with a body condition score of 2+ for treatment.

Based on our literature search results, isoflurane, and ketamine/xylazine are commonly used anesthesia agents in *in vivo* recordings and are capable of maintaining adequate levels of anesthesia. Transcardial perfusions following anesthetic overdose are also commonly performed to efficiently remove blood from tissue and quickly fix the tissue when perfused with formaldehyde. The anesthetic overdose ensures that the animal experiences no discomfort. Microwave fixation is not appropriate for our needs as blood left in the tissue can skew analysis of biochemical pathways.

V.4.1.2.3. Paralytics: None

V.4.1.2.3. Paralytics: None

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures:

Source	Keywords	PubMed
PubMed	Non-painful PTSD model	0
	"in vitro" model PTSD	2
	"in vitro" animal model PTSD	0
	Mouse odorant stress	9

	Mouse odor stressor	20
	Non-painful acoustic startle	1
	Non-painful electric shock	5
	Mouse anesthesia	3954
	Mouse ketamine xylazine	164
	Mouse isoflurane	656
	Mouse euthanasia	301
	Mouse humane euthanasia	19
	Mouse transcardial perfusion	14
	Mouse fixation	5217
	Mouse microwave fixation	69
	Mouse paraformaldehyde	815

A search for *in vitro* models of PTSD returned only two results, one of which examined the effect of cancer diagnosis on PTSD-like symptoms in humans and the second was a review that cited the first article. Several studies have successfully used odorants, often based on odors associated with predators, to induce stress responses in mice. Currently, no *in vitro* models of PTSD are available. Computer modeling of PTSD is also currently not feasible since the biological mechanisms leading to this condition are not sufficiently understood. Searches for alternatives to animal models on the USDA's Animal Welfare Information Center (awic.nal.usda.gov) and the Johns Hopkins Bloomberg School of Public Health (altweb.jhsph.edu) did not identify any viable alternatives to using mice in these studies.
Anesthesia in mice is frequently induced with a mix of ketamine and xylazine or isoflurane. Both approaches provide sufficient levels of anesthesia for prolonged surgical procedures beyond the timeframes needed for our own experiments. Microwave fixation following anesthetization is not appropriate for our studies as blood removal prior to fixation is required. Anesthetic overdose followed by transcardial perfusion of physiological saline and paraformaldehyde is a widely used method of fixation.

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures:

V.4.1.3.1. Sources Searched: PubMed, USDA Animal Welfare Information Center, and Johns Hopkins Bloomberg School of Public Health site for alternatives to animal models.

V.4.1.3.2. Date of Search: July 6

V.4.1.3.3. Period of Search: All

V.4.1.3.4. Key Words of Search:

PubMed Search **Non-painful PTSD model**	0
PubMed Search **in vitro model PTSD**	2
PubMed Search **in vitro animal model PTSD**	0
PubMed Search **Non-painful acoustic startle**	1
PubMed Search **"Non painful" acoustic startle**	1
	19

PubMed Search **Non-painful "electric shock"** 1
PubMed Search **"Non painful" "electric shock"** 4

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification:

The proposed model of PTSD is based on the helplessness paradigm in which animals undertake an aversive experience without possible adaptive response [54,56,57]. The duration of stress is based on previous demonstrations that repeated stress sessions for 3 days are more effective than a single stress session in producing lasting physiological and behavioral abnormalities, such as elevations in basal plasma corticosterone levels, exaggerated acoustic startle responses and reduced body weight [55,59] and stress sessions, beyond the 3 days, do not appear to produce greater physiological and/or behavioral changes [55,59]. A similar stress model was also applied to mice [64]. These protocols do not produce any damage to the tail tissue. If such unlikely event occurs, this mouse would be removed from the studies, anesthetic or analgesic would be applied to alleviate momentary pain and then mice would be euthanized. The model of PTSD based on a learned helplessness paradigm requires exposure of the animal to unalleviated distress through the administration of restraint and tail-shock.

Study endpoint is survival for 4 weeks post-stress and subsequent behavioral testing. Mice will be euthanized by lab personnel or LAM personnel. Any mice that lose 20% weight (mice will be weigh only outside the pressure chamber and it will be done once a week or more often if recommended by Veterinarian staff) or show three or more following signs of excessive distress that include abnormal breathing, unkempt appearance, self-imposed isolation, abnormal posture, muscle rigidity, lack of muscle tone, and twitching/trembling/tremor, will be removed from the study and euthanized by lab or LAM personnel within 8 h of signs of excessive distress appearing. While inside the (b)(4) chamber where weight measurements are not possible, we will use the body condition scoring technique described Ullman-Culleré and Foltz (Body Condition Scoring: A Rapid and Accurate Method for Assessing Health Status in Mice, (1999) *LAS 49(3)319-23*). We will consult veterinary staff for mice with a body condition score of 2+ for treatment.

No analgesia will be applied since this would compromise the goal of this study because of the potential interference with mice behavior status and plasticity of the brain [50,51,52].

V.4.2. Prolonged Restraint:

No restraint in excess of three hours will be applied during this study. The total time mice will be restraint consists of no more than five minutes prior and post stressed whilst restrained for a 2-h (total restraint time= 5 min prior + 2 hour of restraint and tailshock + 5 min post = 130 min). The immobilization and tail-shocks will be applied during the dark phase of the light-dark cycle. Animals will be restrained in a cloth jacket with their head and torso immobilized in a ventilated plexiglass tube. The duration of stress is effective at producing lasting physiological and behavioral abnormalities. One month after stress, mice will be euthanized and the amygdala and hippocampus excised and frozen.

V.4.3. Surgery:

V.4.3.1. Pre-surgical Provisions: N/A

V.4.3.2. Procedure: N/A

V.4.3.3. Post-surgical Provisions: N/A

V.4.3.4. Location: N/A

V.4.3.5. Surgeon: N/A

V.4.3.6. Multiple Major Survival Operative Procedures: N/A

V.4.3.6.1. Procedures: N/A

V.4.3.6.2. Scientific Justification: N/A

V.4.4. Animal Manipulations:

V.4.4.1. Injections: IP injection of anesthetic will be administrated with 25 – 30 gauge needles in the caudal abdomen before perfusion with sodium pentobarbital 50 mg/kg IP (1.5 mg per 30 g mouse). If sodium pentobarbital creates interference with signaling pathways, a mixture of ketamine 100mg/kg and xylazine 20mg/kg IP will be used.

V.4.4.2. Biosamples:

Except blood No tissue will be collected when animals are still alive. Tissue (brain) will be collected after death. Brain will be dissected from mice after euthanasia.

Blood collection and platelet preparation

We will follow an established procedure described e.g. [65,66]. Mice will be anesthetized with a mixture of ketamine and xylazine (100 mg/kg ketamine and 20 mg/kg xylazine), or sodium pentobarbital (50 mg/kg) administered intraperitoneally. Blood will be collected into citrated syringes from the vena cava or by cardiac puncture. These are terminal procedures performed with a large gauge needle and we will collect as much blood as we can recover from each animal.

Red blood cells will be removed by centrifugation and platelet-rich plasma will be recovered and subsequently platelets will be pelleted by second centrifugation. Half of the platelets will be resuspended in modified Tyrode's buffer and then platelet aggregation characteristics will be determined turbidimetrically as described [66].

V.4.4.3. Adjuvants: N/A

V.4.4.4. Monoclonal Antibody (MAbs) Production: N/A

V.4.4.5. Animal Identification: Ear tag, tattoo and cage cards.

V.4.4.6. Behavioral Studies: Male mice 5-6 week old will be exposed to immobilization and tail shocked for 2 h per day for 3 consecutive days. This procedure will be done during the dark or active phase of the light–dark cycle (adapted for mice from (b)(6) (b)(6) Mice will be restrained but wrapped in a cloth jacket and immobilized in a ventilated plexiglass tube. (b)(4) electric shocks (b)(4) Animal Test Cage Grid Floor Shocker, Coulbourn Instruments, USA, [59]) will be delivered to their tails at semi-random intervals of 150 to 210 s (Graphic State Notation software, Habitest Universal Link, Coulbourn Instruments, USA). This stress protocol is based on the helplessness paradigm in which animals undertake an aversive experience without possible adaptive response [54, 56, 57]. The duration of stress will be based on previous demonstrations that repeated stress sessions for 3 days are more effective than a single stress session in producing lasting physiological and behavioral abnormalities, such as elevations in basal plasma corticosterone levels, exaggerated acoustic startle responses and reduced body weight [55,59] and stress sessions, beyond the 3 days, do not appear to produce greater physiological and/or behavioral changes [55,59]. The efficiency of the stress will be tested using behavioral testing known as acoustic startle response (ASR). After stress animals will be assessed by an heightened acoustic startle and weight loss.

Inescapable tail shock model of traumatic stress causes chronic hyperarousal [58,59] and exaggerated ASR [53,54]. ASR is the unconditioned response to short acoustic stimuli that is used to characterize the CNS response to various treatments. Augmented startle response is a frequent symptom of PTSD and is likely related to changes in the limbic system associated with the stress [61].

ASR testing will be conducted with a Startle Response Acoustic Test System (Coulbourn Instruments, PA). The system is computer-based and all stimulus parameters are specified by entries in Windows based software with protocols saved to disk files. The audio source module placed above the test cage is used to provide acoustic stimuli. The software allows the use of either stimulus type, (tone or noise). For tone stimuli, amplitude, frequency and duration, and for nosie simulus duration of noise bursts is computer controlled.

Before the stress protocol, mice will be placed in ACS chamber with no sound applied for 15 min in order to acclimate them to the equipment. Then one day before exposure to stress protocol, mice will be placed on the weight-sensitive platform in a sound-attenuated chamber and after chamber lid is closed, mouse will be left in darkness for 3-5 min adaptation period (without startle stimuli). Then startle stimuli will be applied (100 &110 dB) as a noise bursts of 20 ms duration, preceded or not by 100-150 ms pre-pulse with 68 dB intensity. Sound intensities will be verified by a sound meter. Six types of stimulus will be applied: 100 &110 dB alone, with pre-pulse, pre-pulse alone and no stimulus. Each trial type will be presented eight times. Trial types will be presented in random order to avoid order effects and habituation. Inter-trial intervals range randomly from 15 to 25 s. The mice movements in response to stimuli will be measured as a voltage change inside platform and then will be converted to grams of body weight change after analog-digital conversion. These changes will be recorded as the maximum response occurring within 100-200 ms of the onset of the startle-eliciting stimulus. All acoustic stimuli will be administered by an amplified speaker placed above the test cage. Mice will spend in the chamber not more than 15 min. The chamber used to ASR experiments will be sanitized with soap, water and then alcohol after each animal.

All animals will be tested 1 day following the final day of the stress procedure and the results will be compared to reaction that startle stimuli evoked before exposure to stress. During an experimental session, the software displays both numeric and response waveform data. A post-hoc viewer is included for critical examination trial-by-trial response data.

Rotarod test. The rotarod is used to evaluate motor coordination. The mouse is placed upon the apparatus, which has a rotating rod. The rod is slowly accelerated from 4 rpm to 40 rpm over 5 minutes, The number of seconds during which each mouse remains on the rod is recorded.

V.4.4.7. Other Procedures:

Cardiac Perfusions: The mice will be anesthetized as previously described before the cardiac perfusions. They will be checked by toe pinching to ensure that the anesthetic has taken effect. Then the mouse chest will be cut open with scissors to expose the beating heart and then perfused through the left ventricle of the heart with heparinized phosphate-buffered saline (10% v/v) for 5 min. followed by 4% (v/v) paraformaldehyde in 0.1 M sodium phosphate at pH 7.4. The animals will be euthanized with overdose of sodium pentobarbital. Tissue will be then cryoprotected by immersion overnight at 4°C in a solution of 25% (w/v) sucrose in PBS. Frozen sections 20-30 microns thick will be cut on a sliding microtome with a freezing stage and will be stored in PBS containing 0.1% sodium azide. Following a previously approved protocol we will investigate the bleeding time at the time of mouse genotyping.

V.4.4.8. Tissue Sharing: We do not anticipate that will have any extra tissue from our experiments.
Any tissue not needed for our experiments will be made available to other investigators upon request.

V.4.5. Study Endpoint: Study endpoint is survival for 4 weeks post-stress and subsequent behavioral testing. Mice will be euthanized by lab personnel or LAM personnel. Any mice that show signs that include self-mutilation, gnawing at limbs, abnormal breathing, unkempt appearance, self-imposed isolation, abnormal posture, muscle rigidity or lack of muscle tone, and twitching/trembling/tremor, mice that lose 20% of initial body weight (measured during the weekly cage change as outline in Special Husbandry Provisions V.5.1.2) and show signs of excessive distress will be removed from the study and euthanized and euthanized by lab or LAM personnel within 8 h of their signs of excessive pain appearing. No analgesia will be applied since this would compromise the goal of this study. While inside the (b)(4) chamber where weight measurements are not possible, we will use the body condition scoring technique described Ullman-Culleré and Foltz (Body Condition Scoring: A Rapid and Accurate Method for Assessing Health Status in Mice, (1999) *LAS 49(3)319-23*). We will consult veterinary staff for mice with a body condition score of 2+ for treatment. The study will also be terminated early if we are unable to maintain an adequate environment inside the chamber as outlined in the Special Husbandry Provisions V.5.1.2.

V.4.6. Euthanasia:
Decapitation after anesthesia with anesthetization as previously described (section V.4.1.2.1.).
The scissors used for decapitation will be maintained in good working order and the blades checked routinely for sharpness. Mice used for immunohistochemistry will be will be deeply

anesthetized with injectable anesthetics then perfused transcardially as previously described. If additional euthanasia methods are necessary, mice will be given an overdose (100-150 mg/kg) of sodium pentobarbital IP as previously described. Mice used for RNA harvest will be decapitated with sharp scissors while deeply anesthetized (*see V.4.1.2.1*). Mice used for blood collection will be euthanized by exsanguination after anesthetic overdose as outlined in V.4.4.2. Mice euthanized by LAM personnel will be euthanized by an overdose of cylinderized CO_2. Euthanasia will be performed in the LAM CAF. Animals will be placed in a chamber that is not overcrowded. With animals in the chamber, the flow rate will displace at least 20% of the chamber volume per minute. Gas flow will be maintained for at least one minute after apparent clinical death. Animals will be verified as dead (lack of heart beat, lack of respirations) before removal of the chamber. A supplemental method to ensure death (cervical dislocation or bilateral thoracotomy) may be used. These methods are in compliance with the most current report of the AVMA Panel on Euthanasia.

V.5. Veterinary Care: Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each mouse in this protocol. Mice will be housed in standard cages up to 5 animals/cage before protocol manipulations.

V.5.1. Husbandry Considerations: Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol.

V.5.1.1. Study Room:

Building(s) _____ Room Number(s) _____

V.5.1.2. Special Husbandry Provisions: Since the shock protocol should be administered during the dark phase of the light cycle therefore we request that our animals will be kept under reverse light cycle conditions. Mice will be maintained in the (b)(4) environment (b)(4) chamber) for up to one week at which point the cages, food, and water will be changed. We request standard filter top cages to minimize odorant stressors between cages. For the two and three week exposure periods, mice will be replaced in the (b)(4) chamber after the weekly cage, food and water change. We request an exception to the bi-weekly cage change requirement to extend the time period to one week. If a cage runs out of water or food at any point or bedding becomes soaked with water, the experiment will be temporarily suspended until the chamber can be opened and the problem corrected. The experiment will then be continued.

A small digital meter with a highly visible readout will be placed inside the chamber to monitor the internal temperature and humidity. As ambient air is used to continuously refresh the internal environment, we expect minimal differences between the chamber and room temperature and humidity. We will consult veterinary staff if the chamber humidity rises above 70% or temperature exceeds 80°F. A similar device will be included to monitor CO_2 levels.

Food Restriction: Yes _____ No _____

Fluid Restriction: Yes No

V.5.1.3. Exceptions:

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care: Animals will be observed at least once daily by Center for LAM personnel, and attending veterinary care will be provided by DLAM vets as needed. PI or research staff will monitor the animals at least once a day during and following stress to monitor for signs of excessive pain. All mice that reveal 20% weight loss, (mice will be weigh only outside the (b)(4) chamber and it will be done once a week or more often if recommended by Veterinarian staff) ruffled fur, lethargy, loss of righting reflex will be removed from the study and euthanasia request will be sent to LAM staff. In the event of any adverse reaction during the protocol procedures PI and/or his designee will be notified and they will consult with the Veterinarian on duty to take the most appropriate action.

V.5.2.2. Emergency Veterinary Medical Care: All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: Except as indicated below, all animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents; balls, toys and food enrichment treats for large animal species.

V.5.3.2. Enrichment Restrictions: N/A

1) Training from USU investigator training course

2) Training from NIH staff during previous employment at NIH and use of rodents on approved protocols

3) Training from PI/Lab staff

4) Training from postdoctoral experience in Italy (Dr. (b)(6)

5) Training from veterinary staff at Cornell University and University of Maryland School of Medicine

(b)(6)

VII. BIOHAZARDS/SAFETY: Isoflurane/oxygen used for anesthesia will be used under fume/chemical hood to prevent exposure of personnel to the vapors. When handling animals all personnel will wear personal protective equipment including lab coats, face masks and gloves to minimize exposure to rodent allergens. Paraformaldehyde, used in perfusions, will be weighed out and used in a fume/chemical hood, with personnel wearing gloves, lab coats and face masks to protect from noxious fumes. All perfusions will also with similar precautions to minimize exposure to vapors.

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User

(b)(6) _____ 07.09.2012
Date

G. Training: The following personnel will attend the next USUHS Investigator/Animal User Training Course:

_____ _____
_____ _____

H. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely, "Responsibility" for implementing animal use alternatives where feasible and conducting humane and lawful research.

(b)(6) _____ 07.09.2012

Principal Investigator Signature Date

I. Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL or WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedu(b)(6) lish the objectives of this proposed experiment.

X. PROTOCOL ABSTRACT:

A. Animal Protocol Number:

B. Animal Protocol Title: Epigenetic biomarkers of post-traumatic stress disorder in mouse model in constant pressure environment

C. Principal Investigator: (b)(6) PhD

D. Performing Organization: Department of Anatomy, Physiology and Genetics

E. Funding: AFMSA, DoD

F. Objective and Approach: In the proposed project, we will determine a genome wide list of targets affected by exposure to (b)(4) conditions alone and in combination with stress. We will perform bioinformatics functional pathway analysis to unravel the signaling pathways involved and propose future treatment targets for PTSD. We will test the impact of differential time course of (b)(4) exposure on mouse behavioral phenotypes as well as hematological, pulmonary and central nervous system pathologies. We plan to determine genome-wide epigenetic profile in mouse brain, blood and lung tissues exposed to (b)(4) (b)(4) pressure/oxygen conditions. We will identify genome-wide epigenetic profile in brain, blood and lung tissues of stressed mouse exposed to (b)(4) pressure/oxygen conditions.

MEMORANDUM FOR DR. (b)(6) DEPARTMENT OF ANATOMY, PHYSIOLOGY AND GENETICS

SUBJECT: IACUC Approval of Protocol – Triennial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Full Committee Review on June 19, 2013:

Animal Protocol Title: "Targeting the 2-AG Hydrolyzing Enzymes MAGL and ABHD6 for the Treatment of EAE (rat and mouse)"

USUHS Protocol Number: (b)(6)

Expiration Date: June 18, 2016

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6). This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. NON-TECHNICAL SYNOPSIS:

Enhancement of endocannabinoid signaling has recently emerged as an alternative and attractive strategy for the treatment of multiple sclerosis (MS) and other neurological diseases. It is generally believed that boosting the endogenous levels of anandamide (AEA) and 2-arachidonoylglycerol (2-AG) can activate cannabinoid receptors in a site-and event- specific manner without causing psychotropic side effects. Although 2-AG is the dominant endocannabinoid in the brain and spinal cord, and has been shown to regulate cell viability, differentiation, synaptic plasticity and immune function, it is still unclear how modulating its biosynthetic and hydrolytic enzymes can affect the pathogenesis of MS. We hypothesize that there is an altered expression of 2-AG signaling components in experimental autoimmune encephalomyelitis (EAE) and that boosting the endogenous levels of 2-AG by targeting its hydrolyzing enzymes, monoacylglycerol lipase (MAGL) and alpha/beta hydrolase domain 6 (ABHD6), can ameliorate EAE by both shared and independent mechanisms. We aim to use primary cultures of olidendrocytes derived from mouse or rat brain to elucidate the role of 2-AG in the development and treatment of EAE with pharmacological and genetic tools.

II. BACKGROUND:

II.1. Background:

MS is one of the most common neurological diseases in young adults. It affects 250,000-350,000 people in the United States and 2-3 million people worldwide (1, 2). The pathological hallmarks of MS are multifocal inflammation, demyelination, gliosis, oligodendrocyte death and axonal injury. Accumulating evidence indicates that neurodegeneration occurs not only as a late consequence of axon demyelination in MS, but also as a very early event (3, 4). Therefore, agents targeting both inflammation and neurodegeneration at the early stage might be desirable for the treatment of MS.

A growing body of evidence suggests that cannabinoids, either exogenous (plant-derived and synthetic) or endogenous, are efficacious for the treatment of several animal models of MS (5). The regulatory action of cannabinoids in EAE-induced neurodegeneration is largely due to cannabinoid type 2 (CB2) receptor-mediated modulation of the inflammatory response and CB1 receptor-mediated neuroprotection (6, 7). However, the clinical application of synthetic and plant-derived cannabinoid agents in MS is still limited by the potential psychoactive effects caused by CB1 receptor activation. Although CB2 receptor activation is supposed to avoid the psychotropic effects, it is difficult to separate the action of CB1 and CB2 receptors exerted by exogenous cannabinoids because of the limited selectivity of the compounds and the interaction between CB1 and CB2 receptors (8, 9). Therefore, boosting the endogenous levels of cannabinoids is now becoming a novel and promising strategy to halt the progression of neurological diseases.

In this animal protocol, we will use the primary cultures of microglia and oligodendrocytes from mouse or rat brain and the mouse EAE model of human MS to elucidate the significance of different pools of 2-AG in the development and treatment of MS through selectively targeting the 2-AG hydrolytic enzymes, MAGL and ABHD6.

α/β hydrolase domain 6 + EAE (0)
cannabinoids + EAE (51)

II.2.5. Results of Search:

There is a growing body of evidence that cannabinoid compounds are effective in the animal models of MS, and sativex, a cannabis-based medicine composed of delta-9-tetrahydrocannabinoid and cannabidiol, has been used to treat pain and plasticity in Canada and some European countries for MS patients. However, the use of sativex in MS patients has not yet been approved in US a major concern is that this drug may still cause psychotropic effect via activation of CB1 receptor, although it has been clearly demonstrated to reduce pain and spasticity in MS patients. Although the use of CB2 receptor selective agonists can avoid the psychotropic effect and is also shown to be effective in the animal models of MS, there is a general consensus that activation of CB2 receptor mainly suppresses the inflammatory and autoimmune response, whereas activation of CB1 receptor provides neuroprotective effects. Therefore, targeting both CB1 and CB2 receptors might be necessary for the maximum therapeutic effects of cannabinoids. It is known that endocannabinoids are synthesized on demand and enhancement of their endogenous levels at the site of injury can exert protective effects and prevent activation of CB1 receptor non-discriminately. However, this theory has not been tested in MS studies because of the lack of selective pharmacological and genetic tools. Several selective and highly potent inhibitors of 2-AG hydrolysis have been developed in recent years, but so far no studies have been reported regarding their efficacy in the animal models of MS. In this protocol, we will test the role of the selective MAGL inhibitor JZL184 and the ABHD6 inhibitor WWL70 in the EAE mouse model.

III. OBJECTIVE\HYPOTHESIS:

Objective: To examine the expression pattern of 2-AG signaling components and determine the therapeutic efficacy of inhibition of 2-AG hydrolyzing enzymes MAGL and ABHD6 in EAE.

Hypothesis: Boosting the endogenous levels of 2-AG by targeting its hydrolyzing enzymes, MAGL and ABHD6, can ameliorate EAE.

IV. MILITARY RELEVANCE:

Multiple sclerosis is a chronic demyelinating disease of the central nervous system. The cause remains unknown but probably involves a combination of genetic and environmental

factors. The average age of onset is between 20 and 40 years of age. Currently there are about 350,000 people in the United States suffering from MS. MS is also relative frequent in the military population. It has been reported that the rate of multiple sclerosis is rising among Gulf War Veterans. Currently more than 25,000 veterans from all wars have been diagnosed with MS, which is now recognized as one of the service connected chronic diseases in the United States.

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures:

The long-term objective of the proposed research is to elucidate the role of 2-AG in the development and treatment of EAE. Our central hypothesis is that boosting the endogenous levels of 2-AG by targeting its hydrolyzing enzymes, MAGL and ABHD6, can ameliorate EAE.

To test our hypothesis, we will test 1) the therapeutic efficacy of inhibition of MAGL and ABHD6 in EAE; and 2) whether mice with targeted gene deletion of DAGLα are vulnerable, whereas mice with either MAGL and ABHD6 knockout or knockdown are resistant to EAE.

Several of the mouse strains used in this protocol will be bred under a separate breeding protocol because the models are not commercially available or the animals are not available at the age, size, quantity, etc., required for this research project. Founder animals will be obtained from the sources listed in the breeding protocol.

Our detailed experiments are listed as follows:

(b)(4)

(b)(4)

V.1.3. Experiment 3: Test the therapeutic efficacy of inhibition of MAGL and ABHD6 in EAE mice.

JZL184 has been shown to selectively inhibit the activity of MAGL and increase the endogenous levels of 2-AG in a dose-dependent manner. Acute inhibition of MAGL by JZL184 at 40 mg/kg elicits a 10-fold increase of brain levels of 2-AG and produces cannabimimatic effect. Chronic treatment with JZL184 at 40 mg/kg for 6 consecutive days sustains the brain levels of 2-AG but causes CB1 receptor desensitization and behavioral tolerance. However, treatment with JZL184 at 8 mg/kg for 6 consecutive days remains its anesthetic and anxiolytic properties, suggesting at optimal concentration, the inhibitor of MAGL might be more therapeutically beneficial. Consistently, our studies have suggested that chronic inhibition of ABHD6, which is known to cause a moderate increase of 2-AG in the CNS, is effective in a mouse model of traumatic brain injury. To test and compare the therapeutic effectiveness of the inhibition of MAGL and ABHD6, female 7- to 9-week-old C57BL/6 mice will be used for EAE induction and then treated with JZL184 and WWL70. JZL184 at 2, 4 and 8 mg/kg and WWL70 at 2, 4 and 8 mg/kg will be given intraperitoneally starting at the immunization (day 3) or at the disease onset (usually occurs around day 10) after EAE induction, and then once a day for 28

days. All the drugs will be dissolved in 200 µl 1% DMSO and given intraperitoneally. Our preliminary studies showed that treatment with WWL70 at 10 mg/kg or JZL184 at 10 mg/kg daily (i.p.) for 3 weeks reduced neurological signs of EAE and did not show any toxic effect by the drugs *per se*. Therefore, we anticipate at the dose range chosen for this study, no drug toxicity should be observed in the treated animals.

At 14 and 28 days after EAE induction, animals will be euthanized and the spinal cord tissues and coronal sections will be used for western blot and immunohistochemistry (IHC), respectively. To determine the role of JZL184 and WWL70 on inflammatory response, T cell infiltration and microglia/macrophage accumulation in the spinal cord white matter will be examined using IHC. The expression of iNOS, components of NADPH oxidase (gp91phox and p67phox), COX-1/2, PGES-1 and the EP1-4 receptors in spinal cord will be assessed by western blot and IHC. The expression of GLT-1, a glutamate transporter which maintains the glutamate in the synaptic cleft below the toxic levels, will be also examined by western blot. The role of JZL184 and WWL70 on EAE-induced demyelination and axonal injury will be examined by analyzing the immunoreactivity of MBP, NF-200 and SMI32. Oligodendrocyte progenitor cells (OPC) and mature OLs will be examined using antibodies against NG2 and CC1, respectively.

This study will require 7 animals per group to have 80% power to detect a difference of 2 points on a 0-5 point scale of clinical signs, using a t-test with a 5%, 2-sided significance level. We will use 10 mice/group because we expect 7 out of 10 to develop EAE. Therefore, the total number of animals used in this experiment (10 animals/group x 2 time points for treatment/group x 8 groups =160) is listed below:

Treatment	Number of animals
Control	20
EAE/vehicle	20
EAE/JZL184 (2 mg/kg)	20
EAE/JZL184 (4 mg/kg)	20
EAE/JZL184 (8 mg/kg)	20
EAE/WWL70 (2 mg/kg)	20
EAE/WWL70 (4 mg/kg)	20
EAE/WWL70 (8 mg/kg)	20

V.1.4. Experiment 4: Test whether inhibition of the 2-AG hydrolytic enzymes affect the 2-AG signaling components with/without EAE induction.

To determine whether treatment with the MAGL and ABHD6 inhibitors can affect the expression and function of the 2-AG signaling components, EAE mice will be given JZL184 (8 mg/kg, i.p.) and WWL70 (8 mg/kg, i.p.) starting at day 3 post-immunization and then once daily until day 28. The same concentration of drugs will be also given to control animals without EAE induction. Animals will be euthanized at 14 and 28 days and the brain and spinal cords are immediately dissected, immerged in liquid nitrogen and kept in -80°C freezer. The expression of 2-AG synthetic and hydrolytic enzymes DAGLα, DAGLβ, MAGL and ABHD6 and the expression of CB1 and CB2 receptors in the spinal cord will be assessed by real time PCR and western blot. Cannabinoid receptor density and function will be also examined by measuring the radioactive activity of [^{3}H]-CP55940 binding and CP55940 stimulated ^{35}S-GTPγS binding,

respectively. The levels of 2-AG, arachidonic acid (AA) and prostaglandins (PGs) in lipid extracts from spinal cord will be analyzed by reverse phase HPLC coupled with tandem mass spectrometry (LC/MS/MS). The total number of animals (10 animals/group x 2 end time points x 6 groups = 120) is as follows:

Treatment	Number of animals
Vehicle	20
JZL184 (8 mg/kg)	20
WWL70 (8 mg/kg)	20
EAE/vehicle	20
EAE/JZL184 (8 mg/kg)	20
EAE/WWL70 (8 mg/kg)	20

V.1.5. Experiment 5: Determine the cannabinoid receptor dependency of the MAGL and ABHD6 inhibitors in the treatment of EAE.

To determine whether the therapeutic effects of the MAGL and ABHD6 inhibitors are mediated by activation of CB1 and CB2 receptors, we will perform another set of study to treat animals with JZL or WWL70 together with CB1 receptor antagonist AM281 and CB2 receptor antagonist AM630 alone or their combination. For this experiment, the optimum dose of JZL184 and WWL70 obtained from the Experiment 3 will be used. All drugs will be dissolved in 1% DMSO and will be given intraperitoneally at the immunization (day 3) or at the disease onset (usually occurs around day 10) after EAE induction. All the drugs will be dissolved in 200 µl 1% DMSO and given intraperitoneally. The treatment groups and the total number of animals (10 animals/group x 2 time points for treatment x 10 groups =200) are listed as follows:

Treatment	Number of animals
Control	20
EAE/vehicle	20
EAE/JZL184	20
EAE/JZL184 + AM281 (3 mg/kg)	20
EAE/JZL184 + AM630 (3 mg/kg)	20
EAE/JZL184 + AM281 + AM630	20
EAE/WWL70	20
EAE/WWL70 + AM281 (3 mg/kg)	20
EAE/WWL70 + AM630 (3 mg/kg)	20
EAE/WWL70 + AM281 + AM630	20

V.1.6. Experiment 6: Use of ABHD6 siRNA injection in EAE mice.

At 14 and 28 days after EAE induction, the expression of ABHD6, MAGL, CB1 and CB2 receptors in the lumbar spinal cord of both ABHD6 siRNA and RISC-free siRNA administered

(i.v.) mice will be examined using real time PCR, western blot, and IHC. 2 mg/kg siRNA in phosphate-buffered saline (PBS) will be injected into the tail vein as described (Yang et al. Ann Neurol. 2010; 67:498-507). We will use radiolabeled cannabinoid receptor agonist and antagonists to determine whether the expression and function of cannabinoid receptors are altered in siRNA injected mice. At 14 and 28 days after EAE induction, the spinal cord levels of 2-AG, AA and PGs and ABHD6 activity will be also evaluated as described above. The total number of animals (10 animals/group x 2 time points/group x 4 groups = 80) is listed below:

siRNA	Number of animals
ABHD6 siRNA	20
RISC-free siRNA	20
ABHD6 siRNA/EAE	20
RISC-free siRNA/EAE	20

V.1.7. Experiment 7: Use of iPLA2 inhibitor in EAE mice.

Our preliminary results found that bromoenol lactone (BEL), a selective calcium independent PLA2 (iPLA2) inhibitor, significantly attenuated peroxynitrite formation in reactive microglia and microglia induced toxicity to OLs. This result suggests that BEL may ameliorate the disease progression of EAE. Female C57BL/6 wild type mice (8- to 10 week old) will be used for the induction of EAE and then treated either with BEL or vehicle alone (equal volume of DMSO, used to dissolve BEL). Mice will be treated with 0.5 mM or 2 mM BEL (200 µl, i.p.) starting on day 3 after the first 2 days of EAE induction or on day 12 after the disease onset, followed by daily injection of the inhibitors (200 µl at 0.5 mM or 2 mM) until day 28. Behavioral monitoring will continue up to 60 days. The clinical scores will be compared in each group.

The study will require 7 animals per group to have 80% power to detect a difference of 2 points on a 0-5 point scale of clinical signs, using a t-test with a 5%, 2-sided significance level. We will use 10 mice/group because we expect 7 out of 10 to develop EAE. Therefore, the total number of animals used in this experiment (10 animals/group x 2 time points for treatment/group x 6 groups =120) is listed below:

Treatment	Number of animals
Vehicle	20
BEL (0.5 mM)	20
BEL (2 mM)	20
EAE	20
BEL (0.5 mM)/EAE	20
BEL (2 mM)/EAE	20

V.1.8. Experiment 8: Cultures of oligodendrocytes from neonatal rats and mice

Oligodendrocyte cultures from control and transgenic mice (C57BL6/NTac, DAGLα

-/-, 129SvEv/C57BL6J, DAGLβ -/- and MAGL -/-) will be prepared according to methods that have been used routinely in our lab to produce highly enriched stage specific rat oligodendrocyte cultures. Postnatal day 0-3 rats and mice will be anesthetized with hypothermia in an ice water bath and then decapitated. The brains will be removed, cleaned of meninges, dissociated to single cells suspensions, and plated under conditions for growth of oligodendrocyte cultures. For cultures of premyelinating OLs (preOLs), platelet-derived growth factor (PDGF) and fibroblast growth factor (FGF) are added in the culture medium. For the cultures of mature OLs, the growth factors are switched to T3 and CNTF after 7 days in the culture medium for preOLs.

For cell cultures using transgenic mice, we estimate that we may require approximately 8 pups per primary culture. We expect to use approximately one primary culture every other month, or 6 per year, for a total of approximately 20 (which include 10% additional for unexpected problems or contamination within the culture, i.e.18 + 2 = 20) over the 3 years of our study. 20 primary cultures per strain x 5 strains x 8 pups per primary culture = 800 pups over the 3 years will be needed for culture preparation. For cell cultures using rats, we estimate that we may require 10 rat pups (and one mother rat) per primary culture. We expect to use one primary culture every other week (26 primary cultures per year x 3 years x 10 pups per culture AND 1 dam per culture = 780 pups and 78 dams = 858 rats) for testing the response of different stages of oligodendrocytes to oxidative stress. The total number of animals required for culture experiments is listed as follows:

Animals	**Numbers over 3 years**	**Age**
Rat	858	Pups (780); mother (78)
Mouse	800	Pups
Mouse	980	Adults

V.2. Data Analysis:

Statistical methods and other calculations used to determine the group's sizes and total numbers of animals are listed under the individual experiments. Prism statistical software and graphing, from GraphPad, will be used for data analysis. Student t-tests will be used to compare the cell density measures. The chi square test will be used to compare the expression differences of proteins interested. ANOVA with post hoc analysis will be used to monitor the neurological deficits across the multiple disease time points.

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered:

We will use the primary oligodendrocyte cultures derived from rat or mouse brain to study the signaling mechanisms of oxidative stress induced toxicity. However, because of the complex cell-cell interactions and multiple signaling pathways involved in the real setting of the disease models, an intact animal model system is required. Our in vitro systems lack the complexity required to comprehensively evaluate the disease process and the interrelated effects of various manipulations on the disease course. We will use several transgenic mouse models to study whether targeted signaling molecules in the pathways of oligodendrocyte toxicity found in vitro play critical roles in the pathogenesis of multiple sclerosis.

V.3.2. Animal Model and Species Justification:

Complete Freund's adjuvant (CFA) is used for emulsifying the myelin proteins and induction of EAE. Although several alternative adjuvants (monophoshoryl lipid A/trehalose decorynomycolate, aluminum hydroxide, titermax, ribi, syntax adjuvant formulation) have been used to introduce peptides, antibodies or vaccines in modulating the immunological responses in several model systems, none of these adjuvants has been used in inducing EAE. The injection of myelin peptides emulsified in incomplete Freund's adjuvants can, in fact, render the mice resistant to the induction of EAE (Marusic and Tonegawa, 1997). To study the pathogenic mechanisms and the pharmacological intervention of the disease activity, we will use myelin proteins emulsified in complete Freund's adjuvant to induce EAE, a commonly used and well established model system.

Myelin oligodendrocyte glycoprotein (MOG) is one of the major myelin proteins used to induce EAE in mice, which resembles the human disease multiple sclerosis. The greater incidence in female population and the better immune response observed in female mice suggest that female mice will be ideal in use for the study of mechanisms of the disease. We have chosen the specific transgenic mouse lines to help us gain more direct evidence for testing the involvement of specific molecules in the pathogenesis of the disease. JZL184 has been shown to selectively inhibit the activity of MAGL and increase the endogenous levels of 2-AG in a dose-dependent manner. Acute inhibition of MAGL by JZL184 at 40 mg/kg elicits a 10-fold increase of brain levels of 2-AG and produces cannabimimatic effect. Recent genetic evidence demonstrates that DAGLα and MAGL are the principal enzymes for 2-AG synthesis and degradation, respectively. 2-AG is the dominant endocannabinoid and a key regulator of synaptic communication in the CNS. ABHD6 is a newly identified 2-AG hydrolyzing enzyme and responsible for only 4% 2-AG inactivation in brain homogenate. However, it contributes to 40% of 2-AG hydrolysis in neurons and has an additive effect with MAGL. Although ABHD6 is known to be expressed and attributable to the 2-AG hydrolysis in BV2 cells, its expression and function in primary cultures of microglia have not been confirmed. With specific gene knockout mice and siRNA injection into mice, we will get a better understanding of the inhibition of 2-AG hydrolyzing enzymes in the development and treatment of EAE.

Rats will be used to prepare cell cultures since neonatal rats brains result in a much higher cell yield than mice brains. Therefore, we will first use rat cultures to study the signaling molecules involved in the toxicity of oxidative stress to oligodendrocytes and then use mice cultures derived from transgenic mice to see whether knockout of the specific molecules affects the toxicity. We have chosen Sprague-Dawley rats because they are widely used for oligodendrocyte and other nerve tissue cultures. We have used SD rats previously in similar work and need to be able to relate results across studies.

V.3.3. Laboratory Animals

	Species #1	Species #2
V.3.3.1. Genus & Species:	Rattus norvegicus	Mus musculus

V.3.3.2. Strain/Stock:	Sprague-Dawley	C57BL/6J DAGLα$^{-/-}$ DAGLβ$^{-/-}$ MAGL$^{-/-}$
V.3.3.3. Source/Vendor:	(b)(4) or other approved vendor	C57BL/6J (b)(4) (b)(4) DAGLα$^{-/-}$, DAGLβ-/- MAGL$^{-/-}$ In-house breeding
V.3.3.4. Age:	0-3 d pups + mother	Cultures: 0-3 d pups EAE mice: 8-10 wks
V.3.3.5. Weight:	As for age	As for age
V.3.3.6. Sex:	Mixed in litters	Cultures: mixed litters EAE mice: female
V.3.3.7. Special Considerations:	Dam should arrive with 10 pups, 0-3 days old, may or may not be litter mates. Alternately, gestational day 17-18 timed-pregnant rats may be ordered.	Cultures: Dam should arrive with 8 pups, 0-3 days old, may or may not be litter mates. Alternately, gestational day 17-18 timed-pregnant mice may be ordered. EAE: General facility and specific pathogen-free barrier
V.3.4. Number of animals Required (by species)	Pups (780) + Mother (78)	Pups (800) +adult mice for EAE study (980)

V.3.5. Refinement, Reduction, Replacement (3 Rs):

V.3.5.1. Refinement:

EAE will be induced with MOG peptides emulsified with CFA. Any animals that develop open lesions or infection secondary to any of the injection methods will be removed from the research groups and be euthanized at an early endpoint. Additionally, animals that are observed to reach the stage 4 behavioral criteria will be euthanized at an early endpoint. No other refinement alternatives are considered.

V.3.5.2. Reduction:

The dose dependent studies of several inhibitors in the lipid metabolic pathways in culture will suggest to us the doses suitable for the animal study. Therefore, we can reduce the groups of animals used for testing the efficacy of the drugs. However, considering the reports that chronic inhibition of MAGL can cause receptor desensitization and downregulation and the differences in vitro and in vivo, a set of dose-dependent study is also proposed for better understanding the mechanisms of drugs' action. We will prepare tissues in a way that allows us to use a given tissue for multiple assays rather than euthanizing a separate animal for each method. No other reduction alternatives are considered.

V.3.5.3. Replacement:

Biological response to multiple sclerosis is highly complex. The in vitro culture system lacks the complexity required to comprehensively evaluate the disease process and the interrelated effects of various manipulations on the disease course. Computer models can also not be utilized as basic information and knowledge is lacking to construct computer simulations. Therefore, the mouse model is a necessary smaller animal model we could use for this study and still obtain acceptable results. No alternative to in vivo experimentation is available.

V.4. Technical Methods:

V.4.1. Pain / Distress Assessment:

V.4.1.1. APHIS Form 7023 Information:

V.4.1.1.1. Number of Animals:

	Species #1	Species #2
V.4.1.1.1.1. Column C:	780	800
V.4.1.1.1.2. Column D:		
V.4.1.1.1.3. Column E:		980

Column C includes the rat and mouse pups for cell culture. **Column E** includes the 980 adult mice undergoing CFA injection and potential paralysis during the EAE induction. The USDA Animal Care Policy #11 describes paralysis as a condition that may cause distress in the animals. This policy also describes the use of CFA as a procedure that may cause pain in the animals, although that pain may range from only slight or momentary to more significant pain. *Although pain was thought to be rare and minor symptoms in MS patients in the past, recent investigations indicate pain is common in MS patients, which is possibly caused or triggered by inflammation, demyelination and axonal injury (Pollmann W and Feneberg W. CNS Drugs. 2008; 22:291-324; O'Connor AB et al. Pain. 2008; 137:96-111).* We will observe the animals and report any differences in pain category during our annual reports.

V.4.1.2. Pain Relief / Prevention:

V.4.1.2.1. Anesthesia/Analgesia/Tranquillization:

For culture preparation derived from neonatal mouse and rat brains, 0-3 day old rats or mice will be anesthetized with hypothermia by cooling in an ice water bath prior to decapitation. The

animals will not be directly in contact with the ice water bath since they will be placed in the finger of a latex glove. Sufficient anesthesia will be determined as lack of movement and lack of response to pinching the toes of the forepaw. Once the pups are sufficiently anesthetized, they will be euthanized by decapitation.

For EAE induction, a 200 µl portion of emulsion containing a 1:1 ratio of MOG/CFA will be administered to each mouse, the use of anesthesia for s.c. immunizations is not required. Although recent studies suggest that EAE mice may also experience pain during the onset or the disease progression (Olechowski et al. Pain. 2009: 141:156-164; Jung et al. J. Neurosci. 2009: 29:8051-8062), the post-procedural administration of an opiate analgesic or a NSAID or related drugs cannot be used to alleviate any possible pain, as most of these agents affect the immune and the inflammatory response and thus the disease severity of EAE. The use of analgesic or NSAID drugs will make it difficult to elucidate the pathogenic mechanisms of EAE and the therapeutic efficacy of several compounds (such as cannabinoid compound) tested.

For transventricular perfusion, mice will be anesthetized once with ketamine (60-90 mg/kg)/xylazine (10-15 mg/kg) by intraperitoneal injection into the caudal ventral abdomen using a 23-28 gauge needle. If 10 mg/ml ketamine and 20 mg/ml xylazine are used for the peritoneal injection and the average mouse weight is 30 grams, the injection volume is (60 mg/kg x 0.03kg /10 mg/ml) + (10 mg/kg x 0.03 mg / 20 mg/ml) = 0.18 ml + 0.015 ml ~ 0.2 ml. Even if the mouse requires a supplemental injection the total IP injection volume will generally not exceed 0.5 ml. Once the animals are deeply anesthetized (as indicated by recumbency, slow, regular breathing, and lack of response to toe pinch) the transventricular perfusion procedures will begin.

Dre (b)(6) **a graduate student, will perform the anesthetic procedures in this protocol.**

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions:

Although we do not expect any complications as a result of the procedural manipulations, we will monitor the mice in their home cages at least once a day for 2 or 3 days following IP injections. If the mice exhibit any signs of peritonitis, to include lethargy, anorexia, hunched posture, unusual vocalizations, appearance of significant weight loss, unkempt appearance, etc., the animals will be removed from the experimental group and euthanized. Mice will be monitored at least once a day for the development of abscesses, open sores, or other lesions at the site of SQ adjuvant injection. *We have found less than 5% of animals undergoing SQ adjuvant inject may develop open lesions near the inject sites.* If there are open lesions or peritonitis due to the adjuvant injections, the animals will be removed from the research groups and euthanized at an early endpoint. At 10 days following induction of EAE, we will monitor the neurological scores of the mice twice a day, including weekends.

V.4.1.3.5. Results of Search:

Complete Freund's adjuvant is used for emulsifying the myelin proteins and induction of EAE. Although several alternative adjuvants (monophoshoryl lipid A/trehalose decorynomycolate, aluminum hydroxide, titermax, ribi, syntax adjuvant formulation) have been used to introduce peptides, antibodies or vaccines in modulating the immunological responses in several model systems, none of these adjuvants has been used in inducing EAE. The injection of myelin peptides emulsified in incomplete Freund's adjuvants can, in fact, render the mice resistant to the induction of EAE (Marusic and Tonegawa, 1997). To study the pathogenic mechanisms and the pharmacological intervention of the disease activity, we will use myelin proteins emulsified in complete Freund's adjuvant to induce EAE, a commonly used and well established model system.

Demyelination is one of the hallmarks of EAE, which can lead to paralysis. Although pain or distress can be associated with paralysis, MS patients usually do not experience pain or

distress because of the paralysis. We can speculate that EAE mice will not experience pain, but it's possible that they may become distressed.

Transventricular perfusion, after deep anesthesia, is a method commonly used to prepare the tissues appropriately for later histological and immunological analyses.

Based on the literature search results, cardiac perfusion and formaldehyde fixation are commonly performed procedures in a wide variety of research applications. The relevant results obtained from the above search described use of this procedure for fixation and analysis of a number of tissues (to include spleen, kidney, liver, lung, stomach, small intestine, lymph nodes, heart, brain, bone marrow, eyes, nasal cavities, cochlea, and uterine tissue) with the majority describing brain fixation. Unrelated articles described transcardial routes of compound delivery and use of cardiac perfusion to clear vessels of blood with or without residual compounds. One article described a minimally invasive technique of transthoracic cardiac infusion without thoracotomy. The authors claimed this procedure yielded higher quality tissue preservation and faster tissue harvesting capabilities without the artifacts of brain swelling and ventricular dilation seen with direct cardiac perfusion. While this less invasive method may offer these advantages, the procedure would be potentially painful or distressful, so animals would still be anesthetized. Until the research staff became proficient with the technique, these benefits may not be readily apparent. Additionally, these benefits may not be recognized with tissues outside the central nervous system. With the possible exception of microwave fixation in select applications, there currently is no other less painful alternative to perfusion to ensure adequate distribution of fixative to the tissues of interest. Microwave euthanasia/fixation is not a viable alternative for our study.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification:

In the past, pain was thought to be a rare and minor symptom in patients with Multiple sclerosis. However, recent investigations suggest pain is in fact quite common in MS patients (Pollmann W and Feneberg W. CNS Drugs. 2008; 22:291-324; O'Connor AB et al. Pain. 2008; 137:96-111). The causes and the pathogenic mechanisms of the pain are still unclear, although inflammation, demyelination and axonal injury may lead to pain. A very recent study using EAE mouse model also suggests that T lymphocytes infiltration and microglia/macrophage activation in spinal cord may be the cause of neuropathic pain (Olechowski et al. Pain. 2009; 141:156-164). In addition, USDA Animal Care Policy #11 considers paralysis in animals to be a distressful condition. In order to thoroughly assess the disease course in these mouse models and determine the role of the molecules of interest in this disease, we must follow the disease progression through various phases, including paralysis. However, it is not possible to administer anti-inflammatory drugs or opiate analgesics to lesson any pain that may be associated with the CFA injections; these compounds are known to affect the immune response (Schneemilch et al. Best Pract Res Clin Anaesthesiol. 2004; 18:493-507; Scholz and Woolf. Nat Neurosci. 2007; 10:1361-1368; Kurosawa and Kato. J Anesth. 2008; 22:263-277) that is an essential component of the model. Morphine and other opioids have immunomodulating effects on nearly all measurable parts of the immune system (macrophages, granulocytes, nk-cells; mediators like Interleukin 1, 2 and 6, TNFα). These will directly interfere with the mechanism involved in the induction of EAE. Although it is possible that Tylenol may be used for reducing pain without affecting the inflammatory response, considering the cannabinoid compounds have been shown to reduce both inflammatory and neuropathic pain, we opt to not using Tylenol in our experiments, in order to better understand the therapeutic potential of targeting the endocannabinoid system for EAE.
The mice will be euthanized once they reach stage 4 of the behavioral criteria.

V.4.4.2. Biosamples:

Following euthanasia by transventricular perfusion, the brain and lumbar spinal cord will be removed from EAE mice. These tissues will be fixed and cut using a cryostat into sections for further analysis as described in Experiment #2.

A postmortem tail biopsy immediately after the brain is removed from postnatal day 0-3 mice will be used to isolate genomic DNA and genotype each mouse by PCR analysis. The terminal 0.5 -1 cm of the tail will be quickly cut with a pair of sterile, sharp surgical scissors. DNA will be extracted from the tail samples for PCR analysis.

V.4.4.3. Adjuvants:

200 μg of MOG in 0.1 ml PBS will be emulsified with 0.1 ml complete Freund's adjuvant (Incomplete Freund's adjuvant containing 0.5-1 mg/ml of heat-inactivated Mycobacterium tuberculosis) will be administered at day 0 (total 0.2 ml injection volume) SQ divided into two sites between the shoulder blades and/or along the back. At day 7, the incomplete Freund's adjuvant will be similarly administered to enhance the immunization of MOG. The use of CFA will be performed accordance with the IACUC policy #2. Research personnel will observe the animals at least once a day following adjuvant injection to monitor for abscesses, open lesions, etc. If open lesions are noted, they will be treated with topical disinfectants and/or antibiotics. Any mice with lesions that are non-responsive to treatment will be removed from the research groups and euthanized at an early endpoint.

As part of EAE induction, an IP injection of 200 ng of pertussis toxin is administered on days 0 and 1 following MOG/adjuvant injection to further enhance the immunogenicity of the MOG. Monitoring after IP injections is as described earlier.

Complete Freund's adjuvant is used for emulsifying the myelin proteins and induction of EAE. Although several alternative adjuvants (monophoshoryl lipid A/trehalose decorynomycolate, aluminum hydroxide, titermax, ribi, syntax adjuvant formulation) have been used to introduce peptides, antibodies or vaccines in modulating the immunological responses in several model systems, none of these adjuvants has been used in inducing EAE. The injection of myelin peptides emulsified in incomplete Freund's adjuvants can, in fact, render the mice resistant to the induction of EAE (Marusic and Tonegawa, 1997). To study the pathogenic mechanisms and the pharmacological intervention of the disease activity, I will use myelin proteins emulsified in complete Freund's adjuvant to induce EAE, a commonly used and well established model system.

V.4.4.4. Monoclonal Antibody (MAbs) Production: None

V.4.4.5. Animal Identification:

Individual mouse will each be given an ear tag with an identification number. Mice will be assigned to several experimental groups depending on the design and recorded based on their identification numbers on ear tags. Each cage will be given a cage card that is numbered by LAM staff. Cage card numbers will be recorded.

V.4.4.6. Behavioral Studies:

Animals will be monitored at least twice a day blind by two independent observers from day 10 following MOG injection and neurological signs will be assessed as follows: 0, normal mouse; 1, piloerection, tale weakness; 2, tail paralysis; 3, tail paralysis plus hindlimb weakness/paralysis; 4, tail, hind and fore limb paralysis; 5, moribund/dead. We expect the disease course to progress over one to two months, so animal behavioral monitoring will continue for up to 60 days after induction of EAE.

V.4.4.7. Other Procedures:

Transventricular perfusions: Weights of mice in EAE experimental groups will be taken to determine appropriate dose of anesthesia prior to transventricular perfusion. For perfusion, the adult mice will be deeply sedated and lack the response to toe pinch. The skin of the chest will be incised with sharp scissors to allow the rib cage to be raised. The heart will be visualized. Perfusate will be passed through the vasculature by inserting a blunted 20g canula through a nick made in the left ventricle and positioning the cannula opening in alignment with the ascending aorta. The right atrium will be nicked to allow exit of blood and perfusate.

V.4.4.8. Tissue Sharing:

We will offer any animal not needed on this study and excess tissues to other investigators.

V.4.5. Study Endpoint:

The endpoint for adult mice on this study is survival until various time points after induction of EAE and treatment with inhibitors/placebo, after which the mice will be euthanized for tissue collection and evaluation. The endpoint for mouse and rat pups on this study is survival for 0-3 days after birth, at which time they will be euthanized and tissues collected for cell culture. The study endpoint for mother rats is survival until pups are removed, after which they will be offered to other investigators or euthanized. If there is inflammation or peritonitis due to the IP injections or non-healing open lesions from the adjuvant injections, the animals will be euthanized at an early endpoint. Any animal observed to be at stage 4 for behavioral monitoring criteria (tail, forelimb and hindlimb paralysis) will be euthanized at an early endpoint.

V.4.6. Euthanasia:

Following deep anesthesia, EAE animals will be euthanized by exsanguinations as a result of the perfusion procedures as described above. These procedures will be performed by Drs. (b)(6) a graduate student.

Carbon dioxide will be used to euthanize the mother rats after the pups are taken away for the cell cultures. Any animal that must be removed from study because of illness or complication from the study will also be euthanized with carbon dioxide. Animals will be euthanized by Center for LAM personnel or research personnel using cylinderized CO2 in compliance with the most current report of the AVMA guidelines on Euthanasia. Euthanasia will be performed in the LAM CAF. If possible, animals will be euthanized in their home cage. If not, a clean rodent cage will be used. Animals will be placed in the cage so that it is not overcrowded (each animal can place all four feet on the bottom of the cage.) With animals in the chamber, the flow rate of CO2 will displace approximately 20% of the chamber volume per minute. Gas flow will be maintained for at least one minute after respiration has stopped before

removing animals from the cage. A supplemental method to ensure death (cervical dislocation or bilateral thoracotomy) may be used.

For culture preparation, 0-3 day old rats or mice will be anesthetized by cooling in an ice water bath and then euthanized by decapitation with sharp scissors. These scissors will be tested for sharpness by cutting a piece of gauze as recommended by Roboz Surgical Instrument Company, Inc. The scissors will be sharpened or replaced as necessary, and a log book will be maintained to describe maintenance or replacement. These procedures will be performed by Drs. (b)(6)

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol.

V.5.1.1. Study Room:

Building(s) (b)(6) Room Number(s) (b)(6) and/or a procedure room as assigned by LAM.

V.5.1.2. Special Husbandry Provisions: When the mice have paralysis and cannot reach the cage top sources after induction of EAE, wet rodent chow and transgel will be provided on cage floor as a source of food and fluids.

Food Restriction:	Yes	_____	No	X
Fluid Restriction:	Yes	_____	No	X

V.5.1.3. Exceptions: N/A

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care:

Research personnel will observe the animals at least once a day for the first 2-3 days following IP and IV injections, and daily following SQ injections of adjuvant. Research personnel will also observe animals twice daily, beginning 10 days post-EAE induction, to assess behavioral criteria as described earlier. Animals will be observed at least once a day for general health and husbandry conditions by LAM personnel. Any animal found to be exhibiting signs of illness not related to the EAE (i.e., phlebitis, peritonitis, etc.) will be examined and removed from the research groups. Moribund animals may be euthanized for welfare reasons at the discretion of the veterinarian.

V.5.2.2. Emergency Veterinary Medical Care: All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary

technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: Except as indicated below, all animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents.

V.5.3.2. Enrichment Restrictions: N/A

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
Anesthesia	(b)(6)	21 years experience	Trained in Hebrew University,1992, Harvard Medical School (HMS), 1999, and USUHS, 2006
Anesthesia		4 year experience	Trained in NIH, USUHS
Neonatal anesthesia and CO_2 euthanasia		21 years experience	Trained from HMS, 1999, and USUHS LAM staff, 2006.
Neonatal anesthesia and CO_2 euthanasia		8 years experience	Trained in USUHS, 2006, and UMDNJ LAM staff, 2005.
Perfusions		21 years experience	Trained in HMS, 1999, and Hebrew University, 1992
Perfusions		4 year experience	Trained in USUHS, 2009
Perfusion		4 year experience	Trained in NIH, USUHS
EAE model		8 year experience	Trained in HMS, 2005
EAE model		3 years experience	Trained in USUHS, 2010
EAE model		5 year experience	Trained in USUHS, 2007
EAE model		1 year experience	Trained in USUHS

Cell culture (rat/mice pups)	(b)(6)	8 years experience	Trained in USUHS, 2006, and UMDNJ, 2005
Cell culture (rat/mice pups)		14 years experience	Trained in HMS, 1999

Intravenous injections		13 years experience	Trained in HMS, 1999 and Hebrew University, 1996
Intravenous injections		4 year experience	Trained in NIH, USUHS
Intravenous injections		2 years experience	Trained in USUHS, 2011

VII. BIOHAZARDS/SAFETY:

200 μg killed mycobacteria (SQ) and 200ng of pertussis toxin (IP) will be used in the induction of EAE. Care will be taken to reduce the potential for needle stick exposure to mycobacterial organism to prevent sensitization of research personnel.

Exposure to animal allergens is minimized according to the precautions and PPE designations for the room animals in which the mice and rats are housed within the LAM facilities. Lab coat, gloves, and masks will be worn when handling animals both in the CAF and in labs.

For preparation of tissues, animals are perfused with 4% paraformaldehyde as a fixative agent. Perfusions will be conducted in a fume hood and gloves, labcoat, and eye protection will

C. **Statistical Assurance:** I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. **Biohazard\Safety:** I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. **Training:** I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. **Training:** I verify that I have attended the USUHS Investigator/Animal User Training Course.

(b)(6) _____ 6/19/2013
Date

G. **Training:** The following personnel will attend the next USUHS Investigator/Animal User Training Course:

_____ _____

H. **Responsibility:** I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely, "Responsibility" for implementing animal use alternatives where feasible and conducting humane and lawful research.

(b)(6) _____ 6/19/2013
Date

I. **Painful Procedure(s):**

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL or WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

PROTOCOL ABSTRACT:

A. Animal Protocol Number: (b)(6)

B. Animal Protocol Title Targeting the 2-AG Hydrolyzing Enzymes MAGL and ABHD6 for the Treatment of EAE (rat and mouse)

C. Principal Investigator: (b)(6) M.D., Ph.D.

D. Performing Organization: Uniformed Services University of the Health Sciences.

E. Funding: The Defense Medical Research and Development Program (DMRDP); USUHS

F. Objective and Approach:

Cannabis-based medicine has a great potential for the treatment of multiple sclerosis (MS), a chronic inflammatory disease of the central nervous system associated with demyelination and neurodegeneration. Through activating both CB1 and CB2 cannabinoid receptors, cannabinoids contribute to anti-inflammation, anti-oxidation and anti-excitotoxity. It is generally believed that boosting the endogenous levels of anandamide (AEA) and 2-arachidonoylglycerol (2-AG) can activate cannabinoid receptors in a site-and event- specific manner without causing psychotropic side effects. However, due to the limited availability of selective pharmacological inhibitors and knockout mice, this theory has not been rigorously tested

2-AG is the dominant endocannabinoid in the brain and spinal cord, and has been shown to regulate cell viability, differentiation, synaptic plasticity and immune function. Monoacylglycerol lipase (MAGL) and α/β hydrolase domain 6 (ABHD6) are 2-AG hydrolyzing enzymes. Our preliminary data have shown that inhibition of those two enzymes significantly reduced the neurological signs of the disease. However, it is still unclear how modulating 2-AG's biosynthetic and hydrolytic enzymes can affect the pathogenesis of MS. In this proposal, we plan to use pharmacological and genetic tools to elucidate the role of 2-AG in the development and treatment of EAE.

Hypothesis: Expression of 2-AG signaling components in EAE change and boosting the endogenous levels of 2-AG by targeting its hydrolyzing enzymes, MAGL and ABHD6, can ameliorate EAE by both shared and independent mechanisms.

Objective: Endocannabinoids play an important role in the pathogenesis of EAE.

Approach: We will use EAE mouse model to study the participation of 2-AG in EAE and the effect of the modulation of 2-AG production on the progression of EAE in the mice. Specifically we will study the role of 2-AG hydrolyzing enzyme inhibitor WWL 70, JZL in the anti-inflammatory protection of EAE mouse model. We will use pharmaceutical and genetic methods to downregulate MAGL and ABHD6 expression to study 2-AG protective role in the EAE.

G. Indexing Terms (Descriptors):

Demyelination, toxicity, MAGL, ABHD6, cannabinoids, 2-AG, AEA, oligodendrocyte, EAE, multiple sclerosis, mice, rat.

MEMORANDUM FOR DR. (b)(6) DEPARTMENT OF ANATOMY, PHYSIOLOGY, AND GENETICS

SUBJECT: IACUC Approval of Protocol – Triennial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on June 18, 2013:

Animal Protocol Title: "Development of Neuroprotection Strategies for Brain Injury Using Rat Models"

USUHS Protocol Number: (b)(6)

Expiration Date: June 17, 2016

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. **NON-TECHNICAL SYNOPSIS:** Traumatic brain injury (TBI) has been called the "signature injury" of the Iraq and Afghanistan wars. Since Afghanistan operations began in 2001, and Operation Iraqi Freedom in 2003, the Department of Defense reports that the most debilitating wounds suffered by military personnel are traumatic brain injuries. According to the Department of Defense Report, "Report to Congress in Accordance with Section 1634 (b) of the National Defense Authorization Act for Fiscal Year 2008," the Military Health System (MHS) has recorded 43,779 patients who have been diagnosed with a TBI in calendar years 2003 through 2007. Thanks to new helmet materials, up-armored vehicles and other new technologies, many combat personnel are surviving head injuries that in previous wars would have been fatal. However, the aftermath of some of these head injuries lead to chronic and debilitating conditions, including when the injuries are not diagnosed due to a lack of clear protocols and biomarkers for assessing milder forms of head injury. Clearly, development of simple and inexpensive adjunct treatment strategies that improve long term outcomes would be highly advantageous, and could even be given to personnel in a prophylactic manner when they are subjected to milder blast or concussive forces, and before any symptoms appear. In the ongoing studies, we showed that intragastric administration of glyceryltriacetate (GTA) improves levels of N-acetylaspartate (NAA) and ATP, markers of brain energy status, and Rotarod balance performance in the controlled cortical impact model (CCI) of TBI in the rat. We propose to extend these studies by including 1) melatonin, a lipid soluble pineal hormone that has anti-inflammatory and antioxidant properties and 2) ketone body molecules that have been found to be neuroprotective in a number of CNS injury models. Furthermore, we propose to investigate the role of NAA as a biomarker for brain injury in body fluids.

II. BACKGROUND:

II.1. Background: There are two separate components In this protocol, one aimed at developing neuroprotection strategies and methods and the second aimed at

developing NAA as a biomarker for TBI. They are discussed under two separate headings.

A. Neuroprotection Strategies for TBI.

Increased production of free radicals via a number of pathologic cascades is one of the many secondary effects of traumatic brain injury (TBI). After TBI, excitotoxicity caused by increased glutamate release leads to increased intracellular calcium in neurons. Furthermore, the release of inflammatory cytokines and intracellular calcium induce activation of enzymes including phospholipase A2 and cycloxygenase -2, which stimulate the eicosanoid cascade. The calcium influx alters mitochondrial membranes disrupting the electron transport chain, leading to accumulation of electron-reduced oxygen intermediates. Production of free radicals resulting from these complex interactions generates a state of oxidative stress. It appears that this oxidative stress plays a significant role in TBI, raising the possibility that antioxidant therapy using nontoxic antioxidants such as melatonin could be very effective in a clinical setting (1-3).

Melatonin as a Neuroprotectant: Melatonin, a product of tryptophan metabolism, was initially identified as a pineal hormone with roles in the control of circadian rhythms and reproductive physiology mainly in seasonally breeding animals. However, recent studies indicate that melatonin is also synthesized in many organs and tissues of the body in which it might act as a paracrine hormone or a signaling molecule (2,3). The best known actions of melatonin, currently supported by experimental and clinical data, include antioxidant and anti-inflammatory abilities, some of them involving transcriptional regulation of a number of related enzymes. Most of the beneficial effects of melatonin administration seem to depend on its effects on mitochondrial physiology. Melatonin effects on mitochondria include increased membrane fluidity, increased activity of electron transport chain complexes and ATP production, increased mitochondrial membrane potential, reduced oxidative stress and closing of the mitochondrial permeability pore (4)

Melatonin is known to protect against oxidative stress in cells. Antioxidant actions of melatonin are observed at different levels including attenuation of radical formation, which is also referred to as radical avoidance. Although melatonin efficiently interacts with various reactive oxygen and nitrogen species as well as with organic radicals, it also upregulates antioxidant enzymes and down regulates pro-oxidant enzymes (1). Efficacy of melatonin as an antioxidant is significantly higher than that of other antioxidants including vitamins E and C. Besides, the metabolites formed when melatonin functions as a free radical scavenger, namely N1- acetyl, N2- formyl, 5-methoxykynuramine (AFMK) and N1- acetyl, 5-methoxy kynuramine (AMK) also possess significant antioxidant and anti-inflammatory activity (5,6). Melatonin is highly lipid and somewhat water soluble and thus melatonin enters all cells and subcellular compartments with highest concentrations possibly being present in the nuclei and mitochondria.

Melatonin has been administered in both physiological and pharmacological amounts to humans and there is widespread agreement that it is a non-toxic molecule(7). In human volunteers, oral administration of melatonin in doses 1-300 mg or 1g of melatonin daily for 30 days resulted in no observable negative side effects (8). In

another study, a randomized double blind clinical trial in healthy adult male subjects by oral administration of melatonin (10 mg/day for 28 days or a placebo) found no evidence of toxicity (9). Also, giving female rats 200mg melatonin/kg body weight (equivalent to an average weight human consuming 14 g melatonin daily) throughout pregnancy caused no maternal or fetal toxicity (10). Exogenous melatonin administration has been shown to provide neuroprotective effects in preclinical models of traumatic brain injury, reducing histological damage and cerebral edema as well as improving neurobehavioral outcomes in mice and rats (11-13) . Also, endogenous melatonin increases in cerebrospinal fluid of patients after severe traumatic brain injury and this increase correlates with oxidative stress and metabolic impairment. Taken together, melatonin appears to be a highly promising candidate to be tested as a neuroprotectant in the proposed studies.

Ketogenic Diet for Neuroprotection: Recent studies have shown that ketogenic diet (KD) and ketone bodies are neuroprotective in a variety of CNS injury models (14). The list includes 1) glutamate toxicity *in vitro* and *in vivo*, 2) kainic acid toxicity in mice, 3) hypoxia/anoxia in mice, 4) global ischemia in rat, 5) focal cerebral ischemia in rat, 6) traumatic brain injury in rat, 7) Alzheimer's mouse model, 8) Parkinson's mouse model, 9) Amyotrophic lateral sclerosis mouse model and 10) brain tumor-astrocytoma in mice. The neuroprotective effect of KD appears to be due to the unique properties of ketone metabolism which make it a more suitable cerebral fuel under various neuropathological conditions. Properties of ketone metabolism that might contribute to neuroprotection are outlined below. First, only three enzymes are involved in the sequential metabolism of the ketone body beta-hydroxybutyrate (β-OHB) to acetyl CoA compared to the 12 enzymatic steps involved in the case of glucose. Second, ketone bodies are more efficient in the mitochondrial energy production via multiple mechanisms. Third, ketone bodies decrease production of free radicals by decreasing the reduced form of coenzyme Q, which decreases its reaction with O_2 to form superoxide $O_2^{\cdot}$. Other mechanisms such as glutathione reduction, which aids in the destruction of H_2O_2, might also play important roles under these conditions. The mechanisms given above relate closely to the increased energy hypothesis (metabolic hypothesis) proposed to explain the antiepileptic actions of KD.

Side Effects of Ketogenic Diets and Ketone Body Esters as Potential Solutions: Adverse side effects have been noted with chronic use of KD in animal studies as well as in human populations. A majority of these findings are derived from pediatric studies due to the greater use of KD to control childhood epilepsy (14). Early problems include dehydration, nausea/vomiting, diarrhea, constipation and hypoglycemia. Later problems include growth retardation due to insufficient protein levels, hepatic failure, vitamin/mineral deficiencies, immune dysfunction, renal stones, hypercholesterolemia and cardiomyopathy. In animal studies, it was found that rats that were fed KD for one month had significantly impaired visual-spatial learning compared with rats that were fed normal diet (15). While KD had minimal effect on activity level and emotionality, brain growth was impaired significantly under strict KD conditions.

Based on studies done in animals with defects in fatty acid oxidation it seems likely that long chain fatty acids and their derivatives play critical roles in multiple aspects of the side effects mentioned above including cardiomyopathy. One way to overcome these long chain fatty acid mediated side effects is to use the ketone bodies

β-OHB and acetoacetate directly, in place of KD. However, infusion of sodium salts of ketone bodies would result in a dangerous sodium overload. This can be overcome by administering ketone bodies in their esterified form. These esters are pH-neutral, sodium-free and easily diffusible precursors of ketone bodies. This approach has the added advantage that their uptake into the brain will be limited only by their concentration in the blood, and not by specific uptake mechanisms (blood brain barrier) due to the hydrophobic nature of the corresponding esters. These esters are hydrolyzed to their corresponding ketone bodies by the action of nonspecific intracellular esterases. As mentioned above, we have tried this approach using the triacetate ester of glycerol (GTA) and have discovered that it is protective against TBI in the CCI model in the rat (16). Also, in a related study, no toxicity was detectable on its chronic usage for as long as 4 months (17).

In earlier studies, different types of ketone body esters have been synthesized and tested for parenteral nutrition as replacement for emulsions of log-chain triacylglycerols. Of these, two ketone body esters were found to be effective with little or no detectable toxicity. They are 1) 1,3-butanediol diacetoacetate and 2) glyceryl bisacetoacetate (18,19). As indicated earlier, metabolism of these esters involves hydrolysis of the esters by nonspecific esterases present in all tissues. In the case of 1,3-butanediol diacetoacetate, the 1,3-butanediol formed as result of the ester hydrolysis is subsequently oxidized in the liver in a sequential fashion, first by alcohol dehydrogenase and then by aldehyde dehydrogenase to form a racemic (R,S) β-OHB which will subsequently form the physiological ketone body acetoacetate (20,21). Intravenous infusion studies have shown that the ketone bodies can be increased in the blood effectively without any notable side effects (21). Based on these studies, the major advantages of administering the ketone bodies in the ester form were determined to be 1) stabilization of acetoacetate which decomposes spontaneously to acetone and CO_2, 2) pH neutrality of the infusate, which minimizes damage to peripheral vein and 3) absence of sodium in the infusate. In some studies done in the pig, the plasma concentrations of the nonhydrolyzed esters were found to be very low and dropped to zero as soon as the infusion was stopped. This reflects the high esterase activity of plasma and tissues of pig. One way to overcome this potential problem is to mix the ketone body esters with anti-esterase flavenoids, such as those found in grapefruit juice, and this will reduce premature hydrolysis in the plasma and liver, increasing delivery of the esters to the brain (22).

B. N-Acetylaspartate: A novel biomarker for traumatic brain injury in body fluids.

The rapid neuronal and glial damage after TBI is resistant to any known neuroprotective regimes so far available for clinical use. Even though it can be reduced to some extent with dedicated intensive care management, the delayed secondary effects of brain trauma can be very severe due to inflammation, edema, diffuse axonal injury and impaired neuronal energy metabolism. Because of these reasons, it is of great importance to start early management tailored according to the extent of injury. For the early determination of severity of injury and assessing the prognosis during and after intensive care treatment there is a critical need for a simple and accurate diagnostic marker for the brain injury. N-acetylaspartate (NAA) has attracted much attention as a noninvasive marker of functional integrity of neurons in traumatic brain injury (TBI) using magnetic resonance spectroscopy (23-27). Not only has NAA been

identified as a marker in traumatic brain injury, its functional roles in neuronal energy metabolism have given it a central role in several forms of progressive and non-progressive neuronal afflictions (28,29). In TBI, the levels of both NAA and ATP in specific areas of brain decrease soon after cerebral injury and their levels return to normal in parallel to the recovery phase (26,27). The reduction in NAA is a reliable measure of injury severity and brain specific mitochondrial dysfunction (27, 30). Interestingly, cyclosporine treatment which prevents mitochondrial injury also prevents the decrease in brain NAA levels (31). Using mass spectrometric method for analysis, it has been shown that the NAA can be used as a serum marker in ischemic stroke as early as 24 hours (32) and that it increases during reperfusion after an ischemic episode (33). NAA can be measured in all body fluids (blood, cerebrospinal fluid and urine) accurately using mass spectrometric analysis (34) and an increase in NAA in the urine is used as a reliable diagnostic marker for Canavan disease, a genetic disease in which NAA is increased in the brain (34, 35). However, NAA has not been tested as a biomarker of TBI in any body fluid. The central hypothesis is that changes of NAA in the brain is reflected in its levels in the body fluids- blood, cerebrospinal fluid and urine-, and that changes in NAA levels in one or more of these body fluids can be used to monitor brain injury and recovery in TBI, from a diagnostic as well as prognostic angle.

II.2. Literature Search for Duplication:

II.2.1. Literature Source(s)

Literature Sources Searched: PubMed, BRD, FEDRIP

II.2.2. Date of Search: 2-19-2013

II.2.3. Period of Search: 1970-present

II.2.4. Key Words and Search Strategy: Glyceryltriacetate, traumatic brain injury, blast overpressure injury, rat, animal model, ketone body ester, melatonin, N-acetylaspartate, TBI biomarker.

II.2.5. Results of Search: ***A. Neuroprotection Strategies for TBI.*** *PUBMED:* Eighty three articles were found when keywords traumatic brain injury and melatonin were combined. None of them involves the proposed work. One article was found when key words traumatic brain injury and ketone body esters were combined. However, 33 articles were found when ketone body instead of ketone body ester was used. None of them involves the proposed work. No additional articles were found when traumatic brain injury was replaced with blast over pressure injury. One article was found when key words traumatic brain injury and glyceryltriacetate (GTA) were combined. This article was a recently published article from the PI's laboratory on the ongoing work. *BRD:* None. *FEDRIP:* One article was found when traumatic brain injury and melatonin were combined. This work was unrelated to the proposed work.

B. N-Acetylaspartate: A novel biomarker for traumatic brain injury in body fluids. PUBMED: Twenty five articles were found when keywords traumatic brain injury, N-acetylaspartate (NAA) and biomarker were combined. All those articles describe the

use of NAA as a biomarker for TBI in the brain by MRS techniques, but not in the body fluids. Thus, none of them involves the proposed work. BRD: None. FEDRIP: None.

Therefore, the proposed research and the goals do not duplicate earlier research in these areas of research.

OBJECTIVE\HYPOTHESIS:

A: Neuroprotection Strategies for TBI. The **central hypothesis** is that melatonin and esters of the ketone bodies are very useful as neuroprotectants for clinical use because of their effectiveness, lack of toxicity and lipophilic properties that help to overcome the blood brain barrier. We propose the following specific aims. First, we will synthesize esters of β-OHB and acetoacetate using glycerol as well as 1,3-butane-diol separately, and test their relative effectiveness as well as that of melatonin alone as well in combinations employing our ongoing CCI model of TBI in the rat. Second, we will determine whether or not these esters and melatonin exhibit acute or chronic toxicity by analyzing blood chemistry and tissue pathology. Subsequently, we will determine whether the effectiveness can be increased by combining with 1) GTA, the acetate ester we have used previously and 2) grapefruit juice, which contains anti-esterase flavenoids that will reduce premature hydrolysis of the esters in the gut and liver, thus increasing delivery of intact esters to the brain. Based on the outcome from the CCI model of TBI, we plan to test selected strategies in the blast over pressure model of brain injury as well.

B. N-Acetylaspartate: A novel biomarker for traumatic brain injury in body fluids:.NAA is present in the human brain at a concentration of approximately 10 mM, and an approximately 1000-fold gradient exists between the intracellular and extracellular compartments. NAA has been found to be a reliable biomarker in ALS patients with an approximately 5 fold higher serum concentration than in healthy age matched controls .Our central hypothesis is that brain injury causes cellular damage and NAA efflux from neurons to the extracellular space and subsequently to the bloodstream. The NAA efflux can be directly measured in the cerebrospinal fluid and will be reflected in body fluids such as blood and urine. Changes in NAA levels in one or both of these body fluids can be used to monitor brain injury and recovery after TBI to aid in diagnosis as well as prognosis. Our immediate goal is to develop a simple and reliable method for analyzing NAA in serum and urine after TBI for diagnostic purposes,validating its specificity to TBI and demonstrating that the NAA measurement can be converted to a point-of-care(POC) test. The long term goal of this proposal is to adapt the NAA biomarker method to a simplified hand held biosensor device for use on injured soldiers in combat support hospitals as well as for use in civilian hospital emergency rooms

III. MILITARY RELEVANCE:

A. Neuroprotection Strategies for TBI

Successful outcomes in the current studies will provide an adjunct therapy to the current TBI regimen of sedatives and anti-inflammatory agents. The most effective ketoesters and GTA can be used intravenously when TBI patients arrive at a medical facility, and can be given orally when appropriate. Bypassing both glucose and N-

acetylaspartate (NAA) metabolism in TBI patients by directly providing acetate and ketone bodies for brain energy production would help compensate for the substantial reductions in NAA and ATP levels observed after head injury. Providing additional acetate for nuclear histone acetylation reactions would help maintain transcriptional control of gene expression during cellular repair and recovery. Prolonged treatment with GTA after brain injury could also contribute to remyelination of injured white matter, and improve long term outcomes. Melatonin can act as an antioxidant and as an anti-inflammatory agent with little or no toxicity on long term usage.

Currently there is no effective pharmacological treatment for reducing the delayed, secondary neurological damage resulting from various forms of traumatic head injury. The proposed ketone body and acetate therapy is a non-pharmacological, nutrient-based method for improving brain energy status and facilitating CNS repair and recovery. Because GTA and the ketoesters are hydrophobic molecules, they will pass through the blood brain barrier, and even reach brain areas that have reduced blood flow resulting from injury. These compounds are inexpensive to manufacture and easy to administer in a field hospital setting. Based on our previous results with GTA we anticipate both improved long term neurological outcomes, and increased recovery rates of soldiers suffering from diffuse (blast overpressure) or traumatic brain injuries. An optimized ketoester and GTA treatment cocktail, possibly including anti-esterase flavenoids, could be ready for phase I trials quickly, and for field trials shortly thereafter. Melatonin also can be very helpful for this purpose.

B. N-Acetylaspartate: A novel biomarker for traumatic brain injury in body fluids: TBI has been called the "signature injury" of the Iraq war. Since Operation Iraqi Freedom began five years ago, the Department of Defense reports that more than 1,500 U.S. soldiers have died and more than eleven thousand American troops have been wounded. Among the most debilitating wounds are traumatic brain injuries. Thanks to such new helmet materials and technology, many war fighters in the global war on terror are surviving head injuries that in previous wars would have been fatal; however, they subsequently are plagued by TBI, which can be a chronic and debilitating condition without proper diagnosis and treatment. Also veterans with less severe brain damage are not getting the medical attention they need due to lack of diagnostic techniques. In view of the above situation, development of a sensitive and cost effective biomarker which could be used for screening hence identifying mild injuries as well as for predicting the progression and prognosis of moderate to severe injuries will be of tremendous importance to the soldiers, their family and the nation as a whole.

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures:

A. Neuroprotection Strategies for TBI

Experimental Plan: A summary chart of the experimental plan is shown in Figure 1 below. As mentioned above, we plan to test four ketoesters for efficacy in our TBI model system. They are 1) 1,3-butane-diol-diaceoacetate (BDAA), 2) 1,3-butane-diol-di-β-hydroxybutyrate (BDHB), 3) glyceryl triacetoacetate (GTAA) and 4) glyceryl tri β-hydroxybutyrate (GTHB). Initially we plan to do a dose-response study in control rats

to test their effectiveness in increasing ketone body concentrations in the brain. We will use the molar dose range we have used earlier for similar studies we have done using GTA (16,17). An HPLC method we have described earlier will be used to simultaneously measure acetoacetate, β-OHB and acetate levels in the brain to determine the optimal dose for each ketoester. Subsequently, we also will do a time course study with the optimal dose obtained from the dose-response study. Groups of five male rats will be used for each time point or dose. This study will be done for all the four ketoesters before they are used in the TBI study. The experimental plan will be adjusted as needed depending on the dose-response and time-course studies. For example, if the time course studies show rapid metabolism of certain esters, then the number of doses per day will be adjusted accordingly. This study also will reveal whether or not any of these ketoesters have any yet unknown acute toxic effects. Brain Injuries will be performed as described in the previous protocol and as detailed below.

Similar dose response and time course studies are not planned for melatonin since we already know the effective dose ranges based on earlier studies in other model systems. We plan to select three doses in the range for the proposed experiments. Also, we plan to use intraperitoneal route in the case of melatonin based on previous studies. In contract, the ketoesters will be given intragastrically using a blunt end syringe as we have done earlier for GTA administration.

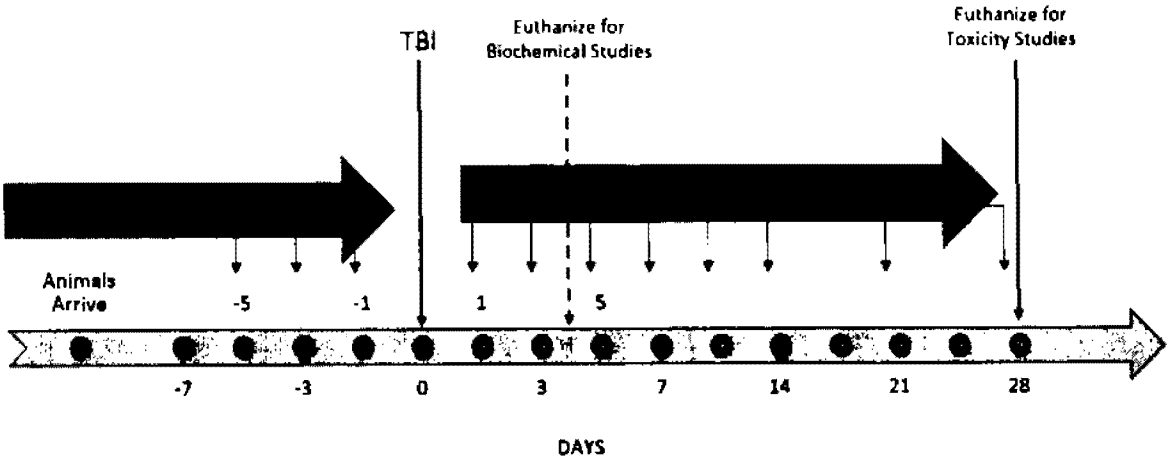

Figure 1: Timeline summary chart for the TBI experiments. See text for details.

In general, the methods we have followed in the case of GTA in the previous protocol will be followed to determine neuroprotective effectiveness with all four ketoesters and melatonin. Two biochemical and three behavioral end points will be followed to assess effectiveness. The biochemical end points will include 1) changes in NAA content in the ipsilateral side and 2) changes in ATP content on the ipsilateral side. The behavioral end points will include 1) neurological score 2) Rotarod balance test and 3) locomotion based parameters. We have found that we cannot perform craniotomy surgery and impact injury on more than 25 animals per day. Therefore we plan to limit each experiment to a total of 25 animals. These will include 5 groups of five animals: 1) sham control (surgery but no CCI injury), 2) injured-untreated and 3-5) three groups of injured and treated animals with the 3 doses selected from the initial dose-response

study. The experiments will be repeated for each of the 4 ketoesters listed above and melatonin. Also, the experiments will be repeated three times to increase the number of animals in each group (5 animals for biochemical end points and 10 animals for behavior end points); these animal numbers are based on our previous experience with the use of GTA as a neuroprotectant in TBI (5). **Our plan is to administer the ketone esters intragastrically, melatonin intraperitoneally, all once daily during the first week and once on alternate days during the next three weeks.** The animals will be tested for neurological score, Rotarod balancing and locomotion activity on alternate days starting from the second day. For measurement of biochemical end points, the studies will be repeated as described above except that the animals will be euthanized on the fourth day following the behavioral testing done on days 1 and 3. We have designed the experimental plan based on our recent experience with testing the neuroprotective effect of GTA on TBI (16). The methods given in our recent publication will be used for determination of NAA and ATP. The biochemical analyses will be done using fresh or frozen tissues obtained from animals euthanized by decapitation under anesthesia. The methods for the neurological scoring, Rotarod and locomotion behavioral tests are given below.

Traumatic brain injury in the rat using controlled cortical impact: Adult male Sprague-Dawley rats (200-300 g wt) will be housed on a 12-h light/dark cycle (06:00-18:00) at 22-23°C with free access to food and water. Rats will be allowed to acclimate for 5-7 days prior to experimental procedures. Rats will be initially anesthetized with 4-5% isoflurane in 100% O_2 in a vented anesthesia chamber. Following endotracheal intubation, rats are mechanically ventilated with a 1-3% isoflurane mixture. The rats are then mounted in the injury device stereotaxic frame in a prone position secured by blunt ear bars and incisor bar. The head is held in a horizontal plane with respect to the interaural line. An incision and an 8-mm craniotomy is made over the right primary and secondary motor cortex. Injury parameters will include using a 6mm flat steel impact tip, with injuries localized around motor cortex at 0.5 mm posterior to the coronal suture and 3 mm lateral to the sagittal suture (5m/s, 2.5mm deformation). Core body temperature will be monitored by a rectal thermometer and maintained at 36 to 37°C. After removal of the bone flap, injury will be produced with the CCI device (Pittsburg Instruments, Inc.) that was recently acquired and calibrated. Target insult parameters will be a penetration depth of 2.5 mm (for moderate injury) and 3.5 mm (for severe injury) and a constant velocity of 4 m/s. These conditions produce a reliable lesion that progresses over 1 week. Impact velocity will be measured for reproducibility. The bone scalp will be replaced and sealed with dental cement, and the scalp incision will be closed with stainless steel clips. The animals will be placed in a heated cage (35-37°C) to maintain body temperature while recovering from anesthesia. Sham-operated controls will receive craniotomy as described above but no impact injury. The impact tip will be placed lightly on the dura, and then removed before sealing the wound. We have has extensive experience in this model of TBI based on our recent work with GTA, as described in the previous protocol and our recent publication of this work (16).

Neurological score: The neurological score for each CCI injured animal will be assessed on the behavioral testing days according to the method of Garcia et al. (36).

Briefly the 6 part scoring is done as described below by investigators blinded to the treatment groups.

1. Spontaneous Activity: The animal will be observed for 5 minutes in its cage. Scores indicate the following: 3, rat moved around and approached at least three walls of the cage; 2, slightly affected rat moved about in the cage but did not approach all sides and hesitated to move, although it eventually reached at least one upper rim of the cage; 1, severely affected rat did not rise up and barely moved in the cage; and 0, rat did not move at all.

2. Symmetry in the Movement of Four Limbs: The rat is held in the air by the tail to observe symmetry in the movement of the four limbs. Scores indicate the following: 3, all four limbs extended symmetrically; 2, limbs on left side extended less or more slowly than those on the right; 1, limbs on left side showed minimal movement; and 0, forelimb on left side did not move at all.

3. Forepaw Outstretching: The rat is brought up to the edge of the table and made to walk on forelimbs while being held by the tail. Symmetry in the outstretching of both forelimbs is observed while the rat reached the table with the hindlimbs kept in the air. Scores indicate the following: 3, both forelimbs were outstretched, and the rat walked symmetrically on forepaws; 2, left side outstretched less than the right, and forepaw walking was impaired; 1, left forelimb moved minimally; and 0, left forelimb did not move.

4. Climbing: The rat is placed on the wall of a wire cage. Normally the rat uses all four limbs to climb up the wall. When the rat was removed from the wire cage by pulling it off by the tail, the strength of gripping is noted. Scores indicate the following: 3, rat climbed easily and gripped tightly to the wire; 2, left side was impaired while climbing or did not grip as hard as the right side; and 1, rat failed to climb or tended to circle instead of climbing.

5. Body Proprioception: The rat is touched with a blunt stick on each side of the body, and the reaction to the stimulus is observed. Scores indicate the following: 3, rat reacted by turning head and was equally startled by the stimulus on both sides; 2, rat reacted slowly to stimulus on left side; and 1, rat did not respond to the stimulus placed on the left side.

6. Response to Vibrissae Touch: A blunt stick is brushed against the vibrissae on each side; the stick is moved toward the whiskers from the rear of the animal to avoid entering the visual fields. Scores indicate the following: 3, rat reacted by turning head or was equally startled by the stimulus on both sides; 2, rat reacted slowly to stimulus on left side; and 1, rat did not respond to stimulus on the left side.

The score given to each rat at the completion of the evaluation is the summation of all six individual test scores. The minimum neurological score is 3 and the maximum is 18.

Rotarod balance test: See section V. 4.4.6

Locomotor activity and Habituation experiments: See section V.4.4.6

Safety/Toxicity Analyses: At the end of the 1 month chronic study, the animals will be euthanized by transcardial perfusion with 10% neutral buffered formalin under anesthesia. While the animal is under anesthesia, about 1 ml blood will be removed

from the heart before the start of the formalin perfusion. Subsequently, the fixed tissue will be removed and used for histological and immunohistochemical analyses. Serum obtained from blood will be used for the biochemical analysis to determine safety/toxicity due to the treatment conditions.

Studies involving treatment combinations: Following successful completion of the ketoester and melatonin studies, we plan to test different combinations for possible additive or synergistic effects. Also, we plan to test effect of grapefruit juice on ketone body ester/GTA effectiveness in view of the fact that grapefruit juice contains potent anti-esterase flavenoids that will prevent premature hydrolysis of the esters in the gut, liver and plasma, possibly increasing delivery of the esters to the brain and enhancing their effectiveness. Our plan is to mix the esters with grapefruit juice in equal proportion and administer them via oral or intragastric routes. We have no reason to think that the effect, if any, will be specific to a particular ketone ester or ketone ester/GTA combination because of the nonspecific nature of these esterases. Therefore, we plan to perform this study with the most effective ketone ester or ketone ester/GTA combination. All other aspects of the study will be as described for individual ketone esters.

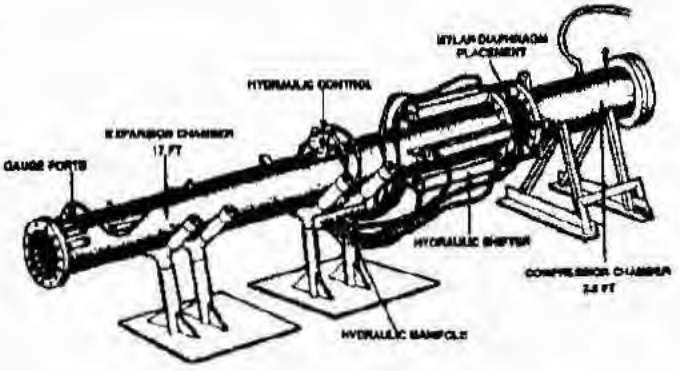

Figure 2. Shock tube used to generate BOP injuries in rats

Blast over pressure injury: The blast injury will be performed at WRAIR (see Figure 2) under the supervision of Dr. (b)(6) a collaborator in the proposed studies (WRAIR animal protocol # 11-PN-23S). Groups of male Sprague Dawley rats (250-300 g) will be anesthetized with isoflurane, placed in a prone position in a holder that is transversely secured across the mouth of the shock tube (Figure 2) and exposed to sham treatment (i.e. anesthesia and positioning without BOP) or moderate BOP (126kPa) using a compression driven shock tube, in which air blast is triggered by mylar membranes rupturing at predetermined pressure (60). Duration of apnea and latency to recover righting reflex after BOP will be recorded for subjects in all the injury groups. Categorization of a 126kPa BOP intensity as moderate is based upon the observations Dr. (b)(6) research group have made with rats exposed to this pressure in experiments conducted to date (37). Higher pressure injury will be tested in subsequent studies based on the results with the moderate injury. Detailed studies using this brain injury model will be planned in the future if the initial results are encouraging.

As mentioned above, the BOP injury will be carried out at WRAIR under the supervision of Dr. (b)(6) We understand that LAM has developed a procedure to

transport animals to and from WRAIR for this purpose. This currently approved procedure at LAM will be followed.

Calculation of the number of animals required

Experiment 1: Initial Dose Response and Time Course Studies using Control Rats.

Dose Response = 120 (5 animals/group x 4 ketoesters x 6 doses (0 dose + 5 doses around the one used for GTA in the earlier studies)

Time Course = 120 [5 animals/group x 4 ketoesters x 6 time points (0, 2h, 4h, 8h and 16h and 32h)]

Total = 240 (120 + 120): **Pain Category: C =240 , D =0 , E =0 .**

Experiment 2: TBI Study with Individual Neuroprotectants.

Animals required for each TBI experiment = 25 (5 animals /group x five groups[sham control --surgery but no CCI injury, injured-untreated, three groups of injured and treated animals with the 3 doses selected from the initial dose-response study].

Repetition of the study = 3

Number of Neuroprotectants = 5 (four ketoesters and melatonin)

Total = 375 (25 x 3 x5). **Pain Category: C =0 , D =0 , E =375**

All the animals will undergo surgery under anesthesia, but the subsequent pain will not be alleviated. So all the animals are listed under category E.

Experiment 3: TBI study with combination of Neuroprotectants

Animals required for each TBI experiment = 25 (5 animals /group x five groups[sham control--surgery but no CCI injury, injured-untreated, three groups of injured animals treated with three optimal doses].

Repetition of the study = 3

Combinations = 4 (ketone body ester + melatonin, GTA + melatonin, ketone body ester + GTA and ketone body ester + grape fruit juice)

Total = 300 (25 x 3 x 4). **Pain Category: C =0 , D =0 , E = 300.**

All the animals will undergo surgery under anesthesia, but the subsequent pain will not be alleviated. So all the animals are listed under category E.

Experiment 4: Blast Over Pressure (BOP) Injury Model

Animals required for each BOP experiment = 25 (5 animals /group x five groups[sham control (surgery but no BOP injury, injured-untreated, three groups of injured and treated animals with 1- optimal ketone body ester, 2-GTA and 3-melatonin]

Repetition = 3

Total = 75 (3 x 25). **Pain Category: C = 15 , D =0 , E = 60 .**

The control animals will be given anesthesia, but no surgery or exposure to BOP. So they are listed under category C. All the other animals will be subjected to BOP under anesthesia, but the subsequent pain will not be alleviated. So these animals are listed under category E.

B. N-Acetylaspartate: A novel biomarker for traumatic brain injury in body fluids:

The goal is to analyze the time course of NAA concentration changes in serum samples after brain injury using the controlled cortical impact model of TBI in rats. Serum samples will be analyzed to determine the time course of the rise and decline of NAA levels after injury and to compare the changes in NAA levels using three levels of injury severity; mild, moderate and severe.

Controlled cortical impact (CCI) model: We will follow our ongoing CCI protocol described in the previous section with minor modifications. The surgery will be conducted on a clean lab bench surface with restricted traffic flow through the area during surgery. The lab bench will be disinfected with 70% alcohol before and after each animal surgery. Briefly, male Sprague-Dawley rats (200-300 g) are anesthetized with 3% isoflurane vaporized in O2 (flow rate = 0.8 L/min) and then maintained with 2% isoflurane during surgery. When the animal is anesthetized, its head will be shaved with a hair clipper. The head will be cleaned with betadine and alcohol, each repeated 3 times alternately. Then the animal will be placed into a stereotaxic frame (appropriate frame size will be used for rats) after treating its pressure points such as ears and nose with lidocaine jelly. A heated pad with thermister-controlled feedback will be put between the animal's body and the base of the stereotaxic frame. Following fixing the head in a stereotaxic frame, and after retracting the scalp, a dental drill-trephine is used to make a 5 mm craniotomy over the left motor cortex, 0.5 mm posterior to the coronal suture and 3 mm lateral to the sagittal suture. Care will be taken to avoid injury to the dura, which will be continuously bathed in sterile physiological saline during the procedure. Body temperature is monitored throughout the surgery by a rectal probe and

maintained at 37.0 ± 0.5°C by using a heated pad, as indicated above. After removal of the bone flap injury is produced with a CCI device (Pittsburg Instruments, Inc.) that is pre-calibrated. Immediately after the injury, the bone flap is replaced and sealed with dental acrylic cement and the scalp is sutured and skin closed. The animals are then placed in a heated cage (35-37°C to maintain body temperature while recovering from anesthesia. Sham-operated controls will receive craniotomy as described above but no impact injury.

This injury model will be used in order to analyze increases in serum NAA levels at several post injury time points and with 3 levels of impact injury severity. The three injury severity models are defined as mild (2mm CCI impact tip with 1mm of cortical deformation0, moderate(6mm impact tip with 1mm deformation) and severe (6mm impact tip with 3mm of cortical deformation). Impact parameters for each of the 3 levels of injury severity will be measured for reproducibility. Injury severity will be confirmed for each rat by monitoring pre and post-injury NAA levels in the brain at several time points using magnetic resonance spectroscopy (MRS) using the small animal MRS system at USUHS. Greater NAA reductions in the left hemisphere as detected by MRS will be indicative of more severe injuries.

Rat blood sample collection: Blood samples will be taken from each rat at multiple post-injury time points via a temporary vein cannula that will be implanted during CCI surgery. Blood samples (0.1 - 0.2 ml) will be taken at 20 min., 40 min., 1hr, 2hr, 4hr, 24hr, 48 h, 1 week, 2 weeks, 3 weeks and 4 weeks. Blood will be centrifuged, and serum samples will be frozen rapidly on dry ice for later analysis.

Noninvasive analysis of brain NAA by MRS: As an independent measure of injury severity and NAA loss from the brain, NAA levels in the left frontal pole will be monitored by MRS prior to injury, and at several post-injury time points including 1 hour, 24 hours, 48 hours, 1 week and 4 weeks post-injury.

In vivo MRS will be performed on the BrukerBioSpec system (Bruker NMR, Inc., Billerica, MA) in the Translational Imaging Facility at CNRM (Center for Neuroscience and Regenerative Medicine). This system consists of a 7-Tesla (T), 20-cm horizontal bore, superconducting magnet (Magnex Scientific, Abingdon UK) with a Biospec 70/20 console and computer workstation with latest Paravision software for imaging and spectroscopy. An Autopac mouse and rat positioning and physiological monitoring system, an 86 mm quadrature transmit coil and a phase array mouse head coil (4 channels) will be used for MRS acquisition. The rats will be anesthetized with isoflurane (1-2%) during positioning and scanning. Localized single voxel PRESS MRS will be applied with parameters of TR=2500ms, TE=25ms, number of average = 256, and voxel size of 3-5 mm3. We have used this system to monitor the levels of NAA in Asp-NAT knockout heterozygote mice with voxels localized to the hippocampus. The system is highly sensitive and can detect even modest changes in brain NAA levels associated with mild CCI injuries.

Total number of rats for the study = 10 animals/group X four groups (control, mild, moderate and severe) X 2 (1 + 1 confirmation study) = 80. **Pain Category C = 0**

; D = 0 ; E = 80.

All the animals will undergo surgery under anesthesia, but the subsequent pain will not be alleviated. So all the animals are listed under category E.

Calculation of total number of animals

A. Neuroprotection Strategies for TBI

Experiment 1 + Experiment 2 + Experiment 3 + Experiment 4 = 240 + 375 + 300 + 75 = 990. **Pain Category C = 255, D = 0 , E = 735**

B. N-Acetylaspartate: A novel biomarker for traumatic brain injury in body fluids.

Experiment 1 = 80. **Pain Category C = 0, D = 0, E = 80**

C. Extra animals for training procedures and anesthesia failures.

10% of the animals in category E = 82

Grand Total = 990 + 80 + 82 = 1152.
Pain Category C =255 ; D = 0 ; E = 897

V.2. Data Analysis: Data will be presented as mean ± SEM. Parametric data (NAA, ATP etc.) will be analyzed using a paired 2-tailed t test for the paired data or a 1-way analysis of variance (ANOVA) followed by (b)(6) multiple comparisons post test. Nonparametric data (histology data, behavioral data) will be analyzed using a Wilcoxon signed rank test for paired data or a Kruskal-Wallis test (nonparametric ANOVA). An associated probability value of $P < 0.05$ will be considered significant.

Power analysis using the quantitative data obtained from our earlier studies have indicated that for behavioral studies a sample size of 10 animals per group will have 80% power to detect a difference of 1.5 standard deviations between groups assuming a 5% significance level, and should be sufficient for the outcomes we intend to measure; power calculations were performed using nQuery Advisor® 4.0 software. Similar calculations have indicated that 5-6 animals/group is sufficient for biochemical and immunohistochemical studies. The total number of animals for each experiment has been calculated based on the above considerations.

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered: The specific nature of the project does not permit use of non-animal alternatives. The global physiological changes occurring in different cell types in the *in-vivo* brain injury models cannot be reproduced in single cell culture system, or any alternatives.

V.3.2. Animal Model and Species Justification: Controlled cortical impact (CCI) in the rat is one of the most extensively used models of TBI in the literature and this allows us to compare our results with those from other established laboratories.

V.3.3. Laboratory Animals

	Species #1	Species #2
V.3.3.1. Genus & Species:	Rattus Norvegicus	
V.3.3.2. Strain/Stock:	Sprague-Dawley	
V.3.3.3. Source/Vendor:		
V.3.3.4. Age:		
V.3.3.5. Weight:	200-300g	
V.3.3.6. Sex:	Male	
V.3.3.7. Special Considerations:		
V.3.4. Number of Animals Required (by Species):	1152	

V.3.5. Refinement, Reduction, Replacement (3 Rs):

V.3.5.1. Refinement:

In the initial studies conducted to test the effect of GTA on traumatic brain injury using the CCI model, we have focused on the obvious behavioral, biochemical and histological parameters which are known to be well associated with TBI. We have found that most of the animals recover fast and start running around in apparent normal way in a matter of hours. Occasionally, some (less than 10%) are found to show a greater impairment. As a refinement, we plan to look for such animals and euthanize them since they are likely to be outliers in the study as well. Also, animals will be acclimated before the behavioral studies.

V.3.5.2. Reduction:

We have considered reducing the total number of control animals by avoiding separate control groups. However, in view of the variations between animals, especially in behavioral parameters, we do not feel comfortable in comparing with a control group done on another day. Therefore, we are unable to reduce the number of animals in the control group. Also, we have tried to use the minimum number of animals for each experiment based on our prior experience with GTA (earlier protocol).

V.3.5.3. Replacement:

In silico methods and tissue culture approaches cannot be used for evaluation of the questions studied here, since these actions can only be observed in an intact living animal. At the present time, animals lower than rodents in the phylogenetic scale cannot be used to model brain injury in human, because of wide anatomic and physiological differences.

V.4. Technical Methods:

V.4.1. Pain / Distress Assessment:

V.4.1.1. APHIS Form 7023 Information:

V.4.1.1.1. Number of Animals:

	Species #1	Species #2
V.4.1.1.1.1. Column C:	255	
V.4.1.1.1.2. Column D:		
V.4.1.1.1.3. Column E:	897	

V.4.1.2. Pain Relief / Prevention:

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization:

For CCI model of TBI, rats will be initially anesthetized with 3-5 % isoflurane in 100% O_2 in a vented anesthesia chamber. Rats under anesthesia will be placed on a stereotaxic instrument and continuous isofluorane anesthesia (2%) will be given using a nose cone.

For blast overpressure exposure, rats will be initially anesthetized as described above. However, continuous anesthesia will not be given because of the short duration of the blast exposure. That rats are under anesthesia will be determined by their lack of response to pinching the toes.

We do not plan to use analgesia for these studies. One of the main purpose of these studies is to evaluate the anti-inflammatory and healing effects of different neuroprotectants or combinations on CCI-induced or BOP-induced brain injuries and the associated pain to be evaluated by behavioral/neurological tests. Thus, any additional pain relief efforts in experiment will interfere with the goal of this study. The same situation applies to the other goal of testing NAA as marker for TBI in body fluids. However, pain will be alleviated to the extent possible without compromising the goals of the project. Carprofen (2-5 mg/kg, SC) or meloxicam (1-2 mg/kg, SC) will be given to rats as an analgesic, if animal show signs of pain or stress such as a hunched posture, not eating/drinking, reluctance to move during the recovery period.

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions:

Animals will be dually housed and adapted to their environment for at least 5 days prior to the experiments. During this time, the animals will be adapted to the behavioral studies by two trial runs on the behavioral study set ups.

V.4.1.2.3. Paralytics: N/A

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures:

V.4.1.3.1. Sources Searched: PubMed, Agricola:

V.4.1.3.2. Date of Search: 3/28/2013

V.4.1.3.3. Period of Search: 1966-2012

V.4.1.3.4. Key Words of Search: animal, rat, mouse, pain, analgesia, transcardial perfusion, controlled cortical impact model.

V.4.1.3.5. Results of Search: PUBMED: A total of 152 publications were obtained when all key words except transcardial perfusion were used. However, none appeared when transcardial perfusion was included in the search. All of the 152 publications involved studies on different aspects of pain, including neural mechanisms and newer pain relieving agents. When key words rat and transcardial perfusion were combined, 47 publications describing studies involving the use of transcardial perfusion were obtained. When key words mouse and transcardial perfusion were combined, 13 publications describing studies involving the use of transcardial perfusion were obtained. None of them provided any alternatives to the proposed painful procedures. Agricola: None of the publications provided an alternative to the painful procedure used in this protocol.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification:

One of the main purpose of this study is to evaluate the anti-inflammatory and healing effects of different neuroprotectants or combinations on CCI-induced or BOP-induced *brain injuries and the associated pain* to be evaluated by behavioral/Neurological tests. Thus, any additional pain relief efforts in experiment will interfere with the goal of this study. The same situation applies to the other goal of testing NAA as marker for TBI in body fluids. However, pain will be alleviated to the extent possible without compromising the goals of the project. Carprofen (2-5 mg/kg, SC) or meloxicam (1-2 mg/kg, SC) will be given to rats as an analgesic, if animal show signs of pain or stress such as a hunched posture, not eating/drinking, reluctance to move during the recovery period.

V.4.2. Prolonged Restraint: N/A

V.4.3. Surgery:

V.4.3.1. Pre-surgical Provisions:

The surgical procedures will be performed aseptically following the LAM guidelines. Anesthesia will be induced by isoflurane vapor in 100% oxygen in a commercially available induction chamber. Once anesthesia is induced, animals will be transferred to the designated surgery area and anesthesia will be maintained via nose cone. See Section V.4.1.2.1 Anesthesia/Analgesia/Tranquilization for details.

When the animal is anesthetized, its head will be shaved with a hair clipper. The head will be cleaned with betadine and alcohol, each repeated 3 times alternately. Then the animal will be placed into a stereotaxic frame (appropriate frame size will be used

for rats) after treating its pressure points such as ears and nose with lidocaine jelly. A heated pad with thermister-controlled feedback will be put between the animal's body and the base of the stereotaxic frame. Ophthalmic ointment will be applied to the eyes to prevent dryness. The body will be covered with a sterile drape with an opening to expose the head.

V.4.3.2. Procedure: *Animal surgery, anesthesia and CCI-TBI:* The surgery will be conducted at the Surgery room, Center of LAM on a clean bench surface under strict aseptic precautions with restricted traffic flow through the area during surgery. The lab bench will be disinfected before and after each animal surgery. Adult male Sprague-Dawley rats (200-300g wt) will be initially anesthetized with 3-5% isoflurane in a 100%O_2 mixture in a vented anesthesia chamber. The rats are then mounted in the injury device stereotaxic frame in a prone position secured by ear bars and incisor bar and are mechanically ventilated with a 1-3% isoflurane in 100% O_2. The rat head will be held in a horizontal plane with respect to the interaural line. An incision and a 6mm craniotomy is made over the left parietal cortex (Bregma 3.70mm, interaural 12.70mm). The core body temperature will be monitored by a rectal thermistor probe and maintained at 36 to 37°C. After removal of the bone flap, injury will be produced with the CCI device. A penetration depth of 2.5mm for moderate injury and 3.5 mm for severe injury with a velocity of 4m/s will be used. Impact velocity will be measured. The bone scalp is replaced and sealed with dental cement, and the scalp incision is closed with surgical clips.

Temporary vein cannula implantation: We plan to implant a temporary cannula on the lateral tail vein since repeated blood samples are required over a relatively short period of time. This will be done during the surgery associated with the CCI. An intravenous catheter is inserted into the vein by puncture of the skin and taped in situ . A heparin flush is used (0.1 ml) after placement and between samples to prevent clotting. An access port is inserted into the exteriorized end of the cannula, which stops the blood from flowing, and the catheter is taped into place. Aseptic technique will be used and a local anaesthetic cream (e.g. EMLA cream) will be applied to the site 30 minutes prior to insertion of the catheter. The tail will be washed with diluted Hibiscrub (1%) in order to see the blood vessel. The lateral tail vein will be accessed approximately one-third along the length of the tail from the tail tip.

V.4.3.3. Post-surgical Provisions: After CCI-TBI surgery, animals will be kept in warm condition by a heated blanket or light until they recover from anesthesia. The surgical area will be observed, and Carprofen (2-5 mg/kg, SC) or Meloxicam (1-2 mg/kg, SC) will be given to rats as an analgesic, if animal show signs of pain or stress such as a hunched posture, not eating/drinking, reluctance to move during the recovery period.The animals will be observed twice daily after surgery and recovery.

V.4.3.4. Location: (b)(6) facilities at USUHS

V.4.3.5. Surgeon: Dr (b)(6)

V.4.3.6. **Multiple Major Survival Operative Procedures**: N/A

V.4.3.6.1. **Procedures**: N/A

V.4.3.6.2. **Scientific Justification**: N/A

V.4.4. **Animal Manipulations**:

V.4.4.1. **Injections**:

Drug name (concentration)	Dose	Frequency	Route	Site	Volume	Needle size
Neuroprotectant keto esters (1 gm/ml)	5-8 g/kg	Once or once daily	intragastric	Stomach via mouth	Up to 2.0 mL	Gavage needle for rat
Melatonin (10 mg/ml)	20 mg/kg	Once daily	Intraperitoneal	Lower abdomen	Up to 0.5 ml	25 ga 1 in
Fatal Plus or equivalent (50 mg/ml)	85-100 mg/kg	Once	Intraperitoneal	Lower abdomen	Up to 0.5 ml	25 ga 1 in
Carprofen (7.5 mg/ml)	2-6 mg/kg	Once	subcutaneous	Interscapular	Up to 0.2 ml	25 ga 1 In
Meloxicam (2.5 mg/ml)	1-2 mg/kg	Once	subcutaneous	Interscapular	Up to 0.2 ml	25 ga 1 in

V.4.4.2. **Biosamples**: Blood will be collected from live animals via temporary vein cannula. Tissues such as brain, lung, liver, kidney, heart and blood will be collected post mortem.

V.4.4.3. **Adjuvants**: N/A

V.4.4.4. **Monoclonal Antibody (MAbs) Production**: N/A

V.4.4.5. **Animal Identification**: The animals will be identified by cage card. However, individual animals after procedure will be given a particular identifying tattoo on their pinna of the ear, tail, arms or legs.

V.4.4.6. **Behavioral Studies**: The behavioral studies will be performed daily starting at 24h following TBI. Given the wide spread nature of the brain damage in focal brain injuries such as in the proposed TBI model, we expect major and multiple behavioral changes in these animals . Our collaborator, Dr (b)(6) has extensive

(Endevco) incorporated into a low profile aluminum holder are used to record the static (i.e. side-on pressure) and dynamic pressure (i.e. blast wind) to which each rat is exposed. Piezoresistive gauges (Endevco) incorporated into a low profile aluminum holder are used to record the static (i.e. side-on pressure) and dynamic pressure (i.e. blast wind) to which each rat is exposed. For whole body exposures, anesthetized rats are placed in a transverse prone position in a mesh pouch that is positioned 2.5 ft within the mouth of the shock tube. The mesh pouch is suspended and tightly secured to the 4 arms of the holder.

V.4.4.8. Tissue Sharing: Tissues may be shared with other investigators upon request.

V.4.5. Study Endpoint: The animals will be euthanized for tissue collections and also for histological analysis at the end of each study. ~~For histological analysis, transcardial formalin perfusion will be performed following injection of a 85-100 mg/kg dose of Fatal Plus or another pentobarbital based euthanasia solution~~.

Early Endpoint: Any of the following will represent a reason for early euthanasia: inability to ambulate or reach food or water, self mutilation, continuous circling, or persistent labored respiration or gasping, loss of 20% of weight below baseline, prostration/inactivity for up to 24 hours, or a significant decline in vital signs. These signs, if observed by animal facility personnel and no study personnel can be reached, may be taken by the veterinarian as cause for euthanasia.

V.4.6. Euthanasia: Some animals in each group will be euthanized by decapitation following injection of a 100 mg/kg dose of pentobarbital based euthanasia solution. Others will be euthanized by transcardial perfusion following euthanasia solution administration (Fatal Plus, 85-100mg/kg or other pentobarbital based euthanasia solution, Intraperitoneal, 400-500µl volume, 25 gauge needle).

Transcardial perfusion will be done as described (16,17). Briefly, animals will be deeply anesthetized with Fatal Plus (85-100 mg/kg), and the heart will be exposed by opening up the thoracic cavity after confirming that the animal is fully under anesthesia. To monitor the depth of anesthesia we will test whether the animal has lost its toe pinch (pedal withdrawal) reflex. The animals will be perfused with either 10% neutral buffered formalin or 4% freshly depolymerized paraformaldehyde through the left ventricle using a peristaltic pump. The right atrium will be cut and approximately 200 ml of fixative solution will be passed through the circulatory system. Following the perfusion, tissues will be removed to a container of fresh fixative solution prior to histopathological analysis.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for all rats in this protocol.

V.5.1.1. **Study Room:** CCI-TBI will be conducted in LAM's surgery room or CNRM facilities.

Part of the experiments in V.1.A will be conducted at WRAIR. For this purpose, we will follow the guidelines given in the LAM SOP No 22-425. Briefly, the rats will be transported in a government van and a temperature of 68-79°F will be maintained inside the van. The van will be thoroughly cleaned before and after use with MB-10. The cages will be restrained using the seat belts to avoid sliding around.

The rats will be at WRAIR for 4-5 hours to give enough recovery time following the anesthesia and blast exposure. The rats will be monitored at 30 min intervals during this period by the PI or an associate and should a rat experience unexpected severe injury, the rat will be euthanized using the procedure given in the USUHS protocol. Also, the transport of rats to and from WRAIR will be coordinated with the veterinarians of both WRAIR and USUHS.

Building(s) (b)(6) Room Number(s) (b)(6) (b)(6)

V.5.1.2.
Special Husbandry Provisions: No separate housing required after surgery

Food Restriction:	Yes		No	X
Fluid Restriction:	Yes		No	X

V.5.1.3. **Exceptions:** _____ _____

V.5.2. **Veterinary Medical Care:**

V.5.2.1. **Routine Veterinary Medical Care:** The animals will be observed daily according to LAM SOPs.

V.5.2.2. **Emergency Veterinary Medical Care:** All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays.

V.5.3. **Environmental Enrichment:**

V.5.3.1. **Enrichment Strategy:** All animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents.

V.5.3.2. **Enrichment Restrictions:**

VI. **STUDY PERSONNEL QUALIFICATIONS AND TRAINING:**

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
Intragastric feeding, euthanasia, decapitation, perfusion, CCI-TBI.	(b)(6)	Ph.D. 8 yers exp in TBI models	Investigator training, 2003, Rodent handling class, 2003
Consulting		Ph.D., 20+ years exp.	Investigator training, 1998, Rodent handling class, 1998
Behavioral studies	(b)(6)	Res. Assistant, 3-6 months experience in rodent handling	Investigator training, 2012, Rodent handling class,2012
Consulting		Ph.D., 15+ years experience	Investigator training, 2000, Rodent handling class, 2000
Supervision of transport of rats, euthanasia		Res. Associate, 1 month experience in rodent handling.	Investigator training, 2013, Rodent handling class, 2013

VII. BIOHAZARDS/SAFETY: Gowns, Gloves, and masks will be used for personal protection and sharp items will be disposed off in separate containers as per safety rules. The volatile anesthetic agents will be properly closed and removed from the procedure area. Chemicals and hazardous waste used in this protocol will be handled in accordance with all applicable state and federal guidelines, regulations, and standing operating procedures. Waste anesthetic gas (isoflurane) will be scavenged and exposure to investigators will be minimized using the set up used in the LAM operating room since the surgeries will be done in one of those operating rooms.

VIII. ENCLOSURES: References

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course. (b)(6) 6/18/2013

Principal Investigator Signature Date

G. Training: The following personnel will attend the next USUHS Investigator/Animal User Training Course:

_____ _____

_____ _____

H. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely, "Responsibility" for implementing animal use alternatives where feasible and conducting humane and lawful research.

_____ _____

Principal Investigator Signature (b)(6) Date 6/18/2013

I. Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

(b)(6) 6/18/2013

X. PROTOCOL ABSTRACT:

A. Animal Protocol Number: (b)(6)

B. Animal Protocol Title: Development of Neuroprotection strategies for Brain injury using Rat models.

C. Principal Investigator: (b)(6) Ph.D.

D. Performing Organization: USUHS

E. Funding: BAA-MRMC

F. Objective and Approach:. .

a: Neuroprotection Strategies for TBI. The central hypothesis is that melatonin and esters of the ketone bodies are very useful as neuroprotectants for clinical use because of their effectiveness, lack of toxicity and lipophilic properties that help to overcome the blood brain barrier. We propose the following specific aims. First, we will synthesize esters of β-OHB and acetoacetate using glycerol as well as 1,3-butane-diol separately, and test their relative effectiveness as well as that of melatonin alone as well in combinations employing our ongoing CCI model of TBI in the rat. Second, we will determine whether or not these esters and melatonin exhibit acute or chronic toxicity by analyzing blood chemistry and tissue pathology. Subsequently, we will determine whether the effectiveness can be increased by combining with 1) GTA, the acetate ester we have used previously and 2) grapefruit juice, which contains anti-esterase flavenoids that will reduce premature hydrolysis of the esters in the gut and liver, thus increasing delivery of intact esters to the brain. Based on the outcome from the CCI model of TBI, we plan to test selected strategies in the blast over pressure model of brain injury as well.

b. N-Acetylaspartate: A novel biomarker for traumatic brain injury in body fluids:.NAA is present in the human brain at a concentration of approximately 10 mM, and an approximately 1000-fold gradient exists between the intracellular and extracellular compartments. NAA has been found to be a reliable biomarker in ALS patients with an approximately 5 fold higher serum concentration than in healthy age matched controls .Our central hypothesis is that brain injury causes cellular damage and NAA efflux from neurons to the extracellular space and subsequently to the bloodstream. The NAA efflux can be directly measured in the cerebrospinal fluid and will be reflected in body fluids such as blood and urine. Changes in NAA levels in one or both of these body fluids can be used to monitor brain injury and recovery after TBI to aid in diagnosis as well as prognosis. Our immediate goal is to develop a simple and reliable method for analyzing NAA in serum and urine after TBI for diagnostic purposes,validating its specificity to TBI and demonstrating that the NAA measurement can be converted to a point-of-care(POC) test. The long term goal of this proposal is to adapt the NAA biomarker method to a simplified hand held biosensor device for use on injured soldiers in combat support hospitals as well as for use in civilian hospital emergency rooms

G. **Indexing Terms (Descriptors)**: . Glyceryltriacetate, traumatic brain injury, blast overpressure injury, rat, mouse, animal model, ketone body ester, melatonin, N-acetylaspartate, biomarker, controlled cortical impact model.

BETHESDA, MARYLAND 20814-4799

July 28, 2013

MEMORANDUM FOR DR (b)(6) DEPARTMENT OF ANATOMY, PHYSIOLOGY, AND GENETICS

SUBJECT: IACUC Approval of Protocol – Triennial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on July 28, 2013:

Animal Protocol Title: "Development of Normative Data for Behavior Testing in the CNRM Mouse Behavioral Assessment Core"

USUHS Protocol Number: (b)(6)

Expiration Date: July 27, 2016

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6). This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. NON-TECHNICAL SYNOPSIS:

This research will develop new behavioral tests for use in brain injury and PTSD research in the Pre-Clinical Studies Core of the Center for Neuroscience and Regenerative Medicine (CNRM). The CNRM Pre-Clinical Studies Core is a shared facility used by many scientists to assess the behavior of laboratory mice after various experimental manipulations. Behavioral testing is used as a measure of nervous system function after experimental manipulations, including other behavioral training experiences, brain injury, and after treatments that alter the impact of those experiences or injuries. The tests currently available to researchers are designed to measure behavior across many functional domains such as motor function, sensory abilities, exploration, learning and memory, anxiety, and depression. There are multiple tests available to test a single functional domain such as "memory", and some tests have been shown to be more sensitive in detecting mild functional abnormalities after experimental manipulations. We aim to find more sensitive cognitive tests that distinguish mild injuries resulting from trauma and/or stress. In addition, measures of other behavioral domains such as circadian rhythms, ingestive behaviors, and neuropsychiatric traits such as irritation and aggression have been successfully modeled in rodents by other investigators, and we will develop these assays and provide baseline and post-injury data through the experiments described in this protocol. These studies will validate and determine the effects of brain injury on these additional tests that will be made available to all CNRM researchers.

II. BACKGROUND:

II.1. Background:

The Pre-Clinical Studies Core was established at the University approximately four years ago and is a facility shared by CNRM researchers (and other investigators) to evaluate the functional performance of mice after experimental manipulations that cause traumatic brain injury (**TBI**), psychological stress or other changes, and the impact of experiential or genetic factors, or pharmacological or cell replacement treatments. The Core currently offers over 20 behavioral tests (Table 1) and several thousand behavioral tests have been performed in the Core facilities by CNRM investigators over the past three years, resulting in numerous publications and scientific abstracts/presentations that have contributed to pre-clinical drug development and translational research.

Table 1. Behavioral tests available in the CNRM Pre-Clinical Studies Core	
TEST	**FUNCTION**
Open field	Exploration
Hole-board test	Exploration/anxiety
Rotarod	Motor coordination
Beam walk	Motor coordination
Grip strength meter	Muscular strength
Hanging wire test	Muscular strength
Fear conditioning	Classical conditioning
Barnes maze	Spatial learning and memory
Morris water maze	Spatial learning and memory/working memory
Novel object recognition test	Episodic memory
Y-maze	Episodic/working memory
Zero maze	Anxiety
Elevated plus maze	Anxiety
Forced-swim test	Depression/learned helplessness
Sucrose preference test	Depression/hedonic motivation
Female urine sniffing test	Depression/hedonic motivation
Intruder test	Aggression
Sociability test	Social interaction
24-hour activity chambers	Circadian rhythms
Acoustic Startle Response	Sensory/anxiety
Hot-plate	Sensory/pain

Despite great success of the tests offered by the Core to date in studies of TBI, several needs of CNRM investigators have arisen: 1. Investigators using transgenic animals have expressed the need for basic sensory testing, 2. As milder, closed-head (no craniotomy) models of brain injury have become increasingly popular, the need for more sensitive behavioral tests has become apparent. In this protocol we propose to develop several new tests that will address these two needs; sensory testing will allow investigators to assess transgenic animals to determine if they have sensory deficits that will interfere with (or alter interpretations of) subsequent cognitive and neuropsychiatric testing, and exploration of alternative protocols for cognitive testing may reveal testing strategies that are sensitive enough to detect behavioral deficits after mild injuries.

The goal of this research is to integrate new behavioral tests into the CNRM Pre-Clinical Studies Core's current offering of functional tests for scientific investigators. Under protocols (b)(6) (b)(6) expired) and (b)(6) the majority of the current tests have been validated in control animals and used in TBI research, and the results are available to all investigators interested in employing behavioral testing in their experiments. This research will expand the offerings to include more sensitive cognitive tests, tests of sensory systems including vision and olfaction, and an assay of irritation, a neuropsychiatric complaint of brain-injured human patients. A database of "normative" information on how uninjured C57BL/6J adult male mice will first be collected to validate testing equipment and data-collecting procedures. We will then use controlled cortical impact (CCI) to induce TBI at mild and severe levels to determine the impact

of this brain injury on functional performance and to identify behavioral tests that are able to discriminate mild injuries.

This protocol first outlines a plan for *pilot studies* to address the above-described needs using new equipment and procedures. This will permit the staff of the Core to gain familiarity with each apparatus, formalize the specific steps in handling the mice and executing the tests, and develop the skill sets required to obtain reliable experimental data. The Core employees, in turn, will have experience that allows them to instruct investigators in how to perform the Core testing protocols. The *pilot studies* serve a second purpose. Although there are literally thousands of published reports concerning mouse behavior testing, to establish an efficient Core facility requires that CNRM investigators are skilled in using the specific equipment in the Core, and that there exist an established data base of information about mouse performance on each apparatus. "Local" data derived from this protocol is critical since the tests will be performed on the instrumentation specific to the Core, which previous studies have shown is an important consideration in attempting to derive comparable data across research groups (Brown, 2007; Wahlsten *et al*, 2003).

Many behavioral testing apparatuses measure a variety of parameters. For example, a single behavioral test may measure the time an animal engages in a certain response, the number of those responses in a testing session, how an animal's response changes over time or repeated trials. Basic information of these parameters can guide investigators to what measures they should record and what measures could be most relevant to the aspect of behavior they wish to model. Thus, statistical data obtained from the second, *full-scale studies* of this protocol can be utilized by investigators when they prepare their own experimental plans where consideration should be given to sample size and statistical power.

Once the *full-scale studies* have resulted in a full set of data on the new behavioral tests, *TBI studies* will commence to identify behaviors that are affected by TBI. Ideally, gross deficits/differences on each of the behavioral tests described in this protocol will result from severe CCI. However, the greater challenge will be to identify the tests that can discriminate between animals with a mild CCI and uninjured mice. The results obtained from the *TBI studies* will be made available to all investigators using the CNRM Pre-Clinical Studies Core. From this work, the Core staff will be more knowledgeable concerning the utility and limitations of each test, and experienced in the precise conditions of each test protocol, helping to guide investigators during the planning and execution of experiments.

II.2. Literature Search for Duplication:
II.2.1. Literature Source(s) Searched: BRD
II.2.2. Date of Search: July 24 19, 2013
II.2.3. Period of Search: 1998-2009
II.2.4. Key Words and Search Strategy:
Mouse, behavior, brain injury and Animal, mouse, behavior, standardization, and traumatic brain injury and active avoidance, Morris water maze, Cliff Test, Olfactory Avoidance Test, Novel Object Recognition Test, Bottle Brush Test

II.2.5. Results of Search:
The BRD database includes thousands of records of previous research programs. The searches derived a total of 14 unique hits. None of these programs pertained to establishing a mouse behavioral core facility or validating the use of specific behavioral tests in pre-clinical brain injury research, and the individual addition of the terms "active avoidance, Morris water maze, Cliff Test, Olfactory Avoidance Test, Novel Object Recognition Test, or Bottle Brush Test" derived 0 hits. **Conclusion**: No related hits indicated there is no overlap with previous research programs in the DoD.

II.2.6. Literature Source(s) Searched: CRISP and NIH RePORTER
II.2.7. Date of Search: July 24, 2013
II.2.8. Period of Search: active projects through fiscal year 2013
II.2.9. Key Words and Search Strategy:
Animal, mouse, behavior, standardization, active avoidance, Morris water maze, Cliff Test, Olfactory Avoidance Test, Novel Object Recognition Test, Bottle Brush Test

II.2.10. Results of Search:
CRISP is no longer an active search engine/web site. The suggested substitution is NIH RePORTER, and this site was used. The keywords animal, mouse, behavior, standardization produced five independent hits. Two of the hits were related to development of animal behavior cores, but were aimed at research on substance abuse. Another hit was for support for molecular phenotyping of mutant mouse lines, and another for development of an animal model of pre-term births. Another hit was for development of a pharmacology core. Search with the terms of specific behavioral tests resulted in 0 hits. Finally, a search was performed with the words, "blast brain injury mouse," and this derived 8 hits, but none of these pertained to developing standardized data. **Conclusion**: No related hits indicated there is no overlap with previous research federally sponsored research programs.

II.2.11. Literature Source(s) Searched: PubMed
I.2.7. Date of Search: July 24, 2013
II.2.12. Period of Search: >22 million references; 1949-2013.
II.2.13. Key Words and Search Strategy:

A. ("behavior, animal"[mesh] OR "stereotyped behavior"[mesh] OR "social behavior"[mesh]) AND "muridae"[mesh] AND ("animal experimentation"[mesh] AND "animals, laboratory"[mesh] AND "models, animal"[mesh])

B. (("muridae"[mesh] AND "brain injuries"[majr] AND "behavior, animal" [majr]) AND ("memory, episodic"[mesh] OR "memory, short-term"[mesh] OR "depth perception"[mesh] OR "avoidance learning"[mesh] OR "circadian rhythm"[mesh] OR "irritable mood"[mesh]))

C. ("behavior, animal"[mesh] OR "stereotyped behavior"[mesh] OR "social behavior"[mesh]) AND "muridae"[mesh] AND ("animal experimentation"[mesh] AND "animals, laboratory"[mesh] AND "models, animal"[mesh]) AND (active avoidance OR Morris water maze OR Cliff Test OR Olfactory Avoidance Test OR Novel Object Recognition Test OR Bottle Brush Test)

II.2.14. Results of Search:

A. PubMed was used with the keywords listed. A total of 39 hits were obtained. A search is each of these hits indicated four relevant publications (Bohannon, 2002; Moy *et al*, 2004; Paylor *et al*, 2006; Schneider *et al*, 2006). These articles related the importance of standardization of housing conditions, vendor source, and the criticality of behavioral testing conditions including the time interval between tests as important mediators of behavioral responses. The P.I. is also aware of the broader literature and has a comprehensive EndNote file system (obtained from searches over the years) of relevant publications. Importantly, there is an interaction between the genotype of a mouse and the environmental housing and testing conditions (Crabbe *et al*, 1999; Tucci *et al*, 2006), and consistency in housing, feeding, handling, behavioral testing procedures, testing sequence, and reducing overall distress are all important variables. Perhaps more relevant to a search are the "how-to" books, which the P.I. has extensively consulted (Buccafusco, 2009; Chen, 2009; Crawley, 2007; Jones and Mormède, 1999). These publications outline many of the same caveats related to animal testing, and the need to strive for consistency and standardization of housing and testing conditions. **Conclusion**: Numerous publications emphasize the need for standardization of housing and testing conditions, and requirements for "local" establishment of procedures.

B. Pubmed was used with the keywords listed to find literature pertaining to TBI and the specific behavioral tests we are proposing to use; nineteen hits were obtained. Of the 19 hits, five of those specifically related to behavioral testing after TBI (Baratz *et al*, 2011; Schwarzbold *et al*, 2010; Tweedie *et al*, 2007; Vonder Haar *et al*, 2011; Zohar *et al*, 2011). Although these papers describe behavioral deficits after traumatic brain injury in mice, none use the specific tests we plan to employ. We have an extensive database of articles describing prior research on TBI in rodents, and have considered these sets of data as we have planned our future TBI experiments.

C. Search "C" above that included the specific names of behavioral tests resulted in 0 hits for active avoidance, 7 hits for Morris water maze, but none of these references pertained to TBI or blast brain injury, zero hits for the Cliff Test, 0 hits for the Olfactory Avoidance Test, 1 hit for the Novel Object Recognition Test, but this reference pertained to study of the Fragile X syndrome mouse model and not TBI or blast brain injury, and 0 hits for the Bottle Brush Test.

III. OBJECTIVE\HYPOTHESIS:

The *objective* of this project is to provide investigators with novel behavioral tests in the CNRM Pre-Clinical Studies Core for use in studies on TBI and post-traumatic stress disorder (PTSD). We will perform pilot studies to formalize precise testing procedures and to acquire the necessary skills to consistently apply the procedures in an attempt to normalize the data-collection procedures used across laboratories. Once standard procedures are determined, we will collect full-scale normative data from control mice on each of the new tests, and determine the impact of mild or severe brain injury on behavioral performance on each of these tests. It is *hypothesized* that the establishment of formal testing procedures and the acquisition of skills in the consistent application of procedures will enhance the reliability and validity of behavioral testing data generated by investigators who use the Core facility in their research. In the short term no set criteria will be established to directly evaluate this hypothesis in terms of predicted quantitative outcome. However, the P.I. and staff have experience in behavioral testing, and will

use the data to formalize detailed experimental protocols for test execution and assess the overall consistency of results over the course of the protocol. We further *hypothesize* that a relatively severe brain injury induced by CCI will alter performance on the majority of the tests that we plan to add to the Core's offerings. However, identifying functional differences after a mild injury is a greater challenge, and we hope and expect that these additional tests will be sensitive enough to provide opportunities for measurement of significant differences between mildly-injured mice and control animals.

IV. MILITARY RELEVANCE:

The *relevance* of this protocol harkens to the major stated objective of the CNRM and for establishing a mouse behavior testing core facility at the University: "to address the current needs of the medical community to better diagnose and intervene for the prevention of the long term consequences resulting from traumatic brain injury, particularly in the context experienced by service members in Operation Iraqi Freedom (OIF) and Operation Enduring Freedom (OEF)." According to a respected RAND Corporation report (Tanielian and Jaycox, 2008), as many as 18.5% of the service members returning from these conflicts meet the criteria for a diagnosis of either PTSD or depression, and 19.5% of service members have reported experiencing a probable TBI during deployment. These estimates translate to approximately 320,000 cases of "probable TBI" and 300,000 cases of reported symptoms for depression or PTSD. Investigators with projects related to developing a better understanding of the biological processes and treatment for TBI and/or psychological trauma is necessary for the care of our service members. The laboratory mouse is used as an animal model for symptoms resulting from TBI and PTSD; many of the behavioral tests described in this protocol model symptoms reported in veterans such as irritability, sleep disturbances and memory loss. Basic research using this model will advance our knowledge of biological mechanisms of brain injury and psychological maladies and may lead to more effective treatments.

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures:

General Approach: The CNRM Pre-Clinical Studies Core has eight novel behavioral tests (described below) it will make available to CNRM researchers. In addition, one of the behavioral tests from prior protocols has not been fully developed (Novel Object Recognition) and we would like to continue development of this assay, resulting in a total of nine behavioral tests described in this protocol. The plan for this protocol is to employ separate groups of mice in six testing modules, labeled "Experiments" (see below).

Overall experimental design. The work for establishing procedures for all behavioral testing will be conducted in three phases. First, *pilot studies* are considered an important first step to gain familiarity with the apparatuses, develop specific details of testing procedures, streamline practical matters in the sequence of testing, and for practice in data collection (Festing and Altman, 2002). Following completion of pilot studies, *full-scale studies* will be performed to collect statistical data on the performance of mice on each test. Following completion of the full-scale studies, *TBI studies* will begin and determine the effects of mild and severe levels of controlled cortical impact (CCI) on functional performance on each of the described tests.

Separate groups of mice will be evaluated on one of the six behavioral experiments. The rationale for not testing an individual mouse on all nine tests is based upon findings that repeated testing of mice alters response patterns due to general stress, fatigue, "testing experience," and

learning (McIlwain *et al*, 2001; Võikar *et al*, 2005). The testing schemes have been designed to try and avoid exposing mice to more than one behavioral testing "domain." For example, the Morris water maze, modified hole-board, and novel object recognition test all assess memory and cognitive performance. An attempt is also made to avoid testing animals on tests that assess similar neurological functions. Nevertheless, many of the tests outlined below assess overlapping psychological dimensions or challenge several neurological systems at once. Separate measurements obtained by a single testing apparatus can assess distinct neurological systems (Wahlsten *et al*, 2003) and, when possible, multiple measures are recorded so that these separate systems are evaluated. For example, the Any-Cage isolation chambers (cf. V.1.2. Experiment 2) are home-cages that allow multiple measurements of mice in home-cage environments: wheel-running activity and general exploration in the cage, diurnal rhythms and ingestive behaviors among many others.

Coordination of behavioral testing with CNRM investigators. In May, 2009, CNRM investigators assented that, when feasible, their mice will be assessed using the tests described in CNRM#2 SOP "Pre- and Post-TBI Behavioral Assessment in Mice" (Anon., 2009). Investigators may wish to evaluate their experimental subjects on additional behavioral tests depending upon the animal model and hypotheses of their work. Core staff will coordinate behavioral testing with investigators in how best to validate the findings of their work with respect to additional behavioral testing, including how the testing best fits with the experimental treatments of their research.

Sequence of testing. Logistical constraints in testing procedures, animal distress and fatigue (both physical and psychological) require that each animal is employed on 1-3 tests. In addition, when an Experiment (described below) involves more than one test the more distressful or aversive task is scheduled last; an attempt to reduce confounding of test results from previous distress.

Strain choice. The strain choice for this protocol is the male C57Bl/6J strain (b)(4) (b)(4) The C57Bl/6J mouse was selected since this strain generally performs "average" on many behavioral tests (Crawley, 2008). The data set derived from the use of this strain is also perhaps most useful to CNRM investigators. The Bl/6 mouse is an inbred strain, providing a very high degree of genetic homogeneity (Crabbe, 1999)and it is one of the traditional strains used for studies that will eventually employ this strain as the "control" or "wild type" condition for a related mouse strain that harbors a transgene or gene "knockout" (Crawley *et al*, 1997; Mishina and Sakimura, 2007).

V.1.1. Experiment 1: *Development of an assay for active and passive avoidance in naïve and brain-injured mice.*

Experiment 1a will collect pilot and full-scale data regarding the performance of 39 mice (**Table 2a**) on a passive and active avoidance place task (c.f. Experiment 1, V.4.4.6). In avoidance tests, an animal learns to avoid an environment in which an aversive stimulus (i.e, shock) was previously experienced. For individual cohorts of mice, the experiment will take place over four days. Fifteen of the mice will be used in pilot work to train Core staff in the operation of the newly-acquired equipment. Most likely, the mice for the pilot studies will be purchased in groups of five, allowing investigators three independent opportunities to test the equipment and experimental protocol. When all pilot work is completed, another 24 mice will be used in a

Table 2a		
Experiment	**No. of Mice**	**Pain Category**
Pilot	15	E
Full-Scale	24	E
Total	**39**	

formal, *full-scale study* to collect "normative" data that will be summarized and provided as a guide for expected mouse performance on the behavioral tests.

Table 2b		
Group	**No. of Mice**	**Pain Category**
Naive	20	E
Sham	20	E
Mild	20	E
Severe	20	E
Total	**80**	

After completion of the full-scale study, *TBI studies* (Experiment 1b) will commence in which performance on the active and passive avoidance behavioral tests will be compared between naïve, sham-operated, mildly-injured and severely-injured (mild vs. severe determined by depth of impact) mice. Twenty mice will be included in each surgical group (**Table 2b**), and behavioral testing will begin seven days after sham or TBI surgery. Because foot-shock is a necessary component of the avoidance training trials, for pain/distress (Section V.4.1.1. APHIS Form 7023 Information), all mice in Experiment 1 are in Category E.

V.1.2. Experiment 2: *Evaluation of 24-hour home cage phenotypic behaviors and circadian rhythms.*

The goal of Experiment 2 is to evaluate 24 hour activity of mice. The apparatus (Any-Maze Cage (AMc; Stoelting CO, Wood Dale, IL) is a home cage encased within an isolation chamber that limits external influences from the housing facilities and other animal activities and odors. Mice will remain in the isolated home cages for up to four weeks (c.f. Experiment 2, V.4.4.6). The chamber is equipped with an infrared sensitive light and LEDs that provide continuous tracking of the animal via a built-in camera linked to Any-Maze tracking software. The chambers collect continuous data related to behaviors, including but not limited to, movements and spontaneous activity, wheel-running activity, diurnal activities, rearing behaviors, and food and water consumption. Monitoring activity cycles in rodents is a challenge. Rodents are highly responsive to environmental cues. In the AMc system, the isolation reduces disturbances from lights and sounds generated by human activities in the animal facility and it reduces access to the smells and movement of neighboring animals in adjacent home cages. The chambers, then, may reduce variability in behavioral responses from fluctuations in external activities in the animal facility, while allowing investigators and technicians to enter the room to monitor temperature and humidity and to ensure the chambers are operating properly. The Core is in the process of obtaining eight of these cages and will utilize the system twice for pilot studies (thus, a need for 16 mice for the *pilot studies*). Twenty-four additional mice will be used in a *formal study* for the acquisition of "normative" data that will be summarized and provided as a guide for expected mouse performance (wheel running, amount of food and water consumption, inactivity, etc.; **Table 3a**). For pain/distress (Section V.4.1.1. APHIS Form 7023 Information), the 40 mice are in Category C.

Table 3a		
Experiment	**No. of Mice**	**Pain Category**
Pilot	16	C
Full-Scale	24	C
Total	40	

After completion of the full-study (normative data collection), *TBI studies* will begin to determine the effects of cortical brain injury on home cage activities including locomotion, rearing, eating and drinking, and diurnal rhythms. Twenty mice will be included in each surgical group (**Table 3b**); mice will be housed in the AMc beginning immediately after surgery and will remain in the cages for up to four weeks. For pain/distress (Section V.4.1.1. APHIS Form 7023

Table 3b		
Group	**No. of Mice**	**Pain Category**
Naive	20	C
Sham	20	D
Mild	20	D
Severe	20	D
Total	**80**	

Information), naïve mice (n=20) utilized in Experiment 1b are in Category C; the remaining 60 mice are in Category D.

V.1.3. Experiment 3: *Assessment of spatial learning and memory and visual acuity in mice.*
In Experiment 3 (c.f. Experiment 3, V4.4.6), we will use a modified and extended version of the Morris water maze (MWM) to evaluate learning and memory in mice. This procedure has been demonstrated to be effective in detecting cognitive differences in mice with mild TBI (Zhao *et al*, 2012). Finally, two or more days after completion of the MWM, a final vision assessment will be performed with the *visual cliff test*, which provides a simple and gross measure of visual abilities by evaluating the animal's ability to detect a false drop-off at the edge of a surface. We are combining the MWM and visual cliff test into one experiment as the visual cliff tests is relatively simple and can be performed in combination with the MWM test without affecting results. Additionally, tests of visual acuity are often performed after the MWM test to ensure that any deficits on the test can be attributed to true learning and memory deficits rather than to a loss of visual acuity as a result of experimental manipulations or genetic modifications.

As the basic apparatus and testing procedures for the MWM have been perfected under prior protocols (b)(6) and the visual cliff test is relatively simple and does not require specialized equipment, we have reduced the number of animals requested for pilot testing in this experiment. A total of 95 mice are requested for both normative data collection and TBI studies (**Table 4**). Fifteen of the mice will be used in pilot work and we believe that these data in combination with subsequent data from control animals in the TBI studies can be combined and used as "normative" data that will be summarized and provided as a guide for expected mouse performance in these behavioral tests. The 15 pilot animals will be tested first, after which TBI studies will take place. For pain/distress (Section V.4.1.1. APHIS Form 7023 Information), the 35 mice in the pilot and naïve categories were deemed as appropriate for Category C; the remaining mice (n=60) are in Category D.

Table 4		
Experiment	**No. of Mice**	**Pain Category**
Pilot	15	C
Naive	20	C
Sham	20	D
Mild CCI	20	D
Severe CCI	20	D
Total	95	

V.1.4. Experiment 4: *Mouse performance on a working memory MWM task and olfactory-avoidance test.*
Mice will be used to assess group performance on a modified version of the MWM designed to evaluate short-term (working) memory. This version of the test requires only two trials per day with a short inter-trial interval and tests the ability of a mouse to use information gained in the first "sample" trial to locate the platform in the second trial. In addition, prior to MWM testing, basic olfactory function will be assessed with an olfactory avoidance test in which the average distance from a piece of filter paper infused with an aversive odor is measured (c.f. Experiment 4, V.4.4.6 for details of both testing procedures). As basic testing procedures were acquired successfully under prior protocols, pilot testing will be limited to 15 mice and the data from those animals will be combined with the results from control animals in subsequent TBI studies

and used as a normative data set. Eighty mice are requested for the TBI studies (**Table 5**), which will begin once the pilot studies are completed successfully.

Table 5		
Experiment	**No. of Mice**	**Pain Category**
Pilot	15	C
Naive	20	C
Sham	20	D
Mild	20	D
Severe	20	D
Total	95	

For pain/distress (Section V.4.1.1. APHIS Form 7023 Information), the 35 mice in the pilot and naïve categories were deemed as appropriate for Category C; the remaining mice (n=60) are in Category D.

V.1.5. Experiment 5: *Exploration, anxiety and spatial memory in a modified hole-board environment.*

The goal of Experiment 5 is to evaluate multiple dimensions of mouse behavior in a modified hole-board test (c.f. Experiment 5, V.4.4.6). Under prior protocols (b)(6) we collected baseline data and evaluated the effects of TBI on simple exploratory behavior in the hole-board. In the current protocol we propose to elaborate on the experimental design to allow measurement of exploration, anxiety and spatial memory all in a single test. We will collect pilot data and subsequently conduct TBI studies (**Table 6**); the results from the pilot experiment and control animals in the TBI studies will be combined to create a normative data set. The mice are habituated to the hole-board environment for two consecutive days, and each of the 16 holes in the apparatus is baited with a small piece (~ .03g) of almond to encourage hole-exploration. On Days 3-6, four of the holes are baited with almond and the mice must use spatial cues to learn the pattern of distribution of the food rewards. The number of hole pokes and distance traveled in the habituation trials provide measures of exploration, risk-assessment (visits to center holes, stretch-attenuated postures) assess anxiety-levels, and the latency to acquire food reward during the training trials measure spatial learning and memory. For four days prior and for the duration of the experiment, mice will be fed a restricted diet such that body weights are reduced to approximately 85% of free-feeding weight.

Table 6		
Experiment	**No. of Mice**	**Pain Category**
Pilot	15	C
Naive	20	C
Sham	20	D
Mild CCI	20	D
Severe CCI	20	D
Total	95	

For pain/distress (Section V.4.1.1. APHIS Form 7023 Information), the 35 mice in the pilot and naïve categories were deemed as appropriate for Category C; the remaining mice (n=60) are in Category D.

V.1.6. Experiment 6: *Evaluation of episodic learning and memory with the Novel Object Recognition test.*

The goal of Experiment 6 is to evaluate a mouse's ability to remember objects they previously had explored. This memory test has the benefit of not requiring extensive training trials and the ability to be completed in three short trials over two days. The mouse is placed in the test arena on the first day for 10 minutes to acclimate to the testing environment. On the second day, two identical objects are placed in the arena and Any-Maze tracking software records the amount of time the mouse spends exploring the two objects.

Table 7a		
Experiment	**No. of Mice**	**Pain category**
Pilot	15	C
Full-Scale	24	C
Total	39	

During the second trial, four hours later, one of the objects is replaced with a new object and the animal is returned to the arena. Tracking software records the amount of time the animal spends exploring the "new" object vs the "old" object. As we had difficulty fine-tuning the precise testing conditions under prior protocol APG-10-754, we have simplified the testing procedure and propose complete pilot (n=15) and full-scale (n=24) experiments (**Table 7a**) to perfect this assay. After successful completion of the full-scale studies, TBI studies (**Table 7b**) will begin in which the effects of brain injury on episodic memory will be evaluated.

Table 7b		
Group	**No. of Mice**	**Pain category**
Naive	20	C
Sham	20	D
Mild CCI	20	D
Severe CCI	20	D
Total	**80**	

After completion of the Novel Object Recognition test, mice will be individually housed for five days to assess irritability using the "bottle brush test" (c.f. V.4.4.6, Experiment 6) (Riittinen *et al*, 1986).

For pain/distress (Section V.4.1.1. APHIS Form 7023 Information), the 39 mice in the pilot and full-scale studies of Experiment 6a (n=39) are in Category C; naïve mice of Experiment 6b (n=20) are also in Category C and the remaining surgical animals (n=60) are in Category D. The "bottle brush" test has been categorized as Category "C," since the distress is momentary and the mouse does not sustain any physical harm or long-lasting damage (Anon., 2012).

V.2. Data Analysis:

To estimate the number of animals needed, the scheme outlined by Wahlsten was used (Wahlsten, 1999). Wahlsten suggests that *effect size*, δ, between two experimental groups for mouse experiments can be generally classified as *small*, *moderate*, or *large*, with δ values of 0.5, 0.75, and 1, respectively, where $\delta = \frac{(\mu_1 - \mu_2)}{\sigma}$. For an estimation of the number of mice for the *full-scale studies*, it is assumed that a 30% difference between the average behavioral scores for two groups could represent a moderate effect. The formula above was transformed to $\sigma = \frac{(\mu_1 - \mu_2)}{\delta}$ to compute an estimate of the expected standard deviation of the residuals (σ) when there is a 30% change in behavioral score (e.g., $\mu_1 = 100$, $\mu_2 = 130$) and an expected "moderate effect" ($\delta = 0.75$). This suggests $\sigma \approx 40$ as an estimate of the standard deviation of the residuals.

The SigmaStat computer program, *Determination of Computing Power and Sample Size* was then used to estimate the number of animals needed for the *full-scale* experiments. This program calculates the minimum number of data units (mice) per group that is needed to achieve a certain level of *power* (sensitivity) of a statistical test based upon certain probability estimates. To achieve a power ≈ 0.80, in this case using $\mu_1 = 100$, $\mu_2 = 130$, and $\sigma \approx 40$, about 28 mice/group would be required. Since this is an estimate, we propose that for the *full-scale* studies outlined in Experiments 1-5, 24 mice may be sufficient and more convenient for the progression of testing procedures in the Core. For many of the tests, 8 mice can be tested simultaneously, allowing all 24 mice to be tested in three rounds of testing. In this case, if the same assumptions hold ($\sigma \approx 40$ with n=24 animals, $\delta = 0.84$), and there would be a possible 33% difference between groups compared to 30%.

From previous experiences a sample size of 20-24 mice/full-scale experiment appears more than ample for behavioral testing and for what is usually reported in publications of mouse behavior testing (number of subjects per group is usually in the mid-teens). However, this estimate is justifiable since the statistical data obtained from this work will be used by multiple

groups as a "standard" of comparison, and the resulting data is vital in seeking to strive for comparability across data obtained by many research teams. In addition, larger sample sizes have been used by previous groups attempting to initially validate their testing procedures. Rogers and colleagues (Rogers *et al*, 1997), for instance, used 37-89 mice/group to validate the "SHIRPA protocol" in one study, and two cohorts of 10 mice/group for further validation and statistical reporting (Rogers *et al*, 1999). Likewise, this estimate appears to be in line with suggestions by internationally recognized experts. For example, Crawley suggests that "$N = 20$ mice or more per genotype are often needed to complete the first set of behavioral tests in a new line of mutant mice" (Crawley, 2007). Finally, it is likely that some of the mice will be "uncooperative" (Wahlsten *et al*, 2003). Data from these animals may be eliminated from the statistical calculations—though the percentage of "non-responders" on specific tests will be recorded and reported—since extreme scores can alter summary descriptions of the response pattern. A larger sample size will allow us to better estimate the percentage of "non-responders" on each behavior measure, and maintain adequate sample sizes for statistical estimation should the percentage be high on some measures.

Statistical Analyses: The SigmaStat 2.03 (SPSS) statistical analysis program will be used to compute the arithmetic mean and standard deviation of mouse behavior on each test. In addition, a repeated measures single-factor analysis of variance (ANOVA) will be used to assess whether or not performance on each test is the same when comparisons are made of repeated testing results. If the data suggests there is variation between the testing of each cohort of mice, a nested ANOVA can be used to assess whether or not there are differences between testing events on repeated tests. Finally, to assess some degree of the relationship of performance on tests within an experiment, correlation coefficients will be computed for each animal's score on each subtask.

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered:

The need to employ animals for this research is required in order to assess *in vivo* behavioral performance. These data will provide a means for relating behavioral responses to central nervous system function *in vivo*. Non-animal alternatives do not replicate the three dimensional structure or temporal changes that occur as a function of complex behavioral responses to tasks presented to a live animal. Further, computer modeling and *in vitro* methods will not address experimental questions of the complex, real-time changes and responses that occur during experience.

V.3.2. Animal Model and Species Justification:

By consensus of members of the CNRM, male C57Bl/6J mice [redacted] Stock 000664) have been chosen as a suitable species and animal model for this research (Anon., 2009). This is based upon the previous use of this strain in innumerable studies and their suitability as biomedical models for understanding central nervous system functions in normal and pathological states in humans and in other animals. The mouse is used for these studies because of their well-understood anatomy and endocrine responses, and the very extensive database of prior physiological research that can be integrated with this new information. It is necessary to use mice instead of a more-derived species since the research results should be directly associated with intense efforts in other laboratories throughout the world to try and further our understanding and eventual treatment effectiveness for psychological stress and brain injury.

Mice are a commonly used small animal model for the study of neurobiological genetics research, including the impact of physical injury and environmental stress upon neuron connectivity, experiential effects on synaptic plasticity, signal transduction, and for assessing treatments to reduce neurological damage and improve quality of life. In transgenic and gene knockout models in neuroscience and behavioral research, "wildtype" C57Bl/6 mice often serve as the genetic "background" or control for comparison of genetic and genetic/environmental effects (Crabbe, 1999; Crawley *et al*, 1997; Mishina *et al*, 2007). The employment of only male mice is to minimize the experimental design variation by eliminating the hormone cycling effects of female mice.

V.3.3. Laboratory Animals

	Species #1	Species #2
V.3.3.1. Genus & Species:	*Mus musculus*	
V.3.3.2. Strain/Stock:	C57Bl/6	
V.3.3.3. Source/Vendor:	(b)(4)	
V.3.3.4. Age:	5-12 weeks	
V.3.3.5. Weight:	18-25 grams	
V.3.3.6. Sex:	Males	
V.3.3.7. Special Considerations:	None	

V.3.4. Number of Animals Required (by Species): Mice: 643

V.3.5. Refinement, Reduction, Replacement (3 Rs):

V.3.5.1. Refinement:

Two refinements will be performed or tested in our protocol. 1. Mice will be acclimated to investigator handling before the commencement of behavioral testing, to relieve distress from the potential combination of handling distress and the testing procedures, 2. Pilot studies will be employed to enhance the "quality" of the data acquired in the full-scale and TBI studies. The pilot studies serve as an opportunity to train lab personnel to gain skills in consistency of animal handling. The pilot studies permit "refinement" of the particular parameters of testing procedures and the use of the testing equipment. Finally, 3. Analgesics and anesthetics will be used to decrease possible pain and distress resulting from surgery.

We are using a rodent model (mouse) versus a nonhuman primate model. The mouse model is the least sentient and smallest animal model we could use for this study and still obtain acceptable results. In addition, we are attempting to perform a series of measurements of mouse behavior that

requires making assurances that there is sufficient number of animals to derive valid measures of statistical data.

V.3.5.2. Reduction:

Power calculations have been performed to determine the minimum number of animals needed to reach statistical significance. When possible, mice will be tested in multiple assays (Experiments 3 and 6) and the mice from pilot and full-scale studies will be available for use on other protocols after study completion. Data derived from this protocol will be available to other investigators, allowing them to make better estimates of the minimal number of animals required for their experiments.

V.3.5.3. Replacement:

Biological response to central nervous system injury, psychological stress, and experimental treatments is highly complex; no alternative to *in vivo* experimentation is available or practical.

V.4. Technical Methods:

V.4.1. Pain / Distress Assessment:

V.4.1.1. APHIS Form 7023 Information:

V.4.1.1.1. Number of Animals:

	Species #1	Species #2
V.4.1.1.1.1. Column C:	224	
V.4.1.1.1.2. Column D:	300	
V.4.1.1.1.3. Column E:	119*	

*These animals are used in Experiment 1.

V.4.1.2. Pain Relief / Prevention:

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization:

TBI and sham procedures: Mice undergoing CCI or sham procedures will be anesthetized with isoflurane + 100% oxygen (0.5-4% isoflurane, induction; 0.5-3% isoflurane, maintenance). Isoflurane will be delivered using a precision vaporizer via a rodent anesthesia machine. Induction will occur in an appropriately-sized clear viewing chamber. Following induction, rodents will be moved to the stereotaxic device and anesthesia will be maintained via a nose cone. Waste anesthetic gases will be passively scavenged using a charcoal filter. Lack of paw-pinch reflex will be used to ensure adequate depth of anesthesia prior to beginning the procedure. Close attention will be given to ensure the mice remain unconscious and are unresponsive to pain and, if needed, supplemental administration of anesthetic will be given.

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions:
Mice are will be returned to the animal facility after behavioral testing. They will be monitored in their cages for complications, such as lethargy, reluctance to ambulate, inability to obtain feed, and seizures. It is expected that complications will not be encountered. Any mouse that experiences problems will be evaluated and treated or euthanized as determined by research staff or PI and Veterinarian.

V.4.1.2.3. Paralytics: N.A.

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures:

V.4.1.3.1. Sources Searched: PubMed
V.4.1.3.2. Date of Search: June 20, 2013
V.4.1.3.3. Period of Search: 1986-2013.

V.4.1.3.12. Date of Search: June 20, 2013
V.4.1.3.13. Period of Search: No date limits.
V.4.1.3.14. Key Words of Search: Mouse/murine, behavior, injury, standardization
V.4.1.3.15. Results of Search: AWIC returned 90 references from the query listed. All references related to appropriate care, treatment, reduction of pain and euthanasia in laboratory animals.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification: We request that some animals (cf. V.4.1.1.1.3) be utilized for experiences considered Category E. Category E mice will be used in testing paradigms that inherently involve some discomfort/distress as a means of "motivating" the animal to respond. We wish to test the mice without treatment with sedatives or analgesics. With the exception of administration of brief and mild shock during the active and passive avoidance tasks (V.1.1 Experiment 1), none of these behavioral tests involve pain or any physical injury; thus an analgesic is contraindicated. While some tests evoke mild distress, treatment with a sedative would significantly alter their level of "motivation" and change their responses to the task.

V.4.2. Prolonged Restraint: N.A.

V.4.3. Surgery:

V.4.3.1. Pre-surgical Provisions:
Mice will be individually inspected and weighed before all procedures to assure they are in good health for the procedures.

V.4.3.2. Procedure:
All surgical procedures will be performed as described in CRNM SOP#1 and mice will be selected at random for individual procedures. All mice will first be anesthetized as described in Section V.4.1.2.1. All TBI or sham procedures are conducted in a designated area of the CNRM core facilities (Room (b)(6) on a clean table surface that is covered with clean absorbent cloth. The table will be disinfected before and after animal surgeries.

CCI or sham surgery: Two groups of mice will receive a TBI of differing severity level by controlled cortical impact. The mice will be weighed, head hair clipped, and mounted in a stereotaxic frame in a prone position, secured using atraumatic ear bars and an incisor bar. The mouse calvarium will be held in the horizontal plane with respect to the interaural line. To assess anesthetic depth during surgery, the corneal reflex will be evaluated by lightly touching the cornea with a cotton swab to elicit an eye blink. The assessment of the paw and ear pinch reflexes consists of the gradual application of pressure on the hind paw or ear. Lack of eye blink or paw or ear withdrawal is an indication of deep anesthesia. Disposable sterile surgery gloves will be worn by investigators during the surgery. Surgery utensils will be autoclaved before use and cleaned with 70% ethanol after each animal's surgery and a draping will be used around the surgical area. After aseptic treatment with 3 cycles of povidone-Iodine solution alternative with alcohol, an incision and a 6mm (diameter) craniotomy will be made over the left cortex. The bone flap will be removed, and for the two groups of mice undergoing CCI, injury will be produced with the CCI device (Clark *et al*, 1997; Dixon and Kline, 2009), using an impact tip of 3.0 mm in diameter, a penetration depth of 2.0 mm (severe CCI group) or 1.0 mm (mild CCI group) and a velocity of 5 m/s as insult parameters to the dural surface. The location of the injury will be in the parietal region of the brain (2.5 mm posterior to Bregma, 1.5 mm lateral). Following CCI, the scalp incision is sutured. The CCI impactor will be disinfected by 70% ethanol after each use. Surgical instruments will be rinsed in saline and alcohol and disinfected for 10 seconds in a hot-bead sterilizer. Animals will be returned to their home cages following surgery and monitored until they regain consciousness. Mice undergoing sham surgery will receive all procedures described here except the impact with the CCI device.

V.4.3.3. Post-surgical Provisions:
Mice will be monitored at least once per day following TBI or sham procedures. Animals are not expected to experience pain or discomfort from TBI, but if needed will be provided with acetaminophen (Tylenol) in their drinking water (1 mg/ml; ~200 mg/kg b.w.) as an anti-inflammatory precaution. Animals will be observed again one hour after home cage placement to ensure there are no signs of discomfort. If needed, the DLAM veterinarian will be consulted should there be signs of continued discomfort or distress.

V.4.3.4. Location: Housing in DLAM (b)(6) Any-Maze Cage housing (b)(6) Surgery and behavioral testing in the CNRM Pre-Clinical Studies Core facilities (b)(6)

V.4.3.5. Surgeon: (b)(6)

V.4.3.6. Multiple Major Survival Operative Procedures:
V.4.3.6.1. Procedures: N/A
V.4.3.6.2. Scientific Justification: N/A

V.4.4. Animal Manipulations:
V.4.4.1. Injections: N/A**V.4.4.2.Biosamples:**
Following behavioral testing, the animals will be euthanized and mice used in pilot and full-scale behavioral experiments and made available for tissue sharing by investigators in the CNRM (an e-mail announcing tissue availability will be sent to CNRM PIs), or the live animals will be transferred to the Department of Laboratory Medicine (DLAM). DLAM will use the animals either for training purposes or as 'sentinels' as appropriate. In cases where animals are euthanized by individuals on this protocol, the tissues will be used for validating and/or acquisition of training and data for a variety of assays. For example, for western blotting biosamples the mouse brain from animals will be removed from the calvarium to obtain samples of the cerebral cortex (fronto-occipital region and entorhinal region), hippocampus, diencephalon, and brain stem. Samples are stored in liquid nitrogen before preparation for western blotting. Other mice may be used for transcardial perfusion for immunohistochemistry biosamples. In this case, the mice will be anesthetized as described in Section V.4.1.2.1. Once the mice are deeply anesthetized and unresponsive to paw pinch, a midline thoracotomy (or abdominal incision) is made to expose the heart, a 20-22 gauge blunt tip needle connected to a tube (¼ in ID and 1/16 in wall) inserted into the left ventricle through the apex and the right atrium incised. After an initial washout with 20-30 ml of cold 100 mM phosphate buffered saline (PBS), transcardial perfusion with 50-75 ml cold 4% paraformaldehyde in PBS will be delivered through a gravity perfusion system until adequate perfusion reached. The brain will then be removed from the calvarium and post-fixed before tissue sectioning for immunohistochemical staining.
V.4.4.3. Adjuvants: N/A
V.4.4.4. Monoclonal Antibody (MAbs) Production: N/A
V.4.4.5. Animal Identification:
All animals will be identified with cage cards. Within cages, tail marks with permanent marker and/or ear punches (performed during surgery while animals are under anesthesia) will be used to identify individual mice.

V.4.4.6. Behavioral Studies:

Experiment 1: Development of an assay for active and passive avoidance in naïve and brain-injured mice. A commercial *place-avoidance system* (Bio-Signal Group, Brooklyn, NY) will be used to collect and analyze data from naïve and brain-injured mice. The apparatus consists of a ~50cm (diameter) metal disk with 40 cm high transparent walls that allows the mice to view distal room cues; the apparatus and testing room will remain unchanged throughout the testing protocol. The procedure will be conducted as previously described (Abdel Baki *et al*, 2009), and testing will take place in four phases over four days:

Phase 1 (habituation/open field): No less than three days after CCI or sham surgery, the mice will be habituated to the testing environment in a single ten-minute open field test in which the animals are free to explore the entire arena. The data from this phase of the experiment will be analyzed to assess exploratory and anxiety-like behaviors in a circular open field environment.

Phase 2 (passive avoidance; PA): Phase 2 takes place 24 hours after habituation. Each mouse will receive four 10-min PA training trials in a single day, with a 10-12 min inter-trial interval (ITI). During these trials, a 60° region of the circular arena is electrified by a grid underneath the floor, and the mouse receives a single .3 mA, 500 ms shock each time the electrified region is entered. Additional shocks are administered every 1.5s until the animal leaves the shock zone. Olfactory cues (urine and feces deposited on the arena floor) and visual cues around the room are used by mice in this phase to learn place avoidance and stop entering the shock-region of the apparatus. An overhead camera and video-tracking system are used to track movements of the mouse and calculate the distance traveled and number of shock zone entrances.

Phase 3 (active avoidance; AA): The day after PA trials, each mouse undergoes six 10-min AA trials with a 10-12 min ITI. During these trials, the same 60° shock region of the arena is stationary while the arena rotates. In these trials, although the electrified region of the arena remains in the same spatial location, the arena rotates and the mouse must keep moving to avoid being shocked. In these trials, only visual room cues can be used by the animal to locate the electrified area as the olfactory cues rotate with the arena. Movements of the mouse are tracked and multiple measures are calculated: the latency to first entrance of the shock zone measures memory of the zone location between trials, number of shocks administered assays the motivation to escape shock; distance traveled, average speed and linearity of movement (average each 2s of the ratio dist(linear)/dist(integrated) provide measures of motor function.

Phase 4: (AA; conflict learning (CL): In the CL trials, the shock zone location is shifted 180° from the original location for six 10-min trials (10-12 min ITI). These trials test proactive interference, or whether the avoidance memory obtained in Phase 3 AA trials conflict with avoidance memory currently being learned in Phase 4. Measures calculated from the camera-tracked movements of the mouse include the distance traveled and the number of entrances into the shock zone.

Experiment 2: Evaluation of 24-hour home cage phenotypic behaviors and circadian rhythms.

Twenty-four hour activity will be evaluated in the Stoelting Company's new mouse *Any-Maze Cages (AMc)*. The AMc is a wooden box measuring 15"H x 20"W x13"D that houses a single mouse and acts as an isolation chamber. It contains food and water, as well as a running wheel, and has the capability to monitor the amount of food and water intake 24 hours a day. In

addition, the chamber has a built-in infra-red-sensitive camera and infra-red and ambient light LEDs. Software controls the light period (ambient light LEDs ON) and dark period (infra-red light LEDs ON/ambient light LEDs OFF). Using Any-Maze software, the camera records the animal's movements and circadian activities "24/7." The chambers are also furnished with a ventilation fan and a temperature sensor. The latter allows the temperature to remain constant and stable within the chamber.

Following a five-day habituation period after arrival, or immediately after CCI or sham surgery, individual mice will be placed in the AMc system to monitor 24-hour activity and food/water intake for up to four weeks after surgery. The plan would be to open the chamber doors once per day to visually inspect the cage and animal and provide fresh food and water, if needed.

Experiment 3: Assessment of spatial learning and memory and visual acuity in mice.
Spatial learning and memory will be initially assessed in the *Morris Water Maze (MWM)* using the procedure described for prior CNRM studies (Budinich *et al*, 2013; Yu *et al*, 2012). A Stoelting Morris water maze (diameter 4.0 m) tank is filled with tap water (25°C) to a depth of 20-30 cm. A clear plastic platform is placed in one of the "quadrants" of the tank floor and visual cues (solid geometric shapes) are placed on the room walls in locations that can be viewed by animals in the pool. On day 1 (no less than seven days after CCI or sham surgery), a single pre-training trial is first used where the mouse is gently placed on the platform in the tank and the mouse remains there for 15 seconds. If the mouse jumps into the water during this time, it is allowed a brief swim (< 60 s) before being guided back to the platform. On day 2, training trials begin where the mouse is placed near the side of the tank in a location away from the platform, and is allotted 90 seconds to swim to the platform. Upon finding the platform the mouse remains on the platform for 15 seconds. If the mouse does not reach the platform in the allotted 90 seconds, they are gently guided to the platform and allowed to remain for 15 seconds. A total of four trials, separated by 1-2 min, are performed each day. Swimming movements of the mouse are tracked, and swim speed, distance before reaching the platform and latency to find the platform are calculated by Any-Maze software. Finally, on the fourth day of training (Day 5) approximately one hour after the final training trial, a single trial is performed with the platform removed from the tank. The time spent in the pool quadrant where the platform was located is measured, compared to time spent in the other three quadrants. After all trials, mice are placed in a clean cage underneath a heating lamp until thoroughly dried (approximately five minutes) to maintain thermoregulation.

Beginning the next day, *reversal training trials* will take place in which the location of the hidden platform is moved to the opposite side of the tank (Zhao *et al*, 2012). The pre-training phase is omitted, and each mouse receives four 90-sec trials for four days. A second probe trial will take place approximately one hour after the final reversal training trial. Finally, immediately after the reversal probe trial, a single visible platform trial will be conducted. A pipette with a very visible "flag" will be secured to the platform. The latency of the mouse to navigate to the cued platform is recorded (maximum of 90 sec).

No less than two days later, a final vision test will be performed with the *visual cliff test (VC)* as described previously (Salinger *et al*, 2003). The VC evaluates the ability of a mouse to see a supposed drop-off on the edge of a horizontal surface. A plexiglas box with a horizontal surface connects to a vertical drop (~ .5 m), connected to a second horizontal plane at a lower level. The horizontal surfaces and vertical drop are covered with brightly patterned adhesive to accentuate

the drop-off. A piece of Plexiglas extends from the higher horizontal plane, extending across the drop-off and providing a solid horizontal surface. The mouse is placed close to the edge of the upper horizontal surface and the movements of the mouse are tracked by Any-Maze software. A mouse that "sees" the drop-off will retreat and move away from the false edge; a mouse with reduced visual abilities may move across the "cliff" without pausing (Crawley, 2007). C57BL/6 mice with eyesight intact will show 80-90% safe responses, meaning they step back toward the higher horizontal surface (Fox, 1965).

As this test is often confounded by other sensory abilities (Crawley, 2007), a blind animal may rely successfully on non-visual senses including tactile feedback from the whiskers. We are requesting that we be allowed to shave off the whiskers prior to this test. As this is the last test performed in this experiment, animals will be euthanized within 24-hr after whisker-removal.

Experiment 4: Mouse performance on a working memory MWM task and olfactory-avoidance test.

Mice typically show avoidance behaviors toward spoiled smells including aliphatic acids (Hebb *et al*, 2002). The *olfactory-avoidance test* assesses the ability to detect an aversive scent (Siopi *et al*, 2012) and is performed in a clean open field arena (40 cm x 40 cm) no less than three days after sham or CCI surgery. The mouse is first habituated in the test environment for 10 min, after which two pieces of filter paper (each 5 cm x 5 cm), one sprayed with water and the other with acetic acid (a short aliphatic acid) diluted to 5% are introduced in successive 3-min trials with one minute between each trial. Movements of the mouse during the trials are tracked by an overhead camera linked to Any-Maze software, and the software calculates the average distance of the mouse from the filter paper. Additional scoring performed by an investigator blinded to the surgical condition of the mouse may include the number of investigations of the water- and acid- soaked papers and the comparative amount of time each mouse spends investigating each piece of filter paper. The arenas will be thoroughly cleaned with 70% ethanol and dried after each use to remove all olfactory cues.

No less than three days later, the same mice will be tested in a *modified version of the MWM designed to test short-term (or working) memory* (Steele and Morris, 1999). The water tank and basic procedure used is the same as Experiment 3, but the platform is moved to a new location each training day, creating what is called 'delayed matching to place.' In this modified procedure the animal cannot know the location of the platform on the first trial of each day, but once this information is gained, the information is 'stored' for subsequent trials on that day. Each mouse will receive four trials per day, and acquisition is expected to take 8-10 days. The inter-trial interval can be modified to control difficulty of the task; we will begin with a 1-2 s interval as described in Experiment 3, but may increase that interval to make the test more challenging.

Experiment 5: Exploration, anxiety and spatial memory in a modified hole-board environment.

The modified hole-board test has the advantage and being able to measure exploration, anxiety and memory in a single test (van der Kooij *et al*, 2010). The hole-boards are 40 cm x 40 cm inserts that fit within our current open field chambers, and they contain 16 holes evenly-spaced (~ 7cm), each with a diameter of 3 cm and depth of 1 cm. Several printed geometric shapes

located on the walls of the room serve as spatial cues to the animals in the apparatus. The body-weight of mice will be reduced to approximately 85% of their free-feeding weight for four days prior to the beginning of the experiment; food restriction will begin no less than three days after TBI or sham surgery (Anon.; Rowland, 2007; Toth and Gardiner, 2000). Body weight will be taken each morning to monitor weight loss and adjust food as needed, and animals will be physically inspected to ensure there are no signs of ill health (Anon., 2011). For two consecutive days, the mice are given a single three minute acclimation to the test environment. During habituation, all 16 holes will be baited with a small food reward (.01-.02 g almond) to encourage visits to the holes. Video tracking reports results on locomotion, time spent in the center of the apparatus and the frequency of head-pokes into a hole. On the third day, only four of the holes will be baited with food and the pattern of the location of food rewards will remain consistent for the remainder of the experiment. Each mouse then undergoes spatial learning trials, four trials per day for three days. Each trial lasts until the mouse finds all four food rewards, and the latency to complete the trial is recorded for each mouse. Olfactory cues will be eliminated by placing a small drop of almond extract in the holes that do not contain the food reward. On the sixth day (the day immediately following the final spatial learning trial) a reversal-task will begin. During this part of the test, the locations of the food rewards will be scrambled. Mice will be trained for three days with four trials per day. Each trial lasts until the mouse finds all four food rewards.

Experiment 6: Evaluation of episodic learning and memory with the Novel Object Recognition test, and assessment of irritability in mice

The Novel Object Recognition (NOR) test was first developed by Ennaceur and Delacour (Ennaceur and Delacour, 1988) and adapted for use in mice by Dodart and colleagues (Dodart *et al*, 1997). The NOR test assesses the ability of an animal to remember a prior object in the environment. The task will begin no less than three days after sham or TBI surgery and consists of three phases: a) Habituation – the mouse is allowed to freely explore the environment in the absence of objects for one hour. B) Acquisition – 24 hours after habituation – the mouse is placed back into the familiar arena containing two identical objects for ten minutes. C) Test – one hour after Acquisition – for ten minutes the mouse is returned to the arena containing two objects: one identical to the same from the acquisition phase, the other is novel. During the acquisition and test phases the two objects are located in opposite and symmetrical corners, and the location of novel vs. familiar is counterbalanced between subjects. The amount of time exploring each object in the Test phase is compared; a mouse that remembers the objects from the Acquisition phase will spend a larger proportion of time exploring the novel object of the Test phase.

No less than three days after completion of the NOR test, *irritability* will be assessed in mice employing the "bottle brush" method (Riittinen *et al*, 1986). Mice will be housed individually for the five days of the test. The mouse will be gently prodded, or what is also called, "nudged," in the home cage with a clean white bottle brush moving against it, and each mouse is nudged 20 times daily, consecutively, with 10-15 sec between each stage. Each prodding consists of five stages: a) Rotating brush approaching the mouse from the opposite side of the cage, b) Rotating brush touching whiskers of the mouse, c) Rotating brush returning to starting position on opposite side of the cage, d) Rotating brush in starting position, e) Brush (not rotating) at starting position. Each stage of the prodding is about 1.5-2 sec, except for the last stage which can be prolonged waiting for the mouse to return to its end of the cage.

The following responses will be observed and recorded during the prodding: a) Escape, b) Biting, c) Digging, d) Jumping, e) Boxing, f) Grooming, g) Climbing, h) Following, i) Exploration, j) Tail rattling. Behaviors of the mouse are never to be interrupted unless the mouse climbs onto the edge of the cage (at which point the investigator's hand should gently nudge the mouse back down) or if the mouse jumps out of the cage (an unlikely event since the cage walls are ~25 cm height), it will be immediately captured and returned to the appropriate end of the cage. The tests occur in a small room with a closed door that has a sweep guard, so there is a low chance of losing a mouse. If the mouse "follows" the brush to the opposite side of the cage, the mouse is gently nudged by hand to its side of the cage.

V.4.4.7. Other Procedures:

Transfer of mice (after testing) to DLAM. If possible, some of the mice used in this protocol will be transferred to DLAM. DLAM will be notified of the pending availability of mice, which may be used for other training purposes by DLAM or for sentinel purposes.

Decapitation for tissue sharing or for protein analyses by western blotting and immunohistochemistry. At the study endpoint, the mice will be anesthetized as described in Section V.4.1.2.1. Once the mice are deeply anesthetized and unresponsive to paw pinch, mice are decapitated using a guillotine designed for rodents (cf., **V.4.6. Euthanasia**) for western blotting. As indicated under Sections V.4.4.2 and V.4.6. for immunohistochemistry the animals must be perfused with fixative before removal of the brain.

V.4.4.8. Tissue Sharing:

Excess mouse tissue will be made available to other investigators in our or other labs.

V.4.5. Study Endpoint:

The study endpoint is survival for the previously described durations (10-16 weeks of age), at which time mice will be euthanized. Euthanasia will be performed as stated.

V.4.6. Euthanasia:

Euthanasia will be performed in accordance with the guidelines of the "2013 Report of the AVMA Panel on Euthanasia." Methods of euthanasia on this protocol include decapitation and perfusion. Mice are first anesthetized for these procedures.

Perfusion: Following anesthesia per Section V.4.1.2.1 we will ensure mice are deeply anesthetized and unresponsive to paw pinch then a midline thoracotomy is made to expose the heart, a 20-22 gauge blunt tip needle connected to a tube (¼ in ID and 1/16 in wall) inserted into the left ventricle through the apex and the right atrium incised. After an initial washout with 20-30 ml of cold 100 mM phosphate buffered saline (PBS), transcardial perfusion with 50-75 ml cold 4% paraformaldehyde in PBS will be delivered through a gravity perfusion system until adequate perfusion reached. The brain will then be removed from the calvarium and post-fixed before tissue sectioning for immunohistochemical staining.

Decapitation: Following anesthesia per Section V.4.1.2.1 we will ensure mice are deeply anesthetized and unresponsive to paw pinch then use a rodent guillotine to decapitate the anesthetized mice. The decapitation equipment will be cleaned and maintained to ensure the proper function by routinely checking to ensure it is not rusted or blunt. It will be either sharpened or replaced if it does not function properly. A log book will be kept of the maintenance of the guillotine.

In the event that LAM personnel must euthanize an animal for humane reasons, cylinderized carbon dioxide will be used in the LAM necropsy room. Using a clean cage carbon dioxide will be administered at a rate to replace greater than 20% of the cage volume per minute. Once the mice have not moved or breathed for at least one minute they will be removed from the chamber. Euthanasia may be ensured by cervical dislocation or opening of the thorax.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol. Routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for the mice used in this protocol.

V.5.1.1. Study Room:

Building(s) (b)(6) Room Number(s (b)(6)

Building(s) Room Number(s

Building(s) Room Number(s

V.5.1.2. Special Husbandry Provisions:

Food Restriction: Yes X No

Fluid Restriction: Yes No X

V.5.1.3. Exceptions: Mice tested in the modified hole-board experiment (V.1.5. Experiment 5; n=85) will be restricted to approximately 85% of free-feeding body-weight beginning four days before the experiment. This restriction is necessary for the mice to be motivated during the experiment which requires them to remember the location of small food rewards. To ensure proper weight loss, mice will be weighed every morning. The diet provided will be altered to meet the ~85% weight loss. Mice from the same cohort will be used to monitor body weight change (Anon., 2011).

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care:

The PI or research staff will observe the mice following all procedural manipulations. DLAM personnel will observe the mice at least once a day for general health and husbandry condition. Any mouse observed to be lethargic, losing weight, exhibiting gross neurological deficits (such as inability to eat or drink, continual circling, seizures, etc.) or any other signs of distress or illness will be evaluated by the PI and/or veterinary staff then euthanized as previously described.

V.5.2.2. Emergency Veterinary Medical Care:

All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: All animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies except as described below. All mice will be group-housed, and standard nestlets provided by LAM will be provided in each cage.

V.5.3.2. Enrichment Restrictions: After completion of the NOR test in Experiment 6, we are requesting these animals be individually housed for the duration of the irritability part of the experiment (five days).

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
Surgery (controlled cortical impact)	(b)(6)	(b)(6) has several years of experience performing this procedure in mice. She has trained (b)(6) under prior protocol (b)(6) (b)(6) and will instruct him further as necessary.	Prior TBI studies under (b)(6) will be trained by (b)(6) (b)(6)
Rodent Behavioral Testing		(b)(6) has > 15 years of experience in animal handling and behavioral testing and an M.S. in Behavioral Neuroscience. (b)(6) has two years of experience with testing, and (b)(6) has been trained under prior protocol (b)(6)	Personal laboratory experience (b)(6) will be trained by (b)(6) (b)(6)
Anesthetic injections		(b)(6) and (b)(6) all have many years of experience in animal handling and drug administration..	All listed investigators have taken the Rodent Handling and Procedural Techniques.*
Euthanasia by decapitation		(b)(6) experience with rodent decapitation >30 years. He will instruct listed colleagues on this procedure.	Performed similar procedure for recent Protocols (b)(6) (b)(6)
Intracardial perfusions		(b)(6) & (b)(6) have many years of experience with perfusions.	Personal laboratory experience (b)(6) (b)(6) and (b)(6) (b)(6) will receive training from the approved personnel on this protocol.

*All listed investigators have attended the USUHS Investigator Training Course: Dr (b)(6) on August 17, 2005, (b)(6) completed several online USUHS Investigator Training Courses on October 28, 2009 and attended the Rodent Handling and Procedural Techniques on November 19th, 2009. She is previously approved to perform the above procedures under (b)(6) Dr. (b)(6) has completed the online USUHS Investigator Training Course on September 9, 2008 and the Rodent Handling and Procedural Techniques on September 24, 2009. She is approved to perform the above procedures under protocol (b)(6) completed several USUHS online investigator training courses including "Working with the IACUC" (non-VA) on April 23, 2013 and the USUHS Investigator Training Courses on June 6, 2013 (b)(6) completed USUHS online training on February 7, 2013 and attended the USUHS Investigator Training Course on August 16, 2012.

(b)(6)

VII. BIOHAZARDS/SAFETY:

To minimize exposure to animal allergens when working with lab animals, lab personnel will wear lab coats and/or scrubs, gloves and masks. We will always to wear lab coat and gloves when we contact toxic chemicals such as phenol/chloroform during RNA isolation and perform some steps in a fume hood to minimize risk of exposure to these teratogens. Potential fumes

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. **Training:** I verify that I have attended the USUHS Investigator/Animal User Training Course.

(b)(6) 6/24/13

Prin Date

G. **Training:** The following personnel will attend the next USUHS Investigator/Animal User Training Course:

H. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely, "Responsibility" for implementing animal use alternatives where feasible and conducting humane and lawful research.

(b)(6)

X. PROTOCOL ABSTRACT:

A. Animal Protocol Number: (b)(6)

D. **Animal Protocol Title:** Development of normative data for behavior testing in the CNRM Mouse Behavioral Assessment Core

C. Principal Investigator: (b)(6) Ph.D.

D. Performing Organization: Uniformed Services University of the Health Sciences

E. Funding: $491,383

F. Objective and Approach:

The goal of this research is to integrate new behavioral tests into the CNRM Pre-Clinical Studies Core's current offering of functional tests for scientific investigators. In the past three years the Core has offered over 20 behavioral tests for investigators to use for behavioral assessment in their experiments. The majority of these tests have been validated in control animals and used in traumatic brain injury (TBI) research, and the results are available to all investigators interested in employing behavioral testing in their studies on brain injury. This research will expand the offerings to include more sensitive cognitive tests, tests of sensory systems including vision and olfaction, and an assay of irritation, a neuropsychiatric complaint of brain-injured human patients. A database of "normative" information on uninjured C57BL/6 adult male mice will first be collected to validate testing equipment and data-collecting procedures. We will then use controlled cortical impact (CCI) to induce TBI at mild and severe levels to determine the impact of this brain injury on functional performance and to identify behavioral tests that are able to discriminate mild injuries.

To approach this problem we will use laboratory mice. Mice will be used in a series of behavior tests to assess their performance and gather basic statistical information about the scores obtained by a "typical" mouse and by a mouse with brain injury. The data collected will then be summarized using conventional statistical approaches (mean, standard deviation, analysis of variance, correlation and regression analyses). We will use as few mice as possible while still using enough to make valid conclusions. We must undertake this work in live mice to determine behavioral testing scores to "standardize" the procedures for testing mice and to provide other experimenters with "normative" data about what they can expect will be the typical behavioral patterns of their mice when they use the core facility. To do this initial research we must use animals since cells or tissues will not reflect the actual biology of a live organism. We hope that this basic research and use of animals will aid in understanding some of the causes for the long-term effects stress and brain injury has upon warfighters returning home to their towns, work, and families, and that this research may allow us to provide better treatments to help suffering soldiers.

MEMORANDUM FOR DR. (b)(6) DEPARTMENT OF ANATOMY, PHYSIOLOGY, AND GENETICS

SUBJECT: IACUC Approval of Protocol – Initial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on June 20, 2013:

Animal Protocol Title: "Nanotechnology-based Intranasal Brain Delivery of Neuroprotectants in Rat Models"

USUHS Protocol Number: (b)(6)

Expiration Date: June 19, 2016

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. **NON-TECHNICAL SYNOPSIS:** Nose to brain delivery bypasses the blood brain barrier (BBB) to rapidly deliver drugs to the central nervous system (CNS) via multiple neural pathways wherein drugs are observed in the brain within 10 minutes of application in humans. The major advantage of this approach is that charged molecules or even high molecular weight drugs, which cannot bypass the BBB from the general circulation, can be rapidly delivered to the CNS. Efficiency of nose-to-brain delivery can be significantly improved by adjusting the physicochemical properties of the formulations using membrane-adhesive nanoemulsions or biodegradable nanoparticles. Our long term objective is to establish and optimize for human use the efficacy of intranasal brain delivery systems for use with chemical threat agent-related therapeutics, which can be of rapid and practical use in preventing and treating chemical threat agent mediated casualties. The immediate goal is to develop an intranasal nanoemulsion approach for this purpose and optimize effectiveness in a preclinical model system in the rat. Use of nanoemulsion technology for intranasal brain delivery of drugs is an innovative approach to bypass the BBB and efforts along these lines are underway in many laboratories. The successful use of an intranasal brain delivery technology against chemical threat agents will open up its wider application in numerous other areas of clinical medicine and research.

II. BACKGROUND:

II.1. Background:

Exposure to organophosphorous chemical threat agents (CTAs) is a potential risk for military and the civilian populations alike. CTAs exert their toxic effects by inhibiting acetylcholinesterase (AChE) leading to the accumulation of acetylcholine at synaptic and neuromuscular junctions resulting in symptoms of acute CTA poisoning including salivation, lacrimation, defecation, muscular twitching, seizures, status epilepticus and ultimately death due to respiratory failure. Available treatment for acute CTA poisoning includes combinations of: 1) oxime to reactivate the inhibited AChE; 2) atropine to

antagonize the action of excess acetylcholine formed at muscarinic receptors and 3) diazepam or midazolam to allosterically potentiate action of the inhibitory neurotransmitter γ-amino butyric acid (GABA) at GABAA receptors. The two major limitations of the current therapeutic strategies are: 1) poor blood-brain barrier (BBB) permeability of oximes and 2) resistance to reactivation of the CTA-inhibited AChE due to its rapid 'aging' [1]. Quick delivery of oximes to the brain is critical to reactivate the rapidly 'aging' AChE in the brain and protect the brain from acute and subsequent chronic injuries.

Non-invasive intranasal nose-to-brain delivery of therapeutics was first invented by William H. Frey II in 1989 and patented in 1997. This method bypasses the BBB to rapidly deliver drugs to the CNS extracellularly and paracellularly along the olfactory and trigeminal neural pathways [2] wherein drugs are observed in the CSF within 10 minutes of application in humans . Dr. Frey's patented intranasal insulin treatment has been found to improve memory, attention and functioning in patients with Alzheimer's disease in clinical trials performed by Dr. Suzanne Craft and colleagues [3,4] and to improve memory in normal human adults as well [5]. Intranasal treatment has also been used for treating stroke [6], brain tumors [7], seizure and many other neurological disorders in animal models [8-13]. The major advantage of this approach is that charged molecules or even high molecular weight drugs, which cannot bypass the BBB from the general circulation, can be rapidly delivered to the CNS. Efficiency of nose-to-brain delivery can be significantly improved by adjusting the physicochemical properties of the formulations using mucoadhesive nanoemulsions or biodegradable nanoparticles [44, 14-23]. Our central hypothesis is that intranasal administration of therapeutic formulations of oxime, atropine and midazolam in a nanoemulsion formulation can rapidly deliver significant amounts of these drugs to the brain and small amounts to lungs and the blood stream to protect against CTAs up to 30 minutes after exposure. Our long term objective is to establish and optimize for human use the efficacy of intranasal brain delivery systems for use with chemical threat-related therapeutics, which can be of rapid and practical use in preventing and treating CTA casualties. The immediate goal is to develop an intranasal mucoadhesive nanoemulsion approach for this purpose and optimize effectiveness in a preclinical model system.

Use of nanoemulsion technology for intranasal brain delivery of drugs is an innovative approach to bypass the BBB and efforts along these lines are underway in many laboratories. The proposed intranasal brain delivery technique using nanoemulsion needs to be investigated for protection against CTAs or any other situations involving civilian mass casualty. The major advantages of the successful use of this non-invasive technology against CTAs are: 1) it can rapidly deliver oximes (which cannot cross the BBB under physiological conditions) to the brain in addition to the lungs and blood to reactivate the inhibited AChE; and 2) it can be self-administered immediately after exposure to prevent 'aging' of the inhibited AChE and its resistance for reactivation. The successful use of an intranasal brain delivery technology against chemical threat agents will open up its wider application in numerous other areas of clinical medicine and research.

II.2. Literature Search for Duplication:

II.2.1. Literature Source(s)

Literature Sources Searched: PubMed, BRD, FEDRIP

II.2.2. Date of Search: 2-19-2013

II.2.3. Period of Search: 1970-present

II.2.4. Key Words and Search Strategy: Intranasal brain delivery, nanoemulsion, nanoparticle, nerve agent, paraoxon, rat.

II.2.5. Results of Search: PUBMED: Six articles were found when keywords intranasal brain delivery and nanoemulsion were combined. None of them involves the proposed work involving nerve agents. BRD: None. FEDRIP: None.

Therefore, the proposed research and the goals do not duplicate earlier research in these areas of research.

OBJECTIVE\HYPOTHESIS: Our central hypothesis is that intranasal administration of therapeutic formulations of oxime, atropine and midazolam in a nanoemulsion formulation can rapidly deliver significant amounts of these drugs to the brain and small amounts to lungs and the blood stream to protect against CTAs at 30 min or later time points. Our long term objective is to establish and optimize for human use the efficacy of intranasal brain delivery systems for use with chemical threat-related therapeutics, which can be of rapid and practical use in preventing and treating civilian mass casualties. The immediate goal is to develop the intranasal mucoadhesive nanoemulsion approach for this purpose and test them for effectiveness in a preclinical model system.

III. MILITARY RELEVANCE:

Exposure to organophosphorous chemical threat agents (CTAs) is a potential risk for military and the civilian populations alike. Use of nanoemulsion technology for intranasal brain delivery of drugs is a highly innovative approach to bypass BBB and efforts along these lines are underway in many laboratories. The proposed intranasal brain delivery technique using nanoemulsion needs to be investigated for protection against CTAs or any other situations involving civilian mass casualty. The major advantages of the successful use of this non-invasive technology against CTAs are: 1) it can rapidly deliver oximes (which cannot cross the BBB under physiological conditions) to the brain in addition to lungs and blood to reactivate the inhibited AChE; and 2) it can be self administered immediately after exposure to prevent 'aging' of the inhibited AChE and its resistance for reactivation. The successful use of an intranasal brain delivery technology against chemical threat agents will open up its wider application in numerous other areas of clinical medicine and research

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures:

1. Animal studies to determine the optimal mucoadhesive nanoemulsion for the proposed neuroprotection studies: Male Sprague Dawley rats (220 to 250 gm) will be used for these studies. Rats will be anesthetized by exposure to isoflurane (3%). Animals will be given intranasal administration of 2-PAM made in different nanoemulsions (3 different particle sizes of chitosan as well as hyaluronate based mucoadhesive nanoemulsions) as well as nanoparticle forms up to a maximum volume of 50 µl in the supine position with the head tilted back so that the formulation can drain to the olfactory epithelium at the roof of the nasal cavity under anesthesia. Changes in blood pressure or mucous secretions are not expected to affect the uptake of the neuroprotectants under this condition. Also, only one nasal passage way will be used at a time and the viscosity of the emulsion will be adjusted in such a way that it will not have any adverse effect on the epithelial layer. The animals will be euthanized at 30 min and 2 hrs after intranasal administration. Brain, lungs and blood will be collected for measuring the levels of 2-PAM using HPLC/MS. In the case of brain, different regions (olfactory bulb, cortex, hippocampus, cerebellum and brain stem) will be dissected for analysis. Spinal cord also will be collected for determining the delivery to the whole CNS. Group 1: Animals given intranasal administration of 2-PAM made in chitosan based nanoemulsions –30 rats (5 animals each for three different particle sizes and 2 time points). Group 2: Animals given intranasal administration of 2-PAM made in hyaluronate based nanoemulsions –30 rats (5 animals each for three different particle sizes and 2 time points). Group 3: Animals given intranasal administration of 2-PAM made in nanoparticle preparations –30 rats (5 animals each for three different particle sizes and 2 time points). **Total number of rats required for this part is 90. Pain Category C = 0, D = 90 , E = 0**

2. Determination of the optimum doses of drugs for combination in the optimal nanoemulsion or nanoparticle preparation: Three different concentrations of atropine, 2-PAM and midazolam (up to the doses used for intramuscular route) will be made using the optimum mucoadhesive formulation obtained from the above study for determining the optimum doses of drug combination for the neuroprotection studies. The doses used for intramuscular route for atropine, 2-PAM and midazolam are 2 mg/kg, 25 mg/kg and 5 mg/kg respectively. Rats will be anesthetized by isoflurane as mentioned above. Three serial dilutions of the drug combinations will be made in the optimal nanoemulsion/nanoparticle preparation and will be given intranasally as described above and the animals euthanized at 30 min and 2 hrs. Brain, lungs and blood will be collected for measuring the levels of drugs using HPLC/MS. In the case of brain, different regions of the brain (olfactory bulb, cortex, hippocampus, cerebellum and brain stem) will be dissected for analysis. The optimal doses of each drug will be selected based on the highest uptake into the brain. Total number of animals required for this part of the study = 5 animals/group x 3 doses x 2 time points = 30. **Pain Category : C = 0 ; D = 30 ; E = 0 .**

3. To test efficacy of the intranasal brain delivery method of CTA

therapeutic formulation for protection against the insecticide (CTA) paraoxon

The protective efficacy of the optimal therapeutic formulation containing the drug combination obtained from the above study will be tested against the model CTA, the insecticide paraoxon in radiotelemetry probe implanted rats. About one week after the radiotelemetry probe implantation, therapeutic formulation containing the mixture of all the three drugs will be given intranasally 30 min after exposure to paraoxon (1.0 mg/kg s.c). **This dose was selected based on the observation that it will cause status epilepticus in 75% of the animals (24).**The protective efficacy will be compared to that of the traditional intramuscular route. The protective efficacy will be determined using mortality, EEG measurement using radiotelemetry and neuropathological examination using hematoxylin/eosin staining in addition to measuring the activity of AChE and butyrylcholinesterase (BChE) in the blood and different tissues including different regions of the brain. **Group 1: (control, 16 rats)**; Group 2: (Paroxon exposed, 16 rats) – rats given paraoxon; Group 3: (intranasal treatment group, 16 rats) - rats given paraoxon + intranasal treatment 30 min after the paraoxon injection; Group 4: (intramuscular treatment group, 16 rats) – rats given paraoxon + traditional intramuscular treatment with atropine (2 mg/kg), 2-PAM (25 mg/kg) and midazolam (5 mg/kg) 30 min after paraoxon injection. This experiment will be repeated once to confirm it. Total number of rats implanted with radiotelemetry probe is **128. Pain Category C = 0 , D = 32 , E = 96.**

Pilot dose response study: As recommend by the reviewer, a pilot dose response study will be carried out using three doses around the proposed dose given above. The final dose to be used will be determined based on this pilot study. Pain category C = 0, D =16, E = 48. Total = 64.

Mortality and EEG measurements will be carried out up to 24 hrs post paraoxon exposure. At the proposed dose level, the animals are expected to experience prolonged seizures starting in about 5 min of treatment with about 75% of animals exhibiting status epilepticus. Also, the animals are expected to display a combination of chewing, head-bobbing, single and bilateral limb clonus and rearing leading to constant full body tremors. Animals will be monitored at 30 min intervals during the first 2 hours and every 8 hrs intervals thereafter including the evening hours. Half the number of survived animals after 24 hrs will be euthanized and blood/tissues collected for AChE and BChE assay. In the case of brain, different regions of the brain (olfactory bulb, cortex, hippocampus, cerebellum and brain stem) will be dissected for the enzyme analysis.

For histopathological analysis, 24 hrs post-parathion/paraoxon exposure, the other half of rats will be perfused transcardially with 4% paraformaldehyde under anesthesia. Brain and lung will be collected for histopathological analysis using hematoxylin/eosin staining. The histopathological analysis will be carried out by the board certified pathologist available in the Laboratory Animal Medicine at AFFRI. EEG recording and analysis will be carried out with help from our departmental colleague, Dr. (b)(6) using the Stellate (Montreal, Quebeck, Canada) EEG monitoring system. EEG recordings will be visualized offline with filter settings at 0.3 Hz low frequency filter, 60

Hz notch filter, and 70 Hz high frequency filter, using the Harmonie Viewer 6.1c from Stellate. An electrographic seizure will be defined as a period of EEG changes marked by an abrupt starting and termination that includes a minimum of 10 s of consistent, repetitive discharges at least double the amplitude of the background activity and not less than 1Hz in frequency. A single graphoelement will be classified as sharp wave when it is clearly distinguishable from movement artifacts, has twice the amplitude of the background EEG and is less than 1 ms in duration.

Calculation of animal numbers:

Experiment 1 + Experment 2 + Experiment 3 + **Pilot dose response study** +10% extra for training procedures and anesthesia failures = **90 + 30 + 128 + 64 + 31 = 343**; **Pain Category C = 0 , D = 185 , E = 158**

V.2. Data Analysis: Data will be presented as mean ± SEM. Parametric data will be analyzed using a paired 2-tailed t test for the paired data or a 1-way analysis of variance (ANOVA) followed by Dunnett's multiple comparisons post test. Nonparametric data (histology data, behavioral data) will be analyzed using a Wilcoxon signed rank test for paired data or a Kruskal-Wallis test (nonparametric ANOVA). An associated probability value of $P < 0.05$ will be considered significant.

Power analysis using the quantitative data obtained from our earlier studies have indicated that for most of our behavior type studies a sample size of 10 animals per group will have 80% power to detect a difference of 1.5 standard deviations between groups assuming a 5% significance level, and should be sufficient for the outcomes we intend to measure; power calculations were performed using nQuery Advisor® 4.0 software. Similar calculations have indicated that 5-6 animals/group is sufficient for biochemical and immunohistochemical studies. The total number of animals for each experiment has been calculated based on the above considerations. Sixteen animals/group are for the EEG studies involving paraoxon treatment in view of the expected mortality in this study.

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered: The specific nature of the project does not permit use of non-animal alternatives. The global physiological changes occurring in different cell types in the *in-vivo* brain injury models cannot be reproduced in single cell culture system, or any alternatives.

V.3.2. Animal Model and Species Justification: Male Sprague-Dawley (SD) rats (Rattus norvegicus) will be used for these experiments. SD rats have been chosen as a suitable species and animal model for this research because they have been extensively used in nerve agent research to evaluate new medical countermeasures.

V.3.3. Laboratory Animals

	Species #1	Species #2
V.3.3.1. Genus & Species:	Rattus Norvegicus	
V.3.3.2. Strain/Stock:	Sprague-Dawley	
V.3.3.3. Source/Vendor:		
V.3.3.4. Age:		
V.3.3.5. Weight:	220-250g	
V.3.3.6. Sex:	Male	
V.3.3.7. Special Considerations:		

V.3.4. Number of Animals Required (by Species): 343

V.3.5. Refinement, Reduction, Replacement (3 Rs):

V.3.5.1.Refinement:

Rats will be anesthetized with isoflurane and reach a surgical plane of anesthesia for restraint purposes before decapitation for collection of brain tissues. All EEG surgery will be performed under appropriate anesthesia and pre-and post-surgical analgesics will be used to relieve pain. For example, Lidocaine jelly will be used at ear pressure points and Bupivicaine used at EEG electrode placement. Any rat exhibiting signs of pain or impairment beyond that from this model will be euthanized at an early endpoint.

V.3.5.2. Reduction:

We have considered reducing the total number of control animals by avoiding separate control groups. However, in view of the variations between animals, especially in behavioral parameters, we do not feel comfortable in comparing with a control group done on another day. Therefore, we are unable to reduce the number of animals in the control group. Also, we have tried to use the minimum number of animals for each experiment based on our prior experience and experience of other investigators in the field.

V.3.5.3. Replacement:

In silico methods and tissue culture approaches cannot be used for evaluation of the intranasal transit of drugs to the brain, or to assess their effects on paraoxan toxicity, since these actions can only be observed in an intact living animal. Also, animals lower than rodents in the phylogenetic scale cannot be used to model brain injury studies in human, because of wide anatomic and physiological differences.

V.4. Technical Methods:

V.4.1. Pain / Distress Assessment:

V.4.1.1. APHIS Form 7023 Information:

V.4.1.1.1. Number of Animals:

	Species #1	Species #2
V.4.1.1.1.1. Column C:		
V.4.1.1.1.2. Column D:	185	
V.4.1.1.1.3. Column E:	158	

V.4.1.2. Pain Relief / Prevention:

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization:

For surgical implantation of cortical electrodes for EEG recordings, animals will receive one dose of buprenorphine (0.05 mg/kg s.c.) before any incisions are made. The animals will be anesthetized with isoflurane (3% for induction, 2.0-2.5% for maintenance; with oxygen). Anesthesia will be induced by isoflurane vapor in 100% oxygen in a commercially available induction chamber. Once anesthesia is induced, animals will be transferred to the designated surgery area and anesthesia will be maintained via nose cone. To monitor the depth of anesthesia (including during surgery time) we will test whether the animal has lost its toe pinch (pedal withdrawal) reflex.

Prior to incision, animals will receive bupivicaine (0.25% solution, up to 0.5 ml) at electrode placement sites (infusion of surrounding tissue), at a maximum of 0.2 ml within any one animal, and buprenorphine HCl (0.05 mg/kg, s.c.) to assist in post-operative pain management. If animals continue to show signs of pain or stress such as a hunched posture, not eating/drinking, reluctance to move during the recovery period, we plan to give additional doses at 8 hour intervals (see below).

Following surgery for implantation of cortical electrodes, animals will receive buprenorphine HCl (0.05 mg/kg, s.c.), which will be given at a minimum one time at the end of the day of surgery, just before close of business. This is in addition to the preemptive dose given prior to surgery. All surgeries will be performed in the AM. Additional doses will be given every 8-12 hours, up to 3 days after the surgery as needed, in consultation with the attending veterinarian.

The buprenorphine dose may be increased on consultation with a LAM veterinarian, up to a dose of 0.25 mg/kg i.m. or s.c. at each buprenorphine dosing time point, if animals continue to show signs of pain or stress such as a hunched posture, not eating/drinking, reluctance to move.

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions:.

For the EEG studies, following paraoxon exposure the animals will be closely monitored for signs of seizure onset or to determine if they have developed serious complications that may require early euthanasia (see V.4.4.7 and V.4.6 sections below). As mentioned earlier, the animals are expected to experience prolonged seizures starting in about 5 min of treatment with about 75% of animals exhibiting status epilepticus.

V.4.1.2.3. Paralytics: N/A

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures:

V.4.1.3.1. Sources Searched: PubMed, Agricola:

V.4.1.3.2. Date of Search: 3/28/13

V.4.1.3.3. Period of Search: 1966-2012

V.4.1.3.4. Key Words of Search: animal, rat, pain, analgesia, transcardial perfusion, seizure.

V.4.1.3.5. Results of Search: PUBMED: A total of 139 publications were obtained when all key words except transcardial perfusion were used. However, none appeared when transcardial perfusion was included in the search. All of the 139 publications involved studies on different aspects of pain, including neural mechanisms and newer pain relieving agents. When key words rat and transcardial perfusion were combined, 47 publications describing studies involving the use of transcardial perfusion were obtained. None of them provided any alternatives to the proposed painful procedures. Agricola: None of the publications provided an alternative to the painful procedure used in this protocol.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification:

The goal is to develop intranasal brain delivery methods for protection from nerve agents. There is no alternative for inducing brain damage in rats that mimics the damage caused by nerve agents to determine whether a compound is neuroprotective. The only way to determine the neuroprotective efficacy of a putative drug is to cause actual status epilepticus in an animal model to induce damage prior to administration of the neuroprotective compound and to determine the number of surviving neurons and improvements in other CNS pathologies.

Without exposing the animals to nerve agents or model compounds, it is not possible for us to conduct these studies. These studies are justified because the use of nerve agents against military personnel in international conflicts, and also against civilians, is a major threat at the present time. Thus, the knowledge obtained from the proposed investigations may benefit many active duty personnel, as well as civilians.

Paraoxon exposure is thought to cause some pain and/or distress due to the intense physiological changes produced by these toxicants. Anesthetics and analgesics for relief of pain or distress are known to have profound effects on brain function and may also interact with chemical agents, thereby complicating the interpretation of the results. The goal of the study is test the effect of 2-PAM to block the seizure activity in the brain. Therefore, the dose of paraoxon that causes seizure activity in the maximum number of animals was selected for the proposed study.

V.4.2. Prolonged Restraint: N/A

V.4.3. Surgery:

V.4.3.1. Pre-surgical Provisions:

A week prior to the experiments involving EEG recordings, the animals will be implanted with cortical electrodes for electroencephalogram (EEG) recordings. These EEG recordings will be used to confirm the onset and intensity of behavioral convulsions observed in the animals. The surgical procedures will be performed aseptically following the LAM guidelines. Animals will receive one dose of buprenorphine (0.05 mg/kg s.c.) before any incisions are made. Anesthesia will be induced by isoflurane vapor in 100% oxygen in a commercially available induction chamber. Once anesthesia is induced, animals will be transferred to the designated surgery area and anesthesia will be maintained via nose cone. See Section V.4.1.2.1 Anesthesia/Analgesia/Tranquilization for details.

When the animal is anesthetized, its head will be shaved with a hair clipper. The head will be cleaned with betadine and alcohol, each repeated 3 times alternately. Then the animal will be placed into a stereotaxic frame (appropriate frame size will be used for rats) after treating its pressure points such as ears and nose with lidocaine jelly. A heated pad with thermister-controlled feedback will be put between the animal's body and the base of the stereotaxic frame. Ophthalmic ointment will be applied to the eyes to prevent dryness. The body will be covered with a sterile drape with an opening to expose the head. Prior to incision, animals will receive bupivicaine at electrode placement sites (infusion of surrounding tissue) to assist in pain management. The injection volume will be limited to the minimum required for pain control, to minimize health risks. Care will be taken to avoid systemic effects.

V.4.3.2. Procedure:

Surgery to implant cortical electrodes: The skin will be incised longitudinally along the midline from eye level to the neck level and retracted to the sides with hemostats. The periosteum will be scraped off from the skull. Five stainless steel machine screws (the smallest possible size that provide adequate anchoring) will be used as electrode contact and simultaneous anchoring points for the headpiece that will be built from acrylic cement to secure the female electrode connector in place. The screws will be manually positioned in the frontal or parietal bone plates and one over the cerebellum. The screws will be partially screwed in manually without penetrating the dura mater.

V.4.3.3. Post-surgical Provisions:

In the case of the EEG electrode impantation procedure, excess cement will be removed from the headpiece to make its edges smooth. If necessary, skin will be sutured at both ends of the incision line. The animal will be released from the

stereotaxic frame and placed in a recovery cage on a chemical pocket warmer wrapped in cloth or paper until the animal fully recovers from anesthesia. Alternatively, the animals may be placed in a forced-air recovery chamber warmed to 34 °C. Once fully awake and performing purposeful movements, the animal will be moved back to the holding area. At least 7 days will be allowed for recovery after surgery before any experimentation.

We expect that about 90% of the animals will be in good health to be used in the study. This decision will be jointly made by the animal-care personnel and the investigators. All efforts will be made to provide all animals with the best care possible. Each animal will be individually monitored throughout the study by experienced personnel from our laboratory. We will also closely work with the veterinarian and animal-care staff of the animal facility to ensure that adequate treatment is provided in a timely manner should it be deemed necessary.

After surgery, the animals will be placed in a clean cage provided with a recirculating warm-water veterinary heating pad or in a forced-air recovery chamber warmed to 34 °C to maintain proper body temperature. Following surgery for implantation of cortical electrodes, animals will receive buprenorphine HCl (0.05 mg/kg, s.c.), which will be given at a minimum one time at the end of the day of surgery, just before close of business. This is in addition to the preemptive dose given prior to surgery. All surgeries will be performed in the AM. The medication will be administered by the by qualified PI staff. If necessary, based on consultation with the attending veterinarian, additional buprenorphine may be given as needed.

Additional doses of buprenorphine will be given if required, based on assessment of PI and attending veterinarian of animal's condition, which will include assessment of the presence of the following signs of pain/distress: hunching, abnormal gait, abnormal attitude (increased or decreased aggression), inability to move to food/water, excessive porphyrin staining of eyes/nose, shuddering or twitching, unkempt appearance, and vocalization when handled.

Following at least 1 hour on the warming pad or in a forced-air recovery chamber, upon full recovery in which the animal can maintain an upright posture and is ambulatory, the animal will be returned to its holding room cage. Laboratory personnel will provide the care of the animal until full recovery if it has not already occurred. All animals will be checked at least once 30 minutes after return to home cage, to ensure recovery is continuing, and at least once again just prior to the end of the work day to ensure animals are recovering normally. Animals will be examined at least twice daily by the PI staff for one week post-surgery to ensure that no complications occur. Observations will be recorded for each animal in a place that is accessible to the animal care staff (post-surgery cage cards may be used for this purpose). PI staff observations will be separate from routine observations conducted by the animal care staff

V.4.3.6.2. Scientific Justification: N/A

V.4.4. Animal Manipulations:

V.4.4.1. Injections:

Drug name (concentration)	Dose	Frequency	Route	Site	Volume	Needle size
Bupivicaine (2.5 mg/ml)	5.0 mg/kg	Once	subcutaneous	Surgery site	Up to 0.5 mL	25 ga 1 in
Buprenorphine (0.025 mg/ml)	0.05 mg/kg	Q8-12H	subcutaneous	Interscapular	Up to 0.5 ml	25 ga 1 in
Fatal Plus or equivalent (50 mg/ml)	85-100 mg/kg	Once	intraperitoneal	Lower abdomen	Up to 0.5 ml	25 ga 1 in
Paraoxon (0.5 mg/ml)	1.0 mg/kg	Once	subcutaneous	Interscapular	Up to 0.5 ml	25 ga 1 in
Atropine (1 mg/ml)	2.0 mg/kg	Once	Intramuscular	Caudal thigh	Up to 0.5 ml	25 ga 1 in
Midazolam (2.5 mg/ml)	5.0 mg/kg	Once	Intramuscular	Caudal thigh	Up to 0.5 ml	25 ga 1 in
2-PAM (12.5 mg/ml)	25 mg/kg	Once	Intramuscular	Caudal thigh	Up to 0.5 ml	25 ga 1 in

V.4.4.2. Biosamples: Tissues such as brain, lung, liver, kidney, heart and blood will be collected post mortem.

V.4.4.3. Adjuvants: N/A

V.4.4.4. Monoclonal Antibody (MAbs) Production: N/A

V.4.4.5. Animal Identification: The animals will be identified by cage card. However, individual animals after procedure will be given a particular identifying tattoo on their pinna of the ear, tail, arms or legs.

V.4.4.6. Behavioral Studies:

V.4.4.7. Other Procedures: On the day of exposure to the nerve agent, Paraoxon will be administered intraperitoneally and the animals will be connected to recording leads via the connection plug on their heads. Brain EEG activity will be recorded while they are in cylindrical plastic recording chambers, 16" in diameter and 26" high with Iso-pad bedding on the floor, where they are free to move about. The period of confinement in the recording chambers will not exceed 3 hours on the experimental day or 1 hour on the day after, if needed.

V.4.4.8. Tissue Sharing: Tissues may be shared with other investigators upon request.

V.4.5. Study Endpoint: All rats will be euthanized within 24 hrs of receiving the proposed dose of paraoxon. The animals will be euthanized for tissue collections and also for histological analysis at the end of each study. For histological analysis, transcardial formalin perfusion will be performed following injection of a 85-100 mg/kg dose of Fatal Plus or another pentobarbital based euthanasia solution.

Early Endpoint: Any of the following will represent a reason for early euthanasia: inability to ambulate or reach food or water, self mutilation, continuous circling, or persistent labored respiration or gasping, loss of 20% of weight below baseline, prostration/inactivity for up to 24 hours, or a significant decline in vital signs. These signs, if observed by animal facility personnel and no study personnel can be reached, may be taken by the veterinarian as cause for euthanasia.

V.4.6. Euthanasia: Some animals in each group will be euthanized by decapitation following injection of a 100 mg/kg dose of pentobarbital based euthanasia solution. Others will be euthanized by transcardial perfusion following euthanasia solution administration (Fatal Plus, 85-100mg/kg or other pentobarbital based euthanasia solution, Intraperitoneal, 400-500µl volume, 25 gauge needle).

Transcardial perfusion will be done as described (16,17). Briefly, animals will be deeply anesthetized with Fatal Plus (85-100 mg/kg), and the heart will be exposed by opening up the thoracic cavity after confirming that the animal is fully under anesthesia. To monitor the depth of anesthesia we will test whether the animal has lost its toe pinch (pedal withdrawal) reflex. The animals will be perfused with either 10% neutral buffered formalin or 4% freshly depolymerized paraformaldehyde through the left ventricle using a peristaltic pump. The right atrium will be cut and approximately 200 ml of fixative solution will be passed through the circulatory system. Following the perfusion, tissues will be removed to a container of fresh fixative solution prior to histopathological analysis.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for all rats in this protocol.

V.5.1.1. Study Room:

Building(s) (b)(6) Room Number(s) (b)(6) (b)(6)

V.5.1.2. Special Husbandry Provisions:

Food Restriction:	Yes	_____	No	X
Fluid Restriction:	Yes		No	X

V.5.1.3. Exceptions: _____ _____

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care: The animals will be observed daily according to LAM SOPs.

V.5.2.2. Emergency Veterinary Medical Care: All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: All animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents.

V.5.3.2. Enrichment Restrictions:

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)

Consulting		Ph.D., 20+ years	Investigator training

		exp.	1998, Rodent handling class, 1998
Consulting	(b)(6)	Ph.D., more than 10 years experience in EEG studies.	Investigator training 2003. Rodent handling class, 2003
Behavioral studies		Res. Assistant, 3-6 months experience in rodent handling	Investigator training 2012, Rodent handling class,2012
Consulting		Ph.D., 15+ years experience	Investigator training,2000, Rodent handling class, 2000
Euthanasia		Research Associate, M.S.	Investigator training,June, 2013, Rodent handling class, June, 2013

VII. **BIOHAZARDS/SAFETY**: Gowns, Gloves, and masks will be used for personal protection and sharp items will be disposed off in separate containers as per safety rules. The volatile anesthetic agents will be properly closed and removed from the procedure area. Chemicals and hazardous waste used in this protocol will be handled in accordance with all applicable state and federal guidelines, regulations, and standing operating procedures. Waste anesthetic gas (isoflurane) will be scavenged and exposure to investigators will be minimized using the set up used in the LAM operating room since the surgeries will be done in one of those operating rooms. Double gloves will be worn while preparing solutions of Paraoxon to avoid any body contact with the insecticide.

VIII. **ENCLOSURES**: References

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

(b)(6) 6/18/2013

Principal Investigator Signature Date

G. Training: The following personnel will attend the next USUHS Investigator/Animal User Training Course:

H. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely, "Responsibility" for implementing animal use alternatives where feasible and conducting humane and lawful research.

(b)(6) 6/18/2013

Principal Investigator Signature Date

I. Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

X. PROTOCOL ABSTRACT:

A. Animal Protocol Number:

B. Animal Protocol Title: Nanotechnology-based intranasal Brain Delivery of Neuroprotectants in Rat Models.

C. Principal Investigator: (b)(6) Ph.D.

D. Performing Organization: USUHS

E. Funding: NIH

F. Objective and Approach:. .

Intranasal CNS delivery of drugs to protect against organophosphorous threat agents: Our central hypothesis is that intranasal administration of therapeutic formulations of oxime, atropine and midazolam in a nanoemulsion formulation can rapidly deliver significant amounts of these drugs to the brain and small amounts to lungs and the blood stream to protect against CTAs at 30 min or later time points. Our long term objective is to establish and optimize for human use the efficacy of intranasal brain delivery systems for use with chemical threat-related therapeutics, which can be of rapid and practical use in preventing and treating civilian mass casualties. The immediate goal is to develop the intranasal mucoadhesive nanoemulsion approach for this purpose and test them for effectiveness in a preclinical model system.

G. Indexing Terms (Descriptors): . intranasal brain delivery, nanoemulsion. nanoparticles, seizure, insecticide, paraoxon, nerve agent.

MEMORANDUM FOR DR (b)(6) DEPARTMENT OF ANATOMY, PHYSIOLOGY, AND GENETICS

SUBJECT: IACUC Approval of Protocol – Initial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on June 5, 2014:

Animal Protocol Title: "The Effect of Traf2 and Nck Interacting Kinase (Tnik) Knockout on Freezing Behavior in Fear Conditioning (Mouse)"

USUHS Protocol Number: (b)(6)

Expiration Date: June 4, 2017

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. NON-TECHNICAL SYNOPSIS:

Post traumatic stress disorder (PTSD) is a major public health concern in both military and civilian populations. According to recent research as many as 8.6% of military personnel returning from Iraq and Afghanistan show symptoms of PTSD lasting at least 30 days [1]. With so many soldiers returning from combat there will be a high emotional and financial burden on families to support and care for these veterans. To improve current treatments and develop new ones it is important to determine what leads to individual differences between humans that lead to either enhanced risk or resilience in

developing PTSD. This leads to studying genes that lead to the development of PTSD to target for future treatment. To study the genetics of fear, an animal model was developed in which mice were selectively bred over several generations to show high or low levels of fear. Looking for different levels of activity in the brains of these rodents one brain region in particular was found to be more active in the animals more prone to fear. This brain region was the hippocampus which has long been recognized to be important in learning and memory. We identified a gene that is highly expressed in the hippocampus of these fear susceptible animals which is caused Traf2 and Nck Interacting Kinase (Tnik). This gene has been shown in a different animal model to be important to memory as well.

We propose to study several aspects of this gene to determine how it influences fear memory. We propose to determine how Tnik is regulated in brain cells in the hippocampus, how Tnik affects the size, shape and composition of brain cells and how Tnik affects fear memory formation in mice.

II. BACKGROUND:

II.1. Background:

Post traumatic stress disorder (PTSD) is a major health concern in both military and civilian populations with a serious impact on quality of life as well as a large financial burden on individuals experiencing PTSD as well as their families. One of the major aspects of PTSD is the onset of a fearful response to situations involving a context similar to the traumatic event which led to the development of PTSD. Several brain regions have been implicated in PTSD including the amygdala, specifically the lateral amygdala, frontal brain regions including the cingulate cortex, the thalamus and the hippocampus [2, 3]. The hippocampus has also been more generally shown to be an important brain region in learning and memory [4-6]. With many of the symptoms of PTSD being related to memory, including flashbacks, intrusive memories, nightmares and amnesia the importance of the hippocampus in the symptoms of PTSD is apparent [2].

To investigate fear memory on a molecular level animal models of fear memory have been created. One major method for studying fear memory is fear conditioning which can be either cued or contextual. Contextual fear conditioning involves placing an animal in a context for a training session and exposing them to a foot shock. For the test phase animals are placed back in the same context and freezing behavior, which is indicative of fear in animals, is measured. In cued fear conditioning an animal is placed into a training chamber and exposed to a cue, usually a tone, prior to receiving a foot shock. The animal is then placed into a

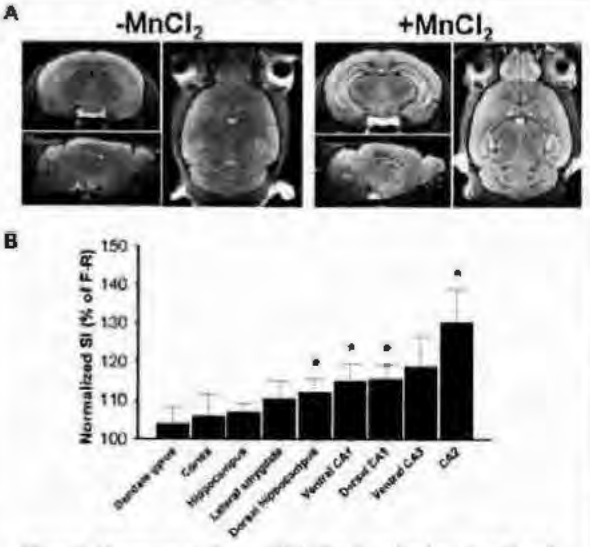

Figure 1. Manganese enhanced MRI data from the brains of FR and FS mice. There were significant differences found in the dorsal hippocampus, dorsal and ventral CA1 as well as CA2 showing heightened activity in those regions in the FS mice. These were the only regions showing significant differences in activity though no work has yet been done investigating the mechanisms underlying these differences [1].

novel context and exposed to the cue and freezing behavior is again measured. These paradigms are similar to symptoms of PTSD where a specific context or cue sets off anxiety like behavior in a person with PTSD.

A recent animal model has been developed in which an intercross line of mice are selectively bred for several generations based on their performance on a fear conditioning task [7]. This led to both fear susceptible (FS) and fear resilient (FR) animals who display high or low levels of freezing respectively. Utilizing these FR and FS mice researchers have identified several quantitative trait loci (QTL) specific to the different lines believed to underlie the observed phenotypes [7]. These include genes in both the prefrontal cortex as well as the amygdala [8, 9]. Functional imaging work done with these mice in the lab of Dr. (b)(6) at USU have displayed functional differences between the FS and FR mice [10]. Interestingly while the researchers anticipated differences in the amygdala the only significant differences found were actually in several regions of the hippocampus including the dorsal hippocampus, dorsal and ventral CA1 as well as CA2 (Figure 1). Since differences in activity have been observed in the hippocampus work into understanding the molecular mechanisms underlying these functional differences are important in determining what drives the behavioral differences between the FS and FR mice.

Recent work in our lab utilizing hippocampal tissue from FS and FR mice and RNA sequencing has revealed a pattern of genes showing differential expression. Among these genes differentially expressed in the FS and FR mice we identified a group of genes which have been recently shown to affect neuronal morphology, synaptic activity and memory performance. Two of these genes, Traf and Nck interacting kinase 2 (Tnik) and cytoplasmic linker associated protein 2, (Clasp2) are more highly expressed in the FS relative to the FR mice. These genes were identified by RNA sequencing and confirmed by qPCR.

Recently Tnik has been identified as an important signaling molecule in hippocampal neurons through research conducted on a Tnik knockout animal [11]. Work with this knockout animal line has shown that Tnik is essential for the incorporation of AMPA receptors into the post synaptic density and absence of Tnik leads to a decrease in synaptic plasticity. The knockout mice also display deficits in spatial learning and memory which have been shown to be dependent on hippocampal neuronal function [11]. Tnik expression has been shown to be highly regionally specific to regions CA1 and the molecular cell layer of the dentate gyrus in the hippocampus (Figure 2, Allen Brain Atlas). These regions have been shown to be important in the formation of fear memory as false fear memories to a novel context have been created

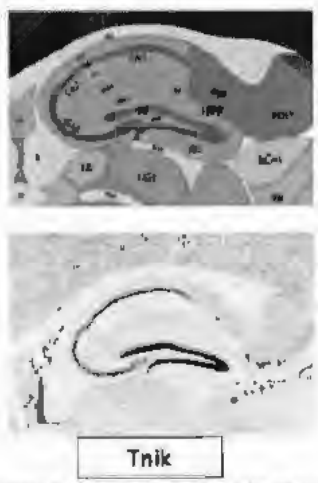

Figure 2. These images are from the Allen Brain Atlas resources. Top- Atlas. Middle- ISH image of mouse brain labeled with Clasp2 specific antibody. Bottom-ISH image from mouse brain slice labeled with Tnik specific antibody. These images show highly regionally specific expression of Tnik restricted to the CA1 area of the hippocampus and the granule cell layer of the dentate gyrus which are two areas important to memory formation and consolidation.

via activation of neurons of the CA1 region of the hippocampus during fear conditioning [12].

Currently we propose performing fear conditioning experiments in a Tnik knockout animal to determine what role Tnik plays in the formation of fear memories. We will be performing both cued and contextual fear conditioning. Using these same knockout animals we intend to analyze slices for synaptic composition and neuronal morphology.

II.2. Literature Search for Duplication:

II.2.1. Literature Source(s) Searched:
Biomedical Research Database (BRD)
Federal Research in Progress (FEDRIP)
PubMed

II.2.2. Date of Search:
3/14/2014

II.2.3. Period of Search:
1950 to present

II.2.4. Key Words and Search Strategy:
We did advanced searches of all databases with the following keywords:
Traf2 and Nck Interacting Kinase (Tnik) fear conditioning
Traf2 and Nck Interacting Kinase (Tnik) hippocampus
Traf2 and Nck Interacting Kinase (Tnik) memory
Traf2 and Nck Interacting Kinase (Tnik) knockout

II.2.5. Results of Search:
There is only one article published pertaining to the Tnik knockout animal. It found a spatial memory deficit but did not do any research with fear memory. Tnik has been shown to associate with proteins in the post synaptic density including DISC1 which has been found to be related to schizophrenia [13]. Tnik has also been found to drive AMPA receptor trafficking in hippocampal neurons which is also related to fear memory [11].
Traf2 and Nck Interacting Kinase (Tnik) fear conditioning- 0 results
Traf2 and Nck Interacting Kinase (Tnik) hippocampus- 2 results
Traf2 and Nck Interacting Kinase (Tnik) memory- 1 result
Traf2 and Nck Interacting Kinase (Tnik) knockout- 2 results

III. OBJECTIVE\HYPOTHESIS:
We believe that Tnik knockout animals will display learning deficits in contextual fear conditioning experiments as shown by decreases in freezing behavior. We also anticipate that neurons in Tnik knockout animals will have fewer projections and decreased cell body size when compared to control.

IV. MILITARY RELEVANCE:

PTSD affects approximately 8.6% of individuals returning from combat missions in Iraq and Afghanistan [14]. New treatments for these returning soldiers with greater efficacy need to be created to aid in their transition back to civilian life and to improve their quality of life post deployment. To aid in the creation of new treatments the molecular mechanisms leading to increased risk or resilience of developing PTSD symptoms is being investigated. Fear memory in animals is used to mimic symptoms of PTSD in humans for research purposes. To study the genetics underlying fear memory an animal model of fear susceptible and fear resilient animals was developed. This gene was identified using deep sequencing technology using hippocampal tissue from these animals. By studying the genetics of fear memory researchers hope to identify new molecular targets for treating soldiers returning home from combat with symptoms of PTSD. This gene serves as a viable candidate for treatment if it is confirmed to be involved in the molecular processes leading to increased susceptibility to fear. Our current proposed research aims to determine what effect this gene has on hippocampal structure and function and how this affects the formation of fear memories in rodents. Confirmation that this gene is important in fear memory development will help determine if it is a viable candidate for human PTSD treatment.

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures:

V.1.1. Experiment 1: Experimental Design and General Procedures:

In experiment 1 we will determine the behavioral differences between Tnik knockout animals and their wild type littermate controls. We will do this by assessing the differences in freezing behavior of these 2 groups in contextual and cued fear conditioning experiments. We will also test basic locomotion and anxiety prior to fear conditioning.

Experimental Timeline. Male mutant and wild type (WT) adult mice (approximately 4 months) will be tested on the behavioral paradigms (open field, elevated plus maze, contextual and cued fear conditioning) according to the details below. Animals will receive 3 days of rest between the open field and elevated plus maze tasks. Fear conditioning will begin 3 days following the elevated plus maze.

Open Field. Open field locomotor activity will be measured using an Accuscan Electronics Digiscan infrared photocell system. Animals are placed singly in a 20 x 20 x 30 cm clear Plexiglas arena and a Plexiglas lid with multiple ventilation holes placed on top of the arena. Data are automatically gathered and transmitted to a computer operating the Fusion 3.4 software system for data collection and analyses. The interfaced software measures two dozen activity variables, including total distance and horizontal and vertical activity. Chambers are cleaned between subjects. The duration of locomotor activity testing is 120 min per session.

Elevated Plus Maze. The EPM is a widely used a measure of anxiety. Mice will be placed individually on the center platform facing a closed arm and allowed to explore the maze for 5 min. Behavior will be videotaped via closed circuit TV camera for scoring. Behaviors scored include: percent time spent in the open arms [(time spent in open arms/total time) X100], percentage of open arm entries [(open arm entries/total

arm entries) X100], and percentage of closed arm entries [(closed arm entries/total arm entries) X 100]. Percent time spent in the open arms and percentage of open arm entries are chosen to index anxiety.

Fear Conditioning. Animals will be habituated for 10 minutes in each context the day prior to conditioning. Approximately 15 animals will be used per condition (n=15, N=30, Power Analysis explanation under heading V.2). The intensity and duration of foot shocks was piloted previously in Dr. (b)(6) lab at the Uniformed Services University. This paradigm has been shown to reliably induce a lasting fear response in mice.

Day 1: Habituation 10 minutes in each context	Day 2: Conditioning Context A- 3 pairings of tone/shock (0.8mA)	Day 3: Contextual Fear Test Context A- 15 minute trial (freezing measured)	Day 4: Cued Fear Test Context B- 20 minute trial 10 30 second tones (freezing measured)

Contextual Fear Conditioning. Mice will be placed in a conditioning chamber (context A) for training for 2 minutes prior to onset of the conditioned stimulus (tone). The conditioned stimulus will last for 30 seconds prior to the onset of the unconditioned stimulus (foot shock, 0.8 mA) which will coincide with the last 2 seconds of the conditioned stimulus. The mice will then remain in the chamber for an additional 30 seconds prior to onset of the next trial. Three training trials will be performed. Mice will then be tested 24 hours later for freezing behavior (lack of movement for at least 5 seconds) in a 15 minute trial in the conditioning chamber (context A) [15].

Cued Fear Conditioning. Following conditioning and 24 hours after the contextual fear testing mice will be placed in a novel context (context B) and presented with the cue (tone) from the conditioning phase. Ten presentations of the tone will be presented at random intervals following a 3 minute habituation period. Freezing behavior will be assessed in this 20 minute test phase as well.

V.1.2. Experiment 2:

In experiment 2 we will perform RNA sequencing analysis of hippocampal tissue from knockout animals and wild type littermates before and after conditioning experiments from experiment 1. This will lead to the comparison of transcriptomes from four different groups: knockout before conditioning, knockout after conditioning, wild type before conditioning and wild type after conditioning.

Experimental Timeline. cDNA libraries will be prepared from hippocampal tissue of each animal from experiment 1 (approximately 4 months). Separately a group of 30 animals (15 KO and 15 WT) that have not undergone behavioral experiments will also be selected for RNA sequencing. This will lead to 60 total animals, 30 from the behavioral experiments (all of which will also undergo RNA sequencing of hippocampal tissue) and an additional 30 animals that have not been fear conditioned for sequencing experiments.

RNA Sequencing. Hippocampi of mice will be isolated 24 hours following either training or the test phase of fear conditioning. Briefly, mice will be anesthetized, decapitated and their hippocampi will be isolated by micro dissection. Brains will be placed in Qiazol (Qiagen) and homogenized prior to RNA isolation using the RNAeasy Mini kit. cDNA will be generated from RNA samples using reverse transcriptase PCR. cDNA libraries for sequencing will be prepared using the Illumina library preparation kit

and clustered to a flow cell for sequencing on the cBot system. Following clustering paired end reads will be obtained on the Illumina deep sequencing platform.

V.2. Data Analysis:

Open Field. Total distance, horizontal and vertical activity and percent time spent in center will be compared between the 2 groups.

EPM. Behaviors to be compared between the 2 groups include: percent time spent in the open arms [(time spent in open arms/total time) X100], percentage of open arm entries [(open arm entries/total arm entries) X100], and percentage of closed arm entries [(closed arm entries/total arm entries) X 100].

Fear Conditioning Analysis. The freezing behavior in the 2 conditions will be compared with a t-test comparing total time freezing.

RNA Sequencing Analysis. Base calls will be made using CASAVA. All subsequent analyses will be performed using tools in Galaxy (Tophat2 and Cufflinks). Differential gene expression analysis and visualization will be performed using GenePattern. Differential analysis will be performed comparing both the effects of conditioning on gene expression (conditioned animals versus naïve) as well as the comparison of Tnik -/- and WT littermates both before and after fear conditioning.

Group Size Calculation. Group numbers were calculated using G Power software (α=0.05, β=0.95) [16]. Several different effect sizes were derived from the literature for calculations (d=1.2-1.5) [17-19]. These effects seizes were drawn from literature performing contextual fear conditioning in animals with genetic knockouts shown to have effects on hippocampal function. This range of effect sizes gave us a range of 11-16 animals required to give sufficient power for our fear conditioning experiments. If significance in our results is achieved before all animals are utilized remaining animals will not be required for our experiments.

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered:

These experiments are part of a larger project in which cell culture experiments will be utilized whenever possible to reduce the number of animals used. For the behavioral experiments animals must be utilized as there are no alternatives. The RNA sequencing experiments are being proposed to make further use of the animals that have already been used for the behavioral experiments.

V.3.2. Animal Model and Species Justification:

This is the only commercially available animal with a genetic deletion of Tnik. This is why we have selected this animal to determine the role that Tnik plays in the formation of different types of fear memory.

V.3.3. Laboratory Animals

	Species #1	Species #2
V.3.3.1. Genus & Species:	*Mus Musculus*	

V.3.3.2. Strain/Stock: B6NTac;B6N-A^{tm1Brd} Tnik$^{tm3a(EUCOMM)Wtsi}$/WtsiBiat

V.3.3.3. Source/Vendor: Colony to be maintained at USU

V.3.3.4. Age: 8-10 weeks

V.3.3.5. Weight: 25-40 g

V.3.3.6. Sex: Male

V.3.3.7. Special Considerations: N/A

V.3.4. Number of Animals Required (by Species):
We will utilize 60 male mice total for experiments #1 and #2.

V.3.5. Refinement, Reduction, Replacement (3 Rs):

V.3.5.1. Refinement:
Fear conditioning is well established in mice and we anticipate that behavioral differences will be easiest to attain in this model. Also the only available genetic knockout is a mouse so this model is the only animal available for our experiments. Measures cannot be taken to relieve the temporary distress of animals during fear conditioning because this will interfere with the behavioral paradigm we have selected. The foot shock and associated minor and temporary pain associated with it are required for the induction of fear memory.

V.3.5.2. Reduction:
The number of animals we anticipate using in these experiments is derived from literature on fear conditioning in mice. We will also be using overlapping animals for both contextual and cued fear conditioning as well as sequencing to reduce the number of animals used.

V.3.5.3. Replacement:
All the parts of this project in which cell line work could replace or pilot test animal work we have already done so. The remaining portion proposed here cannot be done without an animal model. This mouse model is the only genetic knockout for Tnik available.

V.4. Technical Methods: Experiment #1 –
Open Field. Open field locomotor activity will be measured using an Accuscan Electronics Digiscan infrared photocell system. Animals are placed singly in a 20 x 20 x 30 cm clear Plexiglas arena and a Plexiglas lid with multiple ventilation holes placed on

top of the arena. Data are automatically gathered and transmitted to a computer operating the Fusion 3.4 software system for data collection and analyses. The interfaced software measures two dozen activity variables, including total distance and horizontal and vertical activity. Chambers are cleaned between subjects. The duration of locomotor activity testing is 120 min per session.

Elevated Plus Maze. The EPM is a widely used a measure of anxiety. Mice will be placed individually on the center platform facing a closed arm and allowed to explore the maze for 5 min. Behavior will be videotaped via closed circuit TV camera for scoring. Behaviors scored include: percent time spent in the open arms [(time spent in open arms/total time) X100], percentage of open arm entries [(open arm entries/total arm entries) X100], and percentage of closed arm entries [(closed arm entries/total arm entries) X 100]. Percent time spent in the open arms and percentage of open arm entries are chosen to index anxiety.

Contextual Fear Conditioning. Mice will be placed in a conditioning chamber (context A) for training for 2 minutes prior to onset of the conditioned stimulus (tone). The conditioned stimulus will last for 30 seconds prior to the onset of the unconditioned stimulus (foot shock, 0.8 mA) which will coincide with the last 2 seconds of the conditioned stimulus. The mice will then remain in the chamber for an additional 30 seconds prior to onset of the next trial. Three training trials will be performed. Mice will then be tested 24 hours later for freezing behavior (lack of movement for at least 5 seconds) in a 15 minute trial in the conditioning chamber (context A) [15].

Cued Fear Conditioning. Following conditioning and 24 hours after the contextual fear testing mice will be placed in a novel context (context B) and presented with the cue (tone) from the conditioning phase. Following a 3 minute habituation period animals will be presented the tone 10 times at random intervals. Freezing behavior will be assessed in this 20 minute test phase as well.

Experiment #2 – Subjects will be given ketamine and xylazine as the sedative and anesthetic. Animals will be injected (i.p.) with 80 mg/kg of Ketamine and 10 mg/kg Xylazine using a 26-gauge needle. Once an adequate depth of anesthesia has been confirmed by lack of response to toe pinch, the mice will be decapitated. The brain will be removed from the cranium and freshly frozen under dry ice before sectioning and micropunching hippocampal tissue for isolating total RNA using Trizol and Qiagen columns.

V.4.1. Pain / Distress Assessment:

V.4.1.1. APHIS Form 7023 Information:

V.4.1.1.1. Number of Animals:

	Species #1	Species #2
V.4.1.1.1.1. Column C:	30	
V.4.1.1.1.2. Column D:		
V.4.1.1.1.3. Column E:	30	

V.4.1.2. Pain Relief / Prevention:
No measures can be taken to alleviate pain because the painful stimulus is required for the induction of fear memory.

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization:
Prior to brain removal and hippocampal dissection, ketamine and xylazine will be used as the sedative and anesthetic. Animals will be injected (i.p.) with 80 mg/kg of Ketamine and 10 mg/kg Xylazine using a 26-gauge needle. The total volume of injected anesthetic depends on the weight of the animal. For example, a 25 gram mouse will receive a single i.p. injection of 20 μl ketamine (from a 100 mg/ml stock) plus 250 μl xylazine (from a 1 mg/ml stock).

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions: N/A

V.4.1.2.3. Paralytics:
N/A

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures:

V.4.1.3.1. Sources Searched:
PubMed

V.4.1.3.2. Date of Search:

V.4.1.3.3. Period of Search:
1950-Present

V.4.1.3.4. Key Words of Search:
Fear conditioning
Foot shock
Predator Odor
Air Puff

V.4.1.3.5. Results of Search:
While there are alternatives to foot shocking as the unconditioned stimulus for fear conditioning including air puffs and predator odor these also lead to similar stress on the animal as foot shocks. In addition fear conditioning utilizing foot shocks is the most established and commonly used form of conditioning used to date. No measures can be taken to alleviate pain because the painful stimulus is required for the induction of fear memory.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification:
Fear conditioning is commonly used as a model of fear memory. The foot shocks do not cause any physical damage to the animals and the pain is necessary for inducing a fear memory.

Ketamine (80mg/kg) and xylazine (10mg/kg) will be injected IP using a 26-gauge needle. The total volume of injected anesthetic depends on the weight of the animal. For example, a 25 gram mouse will receive a single i.p. injection of 20 μl ketamine (from a 100 mg/ml stock) plus 250 μl xylazine (from a 1 mg/ml stock).

V.4.4.2. Biosamples:
Total RNA from hippocampal brain regions. Hippocampi of mice will be isolated 24 hours following either training or the test phase of fear conditioning. Briefly, mice will be anesthetized, decapitated and their hippocampi will be isolated by micro dissection. Brain tissue will be placed in Qiazol (Qiagen) and homogenized prior to RNA isolation using the RNAeasy Mini kit.

V.4.4.3. Adjuvants:
N/A

V.4.4.4. Monoclonal Antibody (MAbs) Production:

N/A

V.4.4.5. Animal Identification:
Animals will be identified with cage cards throughout this study.

V.4.4.6. Behavioral Studies: See section V.1.1.

V.4.4.7. Other Procedures: N/A

V.4.4.8. Tissue Sharing:
No tissue sharing will take place on this project.

V.4.5. Study Endpoint:
All animals will be euthanized and tissue will be isolated following completion of the behavioral portion of the experiments. If animals display any signs such as dramatic weight loss (>20% compared to cagemates), lethargy, squinting, ruffled fur they will be removed from the study immediately and euthanized by CO2 inhalation in the LAM.

V.4.6. Euthanasia:
Subjects will be given ketamine and xylazine as the sedative and anesthetic. Animals will be injected (i.p.) with 80 mg/kg of Ketamine and 10 mg/kg Xylazine using a 26-gauge needle. Once an adequate depth of anesthesia has been confirmed by lack of response to toe pinch, the mice will be decapitated.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol.

V.5.1.1. Study Room:
Building(s) _____ Room Number(s) (b)(6)

V.5.1.2. Special Husbandry Provisions:

Food Restriction: Yes _____ No X

Fluid Restriction: Yes _____ No X

V.5.1.3. Exceptions:
N/A

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care:
LAM personnel will provide routine checks for health and general husbandry at least once/day. A LAM veterinarian will evaluate any animals exhibiting signs of illness (such as ruffled coat, hunched, squinting, loss of >20% weight loss...etc). Animals will typically be monitored for changes in body weight, behavior, appetite, excretion, hair

coat, etc. After consulting with the PI (if available), moribund animals will be euthanized as described. Animals will also be checked on by the PI or a member of the lab on a daily basis and any issues concerning animal health will be brought to the veterinarians' attention.

V.5.2.2. Emergency Veterinary Medical Care: All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: Except as indicated below, all animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents.

V.5.3.2. Enrichment Restrictions:
N/A

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
Open Field Testing Elevated Plus Maze Fear conditioning	(b)(6)	graduate student (4 years)	USU Investigator Training Course 2011
		PI, 12 years experience	Training from Dr. (b)(6) lab, 2000; USU Investigator Training Course 2012
		17 years of experience in animal research Conducted animal research at University of Alberta, Canada, and UTSW Medical Center at	Attended all the training classes required by USU in order to be approved to conduct animal research on Oct 19, 2010.

		Dallas, TX.	
Euthanasia/Hippocampal Dissection	(b)(6)	graduate student (4 years)	USU Investigator Training Course 2011
		PI, 12 years experience	Training from Dr. (b)(6) lab, 2000; USU Investigator Training Course 2012

VII. BIOHAZARDS/SAFETY:

All personnel handling animals will use protective gloves, lab coat, and masks at all times to minimize exposure to allergens and agents used during experimental procedures.

VIII. ENCLOSURES:

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordinations regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

(b)(6) _____ 4/30/14

P _____ Date

G. Training: The following personnel will attend the next USUHS Investigator/Animal User Training Course:

(b)(6) _____ _____

_____ _____

H. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely, "Responsibility" for implementing animal use alternatives where feasible and conducting humane and lawful research.

(b)(6) [redacted] 4/30/14

I. Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL or WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

(b)(6) [redacted] 4/30/14

Pr Date

X. PROTOCOL ABSTRACT:

Abstract. Post traumatic stress disorder (PTSD) is a major health concern with high economic and quality of life concerns for both military and civilian populations. Intrusive fearful thoughts and memories are one of the hallmarks of PTSD. Accordingly, animal models of fear memory are used to investigate this aspect of PTSD in a controlled setting. In a recent high throughput transcript sequencing study of the hippocampus of an animal model displaying high and low fear several genes were identified which are differentially expressed. Of these genes one candidate, Traf2 and NcK interacting kinase (Tnik) has been discovered with regionally specific expression in the hippocampus and known functions related to synaptic plasticity and neuronal morphology. We propose a series of experiments investigating how this gene affects fear memory formation. We propose experiments in a mutant mouse lacking Tnik expression where performance on fear memory tasks will be assessed. We will also examine the transcriptomes of Tnik -/- and WT animals to determine what genes are altered by Tnik activity. The proposed experiments will lead to a greater understanding of the underlying cellular mechanisms affecting fear memory formation which will further our understanding of inter individual differences determining risk of developing PTSD.

E. Funding:

USUHS

F. Objective and Approach:

Post traumatic stress disorder (PTSD) is a major public health concern in both military and civilian populations with as many as 8.6% of military personnel returning from Iraq and Afghanistan with symptoms of PTSD [1]. To improve current treatments and develop new ones it is important to determine what leads to individual differences between humans that lead to either enhanced risk or resilience in developing PTSD. To study the genetics of fear, an animal model was developed in which mice were selectively bred over several generations to show high or low levels of fear. Looking for different levels of activity in the brains of these rodents one brain region in particular was found to be more active in the animals more prone to fear. This brain region was the hippocampus which has long been recognized to be important in learning and memory. We identified a gene that is highly expressed in the hippocampus of these fear susceptible animals which is caused Traf2 and Nck Interacting Kinase (Tnik). This gene has been shown in a different animal model to be important to memory as well.

We propose to study several aspects of this gene to determine how it influences fear memory. We propose to determine how Tnik affects the genetic composition of brain cells and how Tnik affects fear memory formation in mice. We will do this by assessing performance on fear conditioning tasks in a mutant line of mice that does not express Tnik. We will compare the level of fear shown by these mutant animals to normal controls. We will also perform RNA sequencing to determine how the absence of Tnik signaling affects the expression of other genes in neurons.

October 16, 2014

MEMORANDUM FOR DR. (b)(6) DEPARTMENT OF ANATOMY, PHYSIOLOGY, AND GENETICS

SUBJECT: IACUC Approval of Protocol – Initial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on October 16, 2014:

Animal Protocol Title: "Evaluation of the Effects of Multiple Blast- or Concussive-Brain Injuries on Neuropathological and Behavioral Outcomes in Male and Female Mice (Mus musculus)"

USUHS Protocol Number: (b)(6)

Expiration Date: October 15, 2017

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. NON-TECHNICAL SYNOPSIS:

The goal of this research is to evaluate and compare the brain and behavioral effects of traumatic brain injury (**TBI**) in male and female mice. TBI will be produced using one of two models related to TBI from explosions (no explosions are actually used), or using one of two related to concussions caused by a head injury. Each mouse will be exposed to one of these injury methods one, three or five times. Performance on behavioral tests will be evaluated after TBI, as will brain changes using magnetic resonance imaging (**MRI**), microscope "histology" and molecular biology methods to evaluate pathological changes. This work is critical for standardizing multiple TBI and behavioral procedures used within the Center for Neuroscience and Regenerative Medicine (**CNRM**) Pre-Clinical Studies Core; shared facilities that are used by many scientists to study the effects of TBI. The data collected from this research will be made available to CNRM researchers as a guide to assist them in their choices of which TBI model they will use in their experiments, and which behavioral tests will be appropriate for their experiments. In addition, Core personnel will be better trained in all of the procedures that researchers use within the facilities, and will be better prepared to help investigators perform TBI procedures and behavioral tests. This is an important step for establishing the surgical and behavioral testing procedures that all investigators should follow in their experiments and for establishing standardized procedures so that data collected by different research laboratories can be compared.

II. BACKGROUND:

II.1. Background:

Traumatic brain injury (**TBI**) is defined as the loss of brain function as the result of a penetrating head injury or a blow to the head. Each year over one million people in the United States sustain a TBI [1] and TBI accounts for a significant proportion of casualties in modern day war, with an estimated 15-20% of soldiers sustaining a brain injury during their deployment [2].

Within the field of neurotrauma, there are currently numerous animal models described for inducing brain injury [3-5]. The focus of this protocol is on the effects of single and multiple concussive (closed-head) and blast-like brain injuries. The CNRM Pre-Clinical Studies Core currently has two concussive injury models available to investigators for their experiments: **CBI** (closed-brain injury) and **WDI** (weight-drop injury). CBI [6, 7] is a procedure in which a metal

rod mechanically strikes the surface of the skull and results in damage to the underlying cortex. The severity of the injury is controlled by the depth of the penetration and the velocity with which the impactor strikes the surface. CHI induced by a weight-drop device [8] is a simple and fast procedure in which the skull is left intact and a free-falling weight produces a blunt focal injury. The height from which the weight is dropped and the mass of the weight determine the severity of the resulting brain injury.

In addition to the concussive brain injury models described above, we will also collect data on the effects of single or repeated exposure to the two blast-related injury models available in the core facilities: **HIFU** (high-intensity focused ultrasound) and ABS (advanced blast simulator). HIFU [9] is a model of TBI that was developed in collaboration between USUHS and the FDA, and is a non-surgical procedure that aims to simulate a blast-induced TBI; HIFU employs a high-pressure wave that passes through the scalp, skull, and brain to induce a more diffuse and global brain injury than those resulting from contusive or concussive (CBI and WDI) injuries. Additionally, the Core has a recently-installed Advanced Blast Simulator (**ABS**) for which procedures need to be formalized and anatomical and behavioral effects defined. The ABS produces an atmospheric overpressure shock similar to the shock wave generated by blasts of explosives in combat situations.

The ultimate goal of this research is to formalize the procedures and compare the anatomical and behavioral effects of the four described methods of inducing TBI (CBI, WDI, HIFU, ABS) in C57Bl/6J adult male and female mice. These injury methods are available to CNRM investigators using the Pre-Clinical Studies Core, and the data that result from the experiments described in this protocol will create a database of information about the anatomical effects of TBI and the performance of C57Bl/6J adult mice on a series of behavioral tests within the CNRM Pre-Clinical Studies Core. This will aid CNRM investigators in deciding which procedure for inducing TBI (and which behavioral tests) will be best in their experimental questions. In addition, this protocol will formalize the specific steps in handling the mice, injury procedures, and executing the subsequent behavioral tests. The Core employees, in turn, will gain experience that will allow them to instruct investigators in how to perform the Core protocols.

This protocol serves a second purpose. Although there are hundreds of published reports describing behavioral testing in mice after TBI, establishing an efficient Core facility requires CNRM investigators to be skilled in using the specific equipment in the Core. An established database of information about surgical procedures and performance on behavioral tests after TBI is also necessary. The "local" data set that will be derived from this protocol is critical since previous studies have shown that it is an important step in the attempt to derive comparable data across research groups [10, 11]. Furthermore, a "local" data base affords an opportunity for statistical power calculations, providing better estimation of sample size for investigators' research plans with mice.

Finally, the results of this protocol will be made available to the Core staff and to all investigators using the Core to affirm consistent use in the facility of equipment employed for modeling brain injury and subsequent behavioral testing. These data will be used as an initial confirmation that investigators are properly using the equipment and testing mice in a consistent manner that derives data that is comparable over time, across investigators, and within individual studies [12], as well as comparison of responses in male and female mice [13].

II.2. Literature Search for Duplication:

II.2.1. Literature Source(s) Searched: BRD

II.2.2. Date of Search: August 28, 2014

II.2.3. Period of Search: 1998-2009

II.2.4. Key Words and Search Strategy: All fields: Rodent + behavior ± blast ± concussion

II.2.5. Results of Search:

The BRD database includes thousands of records of previous research programs. The search derived a total of eight unique hits.

1. *Understanding the Impact of Repeated Blast Exposures on Brain Function*, supported by M6: Combat Casualty Care, performance site: Duke University, Durham, NC.
2. *Safety and Efficacy of Recombinant Factor VIIa in the Treatment of Traumatic Brain Injury in Rats*, supported by M6: Combat Casualty Care, performance site: Walter Reed Army Institute of Research. Silver Spring, MD.
3. *CIP#S-06-053 The Efficacy of Pharmacological Treatment of Blast Injury in a Rodent Model*, supported by M6: Combat Casualty Care, performance site: Naval Medical Center San Diego, CA.
4. *Zinc Supplementation and Neurologic Recovery Rate in Rats with Mild Traumatic Brain Injury (mTBI)*, supported by M5: Human Systems Technology, performance site: U.S. Army Research Institute of Environmental Medicine, Natick, MA.
5. *Blockage of Nociceptin Signaling Reduces Biochemical, Structural, and cognitive Deficits after Traumatic Brain Injury*, supported by M6: Combat Casualty Care, performance site: University of Oklahoma, College of Pharmacy
6. *Treatment of TBI with hormonal and Pharmacological Support, Preclinical Validation using Diffuse and Mechanical TBI Animal Models*, supported by M6: Combat Casualty Care, performance site: University of Alabama at Birmingham
7. (b)(6)
8. [redacted]

Please note grants 7 and 8 were held by the P.I., supported by approved IACUC Protocols, and the work has been completed.

Conclusion: No related hits indicated there is no overlap with previous research programs in the DoD None of these programs pertained to validating the newly-designed ABS system for use in TBI research.

II.2.6. Literature Source(s) Searched: NIH RePORTER

II.2.7. Date of Search: July 17, 2014

II.2.8. Period of Search: active projects through fiscal year 2014

II.2.9. Key Words and Search Strategy: Rodent, behavior, blast, concussion

II.2.10. Results of Search:

CRISP is no longer an active search engine/web site. The suggested substitution is NIH RePORTER, and this site was used. The keywords rodent, behavior, blast and concussion produced one hit (Projects NIH 1I01RX000380-01 and 5I01RX000380-02, *Blast and blunt mechanisms for mild-TBI induce differing outcomes*). This hit was for a project studying the

behavioral consequences of a single rotational injury or blast in rats. However, the project employed rats and was not as comprehensive as the studies outlined here. **Conclusion**: No related hits indicated there is no overlap with previous research federally sponsored research programs.

II.2.11. Literature Source(s) Searched: PubMed
I.2.7. Date of Search: August 22, 2014
II.2.12. Period of Search: >22 million references; 1949-2014.
II.2.13. Key Words and Search Strategy: ("behavior, animal"[mesh]) AND "rodentia"[mesh] AND "blast injuries"[majr] AND ("animals, laboratory"[mesh] OR "models, animal"[mesh])
II.2.14. Results of Search:
PubMed was used with the keywords listed, and two hits were obtained. One of the hits described chronic traumatic encephalopathy after blast injury in veterans and also in a mouse model of blast-induced TBI [14] , and the other used behavioral and imaging assays to assess blast-induced hearing loss in rats [15]. The P.I. is aware of the broader literature describing pre-clinical animal models, testing procedures, testing sequence, and reducing overall distress (e.g., [16-20]) and has an extensive EndNote bibliography (obtained from searches over the years) of relevant publications. Conclusion: Neither of these experiments used the injury methods or conducted the extensive behavioral analyses and brain imaging that we describe in this protocol.

III. OBJECTIVE\HYPOTHESIS:

The objective of this project is to provide empirical data about the neuropathological and behavioral consequences of different procedures of inducing multiple blast- or concussive-brain injuries in adult male and female C57Bl/6J strain mice. This project also allows investigators working in the Core to formalize the precise injury methods and behavioral testing procedures that will be employed and provide an opportunity for investigators to develop the skills for undertaking the procedures. It is *hypothesized* that different methods of inducing TBI in mice will result in different patterns of behavioral and neuropathological changes. Furthermore, single injuries may incur little to no functional or neuropathological consequences with more severe changes seen only after multiple exposures to a concussive or blast injury.

We also expect that the establishment of formal procedures and the acquisition of skills in the consistent application of procedures will enhance the reliability and validity of data generated by investigators who use the Core facility in their research. In the short term no set criteria will be established to directly evaluate this hypothesis in terms of predicted quantitative outcome. However, the P.I. and staff already have extensive experience in rodent TBI models and behavioral testing, and will use the data to formalize detailed experimental protocols.

IV. MILITARY RELEVANCE:

The military relevance of this protocol complies with the major stated objective of the CNRM and the establishment of a CNRM rodent core facility at the University: "to address the current needs of the medical community to better diagnose and intervene for the prevention of the long term consequences resulting from traumatic brain injury, particularly in the context experienced by service members in Operation Iraqi Freedom (**OIF**) and Operation Enduring Freedom (**OEF**)." Due to the use of improvised explosive devices, the nature of injuries resulting from the wars in Afghanistan and Iraq differ from previous wars with the signature injury being blast injury; it is estimated that about 75% of the casualties from recent conflicts in the Middle

East result from explosions [21], and nearly 10,000 soldiers have been wounded in action from IEDs [22, 23]. According to a respected RAND Corporation report [24], as many as 18.5% of the service members returning from these conflicts meet the criteria for a diagnosis of either post-traumatic stress disorder (**PTSD**) or depression, and 19.5% of service members have reported experiencing a probable TBI during deployment. These estimates translate to approximately 320,000 cases of "probable TBI" and 300,000 cases of reported symptoms for depression or PTSD. Most cases of TBI in OIF and OEF arise from blast injury associated with the detonation of explosive devices in the form of non-contact closed head injury with concussive (impact) and primary blast wave exposure. Although there is no doubt, based on anecdotal clinical observation, that blast can induce cognitive deficits and TBI in military personnel, the exact mechanisms by which blast results in injury to the central nervous system are unknown. Furthermore, the actual components of the blast wave, direct or indirect, that result in brain injury are also unclear. Scientific research related to developing a better understanding of the biological processes and treatment for blast-induced TBI and/or psychological trauma is necessary for the care of our service members. The laboratory mouse, using these injury models, is expected to advance our knowledge of biological mechanisms of brain injury and psychological maladies and may lead to more effective treatment.

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures:

General Approach: The CNRM Pre-Clinical Studies Core presently has two concussive-related TBI models available for investigators to use in experiments with mice: closed-brain injury (**CBI;** performed by having a piston strike the exposed skull at a pre-determined location, velocity and depth [6, 7]) and weight-drop injury (**WDI;** a free-falling weight hits the exposed skull [8]). Two blast-related injury models are also available: high-intensity focused ultrasound (**HIFU**; similar to a primary blast injury where a high-pressure wave passes through the brain causing tensile distortion of brain structures, without an acceleration injury [9]) and advanced blast simulator (**ABS**; exposure to an atmospheric overpressure shock similar to the shock wave generated by blasts of explosives in combat situations (in development). TBI will be induced in male and female mice using one of those four methods. Each mouse will receive one, three or five injuries (multiple injuries will be separated by 24 hours), and compared to mice that receive one, three or five sham procedures. Following TBI, mice will either be evaluated on an extensive range of behavioral tests, sacrificed within one week to assess short-term histopathological changes or changes in brain anatomy will be assessed with magnetic resonance imaging (**MRI**). The plan for this protocol is to employ separate groups of mice in four behavioral testing modules, labeled "Experiments 1a-1d" (see below). In addition, separate groups of mice will be imaged with MRI at three different time points after the final induction of TBI ("Experiment 2") or sacrificed within one week of final TBI for assessment of short-term neuropathology following injury ("Experiment 3").

Overall experimental design. The basic design is to compare four injury models with three numbers of exposures, appropriate sham-operated animals, and two genders of mice. Including male and female mice and the appropriate sham control groups, the final number of experimental groups is 42. Statistical analyses of these groups will be limited to meaningful comparisons, e.g., comparing male and female behavioral performance after 1, 3 or 5 exposure to HIFU or sham procedures, or, comparing the effects of number of concussive-like brain injuries (CBI or WDI)

on behavioral and immunohistochemical measures. Full-scale studies will be performed to assess the brain anatomy at multiple time points, and to collect statistical data on the performance of mice on at least 10 behavioral tests after single or multiple TBI induced by blast-related methods: ABS or HIFU, or concussive-type procedures: CBI or WDI. We are aware that this is a very ambitious protocol that will likely not be completed in three years; we anticipate that this protocol will be re-submitted in three years to continue the studies.

Separate groups of mice will be evaluated in one of the four groups of behavioral experiments (Experiments 1a-1d). The rationale for not testing an individual mouse on all the behavioral tests is that repeated testing of mice alters response patterns due to general stress, fatigue, "testing experience," and learning [25, 26]. Many of the tests employed in this protocol have the potential to cause stress to the animals (e.g., fear conditioning and Porsolt forced-swim test) and the experiments have been designed to limit the number of potentially stressful tests to which each animal is exposed to one. This minimizes animal distress and also results in data for which stress is not a potential confounding variable.

Additionally, the testing schemes have been designed to try to avoid exposing mice to more than one behavioral testing "domain." For example, the Morris water maze, Barnes maze, and passive avoidance tests all assess memory and cognitive performance. An attempt is made to avoid using the same animals on tests that assess similar neurological functions, as prior experience on one test within a particular "domain" may affect later performance on tests that assess similar functions. Nevertheless, many of the tests outlined below assess overlapping psychological dimensions or challenge several neurological systems at once. Separate behavioral measurements obtained during a single behavioral test can assess distinct neurological systems [10] and, when possible, multiple measures are recorded so that these separate neurological systems are evaluated. For example, the open field test is one of the most common behavioral tests. A mouse is placed in a closed arena and a software program records a number of measures during the test. Measures of *activity* and *motor function* include distance traveled, changes in activity at half the total duration of testing time, and turning rate (all parameters captured by the software), while grooming, freezing, fecal boli, and thigmotaxis (remaining near area walls and not exploring the center of the arena) reflect *anxiety* (www.jax.org/phenome, Open Field Test).

Sequence of behavioral testing. Logistical constraints in testing procedures, animal distress and fatigue (both physical and psychological) require that each animal is employed on no more than three behavioral tests. Experiment 1a is an exception to this guideline since the majority of the tests are very brief, non-stressful, occur over a period of about four weeks, and have been proven in our prior work to be very robust in detecting the effects of more severe contusive brain injuries such as controlled cortical impact (CCI). In addition, when a sub-study of Experiment 1 (described below) involves more than one test, the more distressful or aversive task is scheduled last, in an attempt to reduce confounding of test results from previous distress.

Strain choice. The strain choice for this protocol is the C57Bl/6J strain. The C57Bl/6J mouse was selected since this strain generally performs "average" on many behavioral tests [27]. The data derived from the use of this strain is also perhaps most useful to CNRM investigators. The C57Bl/6J mouse is an inbred strain, providing a very high degree of genetic homogeneity [28] and it is one of the traditional strains used for studies that will eventually employ this strain as the "control" or "wild type" condition for a related mouse strain that harbors a transgene or gene "knockout" [29, 30]. Due to the recent mandate by the NIH that both male and female mice be

included in pre-clinical animal studies [13], both male and female C57BL/6J mice will employed in these experiments.

V.1.1. Experiment 1: *Neurobehavioral assessment of male and female mice after single or repeated traumatic brain injury.*

Experiment 1 will employ sub-groups of behavioral tests (Experiments 1a-1d) to assess functional deficits after TBI. **Table 1** lists the number of animals needed for the entirety of Experiment 1. (Each sub-study of Experiment 1 will employ 1,008 mice, for a grand total of 4,032 mice in Experiment 1.) Fewer animals will be needed for the evaluation of neuropathological and anatomical changes at multiple time points after TBI using immunohistochemistry and magnetic resonance imaging; the number of animals needed for these studies (Experiments 2 and 3) are listed in Tables 2 and 3, respectively. Note that the procedures used for sham controls for WDI and CBI injuries are identical; only one sham control group is needed for both injury types.

Table 1. Experiments 1a-1d: Short-term neuropathology following single or multiple TBI

TBI procedure	Male C57BL/6J			Female C57BL/6J		
	1X	3X	5X	1X	3X	5X
CBI	96	96	96	96	96	96
WDI	96	96	96	96	96	96
CBI/WDI Sham	96	96	96	96	96	96
HIFU	96	96	96	96	96	96
HIFU Sham	96	96	96	96	96	96
ABS	96	96	96	96	96	96
ABS Sham	96	96	96	96	96	96

Table 1 includes mice for all behavioral studies, Experiments 1-4. Twenty-four mice per group will be included in each of the Experiments, resulting in a total of 96 animals in each group or 4,032 animals for all behavioral studies.

Experiment 1a: *Assessment of the effects of blast and concussive-brain injuries on exploration, motor skills, anxiety, learning and memory and behavioral flexibility.*

Post-TBI behavioral performance will be evaluated in mice on several well-known and widely-used behavioral tests in TBI research. Testing will begin the day after the final injury, and will continue for approximately four weeks.

A total of 1,008 mice (**Table 1**) are requested to measure exploration in an open field environment (Stoelting Open Field Arena with Any-maze Behavioral Tracking Software [31-33]), motor skills on an Ugo Basile Rota-Rod [34], anxiety in an elevated zero maze [35, 36], episodic memory in a Y-Maze [37], and for spatial learning and memory and subsequent behavioral flexibility in standard Morris water maze protocol [32, 38, 39] and reversal tasks [40]. Details of behavioral procedures are found in V.4.4.6. Behavioral Studies.

For pain/distress (Section V.4.1.1. APHIS Form 7023 Information), all mice for Experiment 1a are in Category D.

Experiment 1b: *The effects of repeated concussive or blast TBI on home cage circadian rhythms and on performance in an active place avoidance task.*
Experiment 1b assesses the performance of 1,008 mice (**Table 1**) in specialized home cages (Any-Cages, Stoelting) and on an active place avoidance test (BioSignal Group Interactive Tracking System Active Avoidance System, [41, 42]). Within 1-2 hours after regaining consciousness after the final TBI, mice will be placed in Any-Cages to assess levels of mobility, wheel running, eating and drinking among many other measures. The mice will be left in these cages for no more than four weeks. No sooner than 24 hours prior to removal from the Any-Cages, training on the active avoidance place system will begin (cf V.4.4.6. Behavioral Studies).

For pain/distress (Section V.4.1.1. APHIS Form 7023 Information), all mice for Experiment 1b are in Category D. Please note the description of the experimental procedure for active avoidance, under V.4.4.6. Behavioral Studies, the paragraphs under subheading 2b of Experiment 1b (page 20). Animals in the active avoidance study were categorized as Category D, since mice quickly learn to avoid the momentary exposure to the mild, escapable shock.

Experiment 1c: *Assessment of sociability and classical fear conditioning after repeated concussive or blast TBI.*
In Experiment 1c, (cf. Behavioral Studies, Section V.4.4.6) we will assess behavioral responses to the presence of two unfamiliar mice (the three-chambered sociability test [43, 44] 10 days after TBI. Two days later, mice will be tested for conditioned fear responses and extinction [45].

A total of 1,008 mice are requested (**Table 1**) for Experiment 3. (The "unfamiliar mice" of the sociability test described in Section V.4.4.6, Experiment 3, will be weight-matched sham-treated mice from other experiments described in this protocol. They are not enumerated in Table 1.)

For pain/distress (Section V.4.1.1. APHIS Form 7023 Information), all mice for Experiment 1c are in Category E as the fear conditioning procedures require the use of an unescapable shock.

Experiment 1d: *Performance on a Barnes maze spatial memory test, acoustic startle reflex (ASR) and the Porsolt forced-swim test.*
Details of behavioral testing in Experiment 1d are found in section V.4.4.6. Behavioral Studies). Ten days after the final TBI or sham procedure, spatial learning and memory will be assessed in the Barnes maze [46, 47]. The acoustic startle test [48], and the Porsolt forced-swim test [49] will be conducted, respectively, 20 days and 28 days after surgery. In Experiment 1d, a total of 1,008 mice are requested (**Table 1**).

Since the Porsolt forced-swim test is distressing (animals must tread water to stay afloat), all 1,008 mice that will be used are in Category E (Section V.4.1.1. APHIS Form 7023 Information).

V.1.2. Experiment 2: *Brain imaging after repeat blast- or concussive TBI.*
The goal of Experiment 2 is to assess changes in brain anatomy after TBI using magnetic resonance imaging (MRI). Mice will be anesthetized and imaged with the Bruker 7T MRI system in the Center for Neuroscience and Regenerative Medicine (CNRM) Translational Imaging Facility (TIF), Room G046. This procedure is described in greater detail in V.4.4.7.

Imaging will be performed once before surgical procedures and again at four time points after the final TBI: 24 hours, 72 hours, 30 days and six months. As both imaging and behavioral testing will take place at similar times post-injury, and imaging requires anesthesia, the same mice cannot be used in both Experiments 1 and 2. For this experiment, 210 mice are requested (**Table 2**).

Table 2. Magnetic resonance imaging after single or multiple TBI						
TBI procedure	**Male C57BL/6J**			**Female C57BL/6J**		
	1X	**3X**	**5X**	**1X**	**3X**	**5X**
CBI	5	5	5	5	5	5
WDI	5	5	5	5	5	5

ABS	5	5	5	5	5	5
ABS Sham	5	5	5	5	5	5

Table 2. Number of animals requested for imaging after TBI. (Experiment 2; Total n = 210)

For pain/distress (Section V.4.1.1. APHIS Form 7023 Information), all of the mice in this experiment are in Category D.

V.1.3. Experiment 3: *Neuropathological effects of single and repeat concussive- and blast-injuries.*

The goal of Experiment 3 is to thoroughly describe and quantify the anatomical and immunohistochemical changes that occur following single or repeated traumatic brain injury. *For longer-term neuropathology, brain tissue from mice in Experiment 1 will be used.* The purpose for the additional mice in this experiment is to assess *short-term neuropathological changes* following injury. The mice in this experiment (n = 420; **Table 3**) will be assigned to one of the injury groups, then sacrificed at either 24 or 48 hours, or one week, following injury. No behavioral testing or imaging will take place on these animals. Euthanasia and tissue collection will be performed as described in V.4.4.2. Biosamples. Brain tissue will be processed for the analysis of biomarkers including (but not limited to) MAP-2, APP, GFAP, Iba-1, iNOS, tau, and F4/80.

Table 3. Short-term neuropathology following single or multiple TBI						
TBI procedure	**Male C57BL/6J**			**Female C57BL/6J**		
	1X	**3X**	**5X**	**1X**	**3X**	**5X**
CBI	10	10	10	10	10	10
WDI	10	10	10	10	10	10

HIFU	10	10	10	10	10	10
HIFU Sham	10	10	10	10	10	10
ABS	10	10	10	10	10	10
ABS Sham	10	10	10	10	10	10

Table 3. Number of animals requested for short-term neuropathology after TBI. (Experiment 3; Total n = 420)

For pain/distress (Section V.4.1.1. APHIS Form 7023 Information), the 420 mice that undergo sham or TBI procedures are in Category D.

V.2. Data Analysis:

To estimate the number of animals needed for the behavioral experiments (Experiments 1a-1d), the scheme outlined by Wahlsten was used [50]. Wahlsten suggests that *effect size*, δ, between two experimental groups for mouse experiments can be generally classified as *small*, *moderate*, or *large*, with δ values of 0.5, 0.75, and 1, respectively, where $\delta = \frac{(\mu_1 - \mu_2)}{\sigma}$. For an estimation of the number of mice for the behavioral experiments described in this protocol, it is assumed that a 30% difference between the average behavioral scores for two groups could represent a moderate effect. The formula above was transformed to $\sigma = \frac{(\mu_1 - \mu_2)}{\delta}$ to compute an estimate of the expected standard deviation of the residuals (σ) when there is a 30% change in behavioral score (e.g., $\mu_1 = 100$, $\mu_2 = 130$) and an expected "moderate effect" ($\delta = 0.75$). This suggests $\sigma \approx 40$ as an estimate of the standard deviation of the residuals.

The SigmaStat computer program, *Determination of Computing Power and Sample Size* was then used to estimate the number of animals needed for these experiments. This program calculates the minimum number of data units (mice) per group that is needed to achieve a certain level of *power* (sensitivity) of a statistical test based upon certain probability estimates. To achieve a power ≈ 0.80, in this case using $\mu_1 = 100$, $\mu_2 = 130$, and $\sigma \approx 40$, about 28 mice/group would be required. Since this is an estimation, we propose that for the *full-scale* studies outlined in Experiments 1-8, 24 mice may be sufficient and more convenient for the progression of testing procedures in the Core. In this case, if the same assumptions hold ($\sigma \approx 40$ with n=24 animals, $\delta = 0.84$), there would be a possible 33% difference between groups compared to 30%.

From previous experiences a sample size of 24 mice/full-scale experiment appears more than ample for behavioral testing and for what is usually reported in publications of mouse behavior testing (number of subjects per group is usually in the mid-teens). However, this estimate is justifiable since the statistical data obtained from this work will be used by multiple groups as a "standard" of comparison, and the resulting data are vital in seeking to strive for comparability across data obtained by many research teams. In addition, larger sample sizes have been used by previous groups attempting to initially validate their testing procedures. Rogers and colleagues [51], for instance, used 37-89 mice/group to validate the "SHIRPA protocol" in one study, and two cohorts of 10 mice/group for further validation and statistical reporting [52]. Likewise, this estimate appears to be in line with suggestions by internationally recognized experts. For example, Dr. (b)(6) (p. 32) suggests that "*N* = 20 mice or more per genotype are often needed to complete the first set of behavioral tests in a new line of mutant mice" [53]. Finally, it is likely that some of the mice will be "uncooperative" [10]. Data from these animals may be eliminated from the statistical calculations—though the percentage of "non-responders" on specific tests will be recorded and reported—since extreme scores can alter summary descriptions of the response pattern. A larger sample size will allow us to better estimate the percentage of "non-responders" on each behavior measure, and maintain adequate sample sizes for statistical estimation should the percentage be high on some measures.

Experiments 1a – 1d will be run in two phases. After completion of testing of half the animals requested for each group (n=12), we will analyze the data, determine statistical power, and decide if more animals will need to be added to the groups. It is very unlikely that we will need to include 24 mice in each group as described in this protocol, but the "extra" mice included

in this protocol will give us the flexibility to further refine the TBI and the behavioral testing procedures in an attempt to help investigators in the Core over the next three years. Any change in procedure will be submitted as a request to the IACUC using the guidelines of the descriptions for "minor" and "major" modifications.

For the experiments that do not include a need for behavioral testing (Experiments 2 and 3), we believe we require fewer animals. We estimated that 10 mice/group may be sufficient for the short-term neuropathology studies (Experiment 3) and 5 mice/group adequate for imaging (Experiment 2). This estimation is based upon prior experience that we often obtain reliable data with this number of animals per treatment group.

Statistical Analyses: The SigmaStat 2.03 (SPSS) statistical analysis program will be used to compute the arithmetic mean and standard deviation of surgical groups on each test measurement. A 3-way analysis of variance (ANOVA) can be performed on the factors, Injury (4 levels for CBI, WDI, HIFU, ABS) x Injury Treatment (2 levels for TBI or Sham treatment) x Gender (2 levels), or 4-way mixed model ANOVA, with the same mentioned factors and a "repeated measures" factor when animals receive more than one experience with the same test on different days. *Post* hoc comparisons can then be used to further explore effects. However, experience from previous work indicates, particularly with behavioral data, that the data does not always meet the assumptions of normality and homogeneity of variance. In this case, simpler comparisons can be undertaken or data transformations can be performance (e.g., ln). Non-parametric comparisons may also be employed. Finally, for some comparisons between behavioral test results and histopathology, or mRNA or protein levels, changes to assess the degree of the relationship within an experiment can be determined by computing correlation coefficients.

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered:

Employing animals in this research is necessary to assess the effects of brain injury on brain anatomy and on *in vivo* behavioral performance. These data will provide a means for relating behavioral responses to central nervous system structure and function *in vivo*. Non-animal alternatives do not replicate the three dimensional structure or temporal changes that occur as a function of complex behavioral responses to tasks presented to a live animal. Further, computer modeling and *in vitro* methods will not address experimental questions of the complex, real-time changes and responses that occur during experience.

V.3.2. Animal Model and Species Justification:

By consensus of members of the CNRM, C57Bl/6 mice have been chosen as a suitable species and animal model for this research [54]. This is based upon the previous use of this strain in innumerable studies and their suitability as biomedical models for understanding central nervous system functions in normal and pathological states in humans and in other animals. The mouse is used for these studies because of their well-understood anatomy and endocrine responses, and the very extensive database of prior physiological research that can be integrated with this new information. It is necessary to use mice instead of a "lower species" since the research results should be directly associated with intense efforts in other laboratories throughout the world to try and further our understanding and eventual treatment effectiveness for psychological stress and brain injury. Mice are a commonly used small animal model for the study of neurobiological genetics research, including the impact of physical injury and environmental stress upon neuron

connectivity, experiential effects on synaptic plasticity, signal transduction, and for assessing treatments to reduce neurological damage and improve quality of life. In transgenic and gene knockout models in neuroscience and behavioral research, "wildtype" C57Bl/6J mice often serve as the genetic "background" or control for comparison of genetic and genetic/environmental effects [28, 30, 53]. As a result of the recent directive by the NIH to include female animals in pre-clinical research [13], this work proposes the use of both male and female mice.

V.3.3. Laboratory Animals

		Species #1	Species #2
V.3.3.1.	**Genus & Species:**	*Mus musculus*	
V.3.3.2.	**Strain/Stock:**	C57Bl/6J	
V.3.3.3.	**Source/Vendor:**	(b)(4)	
V.3.3.4.	**Age:**	8-12 weeks	
V.3.3.5.	**Weight:**	20-25 grams	
V.3.3.6.	**Sex:**	Males and Females	
V.3.3.7.	**Special Considerations:**	None	

V.3.4. Number of Animals Required (by Species): Mice: 4,662

V.3.5. Refinement, Reduction, Replacement (3 Rs):

V.3.5.1. Refinement:
Two refinements are included in our protocol. **1.** Mice will be acclimated to investigator handling before behavioral testing to relieve distress from the potential combination of handling distress, surgical procedures and behavioral testing, and **2.** Analgesics and anesthetics will be used to decrease possible pain and distress resulting from surgery.

V.3.5.2. Reduction:
Power calculations have been performed to determine the minimum number of animals needed to reach statistical significance. Data derived from this protocol will be available to other investigators, allowing them to make better estimates of the minimal number of animals required for their experiments. For the sociability test (V.4.4.6 Behavioral Studies, Experiment 1c), mice to be used for Experiments 2 and 3 will be the "unknown mice" placed in the small cylindrical cages. That is, mice from Experiments 2 and 3 will be used in the sociability test prior to injury procedures. We believe their use for the sociability test will not have an impact upon other measures described in this protocol.

Additionally, the same group of animals will be used appropriate sham controls for both CBI and WDI injuries, as the sham procedures for each injury are identical. This reduces the number of sham controls needed for the full experiments.

V.3.5.3. Replacement:
Biological response to central nervous system injury, psychological stress, and experimental treatments is highly complex; no alternative to *in vivo* experimentation is available or practical. We are using a rodent model (mouse) versus a nonhuman primate model. The mouse model is the least sentient and derived animal model we could use for this study and still obtain acceptable results. In addition, we are attempting to perform a series of measurements of mouse behavior that requires making assurances that there is sufficient number of animals to derive valid measures of statistical data.

V.4. Technical Methods:

V.4.1. Pain / Distress Assessment:

V.4.1.1. APHIS Form 7023 Information:

V.4.1.1.1. Number of Animals:

		Species #1	Species #2
V.4.1.1.1.1.	Column C:		
V.4.1.1.1.2.	Column D:	2,646	
V.4.1.1.1.3.	Column E:	2,016	

V.4.1.2. Pain Relief / Prevention:

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization:

CBI, WDI, HIFU and sham procedures: Mice undergoing CBI, WDI, HIFU or sham procedures for the above-listed injuries will be anesthetized with isoflurane + 100% oxygen (0.5-4% isoflurane, induction; 0.5-3% isoflurane, maintenance). Isoflurane will be delivered using a precision vaporizer via a rodent anesthesia machine. Induction will occur in an appropriately-sized clear viewing chamber. Following induction, rodents will be moved to the stereotaxic device and anesthesia will be maintained via a nose cone. Waste anesthetic gases will be passively scavenged using a charcoal filter. Lack of paw-pinch reflex will be used to ensure adequate depth of anesthesia prior to beginning the procedure. Close attention will be given to ensure the mice remain unconscious and are unresponsive to pain and, if needed, supplemental administration of anesthetic will be given.

ABS and sham procedures: Mice receiving ABS exposure or appropriate sham procedures will receive an intraperitoneal injection of sterile ketamine (80 mg/kg) and xylazine (10 mg/kg) in the ventral caudal abdomen with a 26-28 gauge needle. Isoflurane will be used as described above in

future studies if it becomes available in ABS facilities. Lack of paw-pinch reflex will be used to ensure adequate depth of anesthesia prior to beginning the procedure. Close attention will be given to ensure the mice remain unconscious and are unresponsive to pain and, if needed, supplemental administration of anesthetic will be given.

MRI: Prior to imaging, mice will be anesthetized with isoflurane + 100% oxygen (2-4% isoflurane) in a clear induction chamber [55]. During the imaging procedure, animals will be monitored constantly and anesthesia will be maintained with isoflurane (1-3%) via a flow-through nose cone. A facility vacuum will actively scavenge all waste anesthetic gases.

Analgesia: Animals are not expected to experience pain or discomfort from any TBI procedures, but if needed they will be provided with acetaminophen (Tylenol) in their drinking water (1 mg/ml; ~200 mg/kg b.w.) as a precaution. Animals will be observed again one hour after home cage placement to ensure there are no signs of discomfort (difficulty breathing, hunched posture, trembling, lack of reaction to gentle touching (lethargy), or seizure activity). If needed, the LAM veterinarian will be consulted should there be signs of continued discomfort or distress.

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions:
Mice will be returned to the animal facility after TBI or sham procedures, or imaging. They will be monitored in their cages (and during behavioral testing) on Days 1 and 2 for complications, such as lethargy, reluctance to ambulate, inability to obtain feed, and seizures. Complications are not expected. Mice that will be returned to the animal facility after ABS procedures will be monitored in their cages for evidence of peritonitis or other complications following intraperitoneal injection of ketamine and xylazine. It is expected that complications will not be encountered. Any mouse that experiences problems will be evaluated and treated or euthanized as determined by research staff, PI or veterinarian.

V.4.1.2.3. Paralytics: N.A.

V.4.1.3.20. Results of Search: A search for alternatives indicated no prior funded projects addressed this area of research

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification: We request that some animals (cf. V.4.1.1.1.3) be utilized for experiences considered Category E. Category E mice will be used in testing paradigms that inherently involve some inescapable discomfort/distress as a means of "motivating" the animal to respond. We wish to test the mice without treatment with sedatives or analgesics. With the exception of the fear conditioning test (Experiment 1D) that causes momentary discomfort, none of these behavioral tests involve pain or any physical injury; thus an analgesic is contraindicated. While some tests evoke mild distress, treatment with a sedative would significantly alter their level of "motivation" and change their responses to the task.

V.4.4. Animal Manipulations:

V.4.4.1. Injections:
Anesthetic injections will be administered as described in V.4.1.2.1. Anesthesia/Analgesia/ Tranquilization and analgesic as described in Section V.4.3.3. Post-surgical Provisions.

V.4.4.2. Biosamples:
Following behavioral testing and imaging, the mice will be euthanized and available for tissue sharing by investigators in the CNRM, or the live animals will be transferred to the Center for Laboratory Medicine (LAM). In cases where animals are euthanized by individuals on this protocol, the tissues will be used for validating and/or acquisition of training and data for a variety of assays. For example, for western blotting biosamples the brains will be removed from the calvarium to obtain samples of the cerebral cortex (fronto-occipital region and entorhinal region), hippocampus, diencephalon, and brain stem. Samples are stored in liquid nitrogen before preparation for western blotting.

Because of the value of these mice, at the time of euthanasia, animals that are planned for cardiac perfusion and receive a thoracotomy ((c.f., "Perfusion" under V.4.6. Euthanasia) plasma will be obtained from a cardiac puncture blood sample [56] to begin a plasma repository in coordination with the CNRM BioMarkers Group for possible future analyses (plasma stored at -80°C in potassium-EDTA tubes). There presently is no plan for these samples, by my laboratory will keep the samples for possible future use.

V.4.4.3. Adjuvants: N/A

V.4.4.4. Monoclonal Antibody (MAbs) Production: N/A

V.4.4.5. Animal Identification:
All animals will be identified with cage cards.

V.4.4.6. Behavioral Studies:

Reflex Suppression: Several laboratories using concussive brain injury models and shock tubes have developed procedures that permit the employment of isoflurane as anesthetic [57-62]. All animals in the behavioral experiments of the current study (Experiments 1-4) that are anesthetized with isoflurane will be evaluated for "reflex suppression" [63, 64]. Following sham, blast or concussive brain-injury exposure, the duration of the suppression of three reflexes is determined. *Corneal reflex* is evaluated by lightly touching the rodent's cornea and determining when a blink response appears. *Paw flexion* is evaluated by lightly pinching the hind paw until a withdrawal reflex is elicited. A *righting reflex* is determined by gently placing the rodent on its back and determining the time when the animal can right itself to the correct anatomical position.

Behavioral tests specific to Experiments 1a-1d are described in detail below:

1. **Experiment 1a:** Performance on a standard post-TBI battery of behavioral tests: Open field, rotarod, elevated zero maze, Y-Maze and Morris water maze (standard and reversal).

   The following set of behavioral tests was developed under protocol APG-10-789 as a standard assessment of the neurobehavioral effects of TBI on a range of behavioral domains. With the exception of the Morris water maze which will be performed last and just prior to

euthanasia, all tests are non-stressful and no more than two tests are performed on a given day.

a. **Open field testing**: Animals will be placed in an open field environment (40 cm x 40 cm) and allowed to move freely for up to one hour [31]. A camera over the apparatus is paired to Any-Maze video tracking software (Stoelting, Co, Wood Dale, IL) and the position of the animal is tracked for the duration of the test session. The software is able to provide a wealth of information regarding the behavior of the animal in the open field environment, including but not limited to the total distance traveled, movement speed, time spent immobile, and time/distance in user-defined physical zones of the open field arena. In addition, photobeam arrays allow measurement of movement in the z-plane (rearing). These measures allow conclusions regarding exploration, locomotion and anxiety-like states of the rodents. All mice will be tested on days 1, 7, 14, 30, and 60 following final TBI.

b. **Rotarod**: All animals will be evaluated for motor performance using the Ugo Basile rotarod apparatus [34, 65]. Briefly, the animal is placed upon the apparatus, which has a rotating rod. The rod is slowly accelerated from 4 rpm to 40 rpm over two minutes. The amount of time the animal remains on the rod is recorded as the motor performance score. Each animal undergoes three trials, and the average of those trials is calculated and used as the final score. All mice will be trained on this test for three days prior to the first TBI or sham procedures: the animal is first placed on the slowly-rotating (4 rpm) for one minute, after which the rod accelerates to 40 rpm as described above. The score from the third training day is used as a pre-TBI baseline measurement for the test(s) following TBI. After the final TBI, mice will be tested on the rotarod on post-injury days 1, 3, 7, 10, 14 and 30.

c. **Elevated zero maze** – The elevated zero maze will be used to evaluate anxiety-like behaviors following single or repeated TBI [35, 36]. It is a circular apparatus (diameter 50 cm) divided into four equal quadrants. Two of the quadrants (located on opposite sides of the maze) are enclosed by high walls; the other two quadrants are open with 1 cm walls). The test consists of a single trial. Mice are individually placed at the edge of one of the enclosed sections of the maze, facing the inside of the closed quadrant. Each mouse is allowed to explore the maze for five minutes before being returned to the home cage. The time spent in each quadrant is registered from video recordings by the Any-Maze tracking software, and the time spent in the enclosed quadrants is compared to the time spent in the open quadrants, with an increased amount of time in the enclosed quadrants indicating a higher level of anxiety. Typical baseline values are 15-25% time in open quadrants. Following single- or repeated-TBI, mice will be tested in this apparatus on post-injury days 5, 15 and 40.

d. **Y-Maze** – The Y-Maze is a test of visuo-spatial and working memory, and is effective in discriminating between sham-controls and mice with brain injury sustained by controlled cortical impact in the CNRM [37, 66]. The Y-Maze consists of three enclosed arms, 50 cm long, 11 cm wide, and 10 cm high, made of black Plexiglas, set at an angle of 120° to each other, in the shape of a Y. The floor of the maze is covered with the mouse's home cage wood shavings; mixed between trials to eliminate olfactory cues. Visual cues are placed around the maze in the testing room and kept constant throughout the testing sessions. The test

consists of two trials separated by four hours. Briefly, in the first trial (acquisition trial), mice are placed at the end of a pseudo-randomly chosen arm (start arm) and allowed to explore the maze for 5 min with one of the arms closed. Mice are returned to their home cages in a separate room during the inter-trial interval. In the second trial (retention trial), the mice are allowed to explore freely all three arms of the maze for 5 min. The time spent in each arm is registered from video recordings by an observer blind to the treatment condition of the mice. The time spent in the novel arm (previously closed in the first trial) will be calculated as a percentage of the total time in all three arms during the first 2 min of the retention trial. This time corresponds to the maximal exploratory activity in the novel arm, which typically declines in the subsequent 2 min. Values are compared with a random level (chance level) for time spent exploring the three arms. Mice will be tested in the Y-Maze on Day 10 following the final TBI or sham procedure.

e. **Morris water maze** – The Morris water maze is a highly-employed test of reference and spatial memory and has been used successfully in TBI experiments performed by many investigators in the CNRM [37, 67, 68]. A Stoelting Morris water maze (diameter 4.0 m) tank is filled with tap water (25°C) to a depth of 20-30 cm. A clear plastic platform is placed in one of the "quadrants" of the tank floor and visual cues (solid geometric shapes) are placed on the room walls in locations that can be viewed by animals in the pool. On Day 1 (no less than seven days after CCI or sham surgery), a single pre-training trial is first used where the mouse is gently placed on the platform in the tank and the mouse remains there for 15 seconds. If the mouse jumps into the water during this time, it is allowed a brief swim (< 60 s) before being guided back to the platform. On Day 2, training trials begin where the mouse is placed near the side of the tank in a location away from the platform, and is allotted 90 seconds to swim to the platform. Upon finding the platform the mouse remains on the platform for 15 seconds. If the mouse does not reach the platform in the allotted 90 seconds, they are gently guided to the platform and allowed to remain for 15 seconds. A total of four trials, separated by 1-2 min, are performed each day. Swimming movements of the mouse are tracked, and swim speed, distance before reaching the platform and latency to find the platform are calculated by Any-Maze software. Finally, on the fourth day of training (Day 5) approximately one hour after the final training trial, a single trial is performed with the platform removed from the tank. The time spent in the pool quadrant where the platform was located is measured, compared to time spent in the other three quadrants. After all trials, mice are placed in a clean cage underneath a heating lamp until thoroughly dried (approximately five minutes) to maintain thermoregulation.

Beginning the next day, *reversal training trials* will take place in which the location of the hidden platform is moved to the opposite side of the tank [69]. The pre-training phase is omitted, and each mouse receives four 90-sec trials for four days. A second probe trial will take place approximately one hour after the final reversal training trial. Finally, immediately after the reversal probe trial, a single visible platform trial will be conducted. A pipette with a very visible "flag" will be secured to the platform. The latency of the mouse to navigate to the cued platform is recorded (maximum of 90 sec).

Morris water maze training will begin approximately 60 days following final TBI or sham procedures.

2. **Experiment 1b: Home cage circadian activity and active place avoidance**

a. Twenty-four activity will be evaluated in the Stoelting Company's new mouse *Any-Maze Cages (AMc)*. The AMc is a wooden box measuring 15"H x 20"W x13"D that houses a single mouse and acts as an isolation chamber. It contains food and water, as well as a running wheel, and has the capability to monitor the amount of food and water intake 24 hours a day. In addition, the chamber has a built-in infra-red-sensitive camera and infra-red and ambient light LEDs. Software controls the light period (ambient light LEDs ON) and dark period (infra-red light LEDs ON/ambient light LEDs OFF). Using Any-Maze software, the camera records the animal's movements and circadian activities "24/7." The chambers are also furnished with a ventilation fan and a temperature sensor. The latter allows the temperature to remain constant and stable within the chamber.

Immediately after the final TBI or sham procedure, individual mice will be placed in the AMc system to monitor 24-hour activity and food/water intake for up to four weeks after surgery. Visual inspections of the animals will be made by research staff daily via a computer monitor, and scales within the cages provide information regarding amounts of food and water available to each mouse, eliminating disruptive door openings. Check sheets will be filled daily with amounts of food and water remaining in each cage, temperature of each cage, and a check indicating the animal was visually seen on the computer screen. LAM personnel will ensure that daily recordings are made by research staff including weekends and holidays.

b. No sooner than 24 hours after removal from Any-Cages, mice will be tested in an active place avoidance task (Biosignal; [41]). The apparatus consists of a ~50cm (diameter) metal disk with 40 cm high transparent walls that allows the mice to view distal room cues; the apparatus and testing room will remain unchanged throughout the testing protocol. Testing will take place in four phases over four days:

Phase 1 (habituation/open field): No less than three days after CCI or sham surgery, the mice will be habituated to the testing environment in a single ten-minute open field test in which the animals are free to explore the entire arena. The data from this phase of the experiment will be analyzed to assess exploratory and anxiety-like behaviors in a circular open field environment.

Phase 2 (passive avoidance; PA): Phase 2 takes place 24 hours after habituation. Each mouse will receive four 10-min PA training trials in a single day, with a 10-12 min inter-trial interval (ITI). During these trials, a 60° region of the circular arena is electrified by a grid underneath the floor, and the mouse receives a single .3 mA, 500 ms shock each time the electrified region is entered. Additional shocks are administered every 1.5s until the animal leaves the shock zone. Olfactory cues (urine and feces deposited on the arena floor) and visual cues around the room are used by mice in this phase to learn place avoidance and stop entering the shock-region of the apparatus. An overhead camera and video-tracking system are used to track movements of the mouse and calculate the distance traveled and number of shock zone entrances.

Phase 3 (active avoidance; AA): The day after PA trials, each mouse undergoes six 10-min AA trials with a 10-12 min ITI. During these trials, the same 60° shock region of the arena is stationary while the arena rotates. In these trials,

although the electrified region of the arena remains in the same spatial location, the arena rotates and the mouse must keep moving to avoid being shocked. In these trials, only visual room cues can be used by the animal to locate the electrified area as the olfactory cues rotate with the arena. Movements of the mouse are tracked and multiple measures are calculated: the latency to first entrance of the shock zone measures memory of the zone location between trials, number of shocks administered assays the motivation to escape shock; distance traveled, average speed and linearity of movement (average each 2s of the ratio dist(linear)/dist(integrated)) provide measures of motor function.
Phase 4: (AA; conflict learning (CL): In the CL trials, the shock zone location is shifted 180° from the original location for six 10-min trials (10-12 min ITI). These trials test proactive interference, or whether the avoidance memory obtained in Phase 3 AA trials conflict with avoidance memory currently being learned in Phase 4. Measures calculated from the camera-tracked movements of the mouse include the distance traveled and the number of entrances into the shock zone.

3. **Experiment 1c: The three-chambered sociability test and the fear conditioning test**
   a. The Sociability Test [43, 70] allows the mouse to freely visit three connected chambers. No less than 10 days after final TBI or sham exposure, each mouse is placed individually into the middle chamber (with the doors to the side chambers closed) for five minutes to allow the animal to acclimate to the apparatus. After the acclimation period, a small cylindrical wire cage containing a second (unfamiliar) mouse is placed into one of the side chambers. The other side chamber also contains a wire cage, but it is empty. The test mouse is placed in the middle chamber and the video system measures the amount of time (in a 10 minute test period) that the test mouse spends in the chamber containing the second mouse, as well as the time in the middle chamber and the third chamber. The amount of time the test mouse spends in the chamber with the unfamiliar mouse is an indicator of "sociability." This test session is followed immediately by a second session where the wire cage in the third chamber is occupied by a second unfamiliar mouse. Again, measures are taken to assess interactions of the test mouse with the first and second stranger mice, where the latter assesses "social novelty." The test mice placed in the cylindrical chambers are habituated to the wire cages for two days before the sociability test by placing them into the cages for five minutes each day. After their use, they will be returned to the animal facility. Two days after the sociability test, classic fear learning will be assessed in the fear conditioning test. We do not expect their experience in the sociability test to affect results obtained during fear conditioning.
   b. The Ugo Basile Fear Conditioning System is employed to assess contextual fear, where the mouse is initially placed in the test chamber and receives a mild electric shock that induces a fear response to an initially neutral [71]. On the first day of testing, at least 12 days after TBI or sham procedures, the mouse is placed in a sound-proof test chamber that presents a tone (800Hz, 80dB) for 30 seconds. A mild foot shock (2 seconds, 0.5mA) is then delivered 2½ seconds later. This process is repeated four times. The next day, the mouse is placed in a different, novel test chamber and allowed to explore. Freezing is measured over a 6 minute period, where the tone is presented during the last 4 minutes of the trial. Finally,

on the third day the mouse is placed back into the test chamber, for 5 minutes, where they had experienced the electric shock (*no tone or electric shock is given at this time*). Measures of freezing and ambulation are recorded in each test condition.

4. **Experiment 1d: <u>The Barnes maze, acoustic startle test, and Porsolt forced-swim test</u>**
   a. The <u>Barnes maze</u> [46] will employ the method described by Holmes and colleagues [71]. Over trials, mice learn to locate a hidden box located in one of the 20 holes located near the periphery of a round, brightly-lit maze platform. Mice are given three trials/day (trial duration of 180s) over eight days (Days 10-17 after the TBI or sham procedures). The Any-Maze video software records the number of holes visited, distance traveled, and time to reach the escape box for each trial.
   b. Three days after completion of Barnes maze testing, mice will be tested in the San Diego Instruments <u>Startle Reflex System</u> using the protocol described by Curzon and colleagues [72] and the one that was described and approved in protocol numbers (b)(6) In brief: five minutes before testing begins, individual mice are acclimated to the test chamber. The audio system in the test chamber emits "background noise" of 65 dB. After the acclimation period, the mouse is presented with four 120 dB sound bursts (40 msec apart), and the "acoustic startle reflex" is then assessed after these initial tests by presenting three sound pressure levels of stimuli (90, 105, 120 dB; each 40 msec duration; random order; average 15 sec between sounds, but in a range of 5-30 sec). A total of 10 trials per stimulus level are presented to each mouse. On the following day, a second test is performed to measure "pre-pulse inhibition." For these trials, five stimuli combinations are presented: a randomly chosen period to measure startle after no auditory stimulus, a 120-dB pulse alone trial with no pre-pulse stimulus, then three pre-pulse + pulse trials of 70, 75, and 80 dB pulses (20 msec duration) followed 100 msec later by a 120-dB pulse (40 msec duration), respectively. Twelve trials of these five conditions are presented with an average of 20 sec (range 5-25 sec) between trials.
   c. No less than one week after testing in the acoustic startle chambers, mice will be tested in the <u>Porsolt forced swim test</u> which is used to assess "behavioral despair" [29, 49]. The mouse is placed in a cylindrical container of water (10 cm deep, 25±1°C) and the amount of time the mouse swims is recorded. A pre-exposure session of two minutes immediately precedes the test trial, which is four minutes in duration (the total duration of the exposure is six minutes). Mice tend to float with their heads above water if they stop swimming; however, they will be continuously monitored during the test and any animal that appears to be in danger of sinking will be immediately removed from the water by the experimenter.

V.4.4.7. <u>Other Procedures</u>:

All TBI procedures will be performed as described below, and mice will be selected at random for individual procedures. All mice will first be anesthetized as described in Section V.4.1.2.1.

CBI, WDI, HIFU and relevant sham procedures are conducted in a designated area of the CNRM core facilities (Room (b)(6) on a clean table surface that is covered with clean absorbent cloth. The table will be disinfected before and after procedures. ABS procedures will be conducted in the designated area for the advanced blast simulator (b)(6)

CBI or sham procedures: The CBI procedure [6, 7] utilizes the CNRM's Pre-Clinical Core Facility's Impact One™ Sterotaxic Impactor to produce a blow to the surface of the mouse head. For the CBI procedure, mice will be weighed, anesthetized, head hair clipped, mounted in a stereotaxic frame in a prone position, and secured using atraumatic ear bars and an incisor bar. The ear bars are reversed in the stereotaxic device, so that the pointed ends face away from the mouse skull. The flat end of the ear bars are capped with a black stopper from a 5 ml syringe to hold the mouse calvarium in the horizontal plane with respect to the interaural line. To assess anesthetic depth during the procedure, the corneal reflex will be evaluated by lightly touching the cornea with a cotton swab to elicit an eye blink. The assessment of the paw and ear pinch reflexes consists of the gradual application of pressure on the hind paw or ear. Lack of eye blink or paw or ear withdrawal is an indication of deep anesthesia. The impactor tip is then centered over the parietal region of the head/skull (coordinates, -2.5 AP, 2.5 ML, 0 DV; note that no skin incision is made). The tip is then raised 1.2 mm from the surface of the head and the impactor is set to deliver a 5 mm tip extension at a velocity of 5 m/s and dwell time of 100 ms. Just before impact, the isoflurane is turned off to minimize the risk of apnea, the impact is delivered, and the mouse is immediately released from the stereotaxic device. The mouse is then placed in a clean cage on a heating pad for recovery and monitored. Once they regain consciousness, animals will be returned to their home cages and monitored. Following CBI, the impactor tip will be disinfected with 70% ethanol. Mice undergoing sham surgery will receive all procedures described here except the impact with the CBI device.

Mice that undergo multiple injuries (3x or 5x) will be given 24 hours of recovery between each injury. After 24 hours, the mouse is re-anesthetized and the TBI (or sham) procedures are performed exactly as before.

WDI: A closed-head TBI will be induced by a weight-drop method in which a 333g weight on a rod (tip of 3mm) falls from a 3cm height. First, mice will be anesthetized as described in Section V.4.1.2.1 and weighed. Throughout the procedure, anesthetic depth will be monitored by testing corneal, paw and ear pinch reflexes. After head hair is clipped, each mouse will be moved to the platform of the CHI which will be maneuvered to a position underneath the impact rod such that the desired location of impact will be achieved. The rod will then be dropped from a height of 3 cm to result in a moderate to severe TBI. The rod will be retracted immediately to prevent a "rebound" injury that could result in secondary trauma. Mice will be returned to their home cages after the procedure and monitored until they regain consciousness. As sham-controls for this procedure are identical to those from the CBI procedure, no specific sham group will be used for WDI and the CBI sham-operated animals will be used for comparison.

Mice that undergo multiple injuries (3x or 5x) will be given 24 hours of recovery between each injury. After 24 hours, the mouse is re-anesthetized and the TBI procedures are performed exactly as before.

ABS: Mice will receive TBI by an overpressure shock wave generated by the advanced blast simulator (ABS). All mice/rats are first anesthetized as described in Section V.4.1.2.1 and weighed. Mice are individually secured in a holder that is inserted inside the distal end of the shock tube. After sustaining a short duration of shock wave stimulation (<10 msec), animals will

be returned to their home cages after the procedure and monitored until they regain consciousness. A shock of "moderate intensity" as determined in behavioral and neuropathological validation experiments currently approved in protocol (b)(6) will be used for all ABS exposures in this protocol. Sham-treated animals will receive anesthesia and be placed in the holder at the distal end of the shock tube, but no shock wave will be produced. If a mouse is to receive more than one exposure to the ABS, 24 hours will elapse between individual exposures. All animals will be monitored at least once per day following TBI or sham procedures.

HIFU: HIFU procedures will be performed as described in CNRM SOP#1 [73]. In brief, mice are first anesthetized as described in Section V.4.1.2.1 and weighed. The scalp is shaved and the hair-removal product, Nair®, is placed on the scalp using sterile gauze and allowed to set for 4-5 minutes. The product is then wiped off the scalp and the scalp is rinsed with sterile gauze soaked with water and patted dry, then coated with a conduction medium (Aquasonic-100® lotion; to enhance wave transmission into the skull). The HIFU transducer is then gently placed on the scalp over the region of the sagittal suture of the skull and a high pressure wave (1-10 ms) is generated. Mice will be returned to their home cages after the procedure and monitored until they regain consciousness. Sham-treated animals will be anesthetized and scalp hair removed with Nair®, but will not be exposed to the high-pressure wave. Twenty-four hours will be allowed between HIFU or sham exposures for mice that receive more than one injury.

Model characterization: Pre-clinical models have great utility for determination of the biological and behavioral consequences of TBI, and what therapeutic treatments may hold promise for the human condition. However, one difficulty with this research relates to having an idea of the actual stimulus that was employed to cause injury. The usual approach by experimenters is to report general injury treatment conditions. There has been recent commentary, including a guide from the National Institute of Neurodegenerative Disorders and Stroke, that investigators should improve reportage of experimental treatment conditions as a way to improve the quality of pre-clinical data [12, 74-77].

For some experiments, a high speed camera (Motion Pro Y4, IDT) and image acquisition software (Motion Studio, IDT) will be used to capture motion at a rate of 4,500 frames per second. Each video "clip" is approximately 2 seconds in duration. Subsequently, the acquired videos are imported into motion analysis software (Proanalyst Professional Edition, Xcitex) to determine device, and/or head and body movement. This will be performed following the procedures outlined in USUHS IACUC Policy #25 [78]. Video images will be stored on a dedicated laptop that is password protected. In addition, to ensure availability of the data should the hard drive in the laptop fail, a backup external drive will be employed and also stored in the cabinet. The laptop and external drive are located in a secured area of the LAM facility in Room (b)(6) which has a locking door, and is stored in a locked cabinet. The videotaping will be performed by Dr. (b)(6) in the mouse surgery suite (Room (b)(6) or ABS testing suite (Room (b)(6) and viewed in Room (b)(6) Only Dr. (b)(6) and (b)(6) will have access to the videotapes as they analyze and summarize the findings. The data analysis phase is labor-intensive and will require retaining the video recordings until all data analysis is completed, but we request retaining the images for three years after the completion of this protocol (e.g., October 1, 2016 if this is the date for initial approval of this protocol + 3 years to September 30, 2019). At that time the images will be erased from the laptop's hard drive and the external hard drive. Please note the measures are converted to numerical values in a spreadsheet and this information will be retained. Actual video images will never be utilized in a presentation at USU

or outside the University. Should there be any need for a depiction of a rodent in a publication or a lecture, drawings will be created in place of actual images. It is expected that the data presented in graphical format will be adequate for readers or lecture attendees to visualize motion parameters.

Magnetic resonance imaging (Experiment 2). Imaging will be performed on the Bruker 7T MRI system in the Center for Neuroscience and Regenerative Medicine (CNRM) Translational Imaging Facility (TIF), Room (b)(6) before surgical procedures and again at four different time points after TBI: one day, three days, 30 days and six months [55]. Mice will be anesthetized with isoflurane (2-4%) in a clear induction chamber and anesthesia will be maintained via a "flow-through" tube that is used during imaging. T1 and T2-weighted images (1.0 mm thick) will be acquired with gradient echo sequence, and hyper-intense areas (indicating high water content) will be measured to assess acute edema. Hypo-intense regions will be measured to evaluate the extent of hemorrhage. The imaging procedure will last approximately two hours per animal at each time point.

V.4.4.8. Tissue Sharing:
Excess mouse tissue will be made available to other investigators in our or other labs.

V.4.5. Study Endpoint:
The study endpoint is survival for the previously described durations (**Table 4**), at which time mice will be euthanized. Euthanasia will be performed as stated.

Table 4. Summary of Animal Testing and Procedure Days and End Points for Euthanasia

Experiment	Behavior Test	Test Day(s)	Pain Category*	No. Mice	End Point (Day)†
Behavioral Studies					
1a	Open Field	1, 4, 14, 30, 60	D	≤4,032	61-64
	Rotorod	1, 3, 7, 10, 14, 30	D		
	Zero Maze	5, 15, 40	D		
	Y-Maze	10	D		
	Water Maze	20-24	D		
1b	Any-Cage	0-28	D	≤1,008	31-34
	Active Avoidance	29 or 30	D		
1c	Sociability Test	10-11	D	≤1,008	15-18
	Conditioned Fear	12-14	E		
1d	Barnes Maze	10-17	D	≤1,008	29-32
	Acoustic Startle Test	20	D		
	Porsolt Swim Test	27 or 28	E		
Neuropathology		**Euthanasia Days**			
2	–	1, 2, 7	D	210	1, 2, 7
MRI		**Imaging Days**			
3	–	1, 3, 30, 180	D	420	181-185

*Pain **Category D** refers to mice sustaining a TBI or sham procedure that will be alleviated with analgesia treatment. The behavioral tests in this case elicit little or very mild distress and no pain. The behavioral tests in **Category E** refer to animals that will receive alleviation from discomfort by the administration of analgesic following TBI or Sham treatment, but that the behavioral task (Conditioned Fear or the Porsolt Swim Test) involves brief inescapable discomfort. Since all animals in Experiment 1c and 1d receive these behavioral tests, they are classified as Category E.

†*End Point* refers to time after final TBI or Sham treatment. A range of days is indicated to allow for flexibility for investigator absence due to weekends.

Animals will be observed again one hour after home cage placement to ensure there are no signs of discomfort (difficulty breathing, hunched posture, trembling, lack of reaction to gentle touching (lethargy), or seizure activity). If needed, the LAM veterinarian will be consulted should there be signs of continued discomfort or distress.

V.4.6. Euthanasia:
Euthanasia will be performed in accordance with "AVMA Guidelines for the Euthanasia of Animals: 2013 Edition." Methods of euthanasia on this protocol include decapitation and perfusion. Mice are anesthetized before these procedures. Euthanasia will be performed by the PI or the staff in the CNRM Pre-Clinical Studies Core.

Perfusion: Some animals will be used to obtain brain samples for immunocytochemistry. Following anesthesia per Section V.4.1.2.1. , we will ensure mice are deeply anesthetized and unresponsive to paw pinch. Once the mice are deeply anesthetized and unresponsive to paw pinch, a midline thoracotomy is made to expose the heart. A 20-22 gauge tip needle is inserted into the left ventricle to aspirate 1 ml of circulating blood, which will be used to obtain plasma (see V.4.4.2. Biosamples). Next, a 20-22 gauge blunt tip needle connected to a tube (¼ in ID and 1/16 in wall) is inserted into the left ventricle through the apex, and the right atrium is incised. After an initial washout with 50 -100 ml of cold 100 mM phosphate buffered saline (PBS) for approximately 2 min, transcardial perfusion with 100-250 ml cold 4% paraformaldehyde in PBS will be delivered through the pulsatile perfusion system (BRL, CP-600) until adequate perfusion reached. The brain will then be removed from the calvarium and post-fixed before tissue sectioning for immunohistochemical staining.

Decapitation: Some mice will be used to obtain brain mRNA and protein samples. Following anesthesia per Section V.4.1.2.1, we will ensure mice are deeply anesthetized and unresponsive to paw pinch then use a rodent guillotine to decapitate the anesthetized mice. The decapitation equipment will be cleaned and maintained to ensure the proper function by routinely checking to ensure it is not rusted or blunt. It will be either sharpened or replaced if it does not function properly. A log book will be kept of the maintenance of the guillotine.

In the event that LAM personnel must euthanize an animal for humane reasons, cylinderized carbon dioxide will be used in the LAM necropsy room. Using a clean cage, carbon dioxide will be administered at a rate to replace greater than 20% of the cage volume per minute. Once the mice have not moved or breathed for at least one minute they will be removed from the chamber. Euthanasia may be ensured by cervical dislocation or opening of the thorax.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol. Routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for the mice used in this protocol.

V.5.1.1. Study Room:

Building(s) (b)(6) Room Number(s) (b)(6)

Building(s) Room Number(s)

Building(s) (b)(6) Room Number(s) (b)(6)

V.5.1.2.
Special Husbandry Provisions:

Food Restriction: Yes _____ No X

Fluid Restriction: Yes _____ No X

V.5.1.3. **Exceptions:** None.

V.5.2. **Veterinary Medical Care:**

V.5.2.1. **Routine Veterinary Medical Care:**
The PI or research staff will observe the mice following all experimental procedures. LAM personnel will observe the mice at least once a day for general health and husbandry condition. Any mouse observed to be lethargic, losing weight, exhibiting gross neurological deficits (such as inability to eat or drink, continual circling, seizures, etc.) or any other signs of distress or illness will be evaluated by the PI and/or veterinary staff then euthanized as previously described.

V.5.2.2. **Emergency Veterinary Medical Care:**
All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays.

V.5.3. **Environmental Enrichment:**

V.5.3.1. **Enrichment Strategy:** Except as indicated below, all animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies.. Animals are grouped-housed. Standard nestlets, tunnels, or toys provided by LAM will be provided in each home cage.

V.5.3.2. **Enrichment Restrictions:** N/A

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING*

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
Concussive brain injuries (**CBI and WDI**)	(b)(6)	All personnel listed have many years of experience with general rodent surgeries.	Dr [redacted] has four years of experience with rodent surgeries related to her clinical practice as a microsurgeon, and has assisted with TBI procedures in the core facilities for 4 years. All other personnel have many years of personal laboratory experience with aseptic rodent surgeries. (b)(6)
High intensity focused ultrasound (**HIFU**)		All personnel listed have many years of experience with general rodent surgeries.	HIFU has been regularly performed by Core staff for approximately four years.
Advanced blast simulator (**ABS**)		All individuals have experience with animal models of TBI.	All individuals have received extensive on-site training from the manufacturer of the ABS.
Rodent Behavioral Testing		Ms. (b)(6) has 15 years of experience in animal handling and behavioral testing and an M.S. in Behavioral Neuroscience.	(b)(6) has many years of personal laboratory experience (b)(6) has received training from (b)(6) (b)(6)
Magnetic resonance imaging (**MRI**)		Drs (b)(6) will instruct all other personnel.	Drs (b)(6) has many years of experience in animal imaging and will direct this aspect of the work.
IP injections		All listed personnel have many years of experience in rodent handling and drug administration.	All listed investigators have taken the Rodent Handling and Procedural Techniques* and have experience with injections.
Euthanasia by decapitation		Dr (b)(6) experience with rodent decapitation >35 years. He will instruct listed colleagues on this procedure.	Performed similar procedures for recent Protocols (b)(6) (b)(6)
Intracardial perfusions		All listed personnel have many years of experience performing perfusions in rodents.	Performed similar procedures for recent protocols (b)(6) (b)(6)

*Most investigators have attended the USUHS Investigator Training Course: Dr. (b)(6) on August 17, 2005, Ms. (b)(6) completed several online USUHS Investigator Training Courses on October 28, 2009 and attended the Rodent Handling and Procedural Techniques on November 19th, 2009. Ms. (b)(6) is previously approved to perform the above procedures under (b)(6) and (b)(6) Dr [redacted] has completed the online USUHS Investigator Training Course on September 9, 2008 and the Rodent Handling and Procedural Techniques on September 24, 2009. She is approved to perform TBI procedures, drug administration, including drugs for anesthesia, and euthanasia for decapitation under Protocol (b)(6) completed several USUHS online investigator training courses including "Working with the IACUC" (non-VA) on April 23, 2013 and the USUHS Investigator Training Courses on June 6, 2013. In addition, the investigators have recently completed the new required training with the Collaborative Institutional Training Initiative (**CITI**) Program, "Investigators, Staff and Students – Lab Animal Research." Drs (b)(6) and Ms. (b)(6) completed the (b)(6)

(b)(6) course on May 9, 2014, Dr. [redacted] on May 13 & 15, 2014, Dr [redacted] on May 14, 2014, Dr. [redacted] on August 22, 2014.

VII. BIOHAZARDS/SAFETY:

To minimize exposure to animal allergens when working with lab animals, lab personnel will wear lab coats and/or scrubs, gloves and masks. We will always wear lab coats and gloves when we contact toxic chemicals and perform some steps in a fume hood to minimize risk of exposure to these teratogens. Potential fumes from fixative are minimized by allowing the fixative to be constantly washed down the sink drain.

VIII. ENCLOSURES:

Literature search results for Sections II.2 (Searches for unnecessary duplication) are available upon request.

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

(b)(6) _____ 9-3-14
Princi Date

G. Training: The following personnel will attend the next USUHS Investigator/Animal User Training Course:

_____ _____
_____ _____

H. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely, "Responsibility" for implementing animal use alternatives where feasible and conducting humane and lawful research.

(b)(6) _____ 9-3-14
Prin Date

I. Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress (WILL) or **WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

Date

X. PROTOCOL ABSTRACT:

A. **Animal Protocol Number:** (b)(6)

B. **Animal Protocol Title:** Evaluation of the effects of multiple blast- or concussive-brain injuries on neuropathological and behavioral outcomes in male and female mice

C. **Principal Investigator:** (b)(6) Ph.D.

D. **Performing Organization:** Uniformed Services University of the Health Sciences

E. **Funding:** Center for Neuroscience and Regenerative Medicine

F. **Objective and Approach:** ·

The goal of this research is to measure and compare the anatomical and behavioral effects of widely-used methods of inducing traumatic brain injury in mice. There are many animal models of TBI in use in the field of neurotrauma, and there are no studies comprehensively describing and comparing the anatomical damage and behavioral changes that result after the induction of TBI using various procedures. We will use four different methods of inducing TBI and subsequently assess the animals using at least 10 behavioral tests. In addition, mice will undergo magnetic resonance imaging at three different time points after injury to measure anatomical changes and the extent of edema and hemorrhage that results from TBI. All injury and behavioral procedures described in this protocol will be performed within the CNRM Pre-Clinical Studies Core, shared facilities used by many investigators studying TBI. As a result of the experiments described in this protocol, Core personnel aiding investigators will become better trained and more proficient in performing the procedures, and thus be better able to help investigators plan and carry out their studies. This is an important initial step for establishing the experimental procedures that all investigators should follow when they use the Core and for establishing procedures so that data collected by various research programs can be compared across laboratories. In addition, the data collected from this research will be made available to researchers as a "brain injury guide" to help them decide which method of TBI and subsequent behavioral tests will be best for their individual experiments.

To approach this problem we will use laboratory mice. Mice will receive TBI and be imaged and used in a series of behavior tests to assess the consequences of brain injury. The data collected will then be summarized using conventional statistical approaches (mean, standard deviation, analysis of variance, correlation and regression analyses). We will use as few mice as possible while still using enough to make valid conclusions. To do this initial research we must use animals since cells or tissues will not reflect the actual biology and behavioral responses of a live organism. We hope that this basic research and use of animals will aid in understanding some of the causes for the long-term effects stress and brain injury has upon the war fighter returning home to their town, work, and families, and that this research may allow us to provide better treatments to help suffering soldiers.

MEMORANDUM FOR DR (b)(6) DEPARTMENT OF ANATOMY, PHYSIOLOGY, AND GENETICS

SUBJECT: IACUC Approval of Protocol - Triennial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via designated member review on April 17, 2015.

This study was revised and approved by DMR on November 3, 2015.

Animal Protocol Title: (b)(4)
(b)(4)

USUHS Protocol Number: (b)(6)

Expiration Date: April 16, 2018

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. NON-TECHNICAL SYNOPSIS: (b)(4)
(b)(4)

II. BACKGROUND:

II.1. Background:

The effects (b)(4)

The possibility of a terrorist attack against civilians, or military troops deployed overseas is at present in the minds of both citizens and government officials. Mass casualties can be inflicted with chemical or biological toxins/weapons. Nerve agents are lethal chemical weapons that have been used in war and in terrorist attacks, with devastating consequences. Organophosphate nerve agents display a very high affinity for brain acetylcholinesterase (AChE) (9, 10, 11, 63). Inhibition of AChE by OPs and the resulting accumulation of acetylcholine can initiate seizures by activating nicotinic and muscarinic receptors, which are widely distributed throughout the brain. These receptors are present not only at postsynaptic sites in cholinergic synapses, but also on presynaptic terminals of both excitatory and inhibitory synapses, regulating the release of glutamate and gamma-aminobutyric acid (GABA) (37, 108). Therefore, it is conceivable that OP-induced inhibition of AChE can tilt the balance between the two major excitatory and inhibitory neurotransmitter systems—glutamatergic and GABAergic, respectively (38, 55). One of the clinical manifestations of exposure to nerve agents is seizure activity and status epilepticus (SE), which can lead to death or brain damage, with long-term cognitive and other behavioral consequences (8, 35, 56, 91, 99). (b)(4)
(b)(4)

(b)(4) Current medical countermeasures against nerve agent poisoning are not adequately effective in preventing seizure-induced brain damage (57, 89, 96). (b)(4)

(b)(4)

(b)(4) This is very important because in an emergency situation there is no opportunity for pretreatment. Our ultimate goal is to develop a medical countermeasure against nerve agents that will effectively stop seizures and protect from brain damage and the resulting behavioral deficits, and do so without significant acute and/or long-term adverse effects. (b)(4)

(b)(4)

The necessity to study immature, aged, and female rats

Having demonstrated the effectiveness of the (b)(4) (b)(4) we now propose to test if these compounds are equally effective in young and aged rats, as well as in female rats. Are there reasons to expect age- and/or gender-related differences in the (b)(4) (b)(4) First, let us examine if the existing literature suggests differential propensity for seizure generation, and, thereby, differential susceptibility to seizurogenic agents between genders and in different ages. It is well documented that young animals and humans are more prone to generating seizures than adults, but the neuropathology induced by seizure activity is less severe and more transient in the developing brains (41, 42, 67). It is particularly relevant to mention that pilocarpine-induced SE causes inflammation and epileptogenesis in rats, but not in infant rats (64). Aged humans (45, 58) and animals (68,110) are more susceptible to both seizures and the associated neuropathology compared to adults. Gender-related differences in seizure susceptibility exist in animals and humans (47), but more research is needed to clarify and categorize these differences. For example, in humans, males have a greater susceptibility to SE, but females have a higher incidence of idiopathic epilepsies (23, 74). In animals, male rats also are more susceptible to limbic seizures and SE than female rats (94, 83), but aged female mice are more sensitive to kainic acid-induced seizures (113). There are only few studies on the age- and gender-dependency of the susceptibility to nerve agent toxicity. In guinea pigs, the lethal potencies of VX and sarin are significantly higher in the adult males than in any other age or in females (30). In rats, the lethal potency of soman is greater in 5 day-old rats than in 30 day-old rats (106), and in the young (up to 30 days) and the aged males, compared to the adults (101,106), suggesting that the toxicity of soman during an animal's life span approximates a U-shaped curve (101). Our proposed studies will yield data on the age- and gender-related susceptibility to soman toxicity and lethality. Based on the limited information available, as reviewed above, our working hypothesis is that

the LD50 will be lower in the immature and aged rats (greater susceptibility/lethality to soman), greater in female rats or similar to the LD50 in males, but the soman-induced neuropathology –which will be examined at multiple points, 24 hours, 1 week, 1 month, and 3 months after soman exposure– will be lower in the immature rats, and the recovery of the damage will be faster (the reverse will probably be true in the aged rats). It is also possible, however, that the soman-induced SE in the early postnatal rats will produce disruption in the normal brain development, which will become evident in the behavioral studies proposed here.

(b)(4)

(b)(4) On an acute basis, GABA agonists in developing rats can facilitate instead of suppressing seizures (82). In response to metabotropic glutamate receptor-anticonvulsants, different responses have been observed even in a narrow range of young ages (7 to 25 day-old rats) (66), and, in general, young rats are more responsive to NMDA and non-NMDA receptor antagonists used as anticonvulsants compared to adult rats (67). Aged animals and humans also differ from other age groups in their responses to anticonvulsants, one reason being the different pharmacokinetics in the aged organism (45, 58, 68, 110).(b)(4)

(b)(4)

Significance of studying the protection of the amygdala, the hippocampus, and the prefrontal cortex

(b)(4)

(b)(4) There are two reasons that we choose to study these structures. First, the amygdala and the hippocampus are seizure-prone structures that play a central role in temporal lobe epilepsy, which is the most common form of epilepsy, the (5, 6, 7, 76, 85). It is not surprising therefore that the amygdala and the hippocampus also appear to play a central role in the generation of seizures induced by nerve agents (4), as suggested by the rapid increases in extracellular glutamate in these brain regions after nerve agent exposure (52, 53, 54), and the profound damage these structures suffer by exposure to nerve agents (2, 4, 12, 35, 40, 46, 80, 102, 103, 104, 111).(b)(4)

(b)(4)

(b)(4)

(b)(4) The second reason is that the amygdala, the hippocampus and the prefrontal cortex are the most important brain regions in affective and cognitive functions. The amygdala is best known for its central role in emotional behavior, being a key component of the brain's neuronal network that determines the emotional significance of external events (26, 29, 61). Many emotional/psychiatric disorders are associated with pathophysiological changes in the amygdala (21, 28, 88, 109). In addition, both the amygdala and the hippocampus play a pivotal role in mediating or modulating cognitive functions (26, 61). The amygdala modulates memory acquisition and consolidation, decision-making, and interpretation of the emotional significance of external and internal events via extensive, reciprocal connections with the prefrontal cortex (36, 84) (the brain area considered to be the center for cognitive functions) and the hippocampus (76). Long-term memory storage is thought to occur in neocortical areas, but the amygdala appears to be the site for storage of fear-memory (29, 65), whereas the hippocampus is the storage site of short-term memory and the gateway for consolidation of long-term memory in neocortex (20, 33, 60). Therefore, damage to these regions is likely to be significantly responsible for the long-term cognitive and behavioral deficits that follow nerve agent exposure, in both animals (9, 50, 51, 69, 70, 71, 72, 73) and humans (18, 27, 77, 81, 97). For these reasons it is important to determine the neuropathological and pathophysiological changes induced in the amygdala, hippocampus and prefrontal cortex by (b)(4)

(b)(4)

III. OBJECTIVE\HYPOTHESIS: (b)(4)

(b)(4)

female rats. The 16-20 month category is designated as "aged" by the supplier, and even 8 month-old male rats have been shown to be more sensitive to soman than immature or adult rats (101). After exposure to soman, the animals will be euthanized at 24 hours, 1 week, 1 month, or 3 months to evaluate nerve agent-induced pathology. Neuronal loss, using design-based stereology, and neurodegeneration, using Fluoro-Jade-C staining will be studied in the amygdala, hippocampus, and prefrontal cortex, at 24 hours, 1 week, 1 month, and 3 months after soman exposure.

In specific aim 3 we will determine whether treatment of immature (7 to 14 days-old) and adult (50 to 70 days-old) male and female rats with (b)(4) protects the animals against the behavioral alterations that are observed after (b)(4) (b)(4) At 1 month and 3 months after soman exposure, we will perform a comprehensive neurobehavioral evaluation in these animals. These tests will evaluate motor, cognitive, mnemonic and emotional abnormalities known to be associated with (b)(4) Motor performance will be evaluated using the roto-rod test: performance on this test has been shown to be reduced in rats following soman exposure (32). Cognitive impairment will be determined using tests for novelty preference in the open field, and mnemonic cognitive processes will be evaluated using the t-maze test, performance in which has also been shown to be affected by soman exposure (32, 78). Finally, emotional behavior will be evaluated by measuring the acoustic startle response/pre-pulse inhibition, and with tests of unconditioned fear (light/dark boxes, elevated plus-maze); increases in these responses have been seen following exposure to soman in rats (25).

In specific aim 3 we will also determine whether treatment of immature (7 to 14 days-old) and adult (50 to 70 days-old) male and female rats with (b)(4) protects the animals against alterations in synaptic plasticity and neuronal excitability that are observed after (b)(4)
(b)(4)

Behavioral and pathophysiological studies will be performed in both the immature and the adult male and female rats, but not in the aged animals, where variability among rats in cognitive/behavioral and physiological functions may be very high even in the control group, making it difficult to determine the deficits resulting from the (b)(4)
(b)(4)

IV. MILITARY RELEVANCE: (b)(4)
(b)(4)

(b)(4)

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures: (b)(4)

(b)(4)

V.1.1. Experiment 1:

To determine the *in vivo* efficacy of post-exposure administration of (b)(4)

(b)(4)

(b)(4) (7 to 14 days old), adult (50 to 70 days old), and aged (16 to 20 months old) **male** rats. (b)(4)

(b)(4)

A week prior to the experiments, 30%-50% of the animals will be implanted with cortical electrodes for electroencephalogram (EEG) recordings. These EEG recordings will be used to confirm the onset and intensity of behavioral convulsions observed in the rest of the animals. For the EEG recordings, along with behavioral observations, the timing (time to onset and duration) and the intensity of seizures will be measured via continuous EEG monitoring. Animals will be placed in individual recording chambers, and a baseline EEG will be obtained before administration of any drug.

(b)(4)

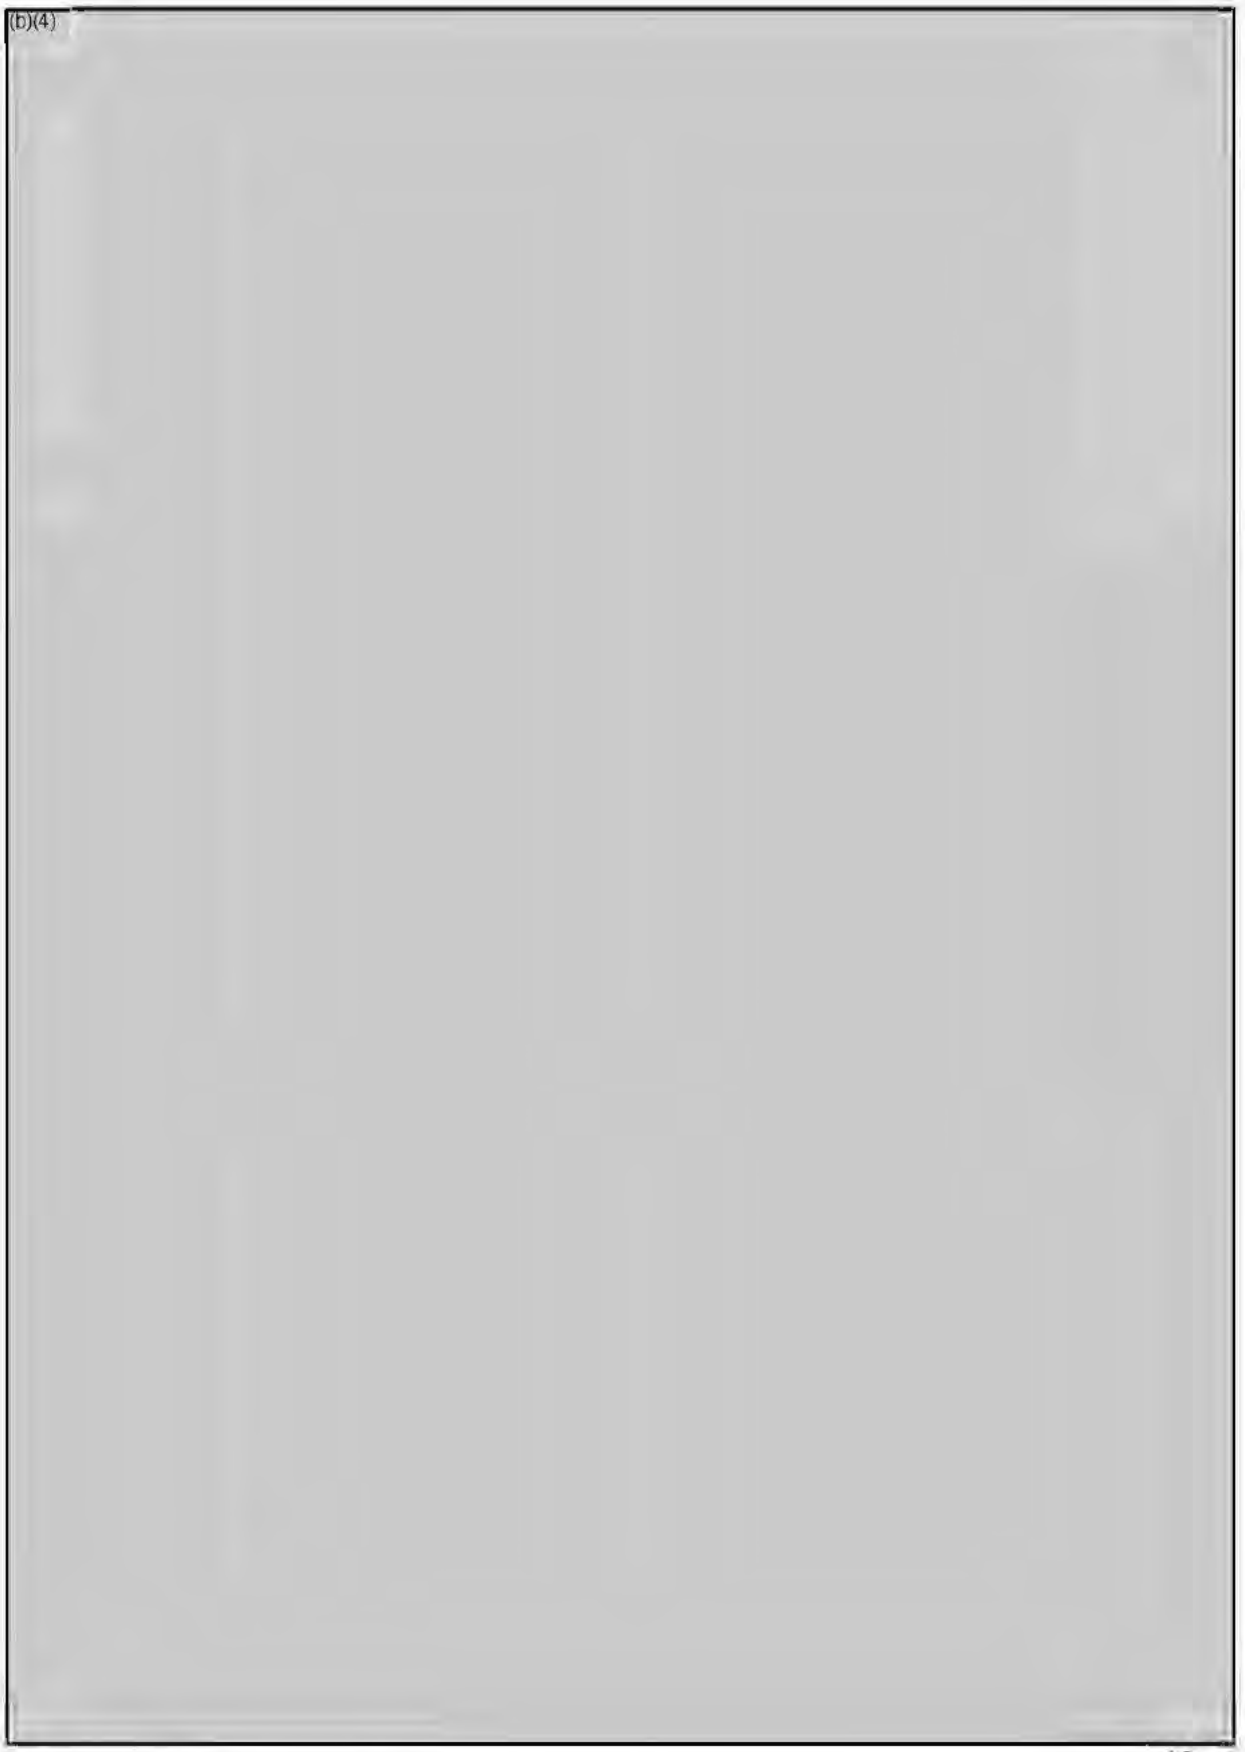
(b)(4)

(b)(4) The determination to classify a seizure as being terminated will be the progressive diminution and eventual elimination of repetitive high amplitude spikes or sharp waves in the EEG and the absence of obvious signs of clonic convulsive behaviors. For a seizure to be considered terminated the EEG will have to be free of repetitive high amplitude spikes or sharp waves within the 3-hour EEG recording period on the day of exposure and during the 30-min EEG sample obtained 24 hours after exposure.

The following dependent measures will be used to establish the effectiveness of the drug treatments: the speed (latency) at which the EEG "normalizes" following drug treatment, the overnight change in body weight and the extent of the neuropathological damage at 24 hours, 1 week, 1 month, and 3 months after soman exposure. With the drug treatment protocol described above, we expect a very high survival rate. However,

(b)(4)

(b)(4)



(b)(4)

Considerations regarding Experiment 1:

1) In a previous protocol we have obtained neuropathology data for adult male rats at 24 hours and 1 week after soman (b)(4) exposure, but not at 1 month and 3 months after exposure. In this study we will perform additional experiments in adult male rats at 24 hours and 1 week after soman, which are necessary for comparisons with other ages and the females.

2) The age we chose for the immature rats (7 to 14 days old at which time they open their eyes) coincides with the rapid developmental changes in the brain. The gender of the immature rats may not be possible to determine at the time of soman exposure, but it will be determined at 1 week, 1 month and 3 months after soman exposure, when neuropathology and behavioral studies will be carried out. The same issue applies to the (nominally female) immature rats in Experiment 2, and it is expected that the numbers of male and female animals will even out between the 2 experiments. If not, additional animals will be ordered.

V.1.2. Experiment 2:

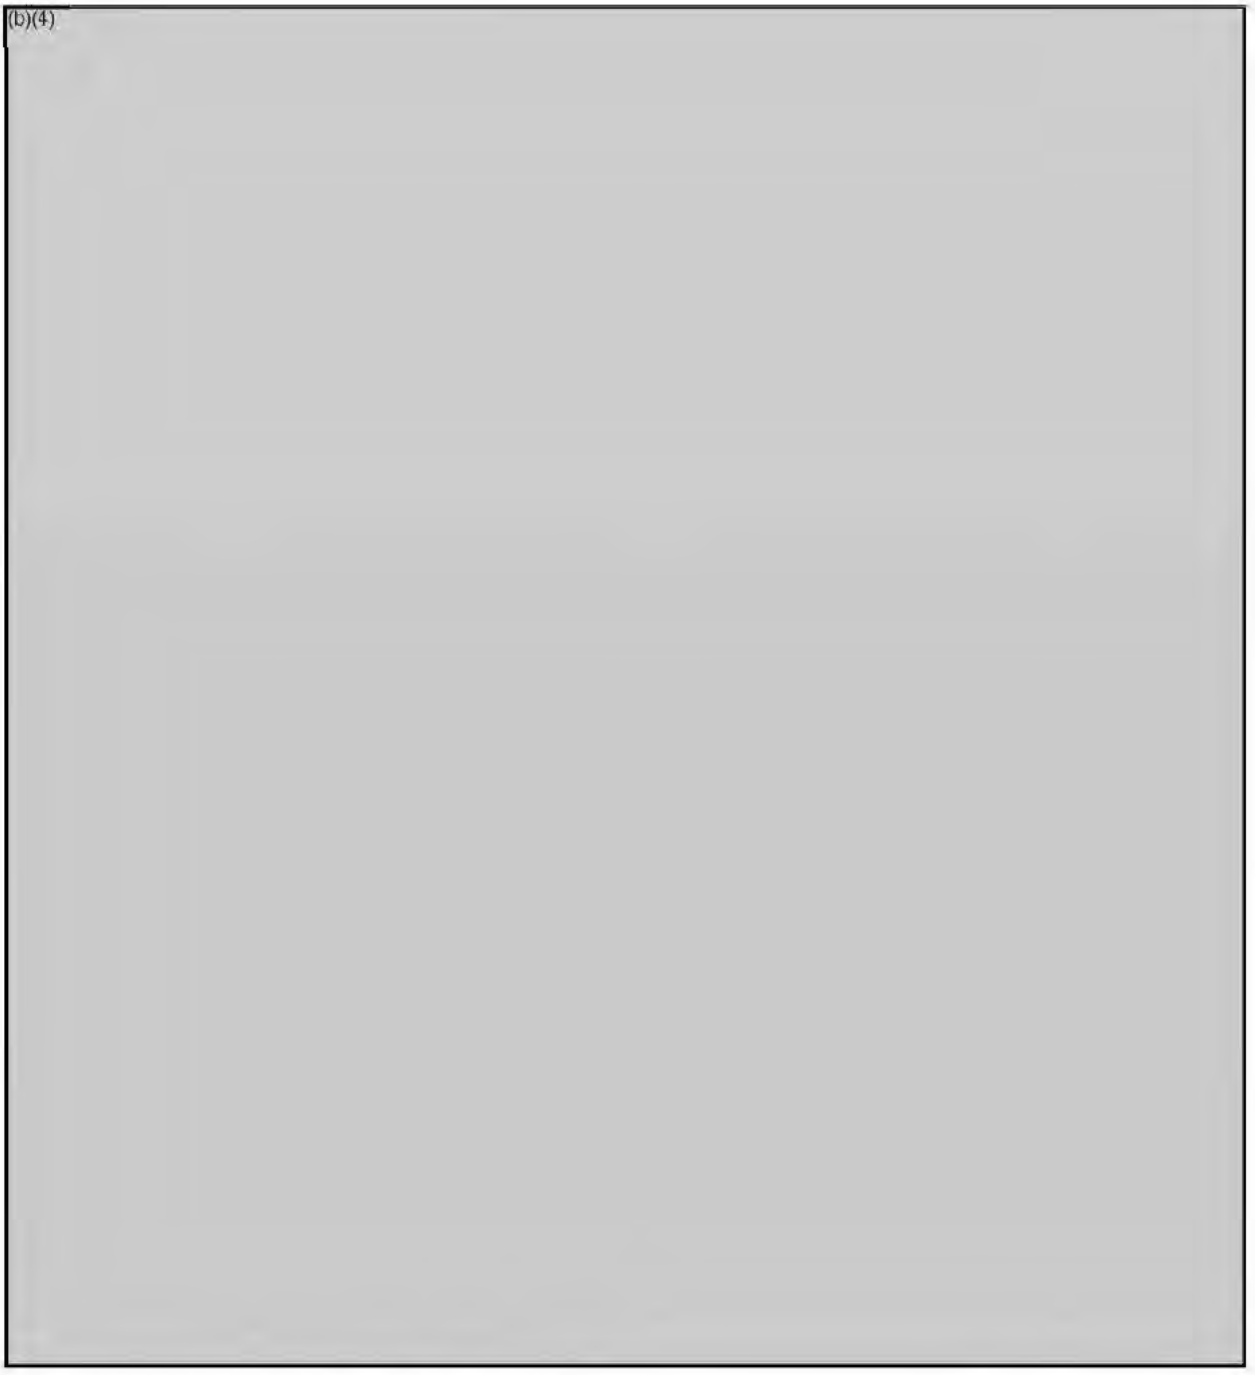
The experimental design of Experiment 2 is exactly the same as described in Experiment 1 with the exception of the use of **female** rats.

(b)(4)

(b)(4)

Immature, adult, and aged **female** rats will be randomly assigned to groups per Tables 4, 5, and 6 below:

(b)(4)



Considerations regarding Experiment 2:

1) The age we chose for the immature rats (7 to 14 days old at which time they open their eyes) coincides with the rapid developmental changes in the brain. The gender of the immature rats may not be possible to determine at the time of soman exposure, but it will be determined at 1 week, 1 month and 3 months after soman exposure, when neuropathology studies will be carried out.

V.1.3. Experiment 3:

In specific aim 3 we will determine whether treatment of immature (7 to 14 days old) and adult (50 to 70 days old) male and female rats with (b)(4) protects the animals against the behavioral alterations that are observed after nerve agent exposure (**Experiment 3A**). At 1 month and 3 months after soman exposure, we will perform a comprehensive neurobehavioral evaluation in these animals. These tests will evaluate motor, cognitive, mnemonic and emotional abnormalities known to be associated with exposure to soman and other organophosphates. Motor performance will be evaluated using the roto-rod test; performance on this test has been shown to be reduced in rats following soman exposure (32). Cognitive impairment will be determined using tests for novelty preference in the open field, and mnemonic cognitive processes will be evaluated using the t-maze test, performance in which has also been shown to be affected by soman exposure (32, 78). Finally, emotional behavior will be evaluated by measuring the acoustic startle response/pre-pulse inhibition, and with tests of unconditioned fear (light/dark boxes, elevated plus-maze); increases in these responses have been seen following exposure to soman in rats (25).

In specific aim 3 we will also perform electrophysiological experiments to determine whether treatment of immature (7 to 14 days old) and adult (50 to 70 days old) male and female rats with (b)(4) protects the animals against alterations in synaptic plasticity and neuronal excitability that are observed after nerve agent exposure (**Experiment 3B**). At 1 month and 3 months after soman exposure, rats will be euthanized, and brain slices containing the amygdala, hippocampus and prefrontal cortex will be prepared. Alterations in neuronal excitability and synaptic plasticity (long-term potentiation) in these three brain regions will be performed using both whole-cell recordings and extracellular, field potential recording techniques.

Behavioral and electrophysiological experiments will be conducted in both immature and adult male and female rats, but not in aged animals. Variability among aged rats in cognitive/behavioral and physiological properties may be very high even in the control group, making it difficult to determine the functional deficits resulting from the exposure to soman and the protection conferred by the (b)(4)

(b)(4)

Experiment 3A: To determine whether treatment of immature (7 to 14 days old) and adult (50 to 70 days old) **male and female** rats with (b)(4) protects the animals against the behavioral alterations that are observed after nerve agent exposure.

(b)(4)

(b)(4)

A week prior to the experiments, 30%-50% of the animals will be implanted with cortical electrodes for electroencephalogram (EEG) recordings. These EEG recordings will be used to confirm the onset and intensity of behavioral convulsions observed in the rest of the animals. For the EEG recordings, along with behavioral observations, the timing (time to onset and duration) and the intensity of seizures will be measured via continuous EEG monitoring (animals will be placed in individual recording chambers, and a baseline EEG will be obtained before administration of any drug).

(b)(4)

(b)(4) The determination to classify a seizure as being terminated will be the progressive diminution and eventual elimination of repetitive high amplitude spikes or sharp waves in the EEG and the absence of obvious signs of clonic convulsive behaviors. For a seizure to be considered terminated the EEG will have to be free of repetitive high amplitude spikes or sharp waves within the 3-hour EEG recording period on the day of exposure and during the 30-min EEG sample obtained 24 hours after exposure.

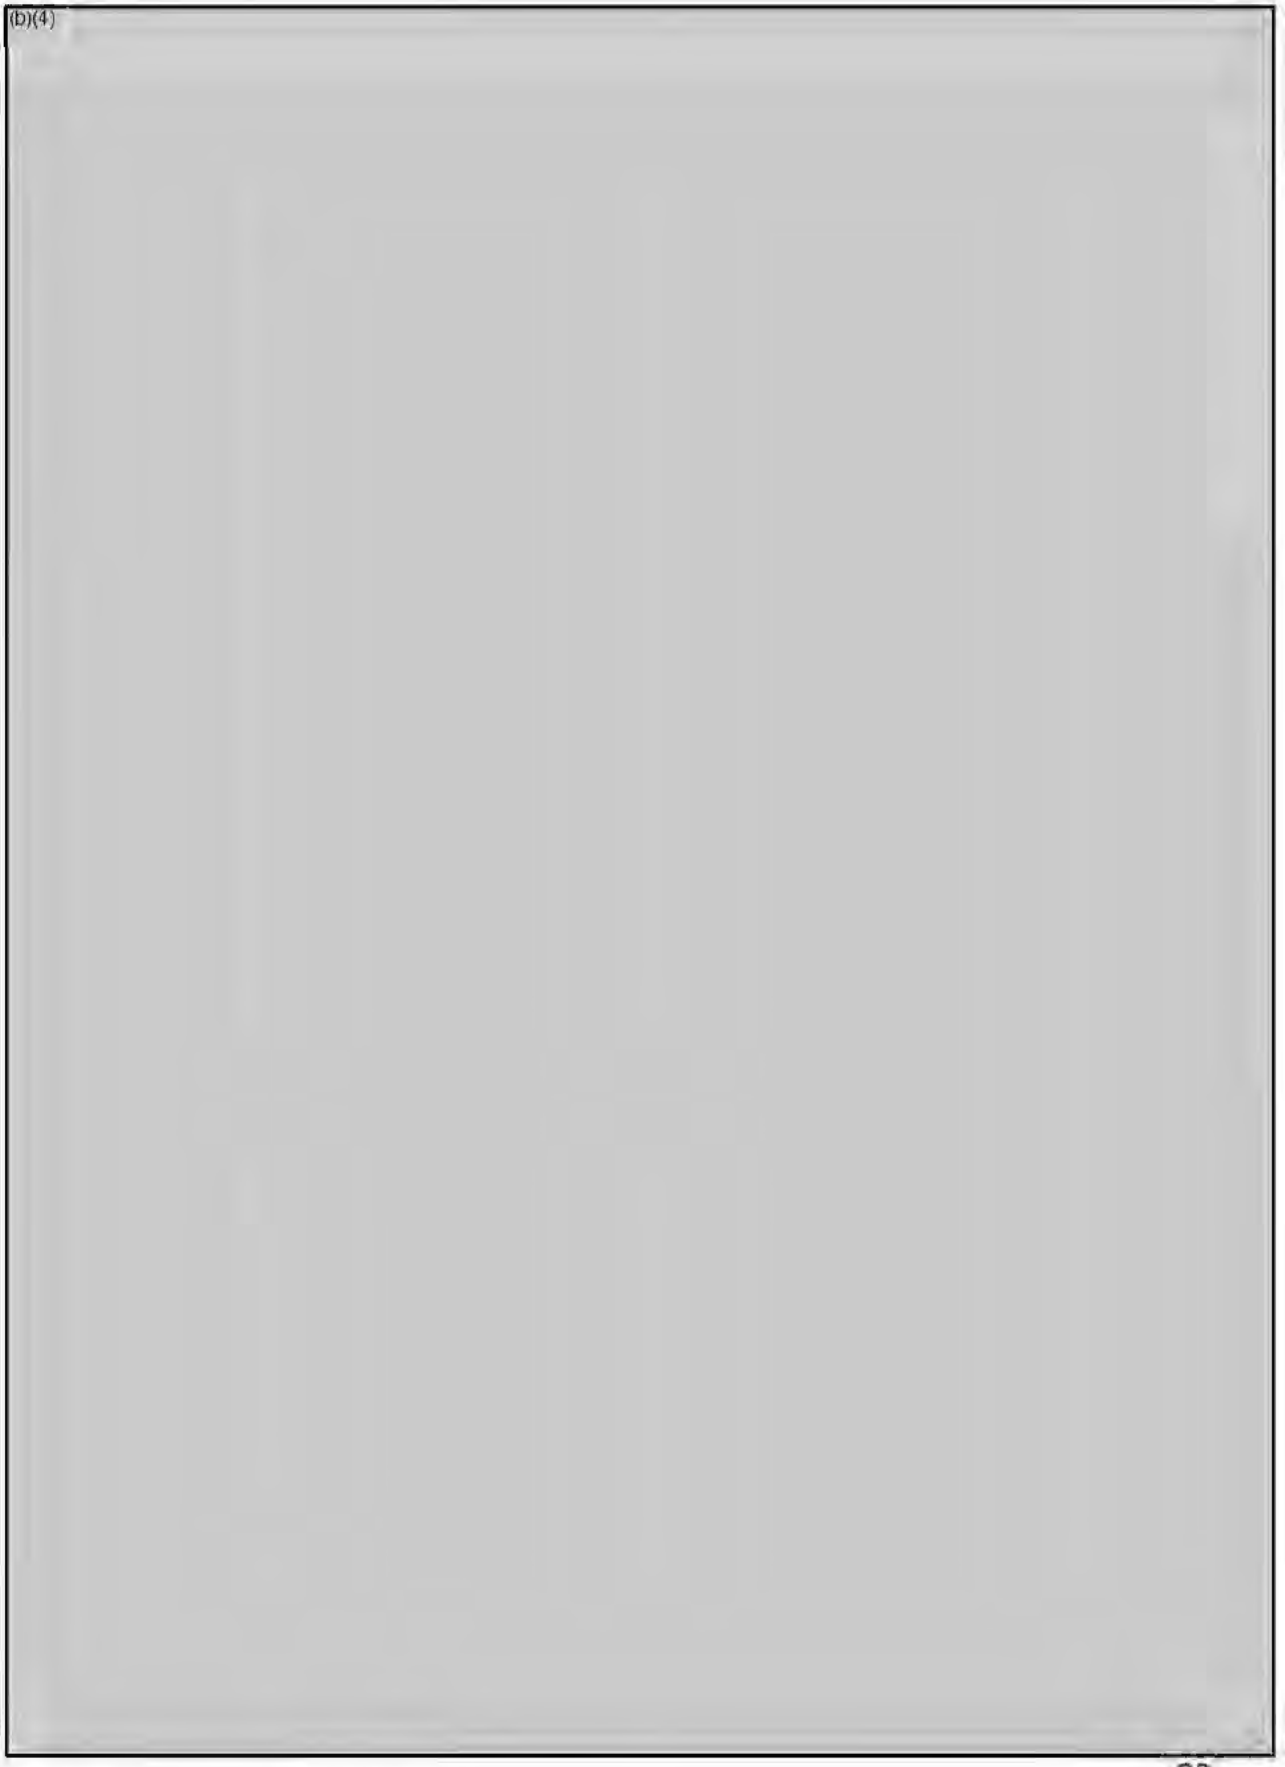
(b)(4)

We will perform a comprehensive battery of behavioral and neurological tests (see Section V.4.4.6. Behavioral Studies) on the (b)(4) rats, the (b)(4) (b)(4) 1 month and 3 months after soman exposure. These tests will evaluate motor, cognitive, mnemonic and emotional abnormalities known to be associated with (b)(4)

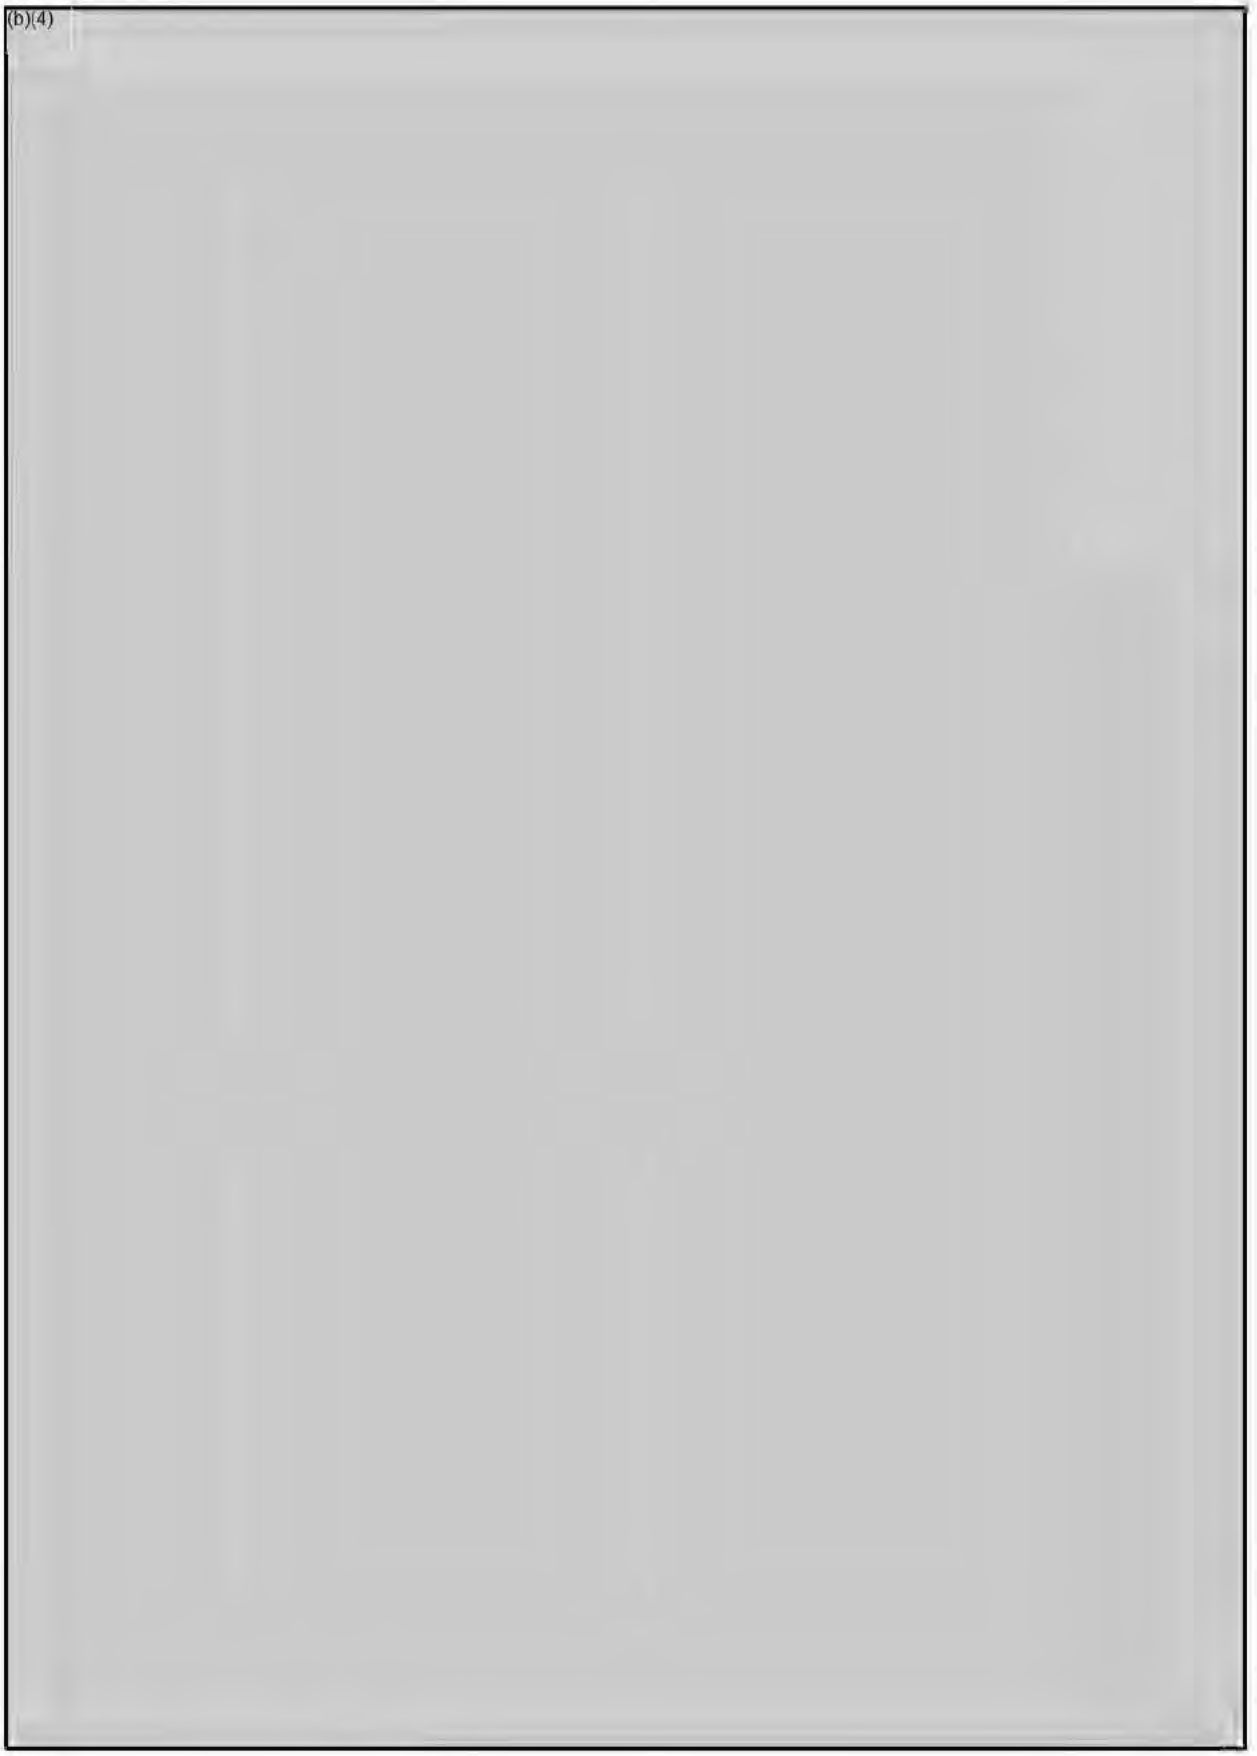
(b)(4) Motor performance will be evaluated using the roto-rod test; performance on this test has been shown to be reduced in rats following (b)(4) (b)(4) Cognitive impairment will be determined using tests for novelty preference in the open field, and mnemonic cognitive processes will be evaluated using the t-maze test, performance in which has also been shown to be affected by soman exposure (32, 78, 79). Finally, emotional behavior will be evaluated by measuring the acoustic startle response/pre-pulse inhibition, and with tests of unconditioned fear (light/dark boxes, elevated plus-maze); increases in these responses have been seen following (b)(4) in rats (25).

(b)(4)

(b)(4)



(b)(4)



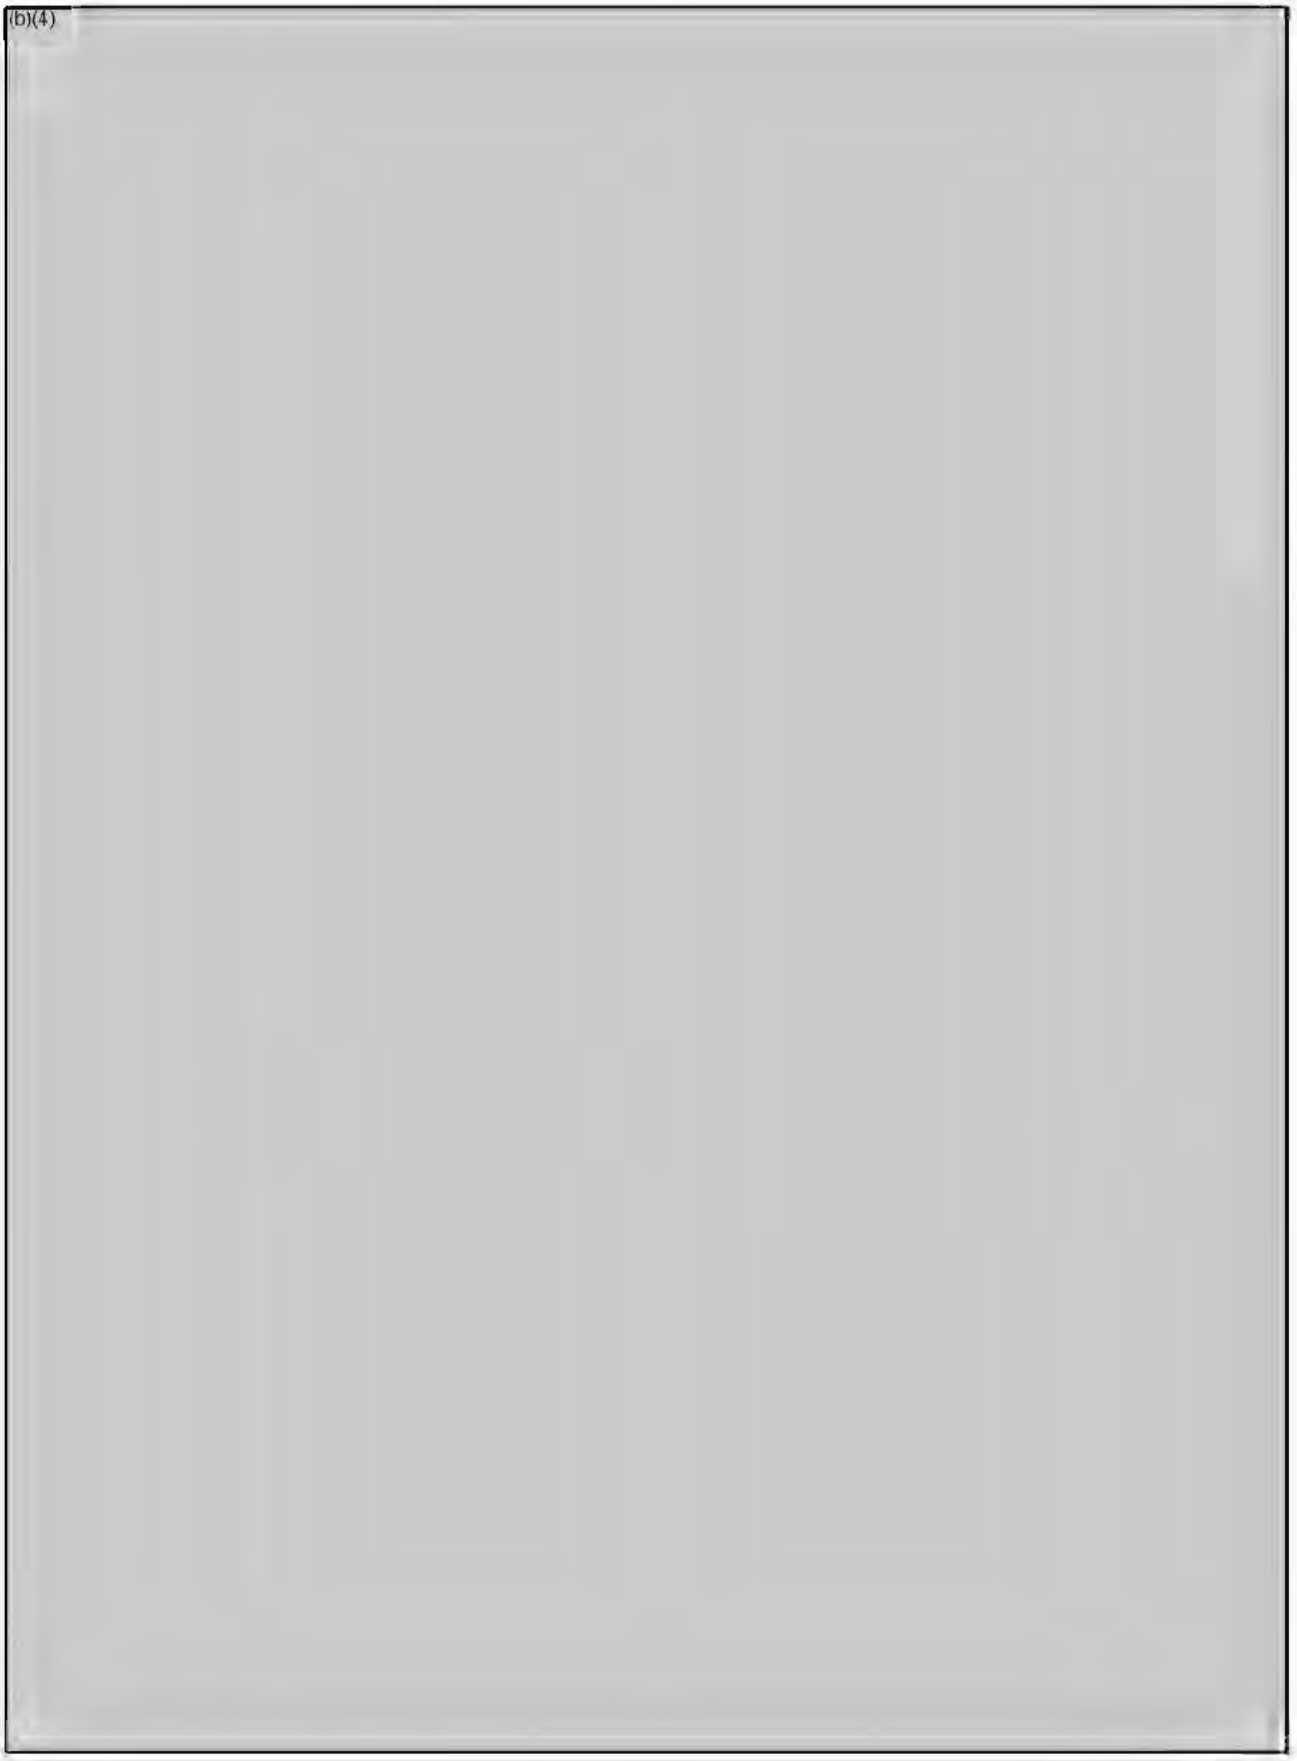
(b)(4)

Immature (7 to 14 days old), and adult (50 to 70 days old) **male and female rats** will be (b)(4) One month or three months after (b)(4) electrophysiological experiments will be conducted in the (b)(4)

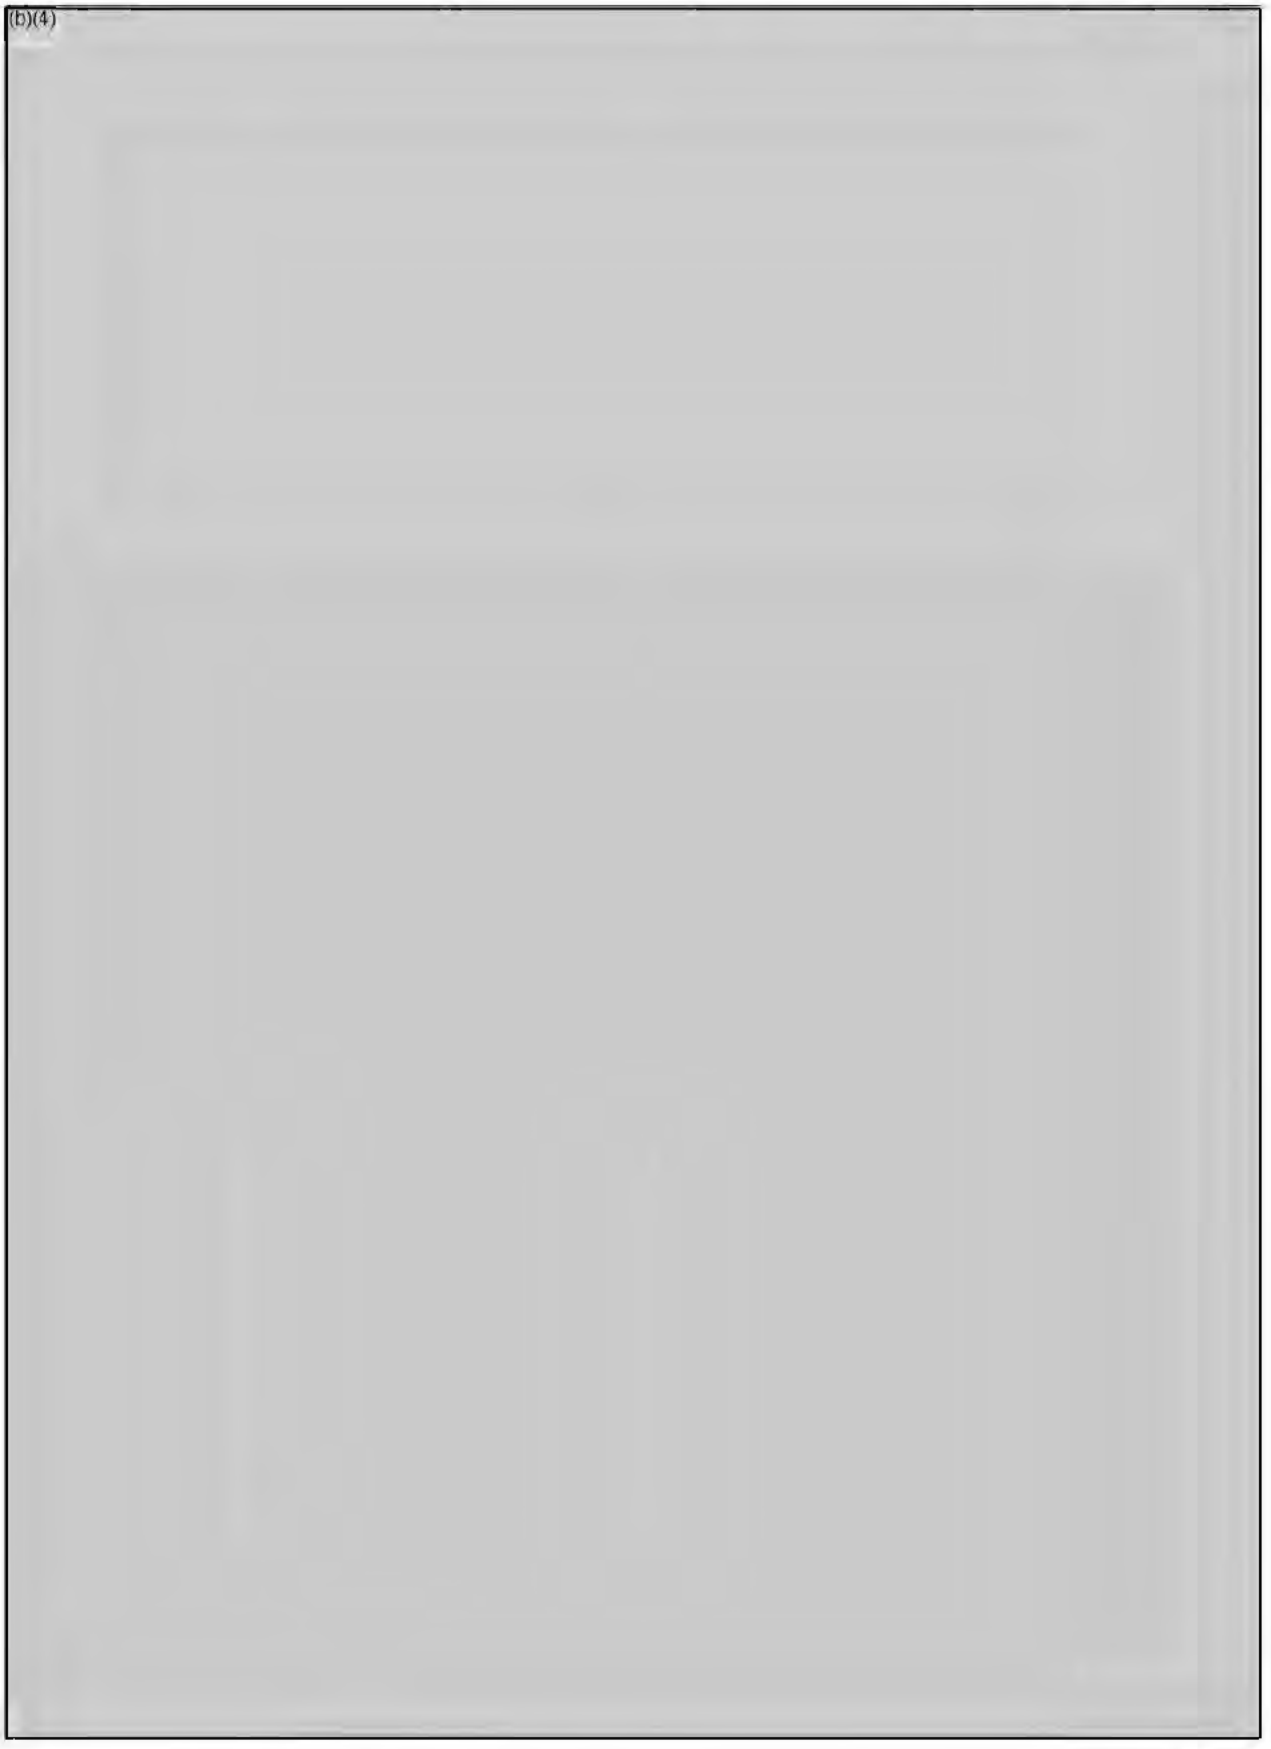
Pathophysiological alterations will be studied in *in vitro* brain slices containing the amygdala and hippocampus and in slices from the prefrontal cortex. These studies will be performed using both extracellular, field potential recording techniques and whole-cell recordings.

(b)(4)

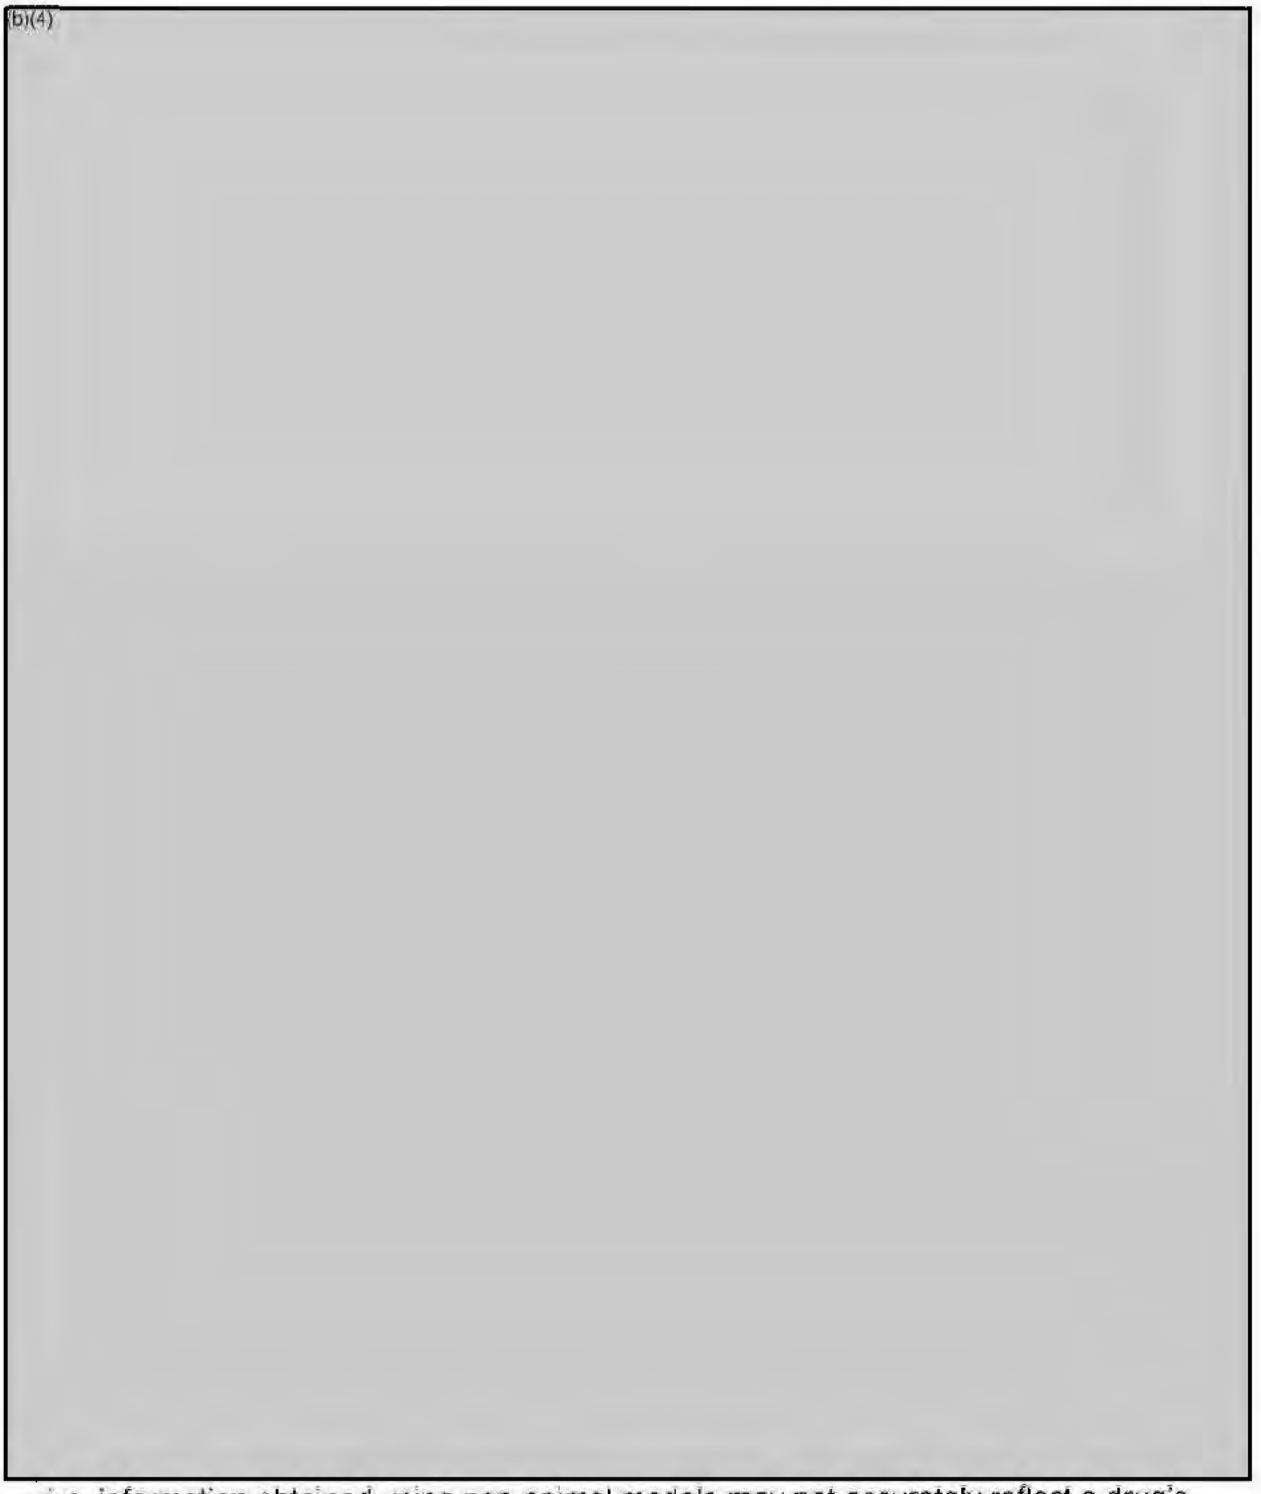
(b)(4)



(b)(4)



(b)(4)



vivo, information obtained using non-animal models may not accurately reflect a drug's action in a whole animal.

V.3.2. Animal Model and Species Justification: Immature (7 to 14 days old), adult (50 to 70 days old), and aged (16 to 20 months old) Male and Female Sprague-Dawley (SD) rats (*Rattus norvegicus*) will be used for these experiments. SD rats have been chosen as a suitable species and animal model for this research because they

have been extensively used in nerve agent research to evaluate new medical countermeasures. Also, the SD rat is a primary model used in studying the pathophysiology of the amygdala, hippocampus, and prefrontal cortex. Consequently, it is helpful to use the same animal to make comparisons with the literature. Rats can provide up to eight 400-µm thick brain slices per animal. By using the SD rats, we can produce high quality slices and thus facilitate and expedite the acquisition of data. The rat brain slice preparation allows stable whole-cell patch clamping recording and various pharmacological manipulations under controlled conditions. Thinner slices can easily be prepared for morphological staining. Lactating surrogate mothers will be required to accompany the rat pups that have not yet been weaned.

V.3.3. Laboratory Animals: Note that all animals used in Experiments 1, 2 and 3A and B will be purchased and received by the principal investigator (b)(6) at USUHS.

		Species #1	Species #2
V.3.3.1.	**Genus & Species**:	*Rattus norvegicus*	
V.3.3.2.	**Strain/Stock**:	Sprague-Dawley (b)(4)	
V.3.3.3.	**Source/Vendor**:	(b)(4)	
V.3.3.4.	**Age**:	7-14 days (males and females) 50-70 days (males and females) 16-20 months (males and females) Adult lactating retired breeders (age to be determined by vendor)	
V.3.3.5.	**Weight**:	Appropriate for age at time of delivery	
V.3.3.6.	**Sex**:	Male and Females for experimental animals Female for lactating surrogate mothers	
V.3.3.7.	**Special Considerations**:	Lactating surrogate mothers (retired breeders from the supplier) will be required to travel with the immature rats that have not yet been weaned and to be housed with pups at USUHS. Single housing is required after EEG surgery on adult and aged rats to prevent animals from interfering with implant healing.	

Single housing is also required after agent exposure when animals may still be sick or debilitated. Animals may be pair-housed until the day of surgery, after which they must be singly housed.

V.3.4. Number of Animals Required (by Species):

(b)(4)

V.3.5. Refinement, Reduction, Replacement (3 Rs):

V.3.5.1. Refinement:
Rats will be anesthetized with isoflurane and reach a surgical plane of anesthesia for restraint purposes before decapitation for preparation of brain slices. All EEG surgery will be performed under appropriate anesthesia and pre-and post-surgical analgesics will be used to relieve pain. Any rat exhibiting signs of pain or impairment beyond that from this model will be euthanized at an early endpoint per paragraph V.4.5.

V.3.5.2. Reduction:
Use of an *in vitro* brain slice preparation in Experiments 3B allows the harvest of multiple brain slices per rat, thus significantly reducing the number of animals needed to obtain the proposed data. Power calculations have been performed to determine the minimum number of rats needed to reach statistical significance for each experiment. If the first 6 animals in *in vivo* treatment groups (Experiments 1, 2 and 3A and B) survive, the remaining 4 animals will not be ordered.

V.3.5.3. Replacement:
Biological response to drug treatment is highly complex; no alternative to animal experimentation is available or practical. We are using a rodent model (rat) versus a

nonhuman primate model. The rat model is the least sentient and smallest animal model we could use for this study and still obtain acceptable results. In addition, we will perform a series of morphological measurements that require a sufficiently large animal to assure that there is sufficient brain mass for multiple samplings. Mice would not be sufficient.

V.4. Technical Methods:

V.4.1. Pain / Distress Assessment:

V.4.1.1. APHIS Form 7023 Information:

In this protocol 288 lactating mothers from Experiments 1, 2, and 3A and B will be available for transfer for training or experimental purposes, or euthanized if they cannot be used (Column B). Six hundred eight (608) male SD rats from Experiment 1 and 3A and B and 608 female SD rats from Experiment 2 and 3A and B will receive an injection of saline instead of nerve agent in combination with (b)(4) and therefore will experience no pain (Column C). Eight hundred (800) male SD rats from Experiment 1 and 3A and B and 800 female SD rats from Experiment 2 and 3A and B will be injected with nerve agent and experience intense seizures. While the drugs/treatments under investigation may reverse some of these signs during certain phases of these experiments, these animals will experience some level of seizure or physical stress and discomfort for some period of time during the experiments and will be included in Column E (Non-alleviated pain).

V.4.1.1.1. Number of Animals:

	Species #1	Species #2
V.4.1.1.1.1. Column C:	(b)(4)	
V.4.1.1.1.2. Column D:	0	
V.4.1.1.1.3. Column E:	(b)(4)	

V.4.1.2. Pain Relief / Prevention:

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization:
For surgical implantation of cortical electrodes for EEG recordings, animals will receive one dose of buprenorphine (0.05 mg/kg s.c.) before any incisions are made. The animals will be anesthetized with isoflurane (3% for induction, 2.0-2.5% for maintenance; with oxygen). Anesthesia will be induced by isoflurane vapor in 100% oxygen in a commercially available induction chamber. Once anesthesia is induced, animals will be transferred to the designated surgery area and anesthesia will be maintained via nose cone. To monitor the depth of anesthesia (including during surgery time) we will test whether the animal has lost its toe pinch (pedal withdrawal) reflex. Prior to incision, animals will receive bupivicaine at electrode placement sites (infusion of surrounding tissue), at a maximum of 0.2 ml within any one animal, and buprenorphine HCl (0.05 mg/kg, s.c.) to assist in post-operative pain management.

Following surgery for implantation of cortical electrodes, animals will receive buprenorphine HCl (0.05 mg/kg, s.c.), which will be given at a minimum one time at the end of the day of surgery, just before close of business. This is in addition to the preemptive dose given prior to surgery. All surgeries should be performed in the AM. Additional doses may be given every 8-12 hours, up to 3 days after the surgery as needed, in consultation with the attending veterinarian.

The buprenorphine dose may be increased, up to a dose of 0.25 mg/kg i.m. or s.c. at each buprenorphine dosing time point, depending on the pain status of the animal. Dose will not be adjusted without approval of the attending veterinarian.

For brain pathology studies, the animals will be anesthetized with 75-100 mg/kg, i.p., sodium pentobarbital prior to euthanasia.

For amygdalo-hippocampal and prefrontal cortex slice preparations, rats will be anesthetized by isoflurane inhalation under a hood until they are non-responsive to toe-pinch, (b)(4)

(b)(4)

*Duplicate citations removed in PubMed/Web of Science bibliography

The references found in this search cited the use of several *in vitro* models, including primary neuronal cultures and acute and organotypic hippocampal slices. The cited studies investigated protection from neurotoxicity, release or uptake of neurotransmitters, gene expression, and electrophysiological effects of ACh stimulation. We will use hippocampal, amygdala, and prefrontal cortex slices obtained from rats in this protocol. None of the other models offer any advantage over the slice preparations we propose to use. None are able to duplicate the behavioral convulsions, electrographic seizures, or brain damage produced in an *in vivo* animal model, which are necessary to evaluate anticonvulsant and neuroprotective drugs.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification:
There is no alternative for inducing brain damage in rats that mimics the damage caused by nerve agents to determine whether a compound is neuroprotective. The only way to determine the neuroprotective efficacy of a putative drug is to cause actual status epilepticus in an animal model to induce damage prior to administration of the neuroprotective compound and to determine the number of surviving neurons.

(b)(4)

(b)(4)

V.4.2. Prolonged Restraint: N/A

V.4.3. Surgery:

V.4.3.1. Pre-surgical Provisions:

A week prior to the experiments described in Experiment 1, 2 and 3A and B, 30%-50% of the animals will be implanted with cortical electrodes for electroencephalogram (EEG) recordings. These EEG recordings will be used to confirm the onset and intensity of behavioral convulsions observed in the rest of the animals. Animals will receive one dose of buprenorphine (0.05 mg/kg s.c.) before any incisions are made. Anesthesia will be induced by isoflurane vapor in 100% oxygen in a commercially available induction chamber. Once anesthesia is induced, animals will be transferred to the designated surgery area and anesthesia will be maintained via nose cone. See Section V.4.1.2.1 Anesthesia/Analgesia/Tranquilization for details.

When the animal is anesthetized, its head will be shaved with a hair clipper. The head will be cleaned with betadine and alcohol, each repeated 3 times alternately. Then the animal will be placed into a stereotaxic frame (appropriate frame size will be used for rats) after treating its pressure points such as ears and nose with lidocaine jelly. A heated pad with thermister-controlled feedback will be put between the animal's body and the base of the stereotaxic frame. Ophthalmic ointment will be applied to the eyes to prevent dryness. The body will be covered with a sterile drape with an opening to expose the head. Prior to incision, animals will receive bupivicaine at electrode placement sites (infusion of surrounding tissue) to assist in pain management. The injection volume will be limited to the minimum required for pain control, to minimize health risks. Care will be taken to avoid systemic effects.

V.4.3.2. Procedure:

The skin will be incised longitudinally along the midline from eye level to the neck level and retracted to the sides with hemostats. The periosteum will be scraped off from the skull. Five stainless steel machine screws (the smallest possible size that provide adequate anchoring) will be used as electrode contact and simultaneous anchoring points for the headpiece that will be built from acrylic cement to secure the female electrode connector in place. The screws will be manually positioned in the frontal or parietal bone plates and one over the cerebellum. The screws will be partially screwed in manually without penetrating the dura mater.

V.4.3.3. Post-surgical Provisions:

Excess cement will be removed from the headpiece to make its edges smooth. If necessary, skin will be sutured at both ends of the incision line. The animal will be released from the stereotaxic frame and placed in a recovery cage on a chemical pocket warmer wrapped in cloth or paper until the animal fully recovers from anesthesia. Alternatively, the animals may be placed in a forced-air recovery chamber warmed to 34 °C. Once fully awake and performing purposeful movements, the animal will be moved back to the holding area. At least 7 days will be allowed for recovery after surgery before any experimentation.

Only the rats that maintain good health following the surgery will be used for experiments. This decision will be jointly made by the animal-care personnel and the investigators. All efforts will be made to provide all animals with the best care possible. Each animal will be individually monitored throughout the study by experienced personnel from our laboratory. We will also closely work with the veterinarian and animal-care staff of the animal facility to ensure that adequate treatment is provided in a timely manner should it be deemed necessary.
After surgery, the animals will be placed in a clean cage provided with a recirculating warm-water veterinary heating pad or in a forced-air recovery chamber warmed to 34 °C to maintain proper body temperature. After recovery from anesthesia (evidence of righting reflex and purposeful movements) the animal will be given at least one dose of an analgesic, buprenorphine HCl (0.05 mg/kg s.c.), for post-operative analgesia, which will be given every 8-12 hours up to 3 days after the surgery. The medication will be administered by the by PI or by qualified PI staff. If necessary, based on consultation with the attending veterinarian, additional buprenorphine may be given as needed. Additional doses of buprenorphine will be given if required, based on assessment of PI and attending veterinarian of animal's condition, which will include assessment of the presence of the following signs of pain/distress: hunching, abnormal gait, abnormal attitude (increased or decreased aggression), inability to move to food/water, excessive porphyrin staining of eyes/nose, shuddering or twitching, unkempt appearance, and vocalization when handled.

Following at least 1 hour on the warming pad or in a forced-air recovery chamber, upon full recovery in which the animal can maintain an upright posture and is ambulatory, the animal will be returned to its holding room cage. Laboratory personnel will provide the care of the animal until full recovery if it has not already occurred. All animals will be checked at least once 30 minutes after return to home cage, to ensure recovery is continuing, and at least once again just prior to the end of the work day to ensure animals are recovering normally. Animals will be examined at least once daily by the PI

staff for one week post-surgery to ensure that no complications occur. Observations will be recorded for each animal in a place that is accessible to the animal care staff (post-surgery cage cards may be used for this purpose). PI staff observations will be separate from routine observations conducted by the animal care staff.

After surgery the animals will be monitored daily and, in case of signs of infection, neomycin will be applied topically.

V.4.3.4. Location:
Surgeries (implantation of electrodes) will be performed at USUHS in LAM, Room (b)(6) Euthanasia and perfusions will be performed in room (b)(6) at USUHS. Euthanization will occur in chemical hoods in (b)(6)

It is anticipated that all of the EEG surgery will be performed at USUHS (LAM).

V.4.4.5. Animal Identification:
Cage cards, headpieces numbered with nontoxic ink. This will be the responsibility of the USUHS research team.

V.4.4.6. Behavioral Studies:
The following procedures will be performed at the USUHS:

Rotarod test: It measures an animal's ability to maintain balance by coordinating movement and making postural adjustments. It also measures the ability to improve these skills with practice. Each rat rotarod treadmill consists of a motor-driven drum with constant speed or accelerating speed modes of operation. The drum (7.0 cm diameter) allows each animal to maintain a suitable grip. It is divided into four test zones (8.9 cm wide) so that up to four animals may be tested at the same time. The device consists of a smooth hard plastic cylinder with concentric circular plastic sides (39.7 cm diameter) to prevent the rat from laterally climbing off the cylinder. Rats are placed on the device facing the wall with the rod rotating in the direction opposite from the animal (so that the rat uses its paws to pace forward and avoid falling off the rod). When a rat falls off the rotating drum (height of 26.7 cm), it breaks a photobeam, stopping the timer associated with that zone. In each trial, the speed of rotation is increased from 0 revolutions per minute (rpm) to 35 rpm for a maximum of 3 or 5 min. The mean duration on the device (based on 3 consecutive trials) is recorded.

Preference for Novelty (Open Field): Testing will be performed in a Plexiglas cage (56cm x 34cm x 20cm) with the floor divided in 18 equal squares. Three identical aluminum cubes will be evenly distributed in the cage in fixed positions. Three other cubes will make up the novel objects. One novel object will be similar to the neutral cubes in that its top will be uneven with tracks making up a square pattern (tactile stimuli). One novel object will be identical with the neutral objects except that a slight smear of cheese will be placed on the side facing the experimenter (olfactory stimuli). The third object will be similar to the neutral blocks except that it will be slightly smaller with uneven sides (visual stimuli). Locomotor activity will be measured using an Omnitech Electronics Digiscan infrared photocell system. One-hour activity measurements are obtained during animals' active or dark cycle.

T-maze: The task is based on the premise that animals have evolved an optimal strategy to explore their environment and obtain food with a minimum amount of effort. The T-maze apparatus is made of white Perspex. The runway of the maze is 80 cm long and its side arms are 30 cm long. The width of the maze is 10 cm and the walls are 10 cm high. A guillotine door is used to open the start box and two additional doors are used to block access to the arms, as necessary. Distinctive extra-maze cues are placed in the surrounding walls. Habituation sessions will be performed during 2 consecutive days, allowing free exploration of the maze for 15 min each day. Each rat will receive 10 precision pellets of food, scattered evenly throughout the maze, on each of the habituation sessions. During training each trial consists of a sample run and a test run. In the sample run, rats will be placed at the start position and required to make a forced choice by blocking the access to one of the arms. Two pellets will be positioned at the end of the open arm. The rats will be allowed to eat the pellets and will be immediately placed in a holding cage for 10 s before being returned to the maze for the test run. In the matching-to-place (MTP) and the non-matching-to-place (NMTP) versions of the task the reinforced choice in the test run is either the previously visited arm (MTP) or the arm opposite (NMTP). Each rat will perform 1 block of 10 trials each day. The sequence of arm visits (sample runs) will be randomized for each experimental subject.

Acoustic Startle Response: ASR testing will be conducted with a Startle Response Acoustic Test System (Coulbourn Instruments, PA). This system consists of a weight-sensitive platform in a sound-attenuated chamber. The animals' movements in response to stimuli will be measured as a voltage change by a strain gauge inside each platform and will be converted to grams of body-weight change following analog to digital conversion. These changes will be recorded by an interfaced computer as the maximum response occurring within 200 ms of the onset of the startle-eliciting stimulus. All acoustic stimuli will be administered by an amplified speaker mounted 24 cm above the test cage. During testing, animals will be individually placed in holding cages (14.5 × 7 × 6.5 cm) that are small enough to restrict extensive locomotion, but large enough to allow the subjects to turn around and make other small movements. These will then be placed on the weight-sensitive platform. Following placement of the animal into the chamber, the chamber lid will be closed, leaving the subject in darkness. A three-minute adaptation period occurs in which no startle stimuli is presented. Startle stimuli consist of 120 dB Sound Pressure Level (unweighted scale; re: 0.0002 dynes/cm2) noise bursts of 20 msec duration. In addition to the 120 dB stimuli, the 110 dB level will also be used for comparison to insure that the 120 dB stimulus level not only will meet a response

threshold but also will not reach a leveling out of the maximum response. Thus confirmed, results will be given for the 120 dB level only. Decibel levels will be verified by a Radio Shack Sound Pressure Machine Model 2800 (Provo, UT). Each stimulus will have a 2-ms rise and decay time such that onset and offset will be abrupt, which is a primary criterion for startle. Each trial type (120 dB, 110 dB, or no stimulus) will be presented eight times. Trial types will be presented at random to avoid order effects and habituation. Inter-trial intervals will range randomly from 15 to 25 s.

First day:
Rats will be tested on the rotorod and light-dark task/open field behavior test in the morning of the first day and they will be tested in the T-Maze test in the afternoon of the first day.

Second day:
On the second day they will be acclimated to the acoustic startle response equipment.

Third day:
On the third day rats will be acclimated to the Open Field equipment and 30 minutes after that they will have a second acclimation to the Acoustic Startle response.

Forth day:
On the fourth day they will be tested on the Open Field test and 30 minutes after that they will be tested on the Acoustic Startle Response.

Each rat in Experiment 3 will be given two rounds of 4 days of behavioral testing as described on page 32.

V.4.4.7. Other Procedures:
On the day of exposure to the nerve agent, the animals will be connected to recording leads via the connection plug on their heads. Brain EEG activity will be recorded while they are in cylindrical plastic recording chambers, 16" in diameter and 26" high with Iso-pad bedding on the floor, where they are free to move about. The period of confinement in the recording chambers will not exceed 3 hours on the experimental day or 1 hour on the day after.

The following 5 procedures will be performed at the USUHS:

Histology: Twenty-four hours, 1 week, 1 month, or 3 months after soman exposure, the animals will be deeply anesthetized using 75-100 mg/kg, i.p., sodium pentobarbital, and transcardially perfused with PBS (100 mL) followed by 4% paraformaldehyde (250 mL) in PBS. The brains will be removed and post-fixed overnight at 4° C, then transferred to a solution of 30% sucrose in PBS for 72 hours, and frozen with dry ice before storage at –80° C until sectioning. Sections containing the rostro-caudal extent of the BLA, the hippocampus, and the prefrontal cortex will be cut at 40 µm on a sliding microtome. One series of sections will be mounted on slides (Superfrost Plus; Daigger, Vernon Hills, IL) in PBS for Nissl staining with cresyl violet. An adjacent series of sections will also be mounted on slides for Fluoro-Jade C staining.

Fluoro-Jade C staining (Histo-Chem, Jefferson, AR) will be used to identify irreversibly degenerating neurons in the amygdala, the hippocampus, and the prefrontal cortex. Mounted sections will be air-dried overnight and then immersed in a solution of 1% sodium hydroxide in 80% ethanol for 5 min. The slides will then be rinsed for 2 min in 70% ethanol and 2 min in deionized water (dH20), and incubated in 0.06% potassium permanganate solution for 10 min. After a 2-min rinse in dH20, the slides will be transferred to a 0.0001% solution of Fluoro-Jade C dissolved in 0.1% acetic acid for 10 min. Following three 1-min rinses in dH20, the slides will be dried on a slide warmer, cleared in xylene for at least 1 min and coverslipped with DPX (Sigma). Fluoro-Jade C stained sections undergo tissue shrinkage, so they cannot be used for stereological quantification.

Stereological quantification: Design-based stereology will be used to quantify the total number of neurons on Nissl-stained and GAD67-stained sections. Sections will be viewed with a Zeiss Axioplan 2ie (Oberkochen, Germany) fluorescent microscope with a motorized stage, interfaced with a computer running StereoInvestigator 7.5 (MicroBrightField, Williston, VT). Estimated totals will be determined using the fractionator probe, and all sampling will be done under a 63× oil immersion objective.

Glutamic acid decarboxylase-67 (GAD67) immunohistochemistry: Our previous studies have demonstrated delayed loss of GABAergic interneurons in the BLA (31, 86). To determine what proportion of the lost neurons are GABAergic interneurons, we will combine stereological quantification with GAD67 immunohistochemistry. To label GAD67-immunoreactive neurons, a 1-in-5 series of free-floating sections will be collected from the cryoprotectant solution, washed three times for 5 min each in 0.1 M phosphate buffered saline (PBS), then incubated in a blocking solution containing 10% normal goat serum (NGS; Chemicon, Billerica, MA) and 0.5% Triton X-100 in PBS for one hour at room temperature. The sections will then be incubated with mouse anti-GAD67 serum (1:1000, MAB5406; Chemicon), 5% NGS, 0.3% Triton X-100, and 1% bovine serum albumin, overnight at 4°C. After rinsing three times in 0.1% Triton X-100 in PBS, the sections will be incubated with Cy3-conjugated goat anti-mouse antibody (1:1000; Jackson ImmunoResearch, West Grove, PA) and 0.0001% DAPI (Sigma-Aldrich, St. Louis, MO) in PBS for one hour at room temperature. After a final rinse in PBS, sections will be mounted on slides, air dried for 30 min, then coverslipped with ProLong Gold antifade reagent (Invitrogen, Grand Island, NY).

Brain slice electrophysiology: Coronal slices containing the amygdala and the hippocampus, and slices containing the prefrontal cortex will be prepared from experimental and control rats, 1 month and 3 months after soman exposure. The rats will be anesthetized with isoflurane and then decapitated. The brain will be rapidly removed and placed in ice-cold artificial cerebrospinal fluid (ACSF) composed of (in mM) 125 NaCl, 2.5 KCl, 2.0 $CaCl_2$, 2.0 $MgCl_2$, 25 $NaHCO_3$, 1.25 NaH_2PO_4, and 22 glucose, bubbled with 95% O_2 and 5% CO_2 to maintain a pH of 7.4. Coronal slices containing both the hippocampus and the amygdala, and coronal slices containing the prefrontal cortex will be cut at 400 µm with a Vibratome (Series 1000; Leica Microsystems, Bannockburn, IL). Slices will be kept in a holding chamber containing oxygenated ACSF at room temperature, and recordings will be initiated ≥1 hr after slice preparation. For whole-cell recordings, slices will be transferred to a submersion-type

recording chamber, where they will be continuously perfused with oxygenated ACSF, at a rate of 3–4 ml/min. Neurons will be visualized with an upright microscope (Nikon Eclipse E600fn; Nikon, Tokyo, Japan) using Nomarski-type differential interference optics through a 60× water immersion objective. Tight-seal (>1 GΩ) whole-cell recordings will be obtained from the cell body of pyramidal-shaped neurons in the BLA region, the pyramidal layer in the CA1 hippocampal area, and the layer III and V pyramidal cells of the prefrontal cortex. Patch electrodes will be fabricated from borosilicate glass to have a resistance of 1.5–5.0 MΩ when filled with a solution containing (in mM) 135 Cs-gluconate, 10 MgCl2, 0.1 CaCl2, 1 EGTA, 10 HEPES, 2 Na-ATP, 0.2 Na3GTP, pH 7.3 (285–290 mOsm). Neurons will be voltage-clamped using an Axopatch 200B amplifier (Molecular Devices, Sunnyvale, CA); some recordings will be obtained in the current-clamp mode. Access resistance (5–24 MΩ) will be regularly monitored during recordings, and cells will be rejected if resistance changes by >15% during the experiment. The signals will be filtered at 2 kHz, digitized (Digidata 1322A; Molecular Devices), and stored on a computer using pClamp9 software (Molecular Devices). Analysis of recorded currents will be performed using pClamp9 software and the Mini Analysis Program (Synaptosoft, Inc., Leonia, NJ). Extracellular field potentials will be obtained from the BLA, while stimulus pulses are applied to the external capsule, the CA1 hippocampal area, while stimulation is applied to the Schaffer collaterals, and layer III and V of the prefrontal cortex slices, while stimulation is applied to the subcortical white matter. Recording electrodes will be filled with ACSF (resistance: 4 to 7 MΩ). To determine alterations in neuronal and network excitability, whole-cell recordings will be performed in the current-clamp mode to determine changes in the intrinsic excitability parameters of pyramidal cells in the BLA region of the amygdala, the CA1 hippocampal area, and layers III and V of the prefrontal cortex, in slices obtained from the experimental and control groups, at 1 and 3 months following exposure to soman (or saline, for the controls). The following parameters will be measured: resting membrane potential, neuronal input resistance, action potential threshold, action potential characteristics, spontaneous firing, and firing characteristics in response to depolarizing current pulses passed via the recording electrode. Whole-cell recordings in the voltage-clamp mode will also be performed to determine differences, among experimental and control groups, in spontaneous GABAergic and glutamatergic activity in the BLA region of the amygdala, the CA1 hippocampal area, and layers III and V of the prefrontal cortex. These experiments will provide an insight into soman-induced alterations in the intrinsic excitability of pyramidal neurons in the BLA, the CA1 region, and the prefrontal cortex, as well as alterations in the basal, spontaneous activity of the two major neurotransmitter systems that control neuronal network excitability (the GABAergic and the glutamatergic system), and the extent to which the [(b)(4)] [(b)(4)] administered 30 or 60 min after soman exposure prevent these alterations. For alterations in synaptic plasticity, we will test the hypothesis that soman-induced seizures and the resulting neuronal damage alter synaptic plasticity in the amygdala, the hippocampus, and the prefrontal cortex, and that termination of the seizures by administration of the [(b)(4)] will minimize these alterations. Synaptic plasticity will be studied by investigating the characteristics of long-term potentiation (LTP) of synaptic transmission, as we have done previously in both amygdala slices (3) and cerebral cortex slices (2a). In brain slices obtained from rats from experimental and control groups, sacrificed 1 or 3 months after exposure to soman (or saline, for the control groups), field potentials and compound EPSCs will be recorded in the BLA, the

CA1 area, and in the prefrontal cortex in response to electric stimulation of the external capsule, the Schaffer collateral/commisural pathway, and the subcortical white matter, respectively. Because LTP is considered to be the cellular mechanism underlying learning and memory, these experiments may provide an explanation for the memory impairment and other cognitive deficits that result from exposure to nerve agents, and will determine if the (b)(4) can prevent alterations in synaptic plasticity by soman.

Animal monitoring: Animals will be examined after return to their home cage, approximately 30 minutes after return, and once again that day near end of the work day by the USUHS research team. Animals will be checked at least once daily for one week post-exposure by the USUHS PI and staff. Observations will be recorded somewhere accessible to animal care staff. USUHS PI and staff observations for specific signs related to surgery will be in addition to routine observations conducted by the animal care staff.

(b)(4)

(b)(4),(b)(6)

V.4.4.8. Tissue Sharing:
Tissues not used in this study may be made available to other investigators as required.

V.4.5. Study Endpoint:
For **Experiments 1, 2, and 3A and B** the endpoint is euthanasia of the male and female rats for neuropathological studies, preparation of brain slices, or at the end of the behavioral experiments, within 4 months of receipt at USUHS. The study endpoint for the surrogate mothers is the time when the pups are weaned or removed for experiments.

(b)(4)

Early Endpoint: Any of the following will represent a reason for early euthanasia: inability to ambulate or reach food or water, persistent seizures, persistent tremors, self mutilation, continuous circling, or persistent labored respiration or gasping, loss of 20% of weight below baseline, prostration/inactivity for up to 24 hours, or a significant decline in vital signs. These signs, if observed by animal facility personnel and no study personnel can be reached, may be taken by the veterinarian as cause for euthanasia. Some behavioral changes may be caused by nerve agent-induced seizures and will not represent early endpoints: lethargy, weakness, inability to walk straight and uncertain

ambulation (as long as it does not interfere with the animal's ability to eat and drink), intermittent abnormal breathing pattern.

V.4.6. Euthanasia:
If any of the experimental animals develop serious complications due to the agent exposure and/or associated treatments while at USAMRICD, the animal may be euthanized early with an overdose of pentobarbital (>75 mg/kg, IP) or carbon dioxide administered from a cylinder upon consultation between the PI and the attending veterinarian. Cervical dislocation will be used to confirm death by CO2.

For brain pathology studies, at USUHS the animals will be anesthetized with 75-100 mg/kg, i.p., sodium pentobarbital, until a surgical plane of anesthesia is reached (non-response to strong toe-pinch) and then exsanguinated via perfusion with normal saline followed by 4% paraformaldehyde.

For brain slice preparations, rats will be anesthetized with isoflurane inhalation under a chemical fume hood and euthanized by decapitation. Each animal will be placed in a transparent chamber containing a gauze pad saturated with 1 mL of isoflurane. A false bottom will be placed over the gauze pad to prevent the animal from contacting the isoflurane. An airtight lid will be placed on the cage and when the animal has lost its toe pinch (pedal withdrawal) reflex and eyelid blink (palpebral) reflex, and is immobilized, it will be removed from the cage and decapitated with a guillotine. Alternatively, the animal may be anesthetized in a commercial induction chamber with isoflurane vapor in 100% oxygen from a vaporizer.

Following the collection of tissues the remaining carcass will be disposed of IAW the most recent version of VMSB SOP VM-08-301, "Animal Euthanasia."

Comments on the use of decapitation: The guillotine will be maintained in a sharpened condition to ensure rapid and clean decapitation. In the past, one guillotine has been effective for approximately 200 rat decapitations without sharpening. Commercial sharpening will be performed after every 200 procedures or sooner if needed to ensure continued sharpness. The PI has utilized guillotines in two other protocols as co-investigator and three as PI and is proficient in their use. Any other personnel on this protocol will not assist until they have been trained in the use and safety considerations by the PI and are proficient. Decapitation is preferred over other euthanasia procedures because it minimizes residual medications that might affect neuronal responses to stimulation.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol.

The rats will be maintained under an AAALAC accredited animal care and use program. They will be acclimated upon arrival for 5 days. Animals will be housed in an approved animal holding room after release from acclimation. They may be pair-housed but must

be individually housed post-surgery to ensure no interference with the surgical sites. Food and water will be freely available except during the exposure period. The veterinary staff will provide daily checks of general health and provisions of food and water.

(b)(4)

V.5.1.1. Study Room:

Building(s) (b)(6) Room Number(s) (b)(6)

V.5.1.2. Special Husbandry Provisions:

Food Restriction: Yes _____ No X

Fluid Restriction: Yes _____ No X

V.5.1.3. Exceptions: (b)(4)

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care:

The PI or research staff will observe the rats at least twice a day following all procedural manipulations. The veterinary staff will observe the rats at least once a day for general health and husbandry condition. Any rat displaying any other signs of pain, distress or illness will be evaluated by the PI and/or attending veterinarian and, if necessary, euthanized as previously described.

(b)(4)

V.5.2.2. Emergency Veterinary Medical Care: All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays.

If any rat experiences non-study related distress or pain prior to the study, the PI or co-PI will consult the attending veterinarian. If necessary, the rat will be treated or euthanized as directed by the attending veterinarian. Euthanized rats will not be entered into the study and additional rats may be requested as replacements.

(b)(4)

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: Except as indicated below, all animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents; balls, toys and food enrichment treats for large animal species.

(b)(4)

V.5.3.2. Enrichment Restrictions:
Animals must be individually housed post-surgery to ensure no interference with the surgical sites and implanted electrodes. Also, after exposure to soman rats must be individually housed as the animals may be experiencing seizures as a result of the nerve agent exposure.

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
Animal handling, agent handling, injections,	(b)(6)	PhD in neuroscience. 20+ yr rodent handling,	Investigator training Dr (b)(6) has performed hundreds

anesthesia, EEG surgery, guillotine usage, euthanasia, electrophysiology	(b)(6)	surgery, tissue dissection, electrophysiological experimentation. Over 200 rats euthanized via guillotine. 6 years performing EEG electrode surgery in rodents.	of surgeries, euthanasia, and anesthesia.
Animal handling, agent handling, injections, anesthesia, EEG surgery, guillotine usage, euthanasia, electrophysiology		PhD in physiology 30+ yr animal handling, injections, surgery, tissue dissection, electrophysiological experimentation. Over 200 rats euthanized via guillotine.	Investigator training Small animal handling workshop 30+ years experience and on-the-job training. Dr. (b)(6) was last trained at USAMRICD on November 1990.
Animal handling, anesthesia, EEG surgery, guillotine usage, euthanasia, perfusions, electrophysiology		PhD in neuroscience. 20+ yr rodent handling, surgery, tissue dissection, and electrophysiological experimentation. Over 200 rats euthanized via guillotine	Dr (b)(6) was retrained as an animal investigator at USUHS in 2007. 20+ years experience and on-the-job training, anesthesia, euthanasia, tissue samples, small animal surgery, perfusions, electrophysiological experimentation.
Animal handling, injections, perfusion, histological preparation, neuropathology		PhD in neuroscience More than 15 years of experience in small animal handling, injections, perfusion, histological techniques, and assessment of neuropathological damage	Investigator training in small animal handling and experimentation, including behavioral tests.
Animal handling, agent handling,		PhD in physiology 20+ yr animal	Investigator training Small animal

injections, anesthesia, EEG surgery, guillotine usage, euthanasia, electrophysiology		handling, injections, surgery, tissue dissection, electrophysiological experimentation. Over 200 rats euthanized via guillotine.	handling workshop 20+ years experience and on-the-job training

VII. BIOHAZARDS/SAFETY:

XCSM agent, decontaminated XCSM agent waste, chemicals, and hazardous waste used in this protocol will be handled in accordance with all applicable state and federal guidelines, regulations, and standing operating procedures.

Use of XCSM: The laboratories follow the standard operating procedures for the use and disposal of XCSM agents, as described IAW the latest version of SOP# 87-201-RS-01, SOP# 87-335-VA-12, and APGR 200-60. These include initial and quarterly monitoring, as well as daily checks, of hood safety.

Use of 4% paraformaldehyde: All operators using paraformaldehyde must wear proper personal protection equipment, i.e., gloves, safety glasses, lab coat, and they will also use a portable chemical hood.

Minimal PPE for animal handling includes nitrile gloves, mask worn in the slung position or readily available, safety glasses with sideshields or goggles, and fully buttoned lab coat. Double gloves will be worn during agent exposure. All agent work will be done in a certified chemical fume hood in a laboratory that has been appropriately permitted IAW USAMRICD Memorandum 385-6.

Waste anesthetic gas (isoflurane) will be scavenged either by evacuation into a chemical fume hood or by extraction with a filter system in a recirculating air cleaning device (Extract-All system, VetEquip Inc., Pleasanton, CA).

VIII. ENCLOSURES:

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

(b)(6) _____ 02/15/2015

Principal Investigator Signature Date

G. Training: The following personnel will attend the next USUHS Investigator/Animal User Training Course:

_____ _____

_____ _____

H. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely, "Responsibility" for implementing animal use alternatives where feasible and conducting humane and lawful research.

(b)(6) _____ _____

Principal Investigator Signature Date

I. Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL or WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment

MEMORANDUM FOR DR (b)(6) DEPARTMENT OF ANATOMY, PHYSIOLOGY, AND GENETICS

SUBJECT: IACUC Approval of Protocol – Initial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on September 10, 2015:

Animal Protocol Title: (b)(4)
(b)(4)

USUHS Protocol Number: (b)(6)

Expiration Date: September 9, 2018

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. NON-TECHNICAL SYNOPSIS:

Every year in the U.S., it is estimated that 1.4 million people are hospitalized with a brain injury.[1] Among U.S. military personnel, incidence of depression, PTSD, suicide risk, and TBI symptom severity are all significantly increased as the number of TBIs sustained increases.[2] Alterations in brain energy metabolism, local neuroinflammation, and fluid balance are among the mechanisms implicated for contributing to repeated TBI-related adverse outcomes. Therefore, a subsequent injury after an initial TBI is associated with severe cumulative consequences.

Recently, it has been determined that the adaptive immune system can develop immunological memory to CNS injury and activate production of autoantibodies with pathogenic potential. Studies have detected autoantibodies in biofluids from individuals with CNS injury as well as from animal subjects in TBI preclinical models. However, the contribution of immunological memory responses after repeated TBI events has not been defined. **Our goal in this project is to determine whether TBI establishes immunological memory and whether a repeated injury results in a secondary adaptive immune response.**

T and B lymphocytes are primary components of the adaptive immune system, yet the role of lymphocytes in TBI is not well understood. Evidence in other CNS injuries suggests that T and B cells play significant roles in post-traumatic inflammation, degeneration, or repair. Since T and B lymphocytes have both potential neuroprotective and neuropathogenic roles, elucidating the response of the adaptive immune system to TBI is needed to better understand the mechanisms of repeated TBI. Modulating the immune system after TBI may innovate treatment strategies for improved recovery after TBI. **Our hypothesis is that an initial TBI results in immunological memory and that a subsequent TBI potentiates adaptive immune alterations.** To test this hypothesis, we will complete experiments for the following specific aims:

Aim 1: Determine adaptive immune components that are altered in a murine model of repeated TBI. The changes in adaptive immune system components after TBI are not well defined. We will profile lymphocyte populations by flow cytometry to determine whether memory cell populations are altered. Expression analysis of

lymphocyte populations will also be accomplished to detect transcripts associated with immunological memory responses.

Aim 2: Determine the status of adaptive immune repertoire alteration as a function of autoantibody presence. Studies have detected autoantibodies in subjects after CNS injury and TBI. The level and nature of autoantibodies after repeated TBI has not been defined. We will measure serum autoantibody levels from TBI subjects using 1-dimensional gel and ELISA-based methodologies. Clonotypic enrichment in lymphocyte repertoire will be profiled by sequencing receptor immunoglobulins.

Aim 3: Demonstrate CNS-directed lymphocyte proximity to the brain after repeated TBI. The blood-brain barrier establishes immunoprivilege to mitigate self-reactive responses to host tissue. CNS antigen-mediated responses and lymphocyte chemotaxis to the brain after TBI may initiate autoimmune reactions. We will determine the immune and inflammatory status of the choroid plexus to assess its modulating role of lymphocyte populations in the CNS after TBI. Furthermore, we will analyze T cell receptor repertoire status of the choroid plexus to detect if repeated brain injury results in increased infiltration of CNS-specific lymphocyte populations to the brain.

II. BACKGROUND:

II.1. Background:

It is estimated that 1.4 million people are hospitalized with a brain injury every year in the United States,[1] which does not include an estimated additional 3.8 million untreated concussions.[3] Among U.S. military personnel, incidence of depression, post-traumatic stress disorder (PTSD), suicide risk, and TBI symptom severity are all significantly increased as the number of TBIs sustained increases.[2] In other words, sustaining more than one TBI is associated with severe cumulative consequences. We are interested in better understanding the collective longer-term effects of TBI and repeated TBI by focusing on the adaptive immune system. A central characteristic of the adaptive immune system is the development of immunological memory, or the capacity of the immune system to remember an antigen encounter via activated T and B cells and to rapidly react to the same antigen in a later encounter. Better understanding the role of immunological memory in TBI may help uncover the basis for cumulative damage from repeated TBIs.

Following a moderate or severe brain injury, necrotic cell death causes the release of damage-associated molecular patterns (DAMPs), a.k.a. alarmins, into the extracellualar space. Examples of DAMPs include high-mobility group box-1 (HMGB1) protein, mitochondrial DNA, and N-formyl peptides. It is known that TBI patients often have systemic lung inflammation, and CSF levels of HMGB1 are markedly increased in children after severe TBI.[4] Recently, evidence suggests that TBI causes lung inflammation through the action of HMGB1 protein and the receptor for advanced glycation end products (RAGE).[5] While mice subjected to CCI injury had systemic hypoxia, acute lung injury, pulmonary neutrophilia, and decreased ability of lung expansions compared to control animals, RAGE knockout mice had total attenuation of all these symptoms after TBI.[5] The theory that TBI can cause the release of DAMPs like HMGB1 which can then cause peripheral tissue inflammation and damage is gaining validity. It is not a far leap to also assume that these DAMPs can also cause changes to the adaptive immune system and particularly, changes in immunological memory.

The pathophysiology of TBI varies enormously, but often, TBI induces a metabolic crisis in the CNS to maintain neuronal membrane potentials and ion balances.[6] Alterations in brain energy metabolism, local neuroinflammation, and fluid balance are among the mechanisms implicated for contributing to repeated TBI-related adverse outcomes. Numerous studies have observed immediate activation and recruitment of the innate immune system following TBI, comprised in part by brain microglia, peripheral macrophages, and neutrophils. While early activation of innate immunity is beneficial to injury outcome, late and sustained activation is suggested to be deleterious. Neutrophils can be toxic to vulnerable neurons, and along with monocytes can exacerbate cerebral edema and brain tissue damage in rodent models of stroke and TBI.[7-10] In fact, the magnitude of inflammatory cell recruitment correlates to the loss of neural tissue after TBI.[11] While chronic inflammatory responses are correlated with poor pathology after TBI, it is unclear if adaptive immune components contribute to long-term neuroinflammation after TBI.

Works in other CNS injuries make it clear that T and B lymphocytes play significant roles in post-traumatic inflammation, degeneration, or repair. After spinal cord injury (SCI), lymphocytes may be detrimental to recovery. In recombination-activating gene (rAG) 2-deficient mice that lack both T and B lymphocytes, locomotor recovery was improved following compression SCI, and recovery was associated with more monoaminergic axons caudal to the injury site.[12] In another study of moderate contusion SCI, B-cell knockout mice that lack mature B cells but have functional T cells had improved Basso Mouse Scale locomotor scores, decreased lesion volume, and lower levels of IgM and IgG in CSF.[13] Additionally, in a cerebral ischemia-reperfusion study of male severe combined immunodeficiency (SCID) mice (that lack both T and B cells), the animals developed 40% smaller infarct volume 90 minutes after focal ischemia and 22 hours reperfusion compared with wild type mice.[14] Other studies found around 60% smaller infarct volumes and improved functional outcomes 24-72 hours in $Rag1^{-/-}$ mice that lack T and B lymphocytes.[15,16] Activated B and T cells are also found to infiltrate and accumulate in the injured spinal cord where they form germinal center like clusters of cells that are normally found in the spleen and lymph nodes.[17] While these studies demonstrate a correlation between T & B cell activity and poor outcome, there are other studies that demonstrate a beneficial role of lymphocytes after CNS injury.

Autoimmune T cells specific to myelin basic protein can protect injured CNS neurons from secondary degeneration after a partial crush of the optic nerve.[18] In this study, rats injected with activated anti-myelin basic protein T cells kept 300% more retinal ganglion cells with functionally intact axons compared to rats injected with activated T cells specific for other antigens.[18] In another study, immune-deficient SCID mice manifested cognitive deficits and behavioral abnormalities that were remedied by restoring T cells from age-matched wild-type mice.[19] This study further showed that T cell-based vaccination using glatiramer acetate, a weak agonist of many self-reactive T cells, can overcome the behavioral and cognitive abnormalities that correspond with neurotransmitter imbalance induced by dizocilpine maleate or amphetamine.[19] T and B lymphocytes have both potential neuroprotective and neuropathogenic roles, and understanding TBI mediated immunological memory formation and peripheral and CNS immune alterations can possibly open new avenues for treatment and diagnosis of TBI. Once clonally expanded populations and/or memory-evoking brain antigens are

identified, immunity-related clinically relevant manipulations can be performed to see if outcomes improve after repeated TBI. We can also examine at what point multiple TBIs can confer "protective autoimmunity" or peripheral tolerance. We believe that chronic exposure to CNS antigens will confer peripheral tolerance, like was observed in a study that immunized newborn rats to myelin antigens at birth. When the rats were subsequently subjected to mechanical crush injury to the optic nerve or spinal cord as adults, significantly fewer neurons survived in the tolerance-induced rats than in their matched controls that were immunized at birth with an irrelevant (non-myelin) protein.[25,26] Conversely, in 1999, Schwartz et al. formulated the concept of protective autoimmunity: T-cell mediated adaptive immunity to specific CNS-related autoantigens is needed to combat destructive self-compounds/DAMPs released from the injury.[18] Depending on the nature, severity, and number of brain injuries suffered, autoimmune responses can be modulated to ensure optimal outcomes are achieved. In future studies, we hope further examine the roles protective autoimmunity and peripheral tolerance may play after TBI.

Literature Search for Duplication:

II.2.1. Literature Source(s) Searched:
Biomedical Research Database (BRD)
Federal Research in Progress database (FEDRIP)
Pubmed

II.2.2. Date of Search: July 9, 2015

II.2.3. Period of Search:
We searched keywords for all dates available through each database.

II.2.4. Key Words and Search Strategy:
We did advanced searches for all databases. The key words used were:
"brain injury and lymphocyte": 13 studies (FEDRIP)
"CNS injury and lymphocyte": 10 studies (FEDRIP)
"brain injury and autoantibody": 3 studies (FEDRIP)
"brain injury and lymphocyte": 0 studies (BRD)
"brain injury and autoantibody": 0 studies (BRD)
"brain injury and B cell": 8 studies (BRD)
"CNS injury and B cell" 4 studies (BRD)
"brain injury and lymphocyte and memory B cell": 1 publication (PubMed)
"brain injury and autoantibody and lymphocyte": 26 publications (PubMed)
"brain injury and "memory B cell"": 0 publications (PubMed)
"brain injury and adaptive immune system and lymphocyte": 47 publications (PubMed)

II.2.5. Results of Search:

There were no relevant publications or reported studies about the role of immunological memory cells in repeated TBI. The current literature discusses the role of adaptive immune cells in other forms of CNS injury (e.g. stroke, MS, spinal cord injury) but not its role after traumatic brain injury. There was one study that looked at innate immune responses in the periphery after closed head injury in mice, but the study did not look into the role of lymphocytes (Schwulst; J Trauma Acute Care Surg; 2013).

III. OBJECTIVE\HYPOTHESIS: Our hypothesis is that an initial TBI results in immunological memory and that a subsequent TBI potentiates adaptive immune alterations.

IV. MILITARY RELEVANCE:

It is estimated that 1.4 million people are hospitalized with a brain injury every year in the United States,[1] which does not include an estimated additional 3.8 million untreated concussions.[3] Among U.S. military personnel, incidence of depression, post-traumatic stress disorder (PTSD), suicide risk, and TBI symptom severity are all significantly increased as the number of TBIs sustained increases.[2] In other words, sustaining more than one TBI is associated with severe cumulative consequences. We are interested in better understanding the collective longer-term effects of TBI and repeated TBI by focusing on the adaptive immune system. A central characteristic of the adaptive immune system is the development of immunological memory, or the capacity of the immune system to remember an antigen encounter via activated T and B cells and to rapidly react to the same antigen in a later encounter. Better understanding the role of immunological memory in TBI may help uncover the basis for cumulative damage from repeated TBIs.

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures:

V.1.1. Experiment 1:

The aim of Experiment 1 is to determine adaptive immune components that are altered in a murine model of repeated TBI. There are two sub-tasks in this experiment. Sub-task 1.1 is to determine if immunological memory-associated transcripts are altered in whole blood. Sub-task 1.2 is to determine if lymphocyte populations are altered in the spleen. The outcome measures of aim 2 (measuring autoantibodies) and aim 3 (choroid plexus RNA expression analysis) are folded into sub-task 1.1 and 1.2.

Rationale: Since T and B cells may either promote repair or further tissue injury as shown in other CNS injury models and disease states, it is important to define their roles in TBI. In our study, we want to discern if immunological memory exists and is strengthened in a rodent CCI model of brain injury long after the initial inflammatory episode subsides. The changes in adaptive immune system components after TBI have not been previously well defined. In order to accomplish specific aim 1, we will profile lymphocytes in whole blood to detect the presence of memory- and/or activation-associated gene expression. Characterizing the memory lymphocyte cell signature of TBI may generate a blood-based diagnostic tool to determine if a TBI event is inducing

memory or pathogenic autoimmunity in a military service member. This may provide vital information to determine a return to duty and/or indicate therapeutic intervention. Furthermore, we will identify lymphocyte populations in the spleen to assess adaptive immune system states after repeated TBI.

1.1: Determine if immunological memory-associated transcripts are altered in whole blood.

In order to accomplish specific aim 1, we will profile lymphocyte-related transcripts in whole blood to detect the presence of memory- and activation-associated gene expression after TBI. Whole blood will be collected 14 and 28 days after CCI brain injury. We expect to find greater lymphocyte-related transcript levels in TBI animals compared to controls, and we expect to find greater immunological memory-associated transcripts in repeated TBI animals.

Methods: C57BL/6J male mice between 9 to 10 weeks of age will be subjected to sham, single, or delayed repeated CCI injuries (two injuries spaced 14 days apart). Animals will be anesthetized using 2-4% isoflurane for CCI surgeries. After an incision is made in the scalp, a craniotomy is performed to remove a circular piece of skull over the injury site to permit impactor brain penetration. Using a 3mm impactor tip, the CCI device will strike 2mm lateral of Bregma (in the left hemisphere) at 1.5 m/s at a 15° angle and 100ms dwell time. The impact depth will be relatively mild at 1mm.

A 14-day interval between CCI surgeries for a cohort of animals will allow development of immunological memory and resolution to near baseline levels. At 1-3 days, 14 days, or 28 days after the final surgery, subjects will be euthanized to obtain whole blood, spleen, and choroid plexus material. Animals will be anesthetized prior to the terminal procedure by an intraperitoneal injection of ketamine and xylazine. Once anesthetized, whole blood will be collected via cardiac puncture using a 1 mL syringe with a 25-guage needle. A portion of the whole blood will be placed in a RNAprotect Animal Blood Tube (Qiagen) to stabilize transcript levels at time of collection, and total RNA will be isolated using RNeasy Protect Animal Blood Kit (Qiagen). The remaining portion of the whole blood will be placed in a MiniCollect serum tube (Greiner Bio-One) to collect serum for Western Blots to identify brain-reactive antibodies in serum (Aim 2).

After total RNA is isolated from the blood, globin mRNA is depleted using a GLOBINclear kit (Life Technologies). Total RNA in whole blood has a high expression of globin mRNA (Up to 70%), which is expressed at high levels in red blood cells and reticulocytes. Depleting alpha and beta globin mRNA from the total RNA preparations allows more sensitivity to detect transcripts relevant to our interests. The mRNA portion in total RNA will be converted into a library of template molecules (TruSeq RNA Sample Preparation Kit v2, Illumina). In summary, mRNA molecules will be enriched and fragmented. The RNA fragments will then be copied into first strand cDNA and then second strand cDNA. The cDNA fragments go through an end repair process, the addition of a single 'A' base, and then ligation of the adapters. The final cDNA library is created by purifying and enriching the products with PCR. The library is then quantified using qPCR (KAPA Library Quantification Kit) and library size distribution is determined (Experion DNA analysis kit). Libraries are then diluted and denatured for cBot clustering. After libraries are amplified to produce clonal clusters, they are sequenced using massive parallel synthesis (TruSeq SBS Kit v5, Illumina).

Choroid plexus material will be collected to determine if immunological memory-associated transcripts are altered in a CNS-proximal tissue. Lymphocyte chemotaxis to the brain after TBI may be due to the elevated release of CNS antigens. We will profile complete transcriptomes of the choroid plexus tissue and determine changes in the immune and inflammatory status of the choroid plexus to assess the modulating role of lymphocytes in the CNS after TBI. We will accomplish choroid plexus expression analysis by RNA-seq to interrogate the inflammatory status of the tissue (Aim 3). Since we know cytokine and chemokine transcript markers for pro-inflammation versus anti-inflammation, we can then see which markers are changed after TBI and if there are further changes after repeated TBI. We will then be able to determine changes in the immune and inflammatory status of the choroid plexus to assess the modulating role of lymphocytes in the CNS after TBI. These transcripts may indicate that the lymphocyte activity is either beneficial or deleterious.

Sub-task 1.1 will require 120 mice. There will be 8 mice per group with 5 experimental groups (naïve, sham, single CCI, double sham, and double CCI) and 3 outcomes time points (1-3 days, 14 days or 28 days post surgery). [8 x 5 x 3 = 120 mice]. Naïve mice will not be subjected to any experimental conditions. Sham mice will be anesthetized and given a craniotomy but no brain impact during surgical procedures.

Expected Outcomes and Alternative Approaches: After TBI, we believe that brain antigens are being presented to the immune system to activate lymphocytes and generate immunological memory and plasma cells. With multiple brain injuries, more brain antigens are presented to the adaptive immune system possibly generating clonal expansion of memory and plasma cells. We expect to find increased lymphocyte-related transcripts in TBI animals compared to controls, and we also expect to find greater immunological memory-associated transcripts in repeated TBI animals. Specifically, we anticipate that transcripts like Dock8 will be altered after TBI. Dock8 helps antibody-producing B cells form stable complexes with other immune cells so that B cells can generate more effective antibodies and become memory cells.[27] Our protocols for expression analysis and CCI surgeries have been thoroughly troubleshooted, so we do not anticipate difficulties with these procedures.

1.2: Determine if lymphocyte populations are altered in spleen.

We will profile lymphocyte populations by flow cytometry in a model of repeated TBI to determine whether cell populations are altered. We are utilizing spleen tissue, because it is the largest secondary lymphoid organ that is responsible for initiating immune reactions to blood-borne antigens and contains about ¼ of the body's lymphocytes.

Methods: C57BL/6J male mice between 9 to 10 weeks of age will be used. For this cohort of animals, the same CCI surgery protocol will be used as described in sub-task 1.1. During the terminal procedure 1-3 days, 14 days, or 28 days after the final CCI surgery, spleens will be dissected for flow cytometry analysis. First, a single-cell suspension will be created and cells will be counted and adjusted to 1 x 10^6 cells/mL. After adding an Fc-block (rat IgG_{2b} anti-mouse CD16/CD32 monoclonal antibody, BD Biosciences), cells will be fixed in 1-4% paraformaldehyde. Fluorochrome-conjugated antibodies will then be added to the cells to label various extracellular markers. Sub-task 1.2 will require additional mice, because spleens will be processed differently than

that described for animals in 1.1. In summary, C57BL/6J male mice between 9 to 10 weeks of age will be subjected to single or delayed repeated controlled cortical impact (CCI) injuries (two injuries 14 days apart). At 1-3 days, 14 days or 28 days after the final surgery, subjects will be euthanized to obtain whole blood and spleen. Sub-task 1.2 will require 72 mice. There will be 8 mice per group with 3 experimental groups (naïve, single CCI, and double CCI) and 3 outcome time points (1-3 days, 14 days or 28 days post surgery). [8 x 3 x 3 = 72 mice].

Expected Outcomes and Alternative Approaches: Our preliminary data revealed that 21 days after a single mild closed-skull TBI, TBI animals had an altered percentage distribution of T helper cells (CD4+) and B cells (CD19+) compared to shams. The level of cytotoxic T (CD8a+) cells remained the same between the TBI and sham animals. The percentage of lymphocytes was consistent among all sham and TBI animals at around 40% of all splenocytes, so we are confident that the percentage distribution in the spleen did not change. One hypothesis that can explain these changes in lymphocyte populations is that perhaps certain B cells that are responding to brain antigens are being clonally expanded meaning that the diversity or range of B cells may be decreasing to one proliferating clone. In order to investigate this hypothesis, we will profile antibody genes (Aim 2 & 3).

We anticipate that memory B cell and plasma cell populations will undergo delayed expansion after TBI. In other studies, B and T cell expansion in the spleen and lymph nodes coincides with an increase in circulating IgG antibodies in mice and rats subjected to spinal contusion injury.[17,28] We anticipate making a similar correlation between circulating autoantibody levels and lymphocyte population changes in the spleen. We further anticipate that a TBI will initially expand the T effector population but that levels will decrease at 28 days post injury. We further anticipate that a repeated TBI will change the lymphocyte response as compared to the first injury event. Namely, a dramatic activation of memory T and B cell clonal populations that persist from the first TBI. If successful, and we are able to identify clonally expanded populations, immunity-related clinically relevant manipulations can be done to see if outcomes improve after repeated TBI.

Sub-task	# of animals	Treatment	Euthanization time point after surgery	Pain category
1.1	8	naïve	1-3 days	C

TOTAL:	192			

V.2. Data Analysis:

We will use analysis of variance (ANOVA) followed by post-hoc t tests to compare blood plasma, chemokine and cytokine data and lymphocyte population data. If data do not meet the assumptions of ANOVA they will be transformed or appropriate nonparametric tests will be used. A sample size of 8 per group will detect differences of 1.5 standard deviations between groups with a 5% two-sided significance level. For histological data, we will quantitate microglia activation by cells per area density and use semi-quantitative descriptive statistics to correlate with the quantitative parameters above.

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered:

We are investigating the role of immunological memory cells after repeated mild TBI. Alternatives to animal models, such as computer models or in vitro cell cultures will not be able to adequately mimic the molecular and cellular events that occur after TBI. In order to learn more about the mechanisms involved after a brain is injured, it is necessary to actually injure a brain in an animal model.

V.3.2. Animal Model and Species Justification:

We will be subjecting the mice to brain injury and then investigating the effects in blood, brain tissue, and spleen, so we need to use an animal with a brain, peripheral lymphoid organs, and blood. We chose to use mice in this study for a variety of reasons: (1) they are mammals with similar cerebral physiology making it possible to study inflammatory and immune-mediated responses; (2) many studies with mice exist where behavior and brain trauma outcomes correlate with human studies making it possible to correlate our findings with previously published data; (3) the relative small size and

short life span of mice will allow us to repeat measures of biochemical and cellular changes after TBI in a feasible manner.

Since we are using this animal model to improve treatment for human TBI patients, we want to do experiments in a laboratory mammal that these techniques have already been worked out in.

V.3.3. Laboratory Animals

	Species #1	Species #2
V.3.3.1. Genus & Species:	**Mus Musculus**	
V.3.3.2. Strain/Stock:	**C57BL/6**	
V.3.3.3. Source/Vendor:	(b)(4)	
V.3.3.4. Age:	**9-10 weeks old**	
V.3.3.5. Weight:	**23-35g**	
V.3.3.6. Sex:	**Male**	
V.3.3.7. Special Considerations:	**N/A**	
V.3.4. Number of Animals Required (by Species):	192	

V.3.5. Refinement, Reduction, Replacement (3 Rs):

V.3.5.1. Refinement:
The animals used will be anesthetized before the surgical injury procedure (TBI/sham injury) as well before the terminal procedures of tissue and blood collection.

V.3.5.2. Reduction:
We will use material from several tissues sources (peripheral blood, spleen, choroid plexus, and brain) in this experiments thereby reducing the number of animals needed. Since the experimental techniques we are proposing to use have already been characterized and well documented in mice, we will not need to use extra animals to establish the techniques.

V.3.5.3. Replacement:
Replacement alternatives such as cell cultures and the use of less sentient animal species were considered, but we need to use mammals with a brain, peripheral lymphoid organs, and circulating blood to examine the CNS effects of TBI.

V.4. Technical Methods:

V.4.1. Pain / Distress Assessment:

V.4.1.1. APHIS Form 7023 Information:

V.4.1.1.1. Number of Animals:
We will have a total of 192 animals. Here are the treatment groups and number of animals in each group:
Naïve: 48 animals
Sham: 24 animals
Single CCI: 48 animals
Double Sham: 24 animals
Double CCI: 48 animals
These animals are categorized in category C (48 naïve animals) and category E (144 sham (craniotomy), double sham, single CCI, and double CCI animals) shown below.

	Species #1	Species #2
V.4.1.1.1.1. Column C:	48	
V.4.1.1.1.2. Column D:		
V.4.1.1.1.3. Column E:	144	

V.4.1.2. Pain Relief / Prevention:

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization:
Prior to TBI/sham procedures, mice will be administered an inhalational anesthetic. Oxygen will be mixed with isoflurane delivered via precision vaporizer using a rodent anesthesia machine. Mice will be placed in an induction chamber and exposed to a mixture of O2 and isoflurane (2-4%) to induce general anesthesia. Following induction, mice will be removed from the chamber and maintained on 1-2% isoflurane administered by nose cone during surgical procedures. We will monitor the depth of anesthesia by noting a lack of response to toe pinch (pedal withdrawal reflex), mucus membrane color, and rate and quality of respirations. Waste anesthetic gases will be actively scavenged through the central vacuum system or passively scavenged using a charcoal canister.

For terminal tissue dissection procedures (including naïve animals for baseline level measurements), ketamine and xylazine will be used as the sedative and anesthetic. Before collection, they will be injected (i.p.) with 80-100 mg/kg of Ketamine and 10 mg/kg Xylazine intraperitoneally using a 26-gauge needle.

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions:
Once animals arrive from the vendor (e.g. (b)(4) , they will acclimate in a reverse light-cycle room for 3 days. The reverse light-cycle room in needed to avoid disturbing the sleep cycle (and circadian rhythms) of animals when administering surgical and weighing procedures. LAM will place animals in cages in the same manner

in which they arrived (ie. if 4 animals arrive in three separate boxes, they will similarly place the same 4 animals in 3 separate cages). Animals will receive regular food and water without restriction. After the procedure, if there is significant brain hemorrhaging, we will eliminate the animal from the study and euthanize it. Animals will be placed on a heating pad in a single cage for 30 minutes to recover from the surgery. During this time, animals will be continuously monitored to make sure they come out of anesthesia and are able to right themselves, lay sternal, and lift their heads. Animals will then be monitored daily after surgical procedures to confirm that they recovered and are conscious without any visible signs of distress. Additionally, animals will be monitored and weighed at least every 2 days for significant weight loss (greater than 20% total weight loss relative to initial body weight prior to injury) as an additional sign of distress. If post-procedural pain or distress induces persistent symptoms beyond the first 24 -36 hrs post injury, including hunched posture, labored or gasping breathing, ruffled fur, immobility, failure to feed or to drink, the affected mice will be immediately removed from the study and euthanized..

V.4.1.2.3. Paralytics: N/A

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures:

V.4.1.3.1. Sources Searched: PubMed

V.4.1.3.2. Date of Search: July 13, 2015

V.4.1.3.3. Period of Search: 1950-current

V.4.1.3.4. Key Words of Search:
Moderate brain injury model and mice; penetrating brain injury and mice; non-invasive brain injury model and mice

V.4.1.3.5. Results of Search:
In order to investigate peripheral immune changes after brain injury, we need to utilize animals that have a brain, nervous system, circulatory system, and peripheral lymphoid organs. In order to investigate brain injury, we need to systematically and reproducibly injure the brain of animals. There are other forms of brain injury models that can be considered alternatives to the controlled cortical impact injury that we administer in our experiments. Our search results revealed other brain injury models such as weight-drop closed head injury, fluid percussion injury, and middle cerebral artery occlusion). Out of all these options, we chose to utilize a controlled cortical impact model, because it is highly reproducible, injury parameters can be adjusted, and we can compare results with many other labs here at USU. All of our search results included brain injury models that did inflict injury to the brain and while some studies provided analgesia after surgical procedures, none of these injury models can be considered pain-free. Administering brain injury is inherently invasive and painful, and we cou dn't find any experimental studies that administered reproducible brain injury to vertebrates in a pain-free manner (ie. without providing some kind of anesthesia and/or analgesia). In our study, we do provide anesthesia during all surgical procedures, but we do not provide analgesia after surgical procedures, because this will impact our results.

"moderate brain injury model and mice": 91 publications
"penetrating brain injury model and mice": 22 publications
"non-invasive brain injury model and mice": 28 publications

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification:
Providing pain medication after brain injury will interfere with our ability to interrogate immune-related outcome measures. We can not investigate the role of lymphocytes and immune alterations after TBI if we are providing medication that alters immune function. While no analgesia will be provided after surgeries, all animals will be properly anesthetized before all surgical procedures with isoflurane and before all euthanization procedures with an i.p. injection of ketamine and xylazine

Buprenorphine, an anti-nociceptive partial μ-opioid receptor agonist, along with other opiates and NSAIDs all have effects on the immune system, and thus, will impact our data in this study. Buprenorphine has been shown to dose-dependently suppress splenic natural killer cell activity, lymphocyte proliferation, and IFN-γ production in rats, and these effects were reversed with naltrexone "demonstrating pharmacological specificity of buprenorphine-induced immune alterations."[29] Further, opioid alkaloids and peptides, such as morphine "directly modulate the function of lymphocytes and other cells involved in host defense and immunity."[30] These analgesic compounds modify immune responses to extracellular stimuli like mitogens and antigens, and immune cells express mRNA transcripts encoding various opioid receptors that were originally described in neuronal tissues.[31]

Here are some studies that either show opiates/NSAIDs impact inflammation or can negatively impact TBI outcome:

a) A study looked at altered hyperpolarization-activated cyclic nucleotide-gated (HCN) channel protein expression in trigeminal sensory neurons following inflammation of the dura using application of complete Freund's adjuvant (CFA) to the dura mater in rats. The increased activity of (HCN) channels has been shown in models of nerve injury-induced pain. Buprenorphine was applied following surgery and inflammation-induced increases in HCN1 and HCN2 were not observed. The authors suggest that "if the peak action of buprenorphine is before the peak of the CFA-inducted inflammatory effect then buprenorphine may attenuate the inflammatory response by acting on immune cells."[32]

b) In a study of immature swine (3-5 day-old piglets), premedication with meloxicam, a COX-2 perferential NSAID, prior to brain injury using rapid head rotations without impact produced a significantly higher mortality rate than buprenorphine.[33] No controls were used in this study.

c) Rats treated with Morphine or propofol for 1 hour after CCI were associated with significantly worse motor function on post-TBI day 1-5 compared to animals without anesthesia and shams.[34]

d) In one 5.5-year retrospective study of patients aged 55 years and older with blunt force TBI, patients who were taking anticoagulants and antiplatelet agents (warfarin,

clopidogrel, dipyridamole/aspirin, enoxaparin, and subcutaneous heparin) experienced a higher rate of inpatient mortality and other adverse outcomes caused by the effects of these agents.[35] Although these patients were taking these medications before sustaining a TBI, and we don't know what the specific effects of these agents are on immune system function after TBI, these agents including aspirin negatively affected TBI outcome.

V.4.2. Prolonged Restraint: N/A

V.4.3. Surgery:

V.4.3.1. Pre-surgical Provisions:
Isoflurane will be administered just prior to and during surgical procedures to provide loss of consciousness. To confirm that animals have a loss of consciousness, the absence of tail, paw reflexes, and corneal reflex will be confirmed.

V.4.3.2. Procedure: Controlled Cortical Impact:
All surgical procedures will take place in the CNRM surgical room for mice. We will follow CNRM's Standard Operating Procedures except for providing post-surgical analgesia (e.g. no Tylenol water will be provided or buprenorphrine). Mice will be anesthetized with isoflurane as described above via inhalation with a nose cose. Corneas will be kept moist during surgery by applying Lubritears ointment. Sterile gloves will be worn for the surgical procedures. The fur on top of the head will be shaved followed by a cleaning of the area with iodine and alcohol three times. All surgical equipment will be thoroughly cleaned, wiped with alcohol, and sterilized using Germinator equipment and allowed to return to room temperature.
Mice will be placed in a stereotaxic apparatus with ear bars. A scalp incision will be made at midline centered approximately at Bregma for 1.5cm incision length. First, the impactor will a 3mm diameter tip will be lined-up directly over Bregma, then moved 2mm to the left. A craniotomy is done (~5mm circular piece of skull is removed) using ahand-held trephine to expose the dura mater. The brain will be impacted at a depth of 1.5mm, velocity 1.5m/s over the exposed area of brain. The burr hole is left open and the incision is closed with absorbable sutures, such as natural chromic gut sutures or polyglycolic acid synthetic sutures. Animals will recover on a circulating heating pad. Once ambulatory, animals will be returned to their cages.

V.4.3.3. Post-surgical Provisions:
If an animal's skull is fractured and there is significant hemorrhaging during the TBI surgical procedure, we will eliminate the animal from the study and euthanize it. After every surgical procedure, animals will be placed on a heating pad in a single cage for 30 minutes to allow recovery from the surgery. During this time, animals will be monitored to make sure they come out of anesthesia and are able to right themselves, lay sternal, and lift their heads. After surgeries, we will monitor animals for any sigs of pain or distress including hunched posture, difficulty breathing, muscle rigidity or lack of muscle tone, twitching, trembling, tremor, self-mutilation, or unkempt appearance (erect, matted, or dull haircoat). Additionally, animals will be monitored for significant weight loss (greater than 20% total weight loss relative to initial body weight prior to injury) as

an additional sign of distress. If post-procedural pain or distress induces persistent symptoms beyond the first 24 -36 hrs post injury, including hunched posture, labored or gasping breathing, ruffled fur, immobility, failure to feed or to drink, the affected mice will be immediately removed from the study and euthanized. No analgesia will be provided after surgeries, because doing so will affect our immune-related outcome measures, which categorizes our animals in CAT E. Additionally, we want to compare our results with those from other labs that do not use any pain relief after TBI surgeries (e.g. Dr. (b)(6) lab).

V.4.3.4. Location: (b)(6)

V.4.3.5. Surgeon: (b)(6)

V.4.3.6. Multiple Major Survival Operative Procedures: N/A

V.4.3.6.1. Procedures: N/A

V.4.3.6.2. Scientific Justification: N/A

V.4.4. Animal Manipulations:

V.4.4.1. Injections:
For terminal procedures, ketamine and xylazine will be used as the sedative and anesthetic. Before animals are euthanized, they will be injected (i.p.) with 80-100 mg/kg of Ketamine and 10 mg/kg Xylazine intraperitoneally using a 26-gauge needle. Again, the total volume of injected anesthetic depends on the weight of the animal. For example, a 25 gram mouse will receive a single i.p. injection of 20-25 µl ketamine (from a 100 mg/ml stock) plus 250 µl xylazine (from a 1 mg/ml stock).

V.4.4.2. Biosamples:
During the terminal procedure, blood samples will be collected via cardiac puncture and 300-800 ul will be collected using a 25 gauge needle attached to a 1mL syringe. Also during the terminal procedure, spleens and choroid plexus material will be collected by surgical removal.

V.4.4.3. Adjuvants: N/A

V.4.4.4. Monoclonal Antibody (MAbs) Production: N/A

V.4.4.5. Animal Identification: Cage cards will identify animals in each cage. Permanent pen markings will be made on the tails of mice to distinguish them apart.

V.4.4.6. Behavioral Studies: N/A

V.4.4.7. Other Procedures:
Saline Perfusion:
For all perfusion procedures, animals will be anesthetized with an i.p. injection of 80-100 mg/kg of Ketamine and 10 mg/kg Xylazine using a 26-gauge needle. We will confirm

that animals are under adequate anesthesia before proceeding with the perfusion (i.e. lack of withdrawal to toe pinch and lack of corneal reflex). The chest cavity will be incised though the abdomen that allows access to the rib cage. Two cuts will be made through the right and left side of the rib cage, and a clamp will be used to open the thoracic cavity and expose the heart. A needle is inserted into the left ventricle up about 5 mm. The right atrium is then cut and the animal is first perfused with PBS + heparin at a flow rate of 20 ml/min. When the blood has been cleared from the body (about 100 ml of PBS used), heads will be decapitated and brain tissue will be dissected so that choroid plexus material can be isolated.

V.4.4.8. Tissue Sharing: There will be no tissue sharing with other labs.

V.4.5. Study Endpoint:

Animals will be euthanized at specified timepoints after TBI/sham injury. If animals die before the completion of the study, they will be removed from the study, and statistical analyses will be performed on the remaining animals. If animals show any visible signs of distress following surgical procedures, such as significant weight loss, they will be euthanized and removed from the study.

V.4.6. Euthanasia:

All animals will be properly anesthetized before terminal procedures with an i.p. injection of 80-100 mg/kg of Ketamine and 10 mg/kg Xylazine using a 26-gauge needle. After animals have been deeply anesthetized, the chest cavity will be incised though the abdomen that allows access to the rib cage. Two cuts will be made through the right and left side of the rib cage, and a clamp will be used to open the thoracic cavity and expose the heart. Blood will be collected via cardiac puncture. Then spleens will be dissected using scissors. Sub-task 1.1 animals will be saline perfused with PBS at a flow rate of 20ml/min, and their brains dissected in order to dissect out choroid plexus material from the ventricles. At the conclusion of every terminal procedure, all animals will be decapitated with sharp scissors to confirm death.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol.

Animals will be observed everyday to confirm health and viability. Animals will be housed in the same cages/cagemates they arrived to the University with and will have unlimited access to food and water. Animals will be kept in temperature controlled rooms in reverse light cycle.

V.5.1.1. Study Room:

Building(s) (b)(6) Room Number(s) (b)(6)

The experimental procedures will be conducted in the LAM/CNRM facilities in the basement of building (b)(6). After the experimental procedures, and after animals have been allowed to recover on heating pads, they will be taken back to the animal housing room.

V.5.1.2. Special Husbandry Provisions:

We do not anticipate that animals will need nutritional support following TBI. Wet mash food may be placed in the cages of mice 1-3 days after surgeries to make sure that they can reach food.

Food Restriction: Yes _____ No __x__

Fluid Restriction: Yes _____ No x

V.5.1.3. Exceptions: N/A

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care:
The veterinary technicians in the LAM will observe animals everyday. The criteria used for health evaluation will be weight loss, hair loss/unkempt fur, and decreased locomotor activity. In the event of a debilitating illness or adverse reaction, the animal will be evaluated by the attending veterinarian and possibly euthanized at an earlier timepoint.

V.5.2.2. Emergency Veterinary Medical Care: All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: Except as indicated below, all animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents; balls, toys and food enrichment treats for large animal species.

V.5.3.2. Enrichment Restrictions: N/A

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
Controlled Cortical Impact; isoflurane anesthesia, ketamine/xylazine injections; daily observation of mice after CCI surgeries	(b)(6)	Graduate Student, 6 years experience	Training from (b)(6) 2012 & 2014; USU Investigator Training Course 2012; Rodent Handling Class 2009
Euthanasia/tissue extraction		Graduate Student, 6 years experience	Training from Dr. (b)(6) 2010-2011; USU

	(b)(6)		Investigator Training Course 2012; Rodent Handling Class 2009
Euthanasia/tissue extraction		PI, 14 years experience	Training from Dr. (b)(6) lab, 2000; USU Investigator Training Course 2012
RNA isolation and sequencing		Research Associate, 7 years experience	Blood borne pathogen training 2013; rodent handling course 2012

(b)(6) took the rodent handling training course at USU in 2009.
took the Investigator/animal user training course at USU on March 8, 2012.
Dr. (b)(6) took the rodent handling training course at USU in 2003 and refresher course in 2005.
Dr. (b)(6) took the PI training course at USU on January 17th, 2012.

VII. BIOHAZARDS/SAFETY:

All personnel handling these animals will use protective gloves, lab coat, and covered shoes at all times to minimize exposure to allergens and agents used during experimental procedures. Isoflurane vapors will be scavenged by the waste vapor apparatus.

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

(b)(6) _____ 8/7/15

P Date

G. Training: The following personnel will attend the next USUHS Investigator/Animal User Training Course:

_____ _____

_____ _____

H. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely, "Responsibility" for implementing animal use alternatives where feasible and conducting humane and lawful research.

(b)(6) _____ 8/7/15

Principal Investigator Signature Date

I. Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL or WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

X. PROTOCOL ABSTRACT:

Every year in the U.S., it is estimated that 1.4 million people are hospitalized with a brain injury.[1] Among U.S. military personnel, incidence of depression, PTSD, suicide risk, and TBI symptom severity are all significantly increased as the number of TBIs sustained increases.[2] Alterations in brain energy metabolism, local neuroinflammation, and fluid balance are among the mechanisms implicated for contributing to repeated TBI-related adverse outcomes. Therefore, a subsequent injury after an initial TBI is associated with severe cumulative consequences.

Recently, it has been determined that the adaptive immune system can develop immunological memory to CNS injury and activate production of autoantibodies with pathogenic potential. Studies have detected autoantibodies in biofluids from individuals with CNS injury as well as from animal subjects in TBI preclinical models. However, the contribution of immunological memory responses after repeated TBI events has not been defined. **Our goal in this project is to determine whether TBI establishes immunological memory and whether a repeated injury results in a secondary adaptive immune response.**

T and B lymphocytes are primary components of the adaptive immune system, yet the role of lymphocytes in TBI is not well understood. Evidence in other CNS injuries suggests that T and B cells play significant roles in post-traumatic inflammation, degeneration, or repair. Since T and B lymphocytes have both potential neuroprotective and neuropathogenic roles, elucidating the response of the adaptive immune system to TBI is needed to better understand the mechanisms of repeated TBI. Modulating the immune system after TBI may innovate treatment strategies for improved recovery after TBI. **Our hypothesis is that an initial TBI results in immunological memory and that a subsequent TBI potentiates adaptive immune alterations.**

A. **Animal Protocol Number**:

B. **Animal Protocol Title**: (b)(4) (b)(4)

C. **Principal Investigator**: Dr. (b)(6) Assistant Professor, APG

D. **Performing Organization**: Uniformed Services University of the Health Sciences

E. **Funding**:

F. **Objective and Approach**:

To test this hypothesis, we will complete experiments for the following specific aims:

Aim 1: Determine adaptive immune components that are altered in a murine model of repeated TBI. The changes in adaptive immune system components after TBI are not well defined. We will profile lymphocyte populations by flow cytometry to determine whether memory cell populations are altered. Expression analysis of lymphocyte populations will also be accomplished to detect transcripts associated with immunological memory responses.

Aim 2: Determine the status of adaptive immune repertoire alteration as a function of autoantibody presence. Studies have detected autoantibodies in subjects after CNS injury and TBI. The level and nature of autoantibodies after repeated TBI has

not been defined. We will measure serum autoantibody levels from TBI subjects using 1-dimensional gel and ELISA-based methodologies. Clonotypic enrichment in lymphocyte repertoire will be profiled by sequencing receptor immunoglobulins.

Aim 3: Demonstrate CNS-directed lymphocyte proximity to the brain after repeated TBI. The blood-brain barrier establishes immunoprivilege to mitigate self-reactive responses to host tissue. CNS antigen-mediated responses and lymphocyte chemotaxis to the brain after TBI may initiate autoimmune reactions. We will determine the immune and inflammatory status of the choroid plexus to assess its modulating role of lymphocyte populations in the CNS after TBI. Furthermore, we will analyze T cell receptor repertoire status of the choroid plexus to detect if repeated brain injury results in increased infiltration of CNS-specific lymphocyte populations to the brain.

August 31, 2015

MEMORANDUM FOR DR. (b)(6) DEPARTMENT OF ANATOMY, PHYSIOLOGY, AND GENETICS

SUBJECT: IACUC Approval of Protocol – Initial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on August 31, 2015:

Animal Protocol Title: "The Impact of Blast Exposure on Mouse Daily Activities"

USUHS Protocol Number: (b)(6)

Expiration Date: August 30, 2018

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. NON-TECHNICAL SYNOPSIS:

Blast exposure is a common type of traumatic brain injury (**TBI**) experienced by military service members in theater; particularly those who have served in Operation Iraqi Freedom (OIF) and Operation Enduring Freedom (OEF). Many of these service members report experiencing significant changes in behavior and mood post-injury. Clinical reports have documented that a subset of these TBI patients demonstrate changes in overall daily activity, including changes in arousal and attention, excessive daytime sleepiness, as well an unrestful sleep at night. In post mortem studies, these clinical observations have been linked to injury in a brain area called the hypothalamus, which contains brain cells that control arousal and sleep-wake cycles. We will study in laboratory mice how exposure to blast wave(s) affects daily activity of the mice, and study how the blast may change certain chemicals in the brain. We hope this research will shed light on the effects of overpressure shock waves on behavioral homeostatic mechanisms that could play an important role in recovery from TBI.

II. BACKGROUND:

II.1. Background:

Due to military conflicts overseas, in recent years there has been increasing interest in the effects of *blast overpressure* on the brain. Animal models of blast injury are being employed to investigate the physical and neuropsychological symptoms faced by military personnel exposed to blast waves resulting from the detonation of explosive devices (Goldstein *et al*, 2012). Animal models of blast have used both rats and mice, and these studies have aided in the elucidation of the acute and chronic gross neuropathological and behavioral symptoms that arise after exposure to blast overpressure (Ahlers *et al*, 2012; Cernak *et al*, 2011; De Gasperi *et al*, 2012; Goldstein *et al*, 2012; Koliatsos *et al*, 2011; Rubovitch *et al*, 2011; Tweedie *et al*, 2013; Valiyaveettil *et al*, 2013; Xie *et al*, 2013). Animal blast models show promise for providing critical information in line with the goals of the CNRM in exploring and developing treatments for TBI and post-traumatic stress disorder (**PTSD**)-related symptoms in military personnel and veterans. The CNRM Pre-Clinical Studies Core has a newly-designed, state-of-art Advanced Blast Simulator (**ABS**; ORA Inc, Fredericksburg, VA) for investigators to employ in research examining TBI and PTSD. The area of blast effects on daily activity homeostasis has received no prior attention. Pre-clinical modeling may be an important approach for determining the mechanisms that underlie arousal and activity changes after TBI.

Based on prior evidence from clinical studies and animal research, the hypothalamic hormone, orexin, is known to play a significant role in activating many pathways throughout the central nervous system that maintain arousal during the waking state. Excessive sleepiness in narcoleptic patients, for example, has been linked with loss of orexin neurons. Similar findings have been observed in Parkinson patients who report experiencing sleep attacks and difficulty staying awake. Furthermore, close to half of TBI patients report experiencing sleep disorders, which have adverse effects on recovery and quality of life. Orexin has been shown to decrease following TBI—both in the acute setting and chronically as measured in the CSF of patients (Baumann *et al*, 2005b; Baumann *et al*, 2007). Post mortem studies further delineate loss of orexin neurons in patients with known TBI (Baumann *et al*, 2009). Like orexin, melanin concentrating hormone (**MCH**) plays a role in sleep-wake regulation, where overall it promotes the induction of REM sleep. Postmortem studies of patients with TBI have also shown a decrease in MCH neurons along with orexin neurons (Baumann *et al*, 2009), linking both of these neuropeptides to arousal and general activity levels, as well as sleep-wake cycle regulation. This project will examine the impact of blast exposure on mouse daily activity cycles and whether or not blast alters brain levels of orexin and MCH.

II.2. Literature Search for Duplication:

II.2.1. Literature Source(s) Searched: Biomedical Research Database (BRD)

II.2.2. Date of Search: July 13, 2015

II.2.3. Period of Search: 1998-2009

II.2.4. Key Words and Search Strategy: All fields: Rodent, behavior, blast; orexin, melanin concentrating hormone, mice. Results: 2 hits

II.2.5. Results of Search:

The BRD database includes thousands of records of previous research programs. No hits were found relating to the full set of keywords, "Rodent, behavior, blast; orexin, melanin concentrating hormone, mice." A second search was performed for the words, mouse, blast TBI and orexin. No hits were found. A third search was performed to see if any studies had been performed on orexin and this search derived two hits. One project was entitled, "Molecular connections between arousal and metabolic disease: Orexin and Modafinil" that investigated chronic pharmacological activation of orexin-A and related pathways on metabolic status and obesity. A second project entitled, "Role of CRF and orexin in driving ethanol consumption," investigated the "mechanistic relationship between acute exposure to corticotrophin releasing factor (CRF) and orexin and how forced abstinence and extinction from ethanol self-administration alters the properties of CRF receptors and orexin receptor-dependent potentiation of NMDA receptors in the ventral tegmental area." **Conclusion**: No related hits indicate there is no overlap of this protocol with previous research programs in the DoD.

II.2.6. Literature Source(s) Searched: NIH RePORTER

II.2.7. Date of Search: July 14, 2015

II.2.8. Period of Search: Projects through fiscal year 2015

II.2.9. Key Words and Search Strategy: Orexin, traumatic brain injury, mice

II.2.10. Results of Search:

The NIH website, RePORTER, was used. The keywords orexin, mice and traumatic brain injury produced no hits. The keywords orexin and traumatic brain injury produced one hit. The hit was NIH grant R01NS065069-07, entitled "Mechanisms underlying tauopathy following traumatic brain injury." The project description does not directly mention orexin, but this group recently

published a paper related to this support (Willie *et al*, 2012). **Conclusion**: No related hits indicated there is no overlap with previous research federally sponsored research programs.

II.2.11. Literature Source(s) Searched: PubMed
I.2.7. Date of Search: July 14, 2015
II.2.12. Period of Search: >24 million references: 1949-2015.
II.2.13. Key Words and Search Strategy: Orexin, mice, and traumatic brain injury
II.2.14. Results of Search:

PubMed was used with the keywords, mice, orexin and traumatic brain injury, and six hits were derived. One recent publication described the trouble with wakefulness seen in mice after fluid percussion injury (Lim *et al*, 2013). A second finding was the paper just noted above in II.2.6, where reduced wakefulness was seen after controlled cortical impact TBI (Willie *et al*, 2012). A third report describes changes in orexin receptor immunostaining in the brain region surrounding the injury site from controlled cortical impact (Mihara *et al*, 2011). A 4th report was a metanalysis of the effects of various factors on locomotor activity. It reports that "genetic and pharmacological alterations that enhance the dopamine, orexin, histamine, cannabinoids systems or that antagonize the cholinergic system induce an increase in locomotor activity" (Viggiano, 2008). Finally the 5th and 6th publications were reviews (Baumann and Bassetti, 2005a; Harrington, 2014). With the keywords orexin and traumatic brain injury, 29 hits were obtained. In general, these publications were reports that orexin is related to activity levels, and that TBI has a deleterious impact on arousal and activity and/or sleep-wake cycles. However, none of these publications related to the possible effect of blast overpressure on activity and orexin in a pre-clinical model. Conclusion: There are no reports of the effects of blast on orexin and general activity levels in mice as described in this protocol.

III. OBJECTIVE\HYPOTHESIS:

The objective of this project is to assess the effects of blast TBI (single vs. multiple events) on overall behavioral activity and putative brain systems that regulate activity and sleep-wake cycles. Using a mouse model of blast TBI, we hope this will allow us to elucidate the effects of blast injury on daily behavior cycles, cognition, emotion, and memory, and what impact blast has upon hypothalamic neurons that regulate arousal and sleep. Specifically, we will assess brain tissue post-injury for changes in orexin and melanin concentrating hormone neurons. This study will also allow us to assess any significant differences between single exposure and multiple exposures to blast injury. It is hypothesized that exposure to blast overpressure will reduce mouse overall activity levels and produce fragmented periods of sleep and wakefulness. We predict these changes will correlate with additional signs of TBI, including cognitive deficits and impairment of memory function, and a decrease in brain levels of orexin and melanin concentrating hormone.

IV. MILITARY RELEVANCE:

The *relevance* of this research is to assist in meeting a major objective of the CNRM: "to address the current needs of the medical community to better diagnose and intervene for the prevention of the long term consequences resulting from traumatic brain injury, particularly in the context experienced by service members in Operation Iraqi Freedom (**OIF**) and Operation Enduring Freedom (**OEF**)." According to a respected RAND Corporation report (Tanielian and Jaycox, 2008), as many as 18.5% of the service members returning from these conflicts meet the criteria for a diagnosis of either PTSD or depression, and 19.5% of service members have reported experiencing a probable TBI during deployment. These estimates translate to

approximately 320,000 cases of "probable TBI" and 300,000 cases of reported symptoms for depression or PTSD. Most cases of TBI in OIF and OEF arise from blast injury associated with the detonation of explosive devices in the form of non-contact closed head injury. Scientific research related to developing a better understanding of the biological processes and treatment for blast-induced TBI and/or psychological trauma is necessary for the care of our service members. Specific consequences of TBI include arousal and sleep-wake disorders, which plague up to 43% of people who have experienced TBI (Baumann *et al.* 2006; Castriotta *et al.* 2007). The laboratory mouse, using this injury model, is expected to advance our knowledge of biological mechanisms of brain injury that result in behavioral activity disturbances. Uncovering such mechanisms will allow us to develop strategies for treatment and improve the quality of life for service members with TBI.

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures:

Overall experimental design. The ABS will be used to create a mouse model of blast TBI, from which we will study disruptions in activity and sleep-wake regulation; akin to what has been documented in clinical studies following concussion and impact TBI. The main studies (Experiments 1, 3-5) will comprise four treatment groups of mice: **1.** Mice exposed to a single blast injury. **2.** a second group exposed to multiple blast injuries, and **3.** and **4.** will be groups of mice serving as sham-treated animals for comparison of results obtained for the first and second groups, respectively. As outlined in these experiments, we will assess the effects of blast overpressure on overall behavioral activity, sleep-wake cycles, cognition, emotion, and memory, and neuroanatomical changes.

Table 1. Summary of Experiments 1-5

Experiment	Purpose of Study	Blast Exposure(s)	Home Cage Activity	Behavior Testing	Histology/ Biochemistry	Length of Study
1	Short-term brain changes	Yes	No	No	Yes	7 days
2a	Pilot study of Experiment 3	No	AnyCage	No	No	7 days
2b	Pilot study of Experiment 4	No	Telemetry	No	No	14 days
3	Activity, behavior, and brain changes after blast(s)	Yes	AnyCage	Yes	Yes	30 days
4	Activity, behavior, and brain changes after blast(s)	Yes	Telemetry	Yes	Yes	37 days
5	Long-Term Behavior and brain changes after blast(s)	Yes	No	Yes	Yes	90 days

Table 1 is an overview of the experiments. Experiment 1 (described below) will evaluate short-term changes in brain levels of orexin and melanin concentrating hormone (**MCH**) in the first seven days after exposure to a single blast or repeated blast (1 blast/day for 5 days). Experiment 2 will be a pilot study to verify that the instrumentation (explained below) is

properly working before starting Experiments 3 and 4. Finally, Experiment 5 will evaluate the long-term effects of blast exposure on behavior.

Due to the relative novelty of this approach to blast-related TBI symptoms, two experimental approaches will be used to measure mouse activity. In Experiment 3, mice (across the four treatment groups mentioned above) will be evaluated for daily activity patterns with the Stoelting Company's AnyCage home cage chamber (hereafter described as "chamber"). In Experiment 4, animals will be evaluated for daily activity using the DSI PhysioTel® ETA-F10 transmitter system (hereafter abbreviated as "telemetry system"). The "chamber" approach consists of placing individual mice in an AnyCage home cage, which is an environmentally-regulated, ventilated chamber with a computer that controls the chamber's light-dark cycle. The apparatus also monitors daily food and water intake and running wheel activity, and an infrared camera system measures overall movement. The "telemetry system" employs an implantable device that, under sterile conditions, is positioned subcutaneously in the nape of the mouse. Screws are implanted in the skull to monitor EEG. The mouse is then placed in a standard LAM mouse home cage that is positioned on top of a DSI PhysioTel® Receiver that records radio frequency signals broadcast by the transmitter to monitor EEG, as well as activity as the mouse freely moves about its home cage.

V.1.1. Experiment 1. Short term effects of blast exposure on brain changes in levels of orexin and MCH. The first experiment will evaluate changes in levels of the neuropeptides, orexin and MCH, in the hypothalamus. Separate groups of 30 mice each (**Table 2**) will sustain 1 or 5 blast exposures and on Days 1, 3, or 7 after exposure 10 mice per time point from these samples will be euthanized as described in **V.4.6.Euthanasia**. The brain tissue will be used for immunohistochemistry and western blotting to measure levels of orexin and MCH as a function of treatment and time after injury.

Table 2. Experiment 1. Short Term Effects of Blast

Experimental Treatment	No. of Mice	Pain/Distress Category
1 Blast Exposure	30	D
5 Blast Exposures	30	D
1 Sham Treatment	30	C
5 Sham Treatments	30	C

V.1.2. Experiment 2. Pilot studies to validate use of the AnyCage system and the telemetry system, and refinement of surgical procedures.

The purpose of Experiment 2 will be to verify and refine experimental procedures for measurement of activity. No mice in this study will sustain blast TBI. In Experiment 2A (**Table 3**), a total of 20 mice will be used to ensure the operation of the AnyCage system. Specifically, untreated mice will be placed in individual AnyCage chambers to ensure the software and movable parts in the chamber are working properly. In Experiment 2B, 20 mice will be used to practice the surgical implantation procedure of the telemetry units and to ensure the units are working properly and recorded by the receiver systems. Experiments 3 and 4 (described below) will only take place when we have full procedural success in Experiment 2.

Table 3. Experiment 2. Pilot Studies

Experimental Treatment	No. of Mice	Pain/Distress Category
2A. AnyCage	20	C
2B. Telemetry	20	D

V.1.3. Experiment 3. Effects of blast exposure on daily activity in the AnyCage Chamber. As summarized in **Table 4**, a study will be performed to determine the effects of blast TBI on daily activity, feeding, drinking, and wheel running as evaluated by placement of mice in the AnyCage chambers. Briefly, 20 mice per treatment group will be individually housed in an AnyCage chamber beginning on Day 1 and randomly assigned to sustain one or five blast(s), or one or five sham treatment(s). Following each treatment, they will be placed back in individual AnyCage chambers for a total of 30 days.

Table 4. Experiment 3. Activity Effects of Blast		
Experimental Treatment	No. of Mice	Pain/Distress Category
1 Blast Exposure	20	E
5 Blast Exposures	20	E
1 Sham Treatment	20	E
5 Sham Treatments	20	E

As described later, these animals will receive behavioral testing on Day 8 (Open Field Test), Day 10 (Zero Maze), Days 14-17 (Morris Water Maze) and Day 21 (Porsolt Swim Test). All of the animals in this Experiment are in the Pain/Distress Category E, since that will be tested in the Porsolt Swim Test, where the mouse is placed in an inescapable water trough.

V.1.4. Experiment 4. Effects of blast exposure on daily activity and EEG activity as measured by telemetry.

The experimental design for Experiment 4 (**Table 5**) is identical to what was described for Experiment 3. However, in Experiment 4, the DSI PhysioTel® ETA-F10 transmitter system will be used. One week before blast exposure, animals will be deeply anesthetized and the transmitter will be implanted subcutaneously. Following implantation, the skin incision will be sutured. The two leads from the transmitter will be threaded underneath the animal's skin to attach one wire each to a screw placed over the midline of the skull and over the middle of the parietal bone. The

Table 5. Experiment 4. Short Activity and EEG Effects of Blast		
Experimental Treatment	No. of Mice	Pain/Distress Category
1 Blast Exposure	20	E
5 Blast Exposures	20	E
1 Sham Treatment	20	E
5 Sham Treatments	20	E

scalp wound will then be sutured so the mouse will not have access to the leads. A total of 20 mice per treatment group will then be placed back into their individual home cages that are positioned above the DSI receivers to allow recording of EEG and behavioral activity. On Day 1 (one week after transmitter implantation) animals will be randomly assigned to sustain one or five blast(s), or one or five sham treatment(s). Following each treatment, they will be placed back in their home cage, and they will remain there for 30 days. As described later, these animals will receive behavioral testing on Day 8 (Open Field Test), Day 10 (Zero Maze), Days 14-17 (Morris Water Maze) and Day 21 (Porsolt Swim Test). All of the animals in this Experiment are in the Pain/distress Category E, since that will be tested in the Porsolt Swim Test, where the mouse is placed in an inescapable water trough.

V.1.5. Experiment 5. Long term effects of blast exposure on daily activity.

Experiment 5 will evaluate the long-term effects of blast exposure on behavioral performance and histopathology. Mice in this experiment (**Table 6**) will receive behavioral testing as described in Experiments 3 and 4, but the testing will occur at a later time to determine whether or not there are long-term behavioral impairments from blast exposure. Please note these animals will not be evaluated in the AnyCage or telemetry activity units.

Table 6. Experiment 5. Short Activity and EEG Effects of Blast

Experimental Treatment	No. of Mice	Pain/Distress Category
1 Blast Exposure	20	E
5 Blast Exposures	20	E
1 Sham Treatment	20	E
5 Sham Treatments	20	E

These animals will receive behavioral testing on Day 68 (Open Field Test), Day 70 (Zero Maze), Days 74-77 (Morris Water Maze) and Day 81 (Porsolt Swim Test). All of the animals in this Experiment are in the Pain/distress Category E, since that will be tested in the Porsolt Swim Test, where the mouse is placed in an inescapable water trough.

V.2. Data Analysis:

Based on prior experience, a total of 10 mice for each of the four treatment groups in Experiment 1 should be sufficient. The estimate for the required number of animals needed for Experiment 1 is based upon a recent study we performed in mice that received a closed head injury (b)(6) (b)(6) In this study, there were 8 mice that each received sham treatment or a single closed head concussive injury. An analysis of variance was performed, and indicated there was a significant difference in staining density for orexin in the mouse hypothalamic region as a function of injury (mean difference=23.597, standard deviation of the residuals=13.474, $F_{1,14}$=12.264, p=0.004, power=0.891). I performed simulations using the SigmaPlot program for estimation of power of a similar analysis of variance, but in this case when there are four treatment groups and 10 mice per group. Power estimation indicated that with the aforementioned mean and standard deviation of residuals, power is approximately 0.891. For Experiments 3-5, a sample size of 20 mice/treatment group appears to be ample for behavioral testing and for what is usually reported in publications of mouse behavior testing (number of subjects per group is usually in the mid-teens). This estimate appears to be in line with suggestions by internationally recognized experts. For example, Crawley suggests that "N = 20 mice or more per genotype are often needed to complete the first set of behavioral tests in a new line of mutant mice" (Crawley, 2007).

Statistical Analyses: Food and water intake, and wheel running periods recorded in the AnyCages will be compared across treatment groups. Activity data acquired in the AnyCages will be evaluated to compare any changes during the light and dark phases (Pack *et al*, 2007). Data for activity and EEG wave function will employ the software supplied by the vendor of the transmitters (Data Science International, 2006). The SPSS statistical analysis program (IBM, version 20.0) will be used to compute the arithmetic mean and standard deviation of multiple measures of activity, EEG response and each behavior test employed. In addition, a repeated measures single-factor analysis of variance (ANOVA) will be used to assess whether or not performance on each test is the same when comparisons are made of repeated testing results. Calculations will be performed to determine whether or not the sample sizes/group were adequate to obtain sufficient power (≥0.70). If the data suggests there is variation between the

testing of each cohort of animals, a nested ANOVA can be used to assess whether or not there are differences between testing events on repeated tests. Finally, to assess some degree of the relationship of performance on tests within an experiment, correlation coefficients will be computed for each animal's score on each subtask. Neuropathological data also will be summarized based upon visual inspection and descriptions of level of pathology.

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered:

Animals are required for this research to assess *in vivo* cellular and molecular effects of blast-induced TBI and resulting behavioral performance. These data will provide a means for relating behavioral responses to central nervous system function *in vivo*. Non-animal alternatives do not replicate the three dimensional structure or temporal changes that occur as a function of complex behavioral responses to tasks presented to a live animal, including the evaluation of how TBI affects daily activity cycles. Further, computer modeling and *in vitro* methods will not address experimental questions of the complex, real-time changes and responses that occur during experience.

V.3.2. Animal Model and Species Justification:

By consensus of members of the CNRM, C57Bl/6 mice have been chosen as the suggested species and animal model for mouse TBI research (Anon., 2009). This is based upon the previous use of this strain in innumerable studies and their suitability as biomedical models for understanding central nervous system functions in normal and pathological states in humans and in other animals. The mouse is used for these studies because of their well-understood anatomy and endocrine responses, and the very extensive database of prior physiological research that can be integrated with this new information.

It is necessary to use mice instead of a "lower" species since the research results should be directly associated with intense efforts in other laboratories throughout the world to try and further our understanding and eventual treatment effectiveness for psychological stress and brain injury. Mice are commonly used small animal models for the study of neurobiological and genetics research, including the impact of physical injury and environmental stress upon neuron connectivity, experiential effects on synaptic plasticity, signal transduction, and for assessing treatments to reduce neurological damage and improve quality of life. In the case of murine transgenic and gene knockout models in neuroscience and behavioral research, "wild type" C57Bl/6 mice often serve as the genetic "background" or control for comparison of genetic and genetic/environmental effects (Crabbe, 1999; Crawley *et al*, 1997; Mishina and Sakimura, 2007). Recent work suggests that male and female mice exhibit similar behavioral impairments after TBI (Tucker *et al*, 2015a; Tueker *et al*, 2015b). Half of the mice per treatment group will be of each sex. A sample size of 10/sex/group will permit us to explore possible sex differences resulting from TBI, but this is not expected.

V.3.3. Laboratory Animals

	Species #1	Species #2
V.3.3.1. Genus & Species:	*Mus musuclus*	*Mus musuclus*
V.3.3.2. Strain/Stock:	C57Bl/6	C57Bl/6
V.3.3.3. Source/Vendor:	(b)(4)	

V.3.3.4. Age:	8-12 weeks		8-12 weeks
V.3.3.5. Weight:	20-25 grams		20-25 grams
V.3.3.6. Sex:	Female		Male
V.3.3.7. Special Considerations:	None		None
V.3.4. Number of Animals Required (by Species):	Mice: 200		Mice: 200

V.3.5. Refinement, Reduction, Replacement (3 Rs):

V.3.5.1. Refinement:

Four refinements will be performed in our protocol. **1.** After delivery to the University, rodents will be acclimated to the animal facility for 5-7 days before use. **2.** Investigator handling before the commencement of TBI procedures and behavioral testing will be used, to relieve distress from the potential combination of handling distress and the testing procedures. **3.** Prior to the use of animals in the ABS, the parameters of the blast are measured to ensure that the shock wave characteristics are consistent across days and approximate blast levels described in the literature for animal research. **4.** Analgesics and anesthetics will be used to decrease possible pain and distress resulting from surgery and blast.

V.3.5.2. Reduction:

We will perform pilot studies using the smallest number of animals possible to ensure proper operation of the AnyCage chambers and the telemetry system before using mice. This will ensure use of a larger cohort of animals will derive useful and reliable data. The number of animals for the larger scale studies (Experiments 3-5) is based on experience from working with rodent TBI models and behavioral assessments. If we find that variability in results is low and replicable results are obtained with a fewer number of animals, fewer animals may be used. Finally, we may obtain data that suggests that behavioral results are quite similar for the two sham groups in Experiments 3-5. Specifically, separate groups of mice are exposed to a one-time sham treatment while other mice will receive sham treatment (brought to the ABS room, anesthetized) five times. We may discover we can halve the number of animals in these groups as a means of reduction.

V.3.5.3. Replacement:

Biological response to central nervous system injury, psychological stress, and experimental treatments is highly complex; no alternative to *in vivo* experimentation is available or practical. We use a mouse model versus a nonhuman primate model or other higher species. Mice are the least sentient and derived animal model we could use for this study and still obtain results that are applicable to the mission of the research.

V.4. Technical Methods:
V.4.1. Pain / Distress Assessment:
V.4.1.1. APHIS Form 7023 Information:
V.4.1.1.1. Number of Animals:

	Species #1 (mouse)*	Species #2
V.4.1.1.1.1. Column C:	80	–
V.4.1.1.1.2. Column D:	80	–
V.4.1.1.1.3. Column E:	240	–

*Explanation of pain categories: 60 sham-treated mice used in Experiment 1 (Pilot Study) will receive no invasive or distressful treatment. They are Category C since they will only receive isoflurane treatments as the sham procedure for blast treatment and be placed in the AnyCage chambers. 60 mice in Experiment 1 are considered Category D. These mice will sustain blast exposure, but given analgesic as a safeguard to any pain. In Experiment 2, 20 mice are considered Category C since they will receive no treatment or surgery and will be housed in the AnyCage chambers. The remaining 20 mice in Experiment 2 are Category D since they will sustain surgical implantation of the transmitter, but they will be provided with analgesia to alleviate any pain from the surgical procedure. The 240 mice in Experiments 3-5 are assigned as Category E. They will be tested in the Porsolt Swim Test apparatus. As described below, this test involves inescapable placement in water, where the mouse must swim to maintain itself above water. Since blast exposure and surgery will include analgesia treatment, animals in this group do not meet the criterion of Category E for unalleviated pain from the sham treatment or blast exposure or transmitter implant, but from participation in the Porsolt Forced-Swim Test.

V.4.1.2. Pain Relief / Prevention:V.4.1.2.1. Anesthesia/Analgesia/Tranquilization:

Anesthesia for Blast and Sham Procedures: For the blast and sham procedures, mice will receive the inhalant anesthetic isoflurane + 100% oxygen (0.5-4% isoflurane, induction; 0.5-3% isoflurane, maintenance). Isoflurane will be delivered using a precision vaporizer via a rodent anesthesia machine. Induction will occur in an appropriately-sized clear viewing chamber. Following induction, rodents will be moved to the ABS device and anesthesia will be maintained via a nose cone. Waste anesthetic gases will be passively scavenged using a charcoal filter. Lack of paw-pinch reflex will be used to ensure adequate depth of anesthesia prior to beginning the procedure. Close attention will be given to ensure the rodents remain unconscious and are unresponsive and, if needed, supplemental administration of anesthetic will be given. Should experimental procedures with the ABS require an extended period of unconsciousness for the mice, we request an alternative to isoflurane anesthesia by the administration of an intraperitoneal injection of sterile ketamine (90-100 mg/kg) and xylazine (10 mg/kg) in the ventral caudal abdomen with a 26-28 gauge needle. Following blast or sham procedure, the mice will be monitored to verify anesthesia recovery as evident by ambulation and exploring their cage. During induction with anesthesia and during the recovery period, a warming pad is placed under the cage.

Anesthesia for Surgical Implantation of the ETA-F10 Transmitter: Animals undergoing surgical implantation of a telemetry transmitter will be anesthesized with ketamine (80 90-100 mg/kg b.w.) and xylazine (10 mg/kg b.w.) intraperitoneally in the ventral caudal abdomen with a needle size range of 26-28 gauge. Close attention will be given to ensure the rodents remain unconscious and are unresponsive to a paw-pinch and, if needed, supplemental administration of anesthetic ketamine and xylazine will be given. Following transmitter implantation, the mice will be monitored to verify anesthesia recovery as evident by ambulation and exploring their cage. Following the administration of anesthesia, during the implantation surgery, and during the recovery period, a warming pad is placed under the cage.

Analgesia: Mice exposed to the ABS exhibit a similar awakening time to what is observed in sham-treated animals, and they immediately begin exploring and sniffing behavior. Animals will be observed again one hour after home cage placement to ensure there are no signs of discomfort (difficulty breathing, hunched posture, trembling, lack of reaction to gentle touching (lethargy), or seizure activity). If needed, the LAM veterinarian will be consulted should there be signs of continued discomfort or distress. From previous observation of >100 mice in ABS studies, animals are not expected to experience pain or discomfort from the ABS procedure. However, mice will be provided with acetaminophen (Tylenol) in their drinking water (1 mg/ml; ~200 mg/kg b.w.) for 24 hours as a precaution. A similar procedure will be initiated in mice following implantation of the transmitter and cranial screws. Mice will be provided with acetaminophen (Tylenol) in their drinking water (1 mg/ml; ~200 mg/kg b.w.) for 24 hours.

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions:

Animals will be returned to the animal facility after all procedures. They will be monitored in their cages for complications, such as lethargy, reluctance to ambulate, inability to obtain feed, and seizures. If applicable, mice that will be returned to the animal facility after ABS procedures will be monitored in their cages for evidence of peritonitis or other complications following intraperitoneal injection of ketamine and xylazine (if these medications are employed instead of isoflurane). It is expected that complications will not be encountered. Any animal that experiences problems will be evaluated and treated or euthanized as determined by research staff or PI and Veterinarian.

V.4.1.2.3. Paralytics: N/A

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures:

V.4.1.3.1. Sources Searched: PubMed
V.4.1.3.2. Date of Search: July 9, 2015
V.4.1.3.3. Period of Search: 1986-2015

V.4.1.3.15. Results of Search: This search returned no hits.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification: The mice used in Experiments 3-5 will receive behavioral testing (see Tables 1 and 7). This testing involves use of the Porsolt Forced-Swim Test, which may elicit a moderate degree of distress. As described below, this test involves placing the mouse in a water-filled cylinder for a 2- and then a 4-minute trial. Mice must tread water to remain fully afloat (note that some mice quickly realize they essentially can remain still and float). It is necessary to perform this test with no tranquilization, since the animal must experience the challenge while fully awake and aware.

V.4.2. Prolonged Restraint: N/A

V.4.3. Surgery:
V.4.3.1. Pre-surgical Provisions: N/A
V.4.3.2. Procedure: The mice in Experiments 2B and 4 will receive implantation of an ETA-F10 transmitter for telemetric measurement of activity patterns and EEG in their home cage. The surgical procedure has been described previously by Born and colleagues (Born *et al*, 2014). After administration of anesthetic (see V.4.1.2.1. Anesthesia for Surgical Implantation of the ETA-F10 Transmitter) and ensuring the mouse is unresponsive, sterile technique is used to make a midline sagittal incision (~1 cm) from the posterior edge of the skull and down the nape. First, the fur is shaved from the nape and scalp of the mouse, the skin is washed with Betadine, wiped clean, and then dauhed with 70% ethanol. A subcutaneous pocket is made to position the transmitter (~1.6 g, 1.1 cm^3) in the dorsal midline of the animal, and two insulated wires from the transmitter are then connected to two small stainless steel screws (#80×1/8 in., Small Parts, Miami Lakes, FL) that contact the dura mater over the frontal and parietal bones of the skull (stereotaxic coordinates relative to bregma suture: recording electrode, +2.5 mm ANT, 2.5 mm LAT, and ground electrode, -1.0 mm POST, 1.0 mm LAT). Dental cement will be placed on the wire-screw connection to ensure contact. The incision is then closed using surgical glue (3M Vetbond Tissue Adhesive), the wound will be wiped again with ethanol and the incision is covered with a light coat of antibiotic cream.
V.4.3.3. Post-surgical Provisions: Mice will be provided with acetaminophen (Tylenol) in their drinking water (1 mg/ml; ~200 mg/kg b.w.) for 48 hours after surgery. Each day, they will be handled and visually inspected to ensure there is no sign of tenderness or swelling at the incision. If needed, the LAM veterinarian will be consulted should there be signs of continued discomfort or distress.
V.4.3.4. Location: (b)(6)
V.4.3.5. Surgeons: (b)(6)

V.4.3.6. Multiple Major Survival Operative Procedures: N/A
V.4.3.6.1. Procedures:
V.4.3.6.2. Scientific Justification: N/A

V.4.4. Animal Manipulations:

V.4.4.1. Injections:
Anesthetic injections will be administered as described in V.4.1.2.1. Anesthesia/Analgesia/ Tranquilization. At the completion of all experiments, mice will be euthanized as described in V.4.4.2 Biosamples.

V.4.4.2. Biosamples:
Following completion of behavioral testing and activity analysis, approximately one-half of the mice will receive transcardial perfusion to obtain immunohistochemistry biosamples. In this case, the animals will be anesthetized as described in Section V.4.1.2.1. Once the animals are deeply anesthetized and unresponsive to paw pinch, a midline thoracotomy is made to expose the heart, a 20-22 gauge blunt tip needle connected to a tube (¼ inch ID and $^{1}/_{16}$ inch wall) inserted into the left ventricle through the apex and the right atrium incised. After an initial washout with 20-30 ml of cold 100 mM phosphate buffered saline (PBS), transcardial perfusion with 50-75 ml cold 4% paraformaldehyde in PBS will be delivered through a gravity perfusion system. The brain will then be removed from the calvarium and post-fixed before tissue sectioning for immunohistochemical staining.

Approximately one-half of the mice will be directly euthanized and the brains will be removed from the calvarium to obtain samples of the cerebral cortex (fronto-occipital region and entorhinal region), hippocampus, diencephalon, and brain stem. Samples are quickly frozen and stored in liquid nitrogen before preparation for western blotting. Mice will be anesthetized as had been described in V.4.1.2.1. Anesthesia for Surgical Implantation of the ETA-F10 Transmitter Section.

V.4.4.3. Adjuvants: N/A

V.4.4.4. Monoclonal Antibody (MAbs) Production: N/A

V.4.4.5. Animal Identification:
To ensure long term identification, ear punches will be performed at the time of transmitter implantation, ABS, or sham treatment when the mice are unconscious.

V.4.4.6. Behavioral Studies:
The schedule for behavior testing is outlined in **Table 7**. The mice in Experiments 3-5 will undergo behavioral assessment. The mice in Experiments 3 and 4 will commence testing on Day 8 post-injury or sham treatment, where each animal will be tested in an open field (**OF**) environment for measurement of exploratory and locomotor behaviors. Then, on Day 10 they will be evaluated for performance on the Zero (**Ø**) Maze. On Days 14 through 17, each animal will be tested using the Morris Water Maze for spatial memory. Finally, on Day 28, mice will be tested in the Porsolt Forced-Swim Test. For the three-month study (see Experiment 5 in lower portion of Table 7), the mice will be tested on days as listed.

Table 7. Blast/Sham Treatment and Behavioral Testing Schedule for Mice in Experiments 3-5

Experiments 3 and 4							
Treatment	Day 1	Day 5	Day 8	Day 10	Days 14-17	Day 28	Day 30
	Monday	Friday	Monday	Thursday	Monday-Thursday	Monday	Wednesday
1x Blast	–	Blast	OF	Ø Maze	MWM	Porsolt	Euthanize
5x Blast	Blast Days 1-5		OF	Ø Maze	MWM	Porsolt	Euthanize
1x Sham	–	Sham	OF	Ø Maze	MWM	Porsolt	Euthanize
5x Sham	Sham Days 1-5		OF	Ø Maze	MWM	Porsolt	Euthanize
Experiment 5							
Treatment	Day 1	Day 5	Day 68	Day 70	Days 74-77	Day 88	Day 90
	Monday	Friday	Monday	Thursday	Monday-Thursday	Monday	Wednesday
1x Blast	–	Blast	OF	Ø Maze	MWM	Porsolt	Euthanize
5x Blast	Blast Days 1-5		OF	Ø Maze	MWM	Porsolt	Euthanize
1x Sham	–	Sham	OF	Ø Maze	MWM	Porsolt	Euthanize
5x Sham	Sham Days 1-5		OF	Ø Maze	MWM	Porsolt	Euthanize

Open field testing: Animals will be placed in an open field environment (size: 40 cm x 40 cm) and allowed to move freely for up to one hour. A camera over the apparatus is paired to Any-Maze video tracking software (Stoelting, Co, Wood Dale, IL) and the position of the animal is tracked for the duration of the test session. The software is able to provide a wealth of information regarding the behavior of the animal in the open field environment, including but not limited to the total distance traveled, movement speed, time spent immobile, and time/distance in user-defined physical zones of the open field arena. In addition, photobeam arrays allow measurement of movement in the z-plane (rearing). These measures allow conclusions regarding exploration, locomotion and anxiety-like states of the rodents.

Zero maze: Mice are placed in a darkened (walled) sector of the zero maze for five minutes. The apparatus is in the form of a circle (60 cm in diameter), elevated 50 cm above the floor. Two quadrants of the circular maze are darkened and enclosed, and the other two quadrants are "exposed. When placed in the maze, mice usually spend less time in the "open zones" due to perceived risk of falling and exposure to predators. Thus, reduced time exploring the open quadrants is considered an indicator of anxiety-like behavior. The time the mouse spends in the light versus the dark zones of the apparatus is measured as attest of mild anxiety (Kulkarni *et al*, 2007).

Morris Water Maze: The Morris Water Maze is a standard test of the rodent's spatial memory capabilities and has been used successfully in TBI experiments performed by many investigators in the CNRM. A Stoelting Morris Water Maze (diameter 4.0 m) tank is filled with tap water (25°C) to a depth of 20-30 cm. A clear plastic platform is placed in one of the "quadrants" of the tank floor and visual cues (solid geometric shapes) are placed on the room walls in locations that can be viewed by animals in the pool. On Day 1 (Day 8 post-injury or sham treatment), a single pre-training trial is first used where the mouse is gently placed on the platform in the tank and the mouse remains there for 15 seconds. If the mouse jumps into the water during this time, it is allowed a brief swim (<60s) before being guided back to the platform. On Day 2, training trials begin where the mouse is placed near the side of the tank in a location away from the platform, and is allotted 90 seconds to swim to the platform. Upon finding the platform, the mouse remains on the platform for 15 seconds. If the mouse does not reach the platform in the allotted 90 seconds, they are gently guided to the platform and allowed

to remain there for 15 seconds. A total of four trials, separated by 1-2 min, are performed each day. Swimming movements of the mouse are tracked, and swim speed (distance before reaching the platform) and latency to find the platform are calculated by Any-Maze software. Finally on the fourth day of training (Day 11) approximately one hour after the final training trial, a single trial is performed with the platform removed from the tank. The time spent in the pool quadrant where the platform was located is measured, compared to time spent in the other three quadrants. After all trials, mice are placed in a clean cage underneath a heating lamp until thoroughly dried (approximately five minutes) to maintain thermoregulation.

Additional measurements are possible with the Morris Water Maze. Beginning the next day, *reversal training trials* will take place in which the location of the hidden platform is moved to the opposite side of the tank (Zhao *et al*, 2012). The pre-training phase is omitted, and each mouse receives four 90-sec trials for four days. A second probe trial will take place approximately one hour after the final reversal training trial. Finally, immediately after the reversal probe trial, a single visible platform trial will be conducted. A pipette with a very visible "flag" will be secured to the platform. The latency of the mouse to navigate to the cued platform is recorded (maximum of 90 sec).

Forced-Swim Test: The Porsolt Forced-Swim Test (Porsolt *et al*, 1978) evaluates behavioral despair/learned helplessness. The mouse is placed in a cylindrical container of water (10 cm deep, 25±1°C) and the amount of time the mouse swims is recorded. A pre-exposure session of two minutes immediately precedes the test trial, which is four minutes in duration (the total duration of the exposure is six minutes). Mice tend to float with their heads above water if they stop swimming; however, they will be continuously monitored during the test and any animal that appears to be in danger of sinking will be immediately removed from the water by the experimenter.

V.4.4.7. Other Procedures:

Overpressure (blast)-induced traumatic brain injury

Mice will receive TBI by an overpressure shock wave generated by the ABS. All mice are first anesthetized as described in Section V.4.1.2.1 and weighed. Mice are individually secured in a holder that is inserted inside the distal end of the shock tube. After sustaining a short duration of shock wave stimulation (<10 msec), mice will be returned to their home cages after the procedure and monitored until they regain consciousness. Sham-treated animals will receive anesthesia and be placed in the holder at the distal end of the shock tube, but no shock wave will be produced. All animals will be monitored at least once per day following TBI or sham procedures. Animals are not expected to experience pain or discomfort from TBI, but will be provided with acetaminophen (Tylenol) in their drinking water (1 mg/ml; ~200 mg/kg b.w.) as a precaution. Animals will be observed again one hour after home cage placement to ensure there are no signs of discomfort (difficulty breathing, hunched posture, trembling, lack of reaction to gentle touching (lethargy), or seizure activity). If needed, the LAM veterinarian will be consulted should there be signs of continued discomfort or distress.

For some experiments when mice sustain shock wave overpressure in the ABS, a high speed camera (Motion Pro Y4, IDT) and image acquisition software (Motion Studio, IDT) will be used to capture motion at a rate of 4,500 frames per second. Each video "clip" is approximately 2 seconds in duration. Subsequently, the acquired videos are imported into motion analysis software (Proanalyst Professional Edition, Xcitex) to determine device, and/or head and body movement. This will be performed following the procedures outlined in USUHS IACUC Policy #25 (USUHS, 2013). Video images will be stored on a dedicated workstation that is password protected. In addition, to ensure availability of the data should the hard drive in the workstation

fail, a backup external drive will be employed. The workstation is located in Room (b)(6) (ABS anteroom). The hard drive is in a secured area of the LAM facility in Room (b)(6) which has a locking door, and is stored in a locked cabinet. The videotaping will be performed by Dr. (b)(6) in the mouse surgery suite (Room (b)(6) or ABS testing suite (Room (b)(6) and viewed in Rooms (b)(6) Only Dr. (b)(6) and Dr. (b)(6) will have access to the videotapes as they analyze and summarize the findings. The data analysis phase is labor-intensive and will require retaining the video recordings until all data analysis is completed, but we request retaining the images for three years after the completion of this protocol (e.g., August 1, 2018 if this is the date for initial approval of this protocol + 3 years to September 30, 2021). At that time the images will be erased from the workstation's hard drive and the external hard drive. Please note the measures are converted to numerical values in a spreadsheet and this information will be retained. Actual video images will never be utilized in a presentation at USU or outside the University. Should there be any need for a depiction of a rodent in a publication or a lecture, drawings will be created in place of actual images. It is expected that the data presented in graphical format will be adequate for readers or lecture attendees to visualize motion parameters.

V.4.4.8. Tissue Sharing:

Excess mouse tissue will be made available to other investigators in our or other labs.

V.4.5. Study Endpoint:

The study endpoint is survival for the previously described durations (1 or 3 months), at which time animals will be euthanized.

V.4.6. Euthanasia:

Euthanasia will be performed in accordance with "AVMA Guidelines for the Euthanasia of Animals: 2013 Edition." Methods of euthanasia on this protocol include decapitation and perfusion. Mice are first anesthetized for these procedures. Euthanasia will be performed by the PI or his associates in B2051.

Perfusion: Following anesthesia per Section V.4.1.2.1, we will ensure animals are deeply anesthetized and unresponsive to paw pinch. A midline thoracotomy is made to expose the heart, a 20-22 gauge blunt tip needle connected to a tube (¼ in ID and $^{1}/_{16}$ in wall) inserted into the left ventricle through the apex and the right atrium incised. After an initial washout with 20-30 ml of cold 100 mM phosphate buffered saline (PBS), transcardial perfusion with 50-75 ml cold 4% paraformaldehyde in PBS will be delivered through a gravity perfusion system. The brain will then be removed from the calvarium and post-fixed before tissue sectioning for immunohistochemical staining.

Decapitation: Following anesthesia per Section V.4.1.2.1, we will ensure animals are deeply anesthetized and unresponsive to paw pinch then use a rodent guillotine to decapitate the anesthetized rodents. The decapitation equipment will be cleaned and maintained to ensure the proper function by routinely checking to ensure it is not rusted or blunt. It will be either sharpened or replaced if it does not function properly. A log book will be kept of the maintenance of the guillotine.

In the event that LAM personnel must euthanize an animal for humane reasons, cylinderized carbon dioxide will be used in the LAM necropsy room. Using a clean cage, carbon dioxide will be administered at a rate to replace greater than 20% of the cage volume per minute. Once the

animals have not moved or breathed for at least one minute they will be removed from the chamber. Euthanasia may be ensured by cervical dislocation or opening of the thorax.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol.

V.5.1.1. Study Room:

Building(s)	(b)(6)	Room Number(s)	(b)(6)
Building(s)		Room Number(s)	
Building(s)		Room Number(s)	

V.5.1.2. Special Husbandry Provisions:

Food Restriction: Yes _____ No __X__

Fluid Restriction: Yes _____ No __X__

V.5.1.3. Exceptions: Experiments 2A and 3 will employ the Stoelting Company's (Wood Dale, IL) ANY-Maze Cage chambers. There are eight of these located in Room (b)(6) that can be used to individually house eight mice for continuous measurement of activity as a function of time. The apparatus is a home cage encased within an isolation chamber that limits external influences from the housing facility and other animal activities and odors. The chamber is equipped with an infrared-sensitive light and LEDs that provide continuous tracking of the animal via a built-in camera linked to Any-Maze tracking software. As noted, the chambers collect continuous data related to behaviors, including but not limited to, movements and spontaneous activity, wheel-running activity, diurnal activities, rearing behaviors, and food and water consumption. A computer controls the light-On and light-OFF period similar to the housing rooms in LAM, and a temperature sensor maintains a constant chamber temperature. Investigators will open the chambers once per day to visually inspect the cage and animal and provide fresh food and water, as needed. The cage is provided with wood shaving bedding, as well as nestlet material, which will be exchanged once per week. At the completion of each run with a particular mouse, the chamber will be thoroughly cleaned, where the home cage, feeding hoppers, running wheels, and water tubes are replaced with sanitized pieces that were cleaned in the LAM cage washer. Finally, after cleaning, the NovaLUM device from Charm Sciences, Inc., will be used to swipe surfaces in the cage to monitor for the presence of ATP as a measure of sanitation hygiene. Records from the readings will be documented, and if any surface is found to have detectable amounts of ATP, it will be cleaned again.

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care:

The PI or research staff will observe the mice following all procedural manipulations. LAM personnel will observe the animals in Room (b)(6) at least once a day for general health and husbandry condition. For the AnyCage systems (b)(6) investigators will open the chamber doors once per day to visually inspect the cage and animal and provide fresh food and water, if needed. Any animal observed to be lethargic, losing weight observed by weight recording every other day, exhibiting gross neurological deficits (such as inability to eat or drink, continual circling, seizures, etc.) or any other signs of distress or illness will be evaluated by the PI and/or veterinary staff, then euthanized as previously described.

V.5.2.2. Emergency Veterinary Medical Care: All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: The mice in Experiments 1 and 5 will be group-housed. Animals will be provided routine enrichment as described in LAM SOPs with the exception of V.5.3.2. below.

V.5.3.2. Enrichment Restrictions: For Experiments 2, 3-5, request to singly house mice with wood shaving bedding and nestlet material, but not plastic tunnels or other toys. The AnyCages and telemetry units require single housing to enable recording of data. Regarding enrichment materials, the AnyCages have bedding, nesting material, and a running wheel, which will provide enriching activity for the mice. However, inclusion of plastic tunnels will interfere with data collection. The telemetry systems are standard LAM mouse home cages with wood shavings and nesting material. EEG and activity recording requires a flat cage floor to not alter or lose signal, which might occur should a plastic object be placed in the home cage.

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
ABS traumatic brain injury	(b)(6)	All individuals have experience with animal models of TBI.	All individuals will receive extensive on-site training from the manufacturer of the ABS
Rodent behavioral testing		(b)(6) has > 15 years of experience in rodent handling and behavioral testing and an M.S. in Behavioral Neuroscience. (b)(6) has > 2 years of experience in rodent handling and behavioral testing from UC Irvine.	Personal laboratory experience. (b)(6) be trained by (b)(6) (b)(6)
IP injections		(b)(6) has many years of experience in rodent handling and drug administration.	All listed investigators have taken the Rodent Handling and Procedural Techniques.*
Euthanasia by decapitation		(b)(6) experience with rodent decapitation >30 years. He will instruct listed colleagues on this procedure.	Performed similar procedures for recent Protocols (b)(6) (b)(6)
Intracardial perfusions		(b)(6) and (b)(6) have many years of experience with perfusions. (b)(6) has experience from when she was an undergraduate, but she will observed and be trained by Drs. (b)(6)	Personal laboratory experience. (b)(6) will receive training from the approved personnel on this protocol.
Inhalant anesthesia administration		(b)(6) and (b)(6) have many years of experience with the adminstraiton of inhalant anesthesia..	Personal laboratory experience. (b)(6) will receive training from the approved personnel on this protocol.

*All listed investigators have attended the USUHS Investigator Training Course: Dr (b)(6) on August 17, 2005, (b)(6) completed several online USUHS Investigator Training Courses on October 28, 2009 and attended the Rodent Handling and Procedural Techniques on November 19th, 2009. She is previously approved to perform the above procedures under (b)(6) has completed the online USUHS Investigator Training Course on September 9, 2008 and the Rodent Handling and Procedural Techniques on September 24, 2009. She is approved to perform the above procedures under protocol (b)(6) Dr (b)(6) completed the Investigator Training course on November 19, 2004 and the training of the Collaborative Institutional Training Initiative (CITI) Program. "Investigators, Staff and Students – Lab Animal Research." on May 14, 2014 (b)(6) completed several USUHS online investigator training courses including "Working with the IACUC" (non-VA) on April 23, 2013 and the USUHS Investigator Training Courses on June 6, 2013 (b)(6) completed USUHS online training on June 2nd, 2015 and attended the USUHS Investigator Training Course on July 2nd, 2015.

VII. BIOHAZARDS/SAFETY:

To minimize exposure to animal allergens when working with lab animals, lab personnel will wear lab coats and/or scrubs, gloves and masks. We will always wear lab coats and gloves when

we contact toxic chemicals and perform some steps in a fume hood to minimize risk of exposure to these teratogens. Potential fumes from fixative are minimized by allowing the fixative to be constantly washed down the sink drain.

The Environmental Safety & Occupational Health (**EHS**) Office performed a recent hazard assessment of the noise levels produced by the ABS. Before their visit the staff was already wearing hearing protection devices. EHS determined that the hearing protection practices are sufficient. As a precaution, they propose to develop a hearing conservation program, where ABS operators will receive annual hearing tests.

VIII. ENCLOSURES:

Literature search results for Sections II.2 (Searches for unnecessary duplication) are available upon request.

Attachment: Policy 025 (related to Section 4.4.7. Other Procedures, ABS Characterization).

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

G. Training: The following personnel will attend the next USUHS Investigator/Animal User Training Course:

H. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely, "Responsibility" for implementing animal use alternatives where feasible and conducting humane and lawful research.

I. Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL or WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

X. PROTOCOL ABSTRACT:

A. **Animal Protocol Number:** (b)(6)

Animal Protocol Title: The impact of blast exposure on mouse daily activities

C. **Principal Investigator:** (b)(6) Ph.D.

D. **Performing Organization:** Uniformed Services University of the Health Sciences

E. **Funding:** Defense Health Agency, DoD

F. **Objective and Approach:**

The goal of this research is to determine the impact of traumatic brain injury (TBI) on mouse daily activity-rest cycles. Previous research has shown that TBI can cause changes in overall arousal, agitation and irritability, motor activity, and disturbances in sleep-wake cycles. The studies here will determine whether or not exposure to a single or repeated atmospheric overpressure shock wave (similar to the shock wave generated by blasts of explosives in combat settings) disrupts "normal" activity in mice during waking and sleeping hours.

A series of behavior tests will assess mouse performance to evaluate the behavioral changes from an exposure to an overpressure shock wave to gather basic information about the effects of blast on daily activity rhythms, including motor activity in the home cage, wheel running activity, and food and water intake patterns. It is predicted that much like in patients suffering from TBI these activity patterns will be altered by injury. The data collected will then be summarized using conventional statistical approaches (mean, standard deviation, analysis of variance, correlation and regression analyses). We will use as few rodents as possible while still using enough to make valid conclusions. To do this initial research we must use animals since cells or tissues do not reflect the natural activity cycles of a live organism. We hope that this basic research and use of animals will aid in understanding some of the causes for the long-term effects of brain injury upon warfighters returning home to their towns, work, and families, and that this research may allow us to provide better treatments to help suffering soldiers.

November 06, 2015

MEMORANDUM FOR DR. (b)(6) DEPARTMENT OF ANATOMY, PHYSIOLOGY, AND GENETICS

SUBJECT: IACUC Approval of Protocol - Initial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on November 06, 2015:

Animal Protocol Title: "Targeting the Ubiquitin Proteasome System to Treat Spinal Muscular Atrophy"

USUHS Protocol Number: (b)(6)

Expiration Date: November 05, 2018

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a post approval meeting with LAM (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. NON-TECHNICAL SYNOPSIS:

Goals of Study:
1) To treat mice with drugs that are potential therapeutics for spinal muscle atrophy (SMA). Building on our previous results using trichostatin A, we would like to confirm and expand our experiments using both trichostatin A and bortezomib to study the therapeutic potential of these drugs, alone and in combination.
2) To conduct behavioral testing on these mice in order to determine if there are any improvements in motor function after drug treatment.
3) To interrogate drug mechanisms of action and the role SMN plays in the development and maintenance of motor neurons using primary neuronal cultures from SMA model mice.

II. BACKGROUND:

II.1. Background:

The goal of this study is to determine the mechanism of the disease spinal muscular atrophy (SMA) and to identify novel therapeutics to treat the disease. SMA is a disorder that is characterized by degeneration of motor neurons of the spinal cord leading to muscle paralysis and atrophy. The disease is caused by mutation of the 'survival of motor neuron' (SMN) gene which leads to decreased levels of the SMN protein. The exact function of the SMN gene is yet to be completely determined, but it is believed to be involved in RNA processing. Still, the question remains why reduced levels of the SMN protein affects only motor neurons. In humans SMN is encoded by two genes, SMN1 and SMN2. SMA is caused by deletions and other mutations of the SMN1 gene. All SMA patients lack a functional copy of SMN1 but retain at least one copy of SMN2. Rodents on the other hand, have only one copy of the SMN gene and inactivation of the SMN gene in mice leads to very early cell death in mouse embryos suggesting an important role of SMN in development. (b)(6) lab at Ohio State University has created SMA mice which lack the SMN gene that have been rescued from early death by introducing the human SMN2 transgene [1]. These mice serve as an excellent model system to study SMA and could be used to test possible therapeutics. We will be treating animals with drugs that have been proven to increase both SMN transcript and protein levels in cell culture in order to determine if they will help treat the disease in whole animals and alleviate the severity of the disease.

The purpose of this study is to study the effects of increasing expression of the SMN protein on transgenic SMA model mice. Genetic, histological, and primary tissue culture studies, as well as treating animals with potential therapeutic drugs will be performed.

1. Mouse Model.
(b)(6) lab at Ohio State University created an SMA mouse model which lack the smn gene but carries two copies of the human SMN2 transgene, which rescues lethality [1]. These mice (SMN delta7;SMN2;Smn-/-) aka Delta 7, survive for 14 days on average providing a therapeutic window. At 5 days of age, Delta7 mice have considerable difficulty righting themselves when placed on their backs. The weakness becomes progressively more pronounced over the next week of life. By 10 days of age, it is clear that SMA mice homozygous for the SMNdelta7 and SMN2 transgenes have difficult ambulating and often fall over while walking. When they do walk, they display an abnormal gait and shakiness (fibrillation) of the hind limbs. Our lab will be using SMA mice along with unaffected littermates (wild type and heterozygous mice) to study the role SMN plays in the development and maintenance of motor neurons. These mice serve as an excellent model system to study SMA and could be used to test possible therapeutics.

2. Drug Treatments. The following pharmaceutical grade drugs compounds will be used in this study: Trichostatin A (TSA) from Enzo and Bortezomib from Millenium Pharmaceuticals. Our previous studies demonstrated that repeated daily doses of TSA increased both *SMN2*-derived transcript and SMN protein levels in neural tissues and muscle. When TSA was delivered daily beginning on post--natal day 5, after the onset of weight loss and motor deficit, there was improved survival, attenuated weight loss, and enhanced motor behavior. These results indicated that HDAC inhibitors activate SMN2 gene expression in vivo and have an ameliorating effect on the SMA disease phenotype when started after disease onset[2]. SMN has recently been shown to be turned over by the proteasome and treatment of cells in culture with proteasome inhibitors results in elevated levels of SMN [3, 4]. Both drugs (TSA and bortezomib) will be administered in combination to determine any synergistic effects.

3. Primary neuron cultures. SMA is a motor neuron disease. Primary neurons with low SMN levels are the best tools to study the underlying molecular events that lead to motor neuron death when SMN is deficient. We will isolate and culture motor neurons from affected, heterozygous and wild type embryos and perform RNA sequencing to identify key molecular changes in neurons that could lead to cell death.

II.2. Literature Search for Duplication:
II.2.1. Literature Source(s) Searched: BRD
II.2.2. Date of Search: June 9, 2015
II.2.3. Period of Search: 1998-2015
II.2.4. Key Words and Search Strategy:
Keywords: Mouse, Spinal muscular atrophy, protein degradation, bortezomib, trichostatin A—Results: 0 hits
Keywords: Animal, Mouse, SMA or ubiquitination—Results: 0 hits
II.2.5. Results of Search:
The BRD database includes 12,797 records of previous research programs. No hits were found that identified the terms with protein degradation and spinal muscular atrophy.

Conclusion: No related hits indicated there is no overlap with previous research programs in the DoD.

II.2.6. Literature Source(s) Searched: FEDRIP
II.2.7. Date of Search: June 9, 2015
II.2.8. Period of Search: 1986-2015.
II.2.9. Key Words and Search Strategy:
Animal, Mouse, SMA, protein degradation, bortezomib, trichostatin A, proteasome or ubiquitination
II.2.10. Results of Search:
The keywords, "Animal, Mouse, protein degradation, proteasome or ubiquitination," produced 1 hit. With just the keywords, "SMA and proteasome," there were 0 hits.
Conclusion: Finding no other related hits indicates there is no overlap with previous federally sponsored research programs.

II.2.6. Literature Source(s) Searched: Pubmed
II.2.7. Date of Search: June 1, 2015
II.2.8. Period of Search: 1986-2015.
II.2.9. Key Words and Search Strategy:
Animal, Mouse, SMA, protein degradation, bortezomib, trichostatin A, proteasome or ubiquitination
II.2.10. Results of Search:
The keywords, "Animal, Mouse, protein degradation, proteasome or ubiquitination," produced three hits. With just the keywords, "SMA and proteasome," there were three hits. All three are our previous studies. This proposal builds on our previous work showing that the ubiquitin proteasome system is a potential therapeutic target for treating SMA.
Conclusion: Finding no other related hits indicates there is no overlap with previous research programs.

III. OBJECTIVE\HYPOTHESIS:

The *objective* of this study is to determine the mechanism of the disease, spinal muscular atrophy (SMA), and identify therapeutics that could help treat the disease. SMA is a disorder that is characterized by degeneration of motor neurons of the spinal cord leading to muscle paralysis and atrophy. We will be treating animals with drugs that have been proven to increase both SMN transcript and protein levels in cell culture in order to determine if they will help treat the disease in a whole animal and alleviate the severity of the disease.

IV. MILITARY RELEVANCE:

The military relevance of this protocol relates to the goals of basic, laboratory research to develop therapies that prevent or reduce the long term consequences of spinal muscular atrophy. Better understanding of the biological mechanisms of spinal muscular atrophy may lead to more effective treatments for our service member families and civilians.

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures:

General Approach: The planned experiments have the following goals.

In Vivo:

1) 5 day old (P5) spinal muscular atrophy (SMA) model mice and unaffected littermates and the moms who will be nursing the pups will be transferred from our breeding protocol.

2) To treat mice with drugs that are potential therapeutics to treat SMA. Building on our previous results using trichostatin A, we would like to confirm and expand our experiments using both trichostatin A and bortezomib to study the therapeutic potential of these drugs, alone and in combination.

3) To conduct behavioral testing on these mice in order to determine if there are any improvements in motor function after drug treatment.

In Vitro:

1) To determine any changes in the survival of motor neuron (SMN) gene transcript and protein levels from various tissues of drug treated mice.

2) To look histologically at spinal cord and muscle tissues for any cellular improvements after drug treatment.

3) Pregnant females at E12 will also be transferred from the breeding protocol in order to isolate motor neurons from embryos for in vitro assays. We will study primary cultures of motor neurons from normal and SMA mice in order to learn more about the mechanism of this motor neuron disease.

V.1.1. Experiment 1.1: *Evaluation of compounds that may alter SMN protein levels in SMA mice.*

Experiment 1.1: Drug Treatments: The drug injections will be limited to the histone deactylase (HDAC) inhibitor Trichostatin A (TSA) and the proteasome inhibitor bortezomib (Table 1). Both drugs are solubilized in DMSO. Therefore SMA mice will be treated with DMSO defined as "vehicle" treated mice to serve as our baseline control. Our previous study demonstrated that repeated daily doses of TSA causes increases in both SMN2-derived transcript and SMN protein levels in neural tissues and muscle. When TSA was delivered daily beginning on post-natal day 5, after the onset of weight loss and motor deficit, there was improved survival, attenuated weight loss, and enhanced motor behavior. These results indicated that HDAC inhibitors activate SMN2 gene expression in vivo and have an ameliorating effect on the SMA disease phenotype when started after disease onset. We postulate that we could synergistically improve the disease phenotype by treating these animals with the proteasome inhibitor bortezomib in combination with trichostatin A. SMN has recently been shown to be turned over by the proteasome and treatment of cells in culture with proteasome inhibitors results in elevated levels of SMN. We hypothesize that increasing SMN levels with trichostatin A and inhibiting SMN turnover will further improve the disease phenotype. Both drugs will be administered by themselves or in combination to determine any synergistic effects. Starting at P5 litters and mom will be transferred from breeding protocol and drugs will be administered, daily in the case of trichostatin A and every 48 hours for bortezomib, intraperitoneally using a 33 gauge needle (Hamilton microliter syringe #705 (20 mm (1 in.)); smallest needle available for the volumes of drug to be used). Drugs will be dissolved in 5% DMSO. Vehicle treated animals will be administered 5% DMSO v/v in water. TSA will be dissolved in DMSO to a concentration of 4 µg/µl. SMA mice and their WT and heterozygous littermates will receive 10 mg/kg in a volume of 2.5 µl/g body weight (maximum 35µl). Mice will be genotyped at P10 to confirm which are affected by SMA. Unaffected mice will be used as controls. The intraperitoneal injection would allow rapid diffusion and fast onset of the drug. Pups will be observed and weighed daily from P5 to P20 (20 days). We have performed several published studies using this administration regimen with this mouse model at the designated times [2, 5, 6]. When each mouse has

completed the drug study, (day P20) fluid and food supplements will he supplied as recommended by veterinarians. The major source of nutrients for pups under study will be provided by the female breeder. Based on our experience with these mice we believe that the SMA affected pups are still able to latch onto the mom and feed. Since untreated mice survive 14 days on average, the number of days of survival past day 14 will be observed; representing the experimental endpoint. Study end-point is survival until mice are moribund after which mice will he euthanized and tissues collected. 20% loss in body weight is very early in the progression of the disease in SMA mouse models. We have found that a 30% loss in body weight, calculated based on the maximum weight achieved is a better estimate of moribundity and will allow us to better evaluate the efficacy of drug treatment. This maximum weight is usually achieved at postnatal day 11. If no ability to right after 1 minute OR greater than 30% weight loss (from maximum weight), pup will be euthanized (age P5-P21).

Table 1: Experimental Drugs

Name	Concentration	Dose & Volume	Side-effects
Trichostatin A Vehicle: DMSO	#10 mg/kg/day (Range of possible doses 0.5-10 mg/kg/day) Starting at P5 Ending at P20	IP vol. 10-12 ul/g mice ~ 20 µl total volume	Rough hair coat; diarrhea; lethargy/inactivity
Bortezomib (PS-341) Vehicle: DMSO	*0.15 mg/kg/2 day (Range of possible doses 0.1-1 mg/kg/2 days) Starting at P5 Ending at P20	IP vol. 10-12 ul/g mice ~ 20 µl total volume	Diarrhea; peripheral neurotoxicity.

Experiment 1.2: Starting at postnatal day 5 animals will also be used for behavioral testing of motor function using the time to right test (for motor coordination and balance). The same cohort of animals described in Experiment 1.1 will undergo behavioral testing here.
Procedures: Animals will be transferred from the animal holding room to the experimental room and allowed to habituate to the experimental room for 60 min.

Righting time: Righting time will be measured daily starting at P5 until study endpoint. Right ting time is defined as the better of 2 trials of the time for the pup to turn over to its front after being placed completely on its back (maximum 30 seconds).

Following each procedure mice will be monitored and weighed daily. The PI will consult with LAM veterinarians on a case by case basis to determine pain and distress in all animals. Animals deemed to be in distress will be treated or euthanized by LAM personnel, PI or his staff based on designated endpoint criteria outline **V.4.5**

Table 2: Experiment 1					
Injection	**Total number of experimental animals**	**Injection site (number of experimental animals)**	**Endpoint days (number of experimental animals)**	**Analysis**	**Pain category (number of animals)**
Vehicle (DMSO)	240	Intraperitoneal (60)	Medical endpoint (outline V.4.5)	Survival and behavior	C(45) E(15)
Bortezomib		Intraperitoneal (60)			C(45) E(15)
TSA		Intraperitoneal (60)			C(45) E(15)
TSA + Bortezomib		Intraperitoneal (60)			C(45) E(15)

Approximately 25% of litters will be SMA pups and 75% phenotypically normal mice. We will need approximately 15 TSA, 15 bortezomib, 15 TSA + bortezomib and 15 vehicle (DMSO) treated SMA mice). All SMA mice are category E. All phenotypically normal mice (wild type and hets) are category C.

Therefore, total SMA mice to be treated = 60
Total mice to be treated = 4 x 60 = 240
Total pregnant moms to be used (assuming 6 pups per litter) = 40

Total number of animals = (240 +40) = 280

Flow Outline of Experiments:

The animals used for these experiment are affected SMA mice. SMN delta7; SMN2:Smn -/-.These mice represent only 25 % of each litter; therefore the number of animals required will be 4 times the number of SMA pups. Heterozygous and wild type mice will serve as controls for experiments (Category C). We use the heterozygotes and wild type animals as controls as well as any unforeseen adverse events that may occur due to the drugs and not the disease course.

Flowchart Title: Survival and motor function studies in SMA mice treated with TSA/Bortezomib (**Experiment 1**)

A) **Total number of animals= 280** (40 litters with average litter size of 6 pups + 40 pregnant moms)

(Approximately 25% will be SMA pups and 75% wild type and heterozygous mice. We will require 15 TSA, 15 bortezomib, 15 TSA + bortezomib and 15 vehicle (DMSO) treated SMA mice)

Litter of pups:
25% SMA pups (SMN2+/+/SMNdelta7+/+/mSmn-/-)
75% normal littermates (SMN2+/+/SMNdelta7+/+/mSmn+/- &
SMN2+/+/SMNdelta7+/+/mSmn+/+).

At postnatal day 5 (P5), mice will randomly be assigned to receive daily intraperitoneal injections of vehicle (DMSO), TSA (10 mg/kg) and/or .15 mg/kg bortezomib every other day.

Pups observed, weighed, and treated daily from P5 to P20 (16 days). Genotyped at P10

↓

Pup is euthanized if moribund as defined by inability to right during a 1 minute observation period OR greater than 30% weight loss (from maximum weight achieved).

↓

At P21 pups will be weighed and weaned (if appropriate). Treated pups will then be observed daily until moribund (approximately 21 days) for evidence of any residual drug toxicity such as lethargy, weight loss, exhibiting gross neurological deficits (such as inability to eat or drink, continual circling, seizures, etc.) or any other signs of distress or illness. Pup will be euthanized if moribund as defined by inability to right during a 1 minute observation period OR greater than 30% weight loss (from maximum weight achieved). If pup shows severe respiratory distress, it will be euthanized.

Experiment 2

2.1 Biochemical analysis of SMA tissue

Starting at P5 drugs will be administered, daily in the case of trichostatin A and every 48 hours for bortezomib, intraperitoneally until P12 (doses as described in Experiment 1). Mice will be genotyped at P10 to confirm affected (SMN delta7 +/+;SMN2+/+;Smn-/-). Pups (SMA, het and wild type) will be deeply anesthetized with 2-5% isoflurane at P12. Depth of anesthesia will be verified by pinching all four paws with forceps to make sure that there is no withdrawal reflex. Mice will then be euthanized by cervical dislocation. The brain, spinal cord, liver and hindlimb skeletal muscle will be dissected and quickly frozen. RNA and protein will be extracted from each tissue section by standard procedures. RNA transcript levels will be measured by quantitative RT-PCR and protein levels will be measured by Western blot.

Histology of spinal cords and muscle.

2.2 Hematoxylin-eosin stains will be performed on muscle sections.

1. Starting at P5 drugs will be administered, daily in the case of trichostatin A and every 48 hours for bortezomib, intraperitoneally (doses as described in Experiment 1). Mice will be genotyped at P10 to confirm affected (SMN delta7 +/+;SMN2+/+;Smn-/-). Pups will be deeply anesthetized with 2-5% isoflurane. Depth of anesthesia will be verified by pinching all four paws with forceps to make sure that there is no withdrawal reflex. Deeply anesthetized animals will then be

transcardially perfused briefly with cold 1X PBS. The tibialis anterior muscle and spinal cord tissue will be dissected out, mounted on wooden blocks, and flash frozen in liquid nitrogen-cooled isopentane.
2. 10-12 um thick transverse muscle sections will be cut and mounted on Superfrost slides, and air dried.
3. Sections will be fixed with 100% ethanol, rinsed with water and stained with hematoxylin, rinsed and stained with eosin, rinsed and dehydrated with ethanol and cleared in xylene before mounting in Permount for light microscopy.

Immunocytochemistry will be performed on motor neurons (same mice used in histology of spinal cords section above).
1. After the animals are euthanized by transcardial perfusion, the spinal cord will be dissected. Ventral roots, lumbar spinal cord and the brain stem will be post-fixed 24 h in 100% ethanol as outlined above.
2. The brain stem and spinal cord will then be embedded in paraffin.
3. Serial sections (6 um) will be mounted on glass slides and stained with Nissl's stain.
4. Ventral roots will be post-fixed in 1% osmium tetroxide, rinsed with phsophate buffer and dehydrated.
5. Ventral roots will then be embedded in Spurr resin and 0.5 um sections will be cut and stained with toluidine blue and visualized by light microscopy.

Table 3: Experiment 2

Injection	Total number of experimental animals	Injection site (number of experimental animals)	Endpoint days (number of experimental animals)	Analysis	Pain category
Vehicle (DMSO)	160	Intraperitoneal (40)	12	Histology, Biochemistry	D(30) E(10)
Bortezomib		Intraperitoneal (40)			D(30) E(10)
Trichostatin A		Intraperitoneal (40)			D(30) E(10)
TSA + Bortezomib		Intraperitoneal (40)			D(30) E(10)

Litter of pups:
25% SMA pups (SMN2+/+/SMNdelta7+/+/mSmn-/-)
75% normal littermates (SMN2+/+/SMNdelta7+/+/mSmn+/- & SMN2+/+/SMNdelta7+/+/mSmn+/+).

We will need approximately 10 TSA, 10 bortezomib, 10 TSA + bortezomib and 10 vehicle (DMSO) treated SMA delta 7 mice) - **5 SMA delta 7 pups per treatment group for biochemistry and 5 for histological analysis.** All SMA mice are category E. All normal mice (wild type and het - SMN2+/+/SMNdelta7+/+/mSmn+/- & SMN2+/+/SMNdelta7+/+/mSmn+/+) are category D.

Total SMA mice (SMN delta7 +/+;SMN2+/+;Smn-/-) to be treated = 40
Total animals (given that 25% of each litter will be SMA mice) = 4x40 =160
Total pregnant moms to be used (assuming 6 pups per litter) = 27

Total animals Experiment #2 = 187

Experiment 2
Total number of animals= 187

Flowchart Title: Biochemistry and histology studies in SMA mice treated with TSA/Bortezomib

A) **Biochemistry** - *SMN2* transcript and SMN protein level determination following drug treatment

- 5 TSA, 5 bortezomib, 5 TSA + bortezomib and 5 vehicle (DMSO) treated SMA mice will be used for these experiments.
- Animals will be euthanized.
- The brain, spinal cord, liver and hindlimb skeletal muscle will be dissected and quickly frozen.
- RNA and protein will be extracted from each tissue section by standard procedures.
- RNA transcript levels will be measured by quantitative RT-PCR and protein levels will be measured by Western blot.

B) **Histology**

5 TSA, 5 bortezomib, 5 TSA + bortezomib and 5 vehicle (DMSO) treated SMA mice) will be used to determine histopathological (muscle and nerve) changes following drug treatment.

↓

Animals will be deeply anesthetized then transcardially perfused briefly will cold PBS.

↓

The spinal cord and hind limb skeletal muscle will be quickly removed and frozen and stained.

↓

The muscle slices will be stained with hematoxylin-eosin and immunocytochemistry will be performed on spinal cord slices with Nissl's stain.

Experiment 3

Primary cultures of motor neurons will be generated according to the following protocol from Dr. (b)(6) Pregnant females will be transferred from the breeding protocol at E12, anesthetized no later than E14 using 2-5% isoflurane. Depth of anesthesia will be verified by pinching all four paws with forceps to make sure that there is no withdrawal reflex. Deeply anesthetized animals will then be euthanized by cervical dislocation. The abdomen of the euthanized animal will be sprayed with 70% ethanol prior to performing a caesarian dissection and removal of the uterus. The uterus will be placed in a culture dish and the embryos removed. Embryos collected from the uterus will be placed in a

sterile petri dish in cold basal media and decapitated (Section V4.6). Both neurons and astrocytes will be isolated from sections of the CNS for use in primary cultures. For experiment #3 we use 12 embryos of each genotype, which gives a yield of 80,000-120,000 motor neurons per genotype. Primary neurons do not survive in culture very long so this experiment will be performed once per year.

Table 4: Experiment 3

Genotype	Total number of embryos	Endpoint days	Analysis	Pain category
SMN delta7 $^{+/+}$;SMN2$^{+/+}$;Smn$^{+/+}$	144	E14	Primary culture	C
SMN delta7 $^{+/+}$;SMN2$^{+/+}$;Smn$^{+/-}$			Primary culture	C
SMN delta7 $^{-/-}$;SMN2$^{-/-}$;Smn$^{-/-}$			Primary culture	C

We will need approximately 12 wild type embryos (SMN delta7 $^{-/-}$;SMN2$^{-/-}$;Smn$^{+/+}$), 24 heterozygous embryos (SMN delta7 $^{+/+}$;SMN2$^{+/-}$;Smn$^{+/-}$) and 12 affected SMN delta7 embryos (SMN delta7 +/+;SMN2+/+;Smn-/-) per year (See calculations below). Pregnant females undergoing embryo harvesting would be considered category D. Embryos will be considered category C.

In order to get 12 affect pups, which constitute 25% of each litter, we will need (4 x 12) 48 embryos.
Average litter size – 6 embryos
Therefore, we will need (48 embryos/6) 8 pregnant females to get enough SMA embryos.

Total number of embryos = 8 pregnant females x 6 embryos per litter = 48 embryos.
Total pregnant females required = 8 per year x 3 = <u>24</u>
Total embryos required = 48 per year x 3 = <u>144</u>

<u>Total animals and embryos Experiment #3 = 168</u>

<u>Experiment 3: Flow outline of experiments</u>

Primary cultures of motor neurons

8 embryos per group (per year)

↓

Pregnant moms will be euthanized and E14 embryos will be removed and euthanized.

↓

Spinal cords will be removed and motor neurons will be cultured

V.2. Data Analysis:

For Experiment1, we plan to use sample sizes of 15 animals per group in the comparison of vehicle or proteasome inhibitor treated mice for survival studies. A sample size of 15 per group will have 80% power to detect a difference between groups of 1.1 standard deviations between groups, based on a two-sample t test with a 5%, two-sided significance level. Wahlsten et al (7) indicate that effect sizes of around 1 standard deviation are commonly observed in mouse neurobehavioral studies. Furthermore, in analysis of survival outcomes 15 animals per group will have 80% power to detect a 2/3 reduction in death rate based on a log rank test with 5%, two-sided significance level. For Expt. 2, a sample size of 5 per treatment group will have 80% power to detect a difference between groups of 2.0 standard deviations between groups, based on a two-sample t test with a 5%, two-sided significance level. Experiments 3 is cell culture based approaches that will generate motor neuron for in vitro analysis. Animal use prediction for experiments 3 is based on our data that indicate we can generate 80,000-120,000 motor neurons per genotype from E14 embryos. These numbers of cells are predicted to be sufficient for the desired quantitative qualitative gene expression analysis.

Statistical Analyses: The SigmaStat 2.03 (SPSS) statistical analysis program will be used to compute the arithmetic mean and standard deviation of surgical and treatment groups on each test measurement. For most experiments a one-way analysis of variance (ANOVA) will then be used to assess whether or not performance on each behavioral test differs between experimental groups. For experiments in which individual mice are tested multiple times on the same behavioral test, a one-way ANOVA with repeated measures will be performed. If the ANOVA indicates differences, Tukey's test will be used to compare individual means. In addition, if the data suggest variation between the testing of each cohort of mice, a nested ANOVA can be used to assess whether or not there are differences between testing events on repeated tests. To assess some degree of the relationship of performance on tests within an experiment, correlation coefficients can be computed for each animal's score on each subtask.
Survival and biochemical data will be analyzed using the GraphPad Prism software package (version 6.05; GraphPad Software) and compared statistically with the log-rank test (Kaplan–Meier survival curves), the two-tailed Student's t test or one-way analysis of variance followed by the Newman -Keuls multiple comparison *post hoc* test.

V.3. Laboratory Animals Required and Justification:

1) Animal models provide the only means to study the mechanism of neurological diseases that cannot be accomplished in humans or in cultured cells.
2) In order to have direct relevance for the human disease, the proposed experiments must be carried out in an animal model of SMA. There is no known cellular or computer model that

recapitulates the human disease. Live animals are also required in order to examine the pathology and biochemistry of the normal compared to SMA neuromuscular apparatus.
3) From our cell culture data, we have disease modifying genes that may be promising targets for therapeutics that modulate muscle atrophy and the SMA phenotype and perhaps treat SMA. However, they first need to be validated in an animal model before being presented as an option for drug therapy. Although there are other animal models of SMA (drosophila and zebrafish), the genetically engineered mouse is the animal model of SMA that best mimics the human disease genetically and pathologically. As the purpose of this protocol is to better understand the pathophysiology of the human disease, these studies must be done in the mouse animal model.

V.3.1. Non-animal Alternatives Considered:
1) Animal models provide the only means to study the mechanism of a neurological disease that cannot be accomplished in humans or in tissue culture.
2) Animal models are also the next step for testing drugs that have been shown to work in tissue culture to treat a disease, but need further testing to verify the effectiveness of the drugs prior to trials in humans.
In order to have direct relevance for the human disease, the proposed experiments must be carried out in an animal model of SMA. There is no known cellular or computer model that recapitulates the human disease. Live animals are also required in order to examine the pathology and biochemistry of the normal compared to SMA neuromuscular apparatus.

V.3.2. Animal Model and Species Justification:
Although there are other animal models of SMA (drosophila and zebrafish), the genetically engineered mouse is the animal model of SMA that best mimics the human disease genetically and pathologically. As the purpose of this protocol is to better understand the pathophysiology of the human disease, these studies must be done in the mouse animal model. The SMN delta7+/+;SMN2+/+;Smn-/- (developed by Arthur Burghes at OSU) lack the endogenous mouse Smn gene but express two copies of the human SMN2 transgene. The retention of the SMN2 gene is the genetic circumstance relevant to humans. Phenotypically, they closely mimic the severe human disease phenotype. The SMN delta7$^{+/+}$;SMN2$^{+/+}$;Smn$^{-/-}$ mice, weight loss and weakness begins at approximately P5 and progressive weakness continues until death at approximately P14. . The major source of nutrients for pups under study will be provided by the female breeder. Based on our experience with these mice we believe that the SMA affected pups are still able to latch onto the mom and feed. Death likely occurs due to respiratory failure secondary to severe muscle weakness, just as in the human disease.

Mus musculus is chosen as a suitable species for this research. This is based upon the previous use of this species in innumerable biomedical studies and their suitability for understanding central nervous system functions in normal and pathological states in humans and in other animals. The mouse is used for these studies because of their well-understood anatomy and endocrine responses, and the very extensive database of prior physiological research that can be integrated with this new information. It is necessary to use mice instead of a "lower species" since the research results should be directly associated with intense efforts in other laboratories throughout the world to try and further our understanding and eventual treatment effectiveness for neurological disorders. Mice are a commonly used small animal model for the study of neurobiological genetics research, including the impact of physical injury and environmental stress upon neuron connectivity, experiential effects on synaptic plasticity, signal transduction, and for assessing treatments to reduce neurological damage and improve quality of life.

V.3.3. Laboratory Animals

		Strain #1
V.3.3.1.	**Genus & Species:**	*Mus musculus*
V.3.3.2.	**Strain/Stock:**	FVB/ SMN delta7+/+;SMN2+/+;Smn+/-
V.3.3.3.	**Source/Vendor:**	In house breeding protocol
V.3.3.4.	**Age:**	P5 pups, moms (Expt. 1 and 2) and pregnant females (Expt. 3)
V.3.3.5.	**Weight:**	2-14 grams pups; 25-35 grams post-parturient and pregnant females
V.3.3.6.	**Sex:**	Equal numbers of males and females pups + 91 pregnant/nursing females
V.3.3.7.	**Special Considerations:**	Nursing mothers transferred with litters for experiments 1 and 2. At study endpoint, mothers will be transferred back to breeding protocol. Exp. 3 moms euthanized and pups used at E12

V.3.4. Number of Animals Required 633 (542+ 91 pregnant/nursing females transferred from breeding protocol)

ANIMALS	Total Number
	TOTAL
Experiment 1	280
Experiment 2	187
Experiment 3	168
Total number	**635**

V.3.5. Refinement, Reduction, Replacement (3 Rs):

V.3.5.1. Refinement:
Mice will be acclimated to investigator handling before any procedures to relieve distress from the potential combination of handling distress, surgical procedures and behavioral testing. Also, mice will be anesthetized prior to euthanasia by cervical dislocation.

V.3.5.2. Reduction:
We are attempting to perform a series of measurements of biological functions and mouse behavior that requires making assurances that there is sufficient number of animals to derive valid measures

of statistical data. Power calculations have been performed to determine the minimum number of animals needed to reach statistical significance. Data derived from this protocol will be available to other investigators via peer-reviewed scientific publications.

V.3.5.3. Replacement:
We are using a rodent model (mouse) versus a nonhuman primate model. The mouse model is the least sentient and derived animal model we could use for this study and still obtain acceptable results. Biological response to central nervous system injury and experimental treatments is highly complex: no alternative to *in vivo* experimentation is available or practical.

V.4. Technical Methods:

V.4.1. Pain / Distress Assessment:

V.4.1.1. APHIS Form 7023 Information:

V.4.1.1.1. Number of Animals: 635

V.4.1.1.1.1.	**Column B:**	67 (pregnant and nursing females Expts. 1 and 2)
V.4.1.1.1.2.	**Column C:**	324 (Expts. 1 and 3)
V.4.1.1.1.3.	**Column D:**	120 control mice (Expt.2) and 24 (pregnant females from Expt. 3)
V.4.1.1.1.4.	**Column E:**	100 (Expts. 1 and 2)

V.4.1.2. Pain Relief / Prevention:

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization: Inhalation anesthetics will be used immediately prior to cardiac perfusion-fixation and cervical dislocation (experiment #2). For inhalation anesthetic, oxygen will be mixed with isoflurane delivered via precision vaporizer using a rodent anesthesia machine. Mice will be placed in an induction chamber and exposed to a mixture of O_2 and isoflurane (2-5%) to induce general anesthesia. Following induction, mice will be removed from the chamber and maintained on 0.25-3% isoflurane administered by nosecone during procedures. We will monitor the depth of anesthesia by noting response to toe pinch (pedal withdrawal reflex) and rate and quality of respirations. Waste anesthetic gases will be passively scavenged using a charcoal canister. Anesthetics will be administered either by the PI or his staff.

Experiment #3: For embryo collection: Pregnant females will be anesthetized no later than E14 using 2-5% isoflurane. Depth of anesthesia will be verified by pinching all four paws with forceps to make sure that there is no withdrawal reflex. Deeply anesthetized animals will then be euthanized by cervical dislocation. The abdomen of the euthanized animal will be sprayed with 70% ethanol prior to performing a caesarian dissection and removal of the uterus and collection of embryos.

Experiment #2: For biochemical analysis: On the day of euthanasia, mice will be exposed to a

mixture of O_2 and isoflurane (2-5%) to induce general anesthesia prior to cardiac perfusion or cervical dislocation.

Experiment #2: Histology of spinal cords and muscle. Hematoxylin-eosin stains will be performed on muscle sections. Mice will be deeply anesthetized with 2-5% isoflurane. Depth of anesthesia will be verified by pinching all four paws with forceps to make sure that there is no withdrawal reflex. Deeply anesthetized animals will then be transcardially perfused briefly with cold 1X PBS. The muscle and spinal cord tissue will be dissected out, mounted on wooden blocks, and flash frozen in liquid nitrogen-cooled isopentane.

The PI will consult with DLAM veterinarians on a case by case basis to determine pain and distress in all animals. Animals deemed to be in distress will be treated or euthanized by LAM personnel, PI or his staff.

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions: N/A

V.4.1.2.3. Paralytics: N/A

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures:

V.4.1.3.1. Sources Searched: PubMed
V.4.1.3.2. Date of Search: June 9, 2015
V.4.1.3.3. Period of Search: 1986-2015.
V.4.1.3.4. Key Words of Search: SMA, Spinal Muscular Atrophy, pain, distress, mouse
V.4.1.3.5. Results of Search: A total of 13 references were identified with this search. None of the searches were relevant to alternative methods for investigations of SMA in mice.

V.4.1.3.6. Sources Searched: Agricola
V.4.1.3.7. Date of Search: June 9, 2015
V.4.1.3.8. Period of Search: No date limits.
V.4.1.3.9. Key Words of Search: SMA, Spinal Muscular Atrophy, pain, distress, mouse
V.4.1.3.10. Results of Search: Twenty-five references were returned by this search, but none of the hits were relevant.
V.4.1.3.11. Sources Searched: ALTBIB

V.4.1.3.13. Period of Search: Any year up to 2000
V.4.1.3.14. Key Words of Search: SMA, Spinal Muscular Atrophy, pain, distress, mouse
V.4.1.3.15. Results of Search: No hits

V.4.1.3.16 Literature Source(s) Searched: PubMed
V.4.1.3.17 Date of Search: June 1, 2015
V.4.1.3.18 Period of Search: Presently, >21.3 million references; 1949-2015.
V.4.1.3.19. Key Words and Search Strategy: Cardiac perfusion and mice and pain alternative
V.4.1.3.20 Results of Search:
No published articles provide a painless procedure for cardiac perfusion.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification: SMA is a severe motor neuron disease affecting young humans and mice that causes premature death because of muscle weakness and respiratory failure. There is currently no treatment for this disease in humans or mice and consequently no means by which to relief the distress experienced by SMA mice as part of the natural history of their disease. The aim of our study is to improve survival (hopefully thereby minimizing distress in these mice) using treatment with TSA and bortezomib.

Survival is the outcome measure used in human clinical trials of therapeutic agents. In this mouse study in order to minimize distress we will define survival as an endpoint before death (but representing inevitable death) and pups will be euthanized when they reach this endpoint. In our experience the combined features of severe motor dysfunction and weight loss indicate an irreversible condition that inevitably leads to death. We will make all efforts to minimize distress by euthanizing animals once they reach these endpoints

V.4.2. Prolonged Restraint: N/A

V.4.3. Surgery: Primary cultures of motor neurons (Expt. 3) will be generated according to the following protocol from Dr (b)(6) Pregnant females will be transferred from the breeding protocol at E12, anesthetized no later than E14 using 2-5% isoflurane. Depth of anesthesia will be verified by pinching all four paws with forceps to make sure that there is no withdrawal reflex. Deeply anesthetized animals will then be euthanized by cervical dislocation. The abdomen of the euthanized animal will be sprayed with 70% ethanol prior to performing a caesarian dissection and removal of the uterus. The uterus will be placed in a culture dish and the embryos removed. Embryos collected from the uterus will be placed in a sterile petri dish in cold basal media and decapitated.

V.4.3.1. Pre-surgical Provisions: N/A

V.4.3.2. Procedure: N/A

V.4.3.3. Post-surgical Provisions: N/A

V.4.3.4. Location: Housing in LAM, behavioral testing in (b)(6) located in the Pre-Clinical Studies Core.

V.4.3.5. Surgeon: N/A

V.4.3.6. Multiple Major Survival Operative Procedures:

V.4.3.6.1. Procedures: N/A

V.4.3.6.2. Scientific Justification: N/A

V.4.4. Animal Manipulations:

V.4.4.1. Injections:
Mice will receive intraperitoneal injections of **A)** either 0.15 mg/kg of Bortezomib or **B)**10 mg/kg TSA. **C)** vehicle (5% DMSO solution) or **D)** both TSA (10 mg/kg) + Bortezomib (0.15

mg/kg). TSA will be dissolved in 5% DMSO to a concentration of 4 µg/µl. SMA mice and their wild type and heterozygous littermates will receive 10 mg/kg in a volume of 2.5 µl/g body weight (maximum volume: 35 µl) using a 33-gauge needle (Hamilton microliter syringe #705 (20 mm (1 in.): smallest needle available for the volumes of drug to be used). Control animals received equal volumes of vehicle alone. Bortezomib is FDA approved for treating multiple myeloma and is available in pharmaceutical grade. Pharmaceutical grade TSA is obtained from Enzo Pharmaceuticals.

V.4.4.2. Biosamples:

Tail snips (~5 mm) in length will be removed from the distal tip of the tail using sharpened scissors cleaned with ethanol immediately prior to use for each animal. The tail sample will be transferred into a microcentrifuge tube or 96 well plate for subsequent analysis by PCR. Hemostasis will be ensured following the procedure by applying gauze with gentle finger pressure to the distal tail. Samples will be taken at postnatal day 10 (Expt. 1, 2 and 3) and animals of the appropriate genotype that will be used for breeding (heterozygotes) will be marked with a unique identifying ear tag.

Following treatment (Expt.2), the mice will be euthanized and brain tissue will used for assessment of levels of protein ubiquitination, for protein expression of ubiquitination-related enzymes, as well as for a series of biomarkers conventionally used in the lab to evaluate motor neuron disease. For these needs, animals are euthanized by individuals on this protocol, and the brain is removed from the calvarium to obtain samples of the cerebral cortex (fronto-occipital region and entorhinal region), hippocampus, diencephalon, and brain stem. Samples are stored in liquid nitrogen before preparation for western blotting or for measuring mRNAs.

Transcardial perfusion for immunohistochemistry biosamples (Expt. 2). In addition, some of the mice will be used for immunohistochemistry. Following anesthesia per Section V.4.1.2.1, we will ensure mice are deeply anesthetized and unresponsive to paw pinch. A midline thoracotomy is made to expose the heart, and a 20-22 gauge blunt tip needle connected to a tube (¼ in ID and 1/16 in wall) is inserted into the left ventricle through the apex, and the right atrium is incised. After an initial washout with 30-500 ml of cold 100 mM phosphate buffered saline (PBS), transcardial perfusion with 100-250 ml cold 4% paraformaldehyde in PBS will be delivered through a manual gravity perfusion system until adequate perfusion reached. The brain will then be removed from the calvarium and post-fixed before tissue sectioning for immunohistochemical staining (cf., V.4.4.2. Biosamples).

V.4.4.3. Adjuvants: N/A

V.4.4.4. Monoclonal Antibody (MAbs) Production: N/A

V.4.4.5. Animal Identification:
All animals will be identified with cage cards.

V.4.4.6. Behavioral Studies:
Mice (Experiment 1) will be evaluated on the following tests daily starting at P5:

1. **Righting time:** Defined as the best of 2 trials of the time for the pup to turn over to its front after being placed completely on its back (maximum 30 seconds).

V.4.4.7. Other Procedures: Deeply anesthetized mice will be fixed by transcardial perfusion (Expt. 2) as outlined in **V.4.4.2.**

V.4.4.8. Tissue Sharing:
Excess mouse tissue will be made available to other investigators in our or other labs.

V.4.5. Study Endpoint:
Study end-point is survival until the age required for research sampling (approximately 14 days for untreated mice) after which mice will be euthanized and tissues collected. 20% loss in body weight is very early in the progression of the disease in SMA mouse models. We have found that a 30% loss in body weight is a better estimate of moribundity and will allow us to better evaluate the efficacy of drug treatment. Study end-point for treated mice: if no ability to right after 1 minute OR greater than 30% weight loss (from maximum weight), pup will be euthanized (age P5-P21).

Any mouse observed to be lethargic, losing weight, exhibiting gross neurological deficits (such as inability to eat or drink, continual circling, seizures, etc.) or any other signs of distress or illness will be evaluated by the PI and/or veterinary staff then euthanized as previously described.

V.4.6. Euthanasia:
Euthanasia will be performed in accordance with the guidelines of the "2013 Report of the AVMA Panel on Euthanasia." Methods of euthanasia on this protocol include cervical dislocation and perfusion. Mice are anesthetized before these procedures. Euthanasia will be performed by the PI or the staff in the CNRM Pre-Clinical Studies Core.

Perfusion (Expt. 2): Following anesthesia per Section V.4.1.2.1, we will ensure mice are deeply anesthetized and unresponsive to paw pinch. A midline thoracotomy is made to expose the heart, and a 20-22 gauge blunt tip needle connected to a tube (¼ in ID and 1/16 in wall) is inserted into the left ventricle through the apex, and the right atrium is incised. After an initial washout with 30-500 ml of cold 100 mM phosphate buffered saline (PBS), transcardial perfusion with 100-250 ml cold 4% paraformaldehyde in PBS will be delivered through a manual gravity perfusion system until adequate perfusion reached. The brain will then be removed from the calvarium and post-fixed before tissue sectioning for immunohistochemical staining (cf., V.4.4.2. Biosamples).

Cervical dislocation (Expt.2): Following anesthesia per Section V.4.1.2.1, we will ensure mice are deeply anesthetized and unresponsive to paw pinch. Cervical dislocation will be performed by placing a large hemostat behind the base of the anesthetized mouse's skull and pulling back sharply on the tail. Following dislocation mice will be examined to confirm respiratory arrest and the lack of a heartbeat. This method of euthanizing treated mice mice is preferred over CO_2 given the variability in time to die of neonatal mice following CO_2 exposure and the requirement to harvest tissue for biochemical analysis immediately after euthanizing mice [8].

Embryo harvesting (Expt. 3): Primary cultures of motor neurons will be generated according to the protocol from (b)(6)
Pregnant females will be transferred from the breeding protocol at E12, anesthetized no later

than E14 using 2-5% isoflurane. Depth of anesthesia will be verified by pinching all four paws with forceps to make sure that there is no withdrawal reflex. Deeply anesthetized animals will then be euthanized by cervical dislocation. The abdomen of the euthanized animal will be sprayed with 70% ethanol prior to performing a caesarian dissection and removal of the uterus. The uterus will be placed in a culture dish and the embryos removed. Embryos collected from the uterus will be placed in a sterile petri dish in cold basal media. Each embryo will be decapitated at the infracranial notch just below the base of skull using fine-tip forceps or small curved scissors with the aid of a dissection microscope.

In the event that LAM personnel must euthanize an animal for humane reasons, cylinderized carbon dioxide will be used in the LAM necropsy room. Using a clean cage, carbon dioxide will be administered at a rate to replace greater than 20% of the cage volume per minute. Once the mice have not moved or breathed for at least one minute they will be removed from the chamber. Euthanasia may be ensured by cervical dislocation or opening of the thorax.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol (5 mice per cage).

V.5.1.1. Study Room:

Building(s)	(b)(6)	Room Number(s)	(b)(6)
Building(s)		Room Number(s)	
Building(s)		Room Number(s)	

V.5.1.2. Special Husbandry Provisions:

Food Restriction: Yes _____ No __X__

Fluid Restriction: Yes _____ No __X__

V.5.1.3. Exceptions: None.

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care:
The PI or research staff will observe the mice twice daily following all experimental procedures. LAM personnel will observe the mice at least once a day for general health and husbandry condition. Any mouse observed to be lethargic, losing weight, exhibiting gross neurological deficits (such as inability to eat or drink, continual circling, seizures, etc.) or any other signs of distress or illness will be evaluated by the PI and/or veterinary staff then euthanized as previously described.

V.5.2.2. Emergency Veterinary Medical Care:
All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays. In the case of an emergency health problem, if the responsible person (e.g. PI) is not available or if the

investigator and veterinary staff cannot reach consensus on treatment, the veterinarian has the authority to treat the animal, remove it from the experiment, institute appropriate measures to relieve severe pain or distress, or perform euthanasia if necessary.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: Except as indicated below, all animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents; balls, toys and food enrichment treats for large animal species. Animals are grouped-housed. Standard nestlets, tunnels, or toys provided by LAM will be provided in each home cage.

V.5.3.2. Enrichment Restrictions: None.

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
Perfusion-fixation, intraperitoneal injection, c-section, anesthesia, euthanasia.	(b)(6)	Over 10 years experience with mouse behavior studies, IP injections, perfusion-fixation, euthanasia , mouse surgeries including hysterectomy.	USU LAM Investigator/animal handler training class February 4, 2014. Animal handling and surgery training at the NIH (2006).
Perfusion-fixation, intraperitoneal injection, euthanasia.		Lab technician with over 3 years experience with IP injections, perfusion-fixation, euthanasia	USUHS LAM Investigator/animal handler training class August 24, 2013.

VII. BIOHAZARDS/SAFETY:

To minimize exposure to animal allergens when working with lab animals, lab personnel will wear lab coats and/or scrubs, gloves and masks. Potential fumes from fixative are minimized by allowing the fixative to be constantly washed down the sink drain. This procedure will be carried out in a chemical fume hood.

VIII. ENCLOSURES:

Literature search results for Sections II.2 (Searches for unnecessary duplication) are available upon request.

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

I. Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL** or **WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

X. PROTOCOL ABSTRACT:

A. Animal Protocol Number: (b)(6)

B. Animal Protocol Title: Targeting the ubiquitin proteasome system to treat spinal muscular atrophy (*Mus musculus*)

C. Principal Investigator (b)(6) Ph.D.

D. Performing Organization: Uniformed Services University of the Health Sciences

E. Funding: USUHS Intramural funds

F. Objective and Approach:

The goal of the work is to improve treatments for neurodegenerative diseases by studying the role of the ubiquitin-proteasome pathway in the brain. To approach this problem we will use laboratory mice. We will test if inhibiting the proteasome drugs can increase the stability of proteins critical to neuronal survival and protect against the effects of neurodegeneration. In addition, we will determine if the ubiquitin proteasome system is affected by toxic insults to the brain. This is an important step for establishing whether or not ubiquitin-dependent degradation has a critical role in neurodegeneration, and whether changes in ubiquitination activities in the brain can reduce central nervous system injury and eventually be used to help patients with neurodegeneration.

The data collected will be summarized using conventional statistical approaches (mean, standard deviation, analysis of variance, correlation and regression analyses). We will use as few mice as possible while still using enough to make valid conclusions. To do this initial research we must use animals since cells or tissues will not reflect the actual biology and behavioral responses of a live organism. We hope that this basic research and use of animals will aid in understanding some of the causes for the long-term effects brain injury has upon the war fighter returning home to their town, work, and families, and that this research may allow us to provide better treatments to help suffering soldiers.

MEMORANDUM FOR DR. (b)(6) DEPARTMENT OF ANATOMY, PHYSIOLOGY, AND GENETICS

SUBJECT: IACUC Approval of Protocol – Initial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) by Designated Member Review on June 14, 2016:

Animal Protocol Title: "Acetate Supplementation Using Glyceryl Triacetate as an Adjunct Therapy for Hemorrhagic Shock and Injury in Mice (Mus musculus)"

USUHS Protocol Number: (b)(6)

Expiration Date: June 13, 2019

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. **NON-TECHNICAL SYNOPSIS:** Hemorrhage is responsible for about 30-40% of all traumatic deaths and approximately 50% of battlefield deaths worldwide. Studies have suggested that the ability of tissues to deal with hemorrhage related problems such as hypoxia and hypothermia, is critical and that robustness of this ability differs among individuals, suggesting involvement of genetic or epigenetic mechanisms. Recently it has been shown that acetylation of the transcription factor HIF-2α controls erythropoietin production during pathophysiological stress induced by oxygen deprivation. In earlier studies we have developed acetate supplementation using glyceryl triacetate (GTA), which generates acetate and glycerol on hydrolysis in vivo, to improve outcomes after traumatic brain injury. Based on these and other studies we have found that oral GTA administration is an effective way to increase acetate levels in all tissues and that GTA has no detectable toxic effects on chronic usage even at relatively high doses in animals and children. In subsequent studies, acetate supplementation using GTA has been shown to induce anti-inflammatory effects in multiple rat model systems. Histone deacetylase inhibitors including valproic acid and trichostatin, which increase protein acetylation status in general and histone acetylation status in particular, have anti-inflammatory and protective effects in hemorrhagic shock. This is due in part to the fact that patients who survive acute episodes of blood loss experience systemic inflammatory response syndrome triggered by ischemia-reperfusion injury and organ damage. Based on these earlier findings, we propose to develop oral acetate supplementation using GTA as a way to augment acetylation-based regulatory mechanisms involved in the response to and recovery from bodily injury, blood loss and reperfusion injury. Our immediate goal is to develop GTA treatment as an adjunct therapy for hemorrhagic shock and injury. We and others have shown that acetyl-coenzyme A synthetase-1 (enzyme name: AceCS1, gene: Acss2) is primarily involved in generating acetyl-coenzyme A (acetyl-CoA) for acetylation reactions, especially in cell nuclei, and we currently have an ongoing breeding colony of mice in which the Acss2 gene is knocked out for studying the related genetic

mechanisms. Using this gene knockout model we plan to determine the genetic and epigenetic regulatory mechanisms involved in the acetylation-based regulation of stress responses to blood loss and injury, and the beneficial effects of GTA treatment on survival from hemorrhagic shock and injury. Our central hypothesis is that enhancing acetylation-based endogenous genetic/epigenetic mechanisms is an effective way to minimize chronic disability and death due to hemorrhagic shock. We propose to test this hypothesis using GTA-mediated acetate supplementation in a mouse model of hemorrhagic shock with concomitant injury and determine the associated genetic/epigenetic mechanisms using our Acss2 gene knockout mouse model. The long-term goal of the proposed studies is to improve survival for patients with traumatic hemorrhage and associated shock via regulation of genetic and epigenetic response mechanisms and to provide knowledge that will lead to genetically-informed personalized treatments.

II. BACKGROUND:

II.1. Background: The proposed research is focused on determining the effectiveness of acetate supplementation with GTA in improving recovery from hemorrhagic shock (HS) with concomitant control cortical impact (CCI) -injury to the brain and subsequent ischemia-reperfusion injury (IRI) in wild type mice and Acss2 gene knockout mice. Acss2 encodes the nuclear-cytoplasmic form of the enzyme that converts acetate to acetyl-CoA, and it is the only known enzyme capable of generating acetyl-CoA from acetate in the cytoplasm and nucleus of cells. This enzyme has been found to be critical for acetylation of the transcription factor HIF-2α, and the promotion of erythropoietin production in response to severe anemia (Xu et al., 2014; Chen et al., 2015), making this enzyme an important target for the treatment of HS and IRI. In subsequent studies, we plan to study the genetic/epigenetic mechanisms involved in the protective effects of increased glyceryl triacetate (GTA)-mediated acetylation using the HS and concomitant injury model system in these mice. Hemorrhage is responsible for about 30-40% of all traumatic deaths and approximately 50% of battlefield deaths worldwide (Klemcke et al., 2011). Therefore, the long term goal of the proposed studies is to improve survival for patients with traumatic hemorrhage and associated IRI via acetylation based regulation of genetic and epigenetic response mechanisms and to provide knowledge that will lead to genetically-informed personalized treatments. In pursuit of this long term goal, genetic and epigenetic studies will be carried out using human tissue samples from the CHIRP repository based on the results from the proposed studies in mice.

Individual variations in response to HS: During HS multiple physiological mechanisms come into play to maintain blood pressure and tissue perfusion for as long as possible. When these mechanisms fail or are not effective, tissue perfusion is diminished to critical levels which can subsequently produce end organ injury resulting from hypoxia, hypercapnia or hypothermia. Reperfusion results in additional injury due to excessive inflammatory responses and oxidative damage, among other mechanisms. It has been known for some time that there is considerable variability in the ability of patients to survive these conditions and genetic and epigenetic factors are sure to play critical role in this inter-person variability. As early as 1970, Kim and Shoemaker investigated possible mechanisms underlying physiological differences between survivors and fatalities among HS patients (Kim and Shoemaker, 1970). These and

subsequent studies have indicated that cardiac index, oxygen delivery and tissue oxygen utilization were highly divergent between the groups (Shoemaker, 1976; Bishop et al., 1995; Bishop et al., 1993). Other studies have shown association between patient survival and inflammatory cytokines and heat shock proteins (Roumen et al., 1993; Pittet et al., 2002). Increased survival has been associated with higher respiration rates, arterial PO2, saturation of hemoglobin, blood O2 content, blood pH and lower lactate levels in rat models (Torres Filho et al., 2010; Reynolds et al., 2008). Later studies by other investigators working on cardiovascular function, blood pressure regulation and hypertension have indicated that the variability in the survival time could be accounted for by genetic variability (polymorphism) (Rapp, 2000; Cowley, Jr., 2003). Based on more recent evidence, it seems likely that multiple epigenetic mechanisms affecting transcription factor activation and gene expression are also important components of this inter-individual variability.

Studies have indicated that females are less susceptible to cerebral injury, independent of the effects of sex hormones (Semenas et al., 2010b). In a recent study using a clinically relevant model of severe hemorrhage and circulatory arrest in sexually immature piglets, it was demonstrated that females displayed an enhanced hemodynamic response, cardio-protection, and increased survival (Semenas et al., 2010a). Interestingly, this cardio-protective effect was observed in spite of comparable estradiol and testosterone levels in the male and female animals, indicating an innate gender-related cardio-protection, independent of sex hormone effects. Recent studies also suggest sex-differences in the expression of several enzymes and proteins, such as nitric oxide synthase and superoxide dismutase. Therefore, it is likely that the observed sex benefit in females is multifactorial and relates to the expression of a diverse group of vascular factors, inflammatory mediators and metabolic enzymes. However, possible epigenetic mechanisms involved in these sex-related but sex hormone independent effects remain uncertain.

Regulation of stress erythropoiesis by an acetylation based epigenetic mechanism: Erythropoietin (EPO) is synthesized extensively in the kidney and liver of adult mammals and is involved in controlling erythrocyte production. Synthesis of EPO is regulated by the stress-responsive transcription factor hypoxia-inducible factor-2 (HIF-2). New studies have shown that effective HIF-2 dependent induction of EPO during hypoxia requires acetylation of the HIF-2α subunit and that the lysine acetyltransferase CREB-binding protein (CBP) is required for this HIF-2α acetylation (Xu et al., 2014; Chen et al., 2015). These studies further showed that in acutely anemic mice the nuclear-cytoplasmic form of acetyl-CoA synthetase (enzyme; AceCS1, gene; Acss2) is required in conjunction with CBP for HIF-2 acetylation, CBP-HIF-2α complex formation, CBP-HIF-2α recruitment to the EPO enhancer and efficient induction of EPO gene expression. Furthermore, acetate supplementation with GTA augmented stress erythropoiesis in an Acss2-dependent manner in acutely anemic mice. Additionally, such acetate supplementation increased EPO expression and resting hematocrit in acquired and inherited chronic anemia models in mice. These studies emphasize the regulatory role of transcription factor acetylation in the control of EPO gene expression during pathophysiological states marked by tissue hypoxia, and the key role played by Acss2 in mediating this response.

Acetate supplementation using GTA has anti-inflammatory effects: GTA does not induce acetylation at all protein acetylation sites, but rather has been shown to induce acetylation at specific lysine sites on some histone and non-histone proteins. The reason for this specificity is still uncertain. We compared the effects of GTA and equimolar levels of acetate and glycerol and have shown they have different inhibitory effects on the growth of certain cancer cell lines in culture (Long et al., 2013). Multiple studies have shown that acetate supplementation using GTA has unique anti-inflammatory effects. Most of these studies have focused on the brain using several model systems. In one study, acetate supplementation with GTA was found to attenuate lipopolysaccharide (LPS)-induced neuroinflammation (Reisenauer et al., 2011). In rats subjected to LPS-induced neuroinflammation, a daily treatment with GTA (6g/kg) by oral gavage reduced the percentage of CD-11b-positive microglia by three-fold compared to rats subjected to neuroinflammation and given water. In another study, acetate supplementation using GTA reduced microglial activation and brain IL-1β levels in a rat model of Lyme neuroborreliosis (Brissette et al., 2012). These studies showed that acetate supplementation utilizing GTA is an effective treatment to reduce injury phenotype and progression in Lyme neuroborreliosis. In a subsequent study, acetate supplementation with GTA was found to modulate histone acetylation and decrease IL-1β expression in a rat model of neuroinflammation (Soliman et al., 2012a). In this study, a 28-day dosing regimen of GTA was used for acetate supplementation and the effect on brain histone acetylation and IL-1β expression was determined. It was found that long term acetate supplementation increased the proportion of brain histone H3 acetylated at lysine 9 (H3K9), histone H4 acetylated lysine 8 and histone acetylated lysine 16. Consistent with these findings, acetate supplementation effectively reversed the decrease in H3K9 acetylation that was caused by the LPS-induced neuroinflammation. Further, LPS-induced neuroinflammation increased IL-1β message (10-fold) and protein (1.3 fold), and the levels of this pro-inflammatory cytokine were reduced to control levels by acetate supplementation with GTA. Based on these studies, it can be concluded that dietary acetate supplementation attenuates microglial activation by effectively reducing pro-inflammatory cytokine expression by a mechanism that might involve a promoter site-specific pattern of histone acetylation and possibly acetylation of other transcription factor proteins as well. The proposed studies will determine if this anti-inflammatory effect of GTA is also operative in other tissues including liver, lung, intestine, heart and kidney.

Histone deacetylase inhibition creates a pro-survival phenotype during HS: A number of studies from different laboratories have shown that histone deacetylase (HDAC) inhibitors improve survival in HS victims (reviewed in Halaweish et al., 2015). These drugs act by improving the acetylation status of proteins including histones and transcription factors. In one study, pretreatment with valproic acid (300mg/kg, twice), a HDAC inhibitor, prolonged the survival of severely hypotensive rats by 5 times in a lethal hemorrhage model (Gonzales et al., 2006). Also, acetylation status of histone and non-histone proteins was increased in the heart. In models of HS and polytrauma, treatment with HDAC inhibitors has been shown to provide a significant survival advantage, even in the absence of fluid resuscitation. Multiple polytrauma models studies included two-hit models involving severe hemorrhage and sepsis, and HS combined with traumatic brain injury. However, chronic treatment of HDAC inhibitors is not encouraged due to the effects on global histone acetylation status especially with

pan-HDAC inhibitors. Therefore, efforts are under way to develop isoform selective inhibitors as therapeutic agents (Cheng et al., 2015).

The research plan involves setting up a mouse model of HS based on reduction in mean arterial pressure (MAP) rather than volume since it is more reliable than blood volume reduction (Pfeifer et al., 2013). The HS model will be set up using wild type and Acss2 gene knockout mice following a recently published procedure which combines experimental injury with HS (Sodhi et al., 2015). However, rather than bilateral femur fracture, we will use CCI injury to the brain as the concomitant injury as a model of polytrauma (Dennis et al., 2009). The bilateral femur fracture model is not suitable for chronic studies, whereas CCI injury represents a good model for polytrauma in conjunction with HS. Therefore we plan to use the CCI injury as the additional injury. The levels of cytokines and erythropoietin will be measured in blood, brain, lung, gut, liver, kidney and heart using antibody based protein array methods. Subsequently, the studies will be repeated under optimized conditions based on results from the first set of experiments to investigate the genetic and epigenetic mechanisms involved. Toward this goal, we will use a combination of open chromatin mapping with formaldehyde-assisted isolation of regulatory elements (FAIRE-seq) and enhancer and transcription factor mapping using chromatin immune-precipitation (ChIP-seq). Also, RNA-seq will be used to obtain the gene expression profiles under this condition. All these analyses will be done using multiple tissue samples.

II.2. Literature Search for Duplication:

II.2.1. Literature Source(s) Searched: DTIC, FEDRIP, PUBMED

II.2.2. Date of Search: March 12-14, 2016

II.2.3. Period of Search: All published work (no limit)

II.2.4. Key Words and Search Strategy: Key words were used in sets of three. They are: 1) mice, acetate supplementation and -hemorrhagic shock/injury, 2) mice, Glyceryl triacetate -and hemorrhagic shock/injury, 3) mice, hemorrhagic shock/injury and genetic mechanisms and 4) mice, hemorrhagic shock/injury and epigenetic mechanisms.

II.2.5. Results of Search: 1) PUBMED: No articles were found for key word combinations #1 and #2 and #4. One article was found for combination #3, but it was not relevant for the proposed studies. 2) DTIC: One article was found for key word combinations #1. This work is relevant to the proposed research, but not directly related or repeat of the proposed research. No article was found for combination #2, #3 and #4. FEDRIP: Three articles were found for key word combinations #2 and 444 articles for combination #1, #3 and #4. However no article was found when the search was restricted to scholarly publications.

III. OBJECTIVE\HYPOTHESIS: Our central hypothesis is that enhancing acetylation-based endogenous genetic/epigenetic mechanisms is an effective way to minimize chronic disability and death due to hemorrhagic shock. We propose to test this hypothesis using GTA-mediated acetate supplementation in a mouse model of

hemorrhagic shock with concomitant injury and determine the associated genetic/epigenetic mechanisms using our Acss2 gene knockout mouse model.

IV. MILITARY RELEVANCE: Hemorrhage is responsible for about 30-40% of all traumatic deaths and approximately 50% of battlefield deaths worldwide. Studies have suggested that the ability of tissues to deal with hemorrhage related problems such as hypoxia and hypothermia, is critical and that robustness of this ability differs among individuals, suggesting involvement of genetic or epigenetic mechanisms. The long-term goal of the proposed studies is to improve survival for patients with traumatic hemorrhage and associated shock via regulation of genetic and epigenetic response mechanisms and to provide knowledge that will lead to genetically-informed personalized treatments. As such this project is highly relevant to the health and survival of our military personnel in battlefield situations.

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures: As mentioned above, the research plan in this protocol involves setting up a mouse model of HS based on reduction in mean arterial pressure (MAP) rather than volume since it is more reliable than blood volume reduction (Pfeifer et al., 2013). The HS model will be set up using wild type and Acss2 gene knockout mice following a recently published procedure which combines experimental injury with HS. We will use CCI injury to the brain as the concomitant injury as described earlier (Dennis et al., 2009). The levels of cytokines and erythropoietin will be measured in blood, brain, lung, gut, liver, kidney and heart using antibody based protein array methods to determine the acetylation associated protective mechanisms in this model system. Subsequently, studies will be repeated under optimized conditions based on results from the first set of experiments to investigate the genetic and epigenetic mechanisms involved. Toward this goal, we will use a combination of open chromatin mapping with formaldehyde-assisted isolation of regulatory elements (FAIRE-seq) and enhancer and transcription factor mapping using chromatin immune-precipitation (ChIP-seq). Also, RNA-seq will be used to obtain the gene expression profiles under this condition. All these analyses will be done using multiple tissue samples. We are confident that these preliminary studies will provide reliable leads to pursue our long term goal of providing knowledge that will lead to genetically-informed personalized treatments.

V.1.1. Experiment 1: To determine the protective effects of acetate supplementation with GTA in the mouse model of HS and experimental trauma by analyzing survival, inflammatory responses, end-organ pathology and related chronic responses in wild type and Acss2 gene knocked out mice.

The experimental design and methods are described below briefly:

1. Mouse HS/resuscitation and polytrauma model: Both wild type and Acss2 -/- mice will be used for these studies. All experiments will be done using males approximately 10 weeks of age (~25 g). Mice will be anesthetized and subjected to polytrauma consisting of CCI injury to the brain followed by 60 min HS (Dennis et al., 2009). For comparison purposes, animals with HS alone also will be used. The mice will be treated with GTA (5 gm/kg) intragastrically for three different durations. GTA will be administered twice per day, spaced 4 to 6 hours apart with treatment lasting between 1

and 12 days and the response to injury will be evaluated by multiple methods on the days designated (see Table below). On the designated days animals will be divided into two groups randomly for biochemical and histochemical analyses (4 wild type and 4 Acss2 -/- mice for each procedure). The levels of pro-inflammatory cytokines including IL-1β and TNF-α, as well as erythropoietin, will be measured in blood on the designated days. For ELISA studies the mice will be euthanized and blood will be drawn. The mice will be perfused with PBS to remove the remaining blood, and the brain, small intestine, lungs, liver, kidney and heart will be extracted and analyzed by several methods including antibody based protein array methods and ELISA assays. For histochemical and immunohistochemical analyses mice will be anesthetized and perfused transcardially with 10% neutral buffered formalin and the same organs will be processed for standard histopathology as well as immunohistochemistry to detect end organ pathology and determine the effectiveness of GTA and acetylation-associated protective mechanisms in this model system.

For the surgical procedures mice will be anesthetized with 3-5% isoflurane and maintained with 2% isoflurane in 100% O2 throughout the experiments. Under sterile conditions, a right groin exploration will be performed and the right femoral artery and vein will be exposed and catheterized using sterile polyethylene (PE-50) tubing (Harvard Apparatus). The catheters will be connected to a blood pressure transducer for continuous arterial blood pressure monitoring during the procedure. The mice will be placed in a stereotaxic frame and a 5 mm bone flap will be removed over the parietal cortex. Injury will be produced with a 3 mm flat steel tip with a velocity of 5 m/sec and a penetration depth of 1 mm (Dennis et al., 2009). The bone flap will be replaced and HS will be induced over the course of 15 min by withdrawing blood (approximately 2.0 ml/100gm) until we achieve a MAP between 30 and 35 mm Hg. The MAP will be maintained in this range for 60 min. At the end of the 60 min HS period, mice will be resuscitated to a MAP of at least 60 mm Hg. This will be done over 15 min with their remaining shed blood plus two times the maximum shed blood in lactated Ringer's solution. The catheters will be removed and mice will be taken off isoflurane and returned to their cages. Sham-operated mice will undergo anesthesia and femoral cannulation only.

The mice will be sacrificed for ELISA or histological analyses on the days indicated in Table below. The mice will be deeply anesthetized with a pentobarbital based preparation (Fatal-Plus solution, 75-100 mg/kg, i.p.) and transcardially perfused with PBS (50 ml) for biochemical analyses, or with 10% neutral buffered formalin (60 ml) for histological and immunohistochemical analyses. Blood will be collected by cardiac puncture.

For biochemical analyses tissues (brain, liver, lungs, kidney and small intestine) will be dissected rapidly, frozen on dry ice and stored at -80°C until used. For histology and immunohistochemistry the same tissues will be removed and postfixed in 4% paraformaldehyde overnight at 4°C for histopathological and immunohistochemical analyses. We plan to have 8 mice in each group so that four mice can be used for ELISA/biochemical analysis and four can be used for histopathological and immunohistochemical analyses.

The CNRM SOP #1 Brain Injury Models will be followed for the CCI work in mice. The pain will not be alleviated in the CCI groups (pain category E) since the drugs used can interfere with the inflammatory responses/mechanisms, the primary focus of the proposed studies.

2. GTA Treatment: GTA treatment will be done as described in our earlier studies (Arun, P et al, 2010a). Experimental groups and conditions are given in Table below. Animals will receive the first dose of GTA intragastrically (5g/kg) 30 minutes after resuscitation from HS using a blunt tipped intragastric feeding needle passed down the esophagus. On subsequent days the treated animals will be given the same dose twice a day (morning and evening) until sacrifice. Untreated injured animals will be given an equal volume of water. Groups of 16 mice for each treatment condition will include 8 wild type male mice and 8 Acss2 -/- male mice randomly selected from our breeding colony. Females will be used exclusively for breeding purposes. The three time points will allow us to differentiate between short term and long term effects of GTA treatment on the responses to HS, CCI and IRI.

Injury	Treatment length	Treatment	Analyses
Sham = 16 (8 wild type and 8 Acss2) x 3 (time points) x 2 (water or GTA) x 2 (repeating) = 192	1, 4 or 12 days	water or GTA	ELISA & histology
HS only 16 (8 wild type and 8 Acss2) x 3 (time points) x 2 (water or GTA) x 2 (repeating) = 192	1, 4 or 12 days	water or GTA	ELISA & histology
HS + CCI =16(8 wild type and 8 Acss2) x 3 (time points) x 2 (water or GTA) x 2 (repeating) = 192	1, 4 or 12 days	water or GTA	ELISA & histology

Table 1: Treatment groups and procedures. Animals in the experimental groups will receive either GTA or an equivalent volume of water. The experiments will be conducted on equal numbers of male wild type and Acss2 -/- mice (n = 8 per group for a total of 16 animals per treatment condition). At the end of the designated treatment periods, groups of 8 mice at each time point under each condition will be divided randomly into a group for ELISA measurements and a group for histology and immunohistochemistry (4 wild type and 4 Acss2 -/- mice for each). All animals (total = 576) will be listed under category E since analgesics cannot be used to alleviate the pain in any of the groups including the sham.

3. Cytokine and hormone quantitation by enzyme-linked immunosorbent assay (ELISA): Concentrations of cytokines such as IL-6, TNF-α will be measured using ELISA assays. Other HS-related proteins such as erythropoietin and HMGB1 in the plasma and in tissues will also be measured using ELISA. The CHIRP Laboratory Core has facilities for multiplex ELISAs and this resource will be utilized for our ELISA based studies. At the time points noted (Table 1) mice will anesthetized with Fatal Plus and blood will be drawn by cardiac puncture. The animals will be perfused with approximately 50 ml of PBS to remove remaining blood and tissues will be removed including brain, lungs, liver, kidney, small intestine and heart. Tissues will be frozen rapidly in liquid nitrogen and stored at -80 °C until analyzed.

4. Histochemical and Immunohistochemical analyses to detect multiple organ pathology: Fixation and tissue processing will be done during different time points in the study (Table 1). Mice will be deeply anesthetized with a pentobarbital based preparation

(Fatal-Plus Solution, 75-100 mg/kg, i.p.) and transcardially perfused with PBS (50 ml) followed by 4% paraformaldehyde (100 ml). Tissues including brain, kidney, heart, liver, lungs, and small intestine will be removed and post-fixed in 4% paraformaldehyde overnight at 4 °C, then transferred to a solution of 20% sucrose in PBS. After 18 hours the sucrose solution will be replaced with a fresh 20% sucrose solution and kept for 72 h, and then tissues will be frozen with dry ice and stored at -80-°C until sectioning. Frozen organs will be cryostat-cut at 5-20 µm, mounted onto glass slides. Some of the slides will be used for H & E staining which will be done at Biomedical Instrumentation Center at USUHS. For the immunostaining, endogenous peroxidase will be blocked by Peroxidase Block solution (DAKO). For specific protein detection, sections will be incubated at 0-4-°C overnight in presence of the respective primary antibodies and the immunoreactivity will be detected by using the appropriate Vectastain peroxidase kits according to the manufacturer's instructions.

V.1.2. Experiment 2: To repeat the studies using an optimal time point and perform genetic and epigenetic analyses in blood and different tissues such as liver, heart and kidney to understand the genetic and epigenetic mechanisms involved.

In order to understand the genetic and epigenetic mechanisms involved in the demonstrated protective effects of GTA, we plan to use a combination of open chromatin mapping with formaldehyde-assisted isolation of regulatory elements (FAIRE-seq), and enhancer and transcription factor mapping using chromatin immune-precipitation using anti-pan-acetyl lysine antibodies (ChIP-seq). Also, RNA-seq will be used to obtain the gene expression profiles in response to GTA in wild type and Acss2 -/- mice. We will use an optimal duration for GTA treatment based on the results of Experiment 1 and studies will be repeated under conditions where a maximal response was found in wild type mice using the optimal model system conditions.

Injury	Treatment length	Treatment	Analyses
Sham = 8 (4 wild type and 4 Acss2) x 2 (water or GTA) x 2 (repeating) = 32	Optimum time point	water or GTA	Genetic and epigenetic analyses
HS only = 8 (4 wild type and 4 Acss2) x 2 (water or GTA) x 2 (repeating) = 32	Optimum time point	water or GTA	Genetic and epigenetic analyses
HS + CCI = 8 (4 wild type and 4 Acss2) x 2 (water or GTA) x 2 (repeating) = 32	Optimum time point	water or GTA	Genetic and epigenetic analyses

Table 2: Genetic and epigenetic analyses. Details of the experiment are as given in table 1. Studies will be repeated using the optimal time point from experiment 1. All animals (total = 96) will be listed under category E since analgesics cannot be used to alleviate the pain in any of the groups including the sham.

V.1.3. Experiment 3. To repeat the experiment 2 using female mice of the same age.

The experiment will be done exactly as described in experiment 2, but with female mice.

V.2. Data Analysis: Data will be presented as mean ± SEM. Parametric data (cytokine levels etc.) will be analyzed using a paired 2-tailed t test for the paired data or a 1-way analysis of variance (ANOVA) followed by Dunnett's multiple comparisons post-test. Nonparametric data (histology data, immunohistochemical data) will be analyzed using a Wilcoxon signed rank test for paired data or a Kruskal-Wallis test (nonparametric ANOVA). An associated probability value of $P < 0.05$ will be considered significant.

Power analysis using the quantitative data obtained from our earlier studies have indicated that for behavioral studies a sample size of 10 animals per group will have 80% power to detect a difference of 1.5 standard deviations between groups assuming a 5% significance level, and should be sufficient for the outcomes we intend to measure; power calculations were performed using nQuery Advisor® 4.0 software. Similar calculations have indicated that 5-6 animals/group is sufficient for biochemical and immunohistochemical studies. The total number of animals for each experiment has been calculated based on the above considerations.

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered: The specific nature of the project does not permit use of non-animal alternatives. The global physiological changes occurring in different cell types in the in-vivo injury models cannot be reproduced in single cell culture system, or any alternatives.

V.3.2. Animal Model and Species Justification: Mouse model of hemorrhagic shock is one of the most commonly used animal models for these preclinical studies. Also, controlled cortical impact (CCI) in the rodents is one of the most extensively used models of TBI in the literature and this allows us to compare our results with those from other established laboratories.

V.3.3. Laboratory Animals

ALTERNATIVES CONSIDERATIONS: Does the protocol have any provisions that would qualify it to be identified as one that Refines, Reduces, or Replaces (3R's) the use of animals in relation to other protocols or procedures performed in the past?

Y/N (circle) **SECTION V.3.5.**

Exceptions to the *Guide for the Care and Use of Laboratory Animals* (Please check all applicable):

V.3.3.6.	**Sex:**	**Male and female**	**Male and female**
V.3.3.7.	**Special Considerations:**	None	Homozygous mice only will be used for the proposed studies
		425 (includes 10% extra for unexpected losses)	**425(includes 10% extra for unexpected losses)**

V.3.4. Number of Animals Required (by Species/Strain):

V.3.5. Refinement, Reduction, Replacement (3 Rs):

V.3.5.1. Refinement: In the initial studies conducted to test the effect of GTA on traumatic brain injury using the CCI model, we have focused on the obvious behavioral, biochemical and histological parameters which are known to be well associated with TBI. We have found that most of the animals recover fast and start running around in apparent normal way in a matter of hours. Occasionally, some (less than 10%) are found to show a greater impairment. As a refinement, we plan to look for such animals and euthanize them since they are likely to be outliers in the study as well. Also, animals will be acclimated before the behavioral studies. All the animals will receive local anesthesia during -catherization of the artery and vein. We do not plan to provide

any post-operative analgesia for these animals because use of analgesics can interfere with the goal of the proposed studies.

V.3.5.2. Reduction: We have considered reducing the total number of control animals by avoiding separate control groups. However, in view of the variations between animals, we do not feel comfortable in comparing with a control group done on another day. Therefore, we are unable to reduce the number of animals in the control group. Also, we have tried to use the minimum number of animals for each experiment based on our prior experience with GTA (earlier protocols) and statistical analysis.

V.3.5.3. Replacement: *In silico* methods and tissue culture approaches cannot be used for evaluation of the questions studied here, since these actions can only be observed in an intact living animal. At the present time, animals lower than rodents in the phylogenetic scale cannot be used to model hemorrhagic shock and/or brain injury in human, because of wide anatomic and physiological differences.

V.4. Technical Methods:

V.4.1. Pain / Distress Assessment: NA

V.4.1.1. APHIS Form 7023 Information: NA

V.4.1.1.1. Number of Animals:

	Species/Strain #1	Species/Strain #2
V.4.1.1.1.1. Column C:		
V.4.1.1.1.2. Column D:		
V.4.1.1.1.3. Column E:	**425**	**425**

V.4.1.2. Pain Relief / Prevention:

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization: For CCI model of TBI, mice will be initially anesthetized with 3-5 % isoflurane in 100% O2 in a vented anesthesia chamber. Mice under anesthesia will be placed on a stereotaxic instrument -and continuous isofluorane anesthesia (2%) will be given using a nose cone. That mice are under anesthesia will be determined by their lack of response to pinching the toes.

We do not plan to use analgesia for these studies. One of the main purposes of these studies is to evaluate the anti-inflammatory and healing effects/mechanisms of GTA mediated acetylations on CCI and HS induced injuries. Since most of the pain relief agents have some type of anti-inflammatory mechanisms, pain relief efforts in experiment will interfere with the goal of this study.

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions: Animals will be adapted to their environment for at least 5 days prior to the experiments.

V.4.1.2.3. Paralytics: NA

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures:

V.4.1.3.1. Sources Searched: PubMed, Agricola

V.4.1.3.2. Date of Search: 3/20/2016

V.4.1.3.3. Period of Search: 1966-2016

V.4.1.3.4. Key Words of Search: animal, mouse, pain, analgesia, transcardial perfusion, controlled cortical impact model, hemorrhagic shock

V.4.1.3.5. Results of Search: A total of 452 publications were obtained when -key words animal, mouse, pain and analgesia -were used. However, none appeared when transcardial perfusion or controlled cortical impact or hemorrhagic shock was included in the search. All of the 452 publications involved studies on different aspects of pain, including neural mechanisms and newer pain relieving agents. When key words mouse and transcardial perfusion were combined, 30 publications describing studies involving the use of transcardial perfusion were obtained. None of them provided any alternatives to the propcsed -painfu' procedures. Agricola: the key words combination animal, mouse, pain analgesia provided no publications unlike in the case of PUBMED and therefore adding the other key words was not attempted.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification: One of the main purpose of these studies is to evaluate the anti-inflammatory and healing effects/mechanisms on GTA mediated acetylations on CCI and HS induced injuries. Since -most of the pain relief agents have some type of anti-inflammatory mechanisms, pain relief efforts in experiment will interfere with the goal of this study.

V.4.2. Prolonged Restraint: NA

V.4.3. Surgery:

V.4.3.1. Pre-surgical Provisions: The surgical procedures will be performed aseptically following the LAM guidelines. Anesthesia will be induced by isoflurane vapor in 100% oxygen in a commercially available induction chamber. Once anesthesia is induced, animals will be transferred to the designated surgery area and anesthesia will be maintained via nose cone. See Section V 4.1.2.1 Anesthesia/Analgesia/Tranquilization for details.

When the animal is anesthetized, its head will be shaved with a hair clipper. The head will be cleaned with betadine and alcohol, each repeated 3 times alternately. Then the animal wil. be placed into a stereotaxic frame (appropriate frame size will be used for mice) after treating its pressure points such as ears and nose with lidocaine jelly. A heated pad with thermister controlled feedback will be put between the animal's body and the base of the stereotaxic frame. Ophthalmic ointment will be applied to the eyes

to prevent dryness. The body will be covered with a sterile drape with an opening to expose the head.

V.4.3.2. Procedure: Animal surgery, anesthesia and CCI-TBI and HS: For the surgical procedures mice will be anesthetized with 3-5% isoflurane and maintained with 2% isoflurane in100% O2 throughout the experiments. Under sterile conditions, a right groin exploration will be performed and the right femoral artery and vein will be exposed and catheterized using sterile polyethylene (PE-50) tubing (Harvard Apparatus). The catheters will be connected to a blood pressure transducer for continuous arterial blood pressure monitoring during the procedure. The mice will be placed in a stereotaxic frame and a 5 mm bone flap will be removed over the parietal cortex and kept in a sterile location for reuse. Injury will be produced with a 3 mm flat steel tip with a velocity of 5 m/sec and a penetration depth of 1 mm (Dennis et al., 2009). The bone flap will be replaced and the scalp will be closed using sutures. Subsequently, HS will be induced over the course of 15 min by withdrawing blood (approximately 2.0 ml/100gm) using a heparinized syringe (to avoid clotting) until we achieve a MAP between 30 and 35 mm Hg. The MAP will be maintained in this range for 60 min. At the end of the 60 min HS period, mice will be resuscitated to a MAP of at least 60 mm Hg. This will be done over 15 min with their remaining shed blood plus two times the maximum shed blood in lactated Ringer's solution via the same catheters. The catheters will be removed and the incision closed by sutures: sutures will be removed in 4-5 days or as soon as the wounds are healed. Mice will be taken off isoflurane and returned to their cages. Sham-operated mice will undergo anesthesia and femoral cannulation only.

We plan to use a heparinized syringe for withdrawal of blood. Majority of studies in the literature have used the heparinized syringe approach rather than infusion of a heparin solution before the procedure. In view of the fact that heparin infusion could interfere with clotting mechanism with a chance for interference with experimental outcome we opted to use the heparinized syringe approach. **We are planning to catheterize both femoral arteries and a femoral vein.** One femoral artery will be used to draw the blood and other will be used for continuous measurement of MAP. Femoral vein is reserved for reinjection and resuscitation. This method is expected to represent the clinical scenario better.

A search of the literature (Jespersen, B. et al, 2012) showed that the loss of mobility and potential pain in the affected limb because of loss of blood flow after closure of both the major arterial supply and venous return are not real concerns in the proposed model. Distress to the animal is minimal in this procedure (Jespersen, B. et al, 2012).

V.4.3.3. Post-surgical Provisions: After CCI-TBI surgery/HS, animals will be kept in warm condition by a heated blanket or light until they recover from anesthesia. The animals will be observed twice daily after surgery and recovery by our research staff for 4-5 days.

V.4.3.4. Location: (b)(6) (b)(6) facilities at USUHS

V.4.3.5. Surgeon: Dr (b)(6)

V.4.3.6. Multiple Major Survival Operative Procedures: NA

V.4.3.6.1. Procedures: NA

V.4.3.6.2. Scientific Justification: NA

V.4.4. Animal Manipulations:

V.4.4.1. Injections:
1. Fatal Plus (50-85 mg/kg), Intraperitoneal, volume = 100-200 µl for mice, needle size = 25-27 gauge needle for mice.
2. Isoflurane for anesthesia – volatile anesthetic-2-5% in 100% oxygen-FDA approved agent.
3) GTA administration by oral gavage (5 g/kg)– not FDA approved., GRAS status given by FDA, GTA is used extensively in preclinical studies. The PI's group has used GTA for acetate supplementation studies during the last 10 years.
4) Heparin contained in heparinized syringe. FDA approved. Extensively used in similar studies.

V.4.4.2. Biosamples: Tissues such as brain, lung, liver, kidney, heart and blood will be collected post mortem.

V.4.4.3. Adjuvants: N/A

V.4.4.4. Monoclonal Antibody (MAbs) Production: N/A

V.4.4.5. Animal Identification: The animals will be identified by cage card. However, individual animals after procedure will be given a particular identifying tattoo **during surgery** on their pinna of the ear, tail, arms or legs.

V.4.4.6. Behavioral Studies: None planned.

V.4.4.7. Other Procedures: Oral gavage: Treatment of mice with GTA to test effectiveness against HS and injury will be done via oral gavage. The details are given in the experimental method section V.1.1 Experiment 1. Animals will be held in a supine position and the blunt needle will be inserted into the mouth, directed at a dorsal caudal direction and gently lowered into the stomach. Projecting the needle to the top part of the mouth will avoid any chance of entering the respiratory tract and the lung. We have extensive experience in doing oral gavage in mice based on our ongoing and prior work.

V.4.4.8. Tissue Sharing: Tissues may be shared with other investigators upon request.

V.4.5. Study Endpoint: Study Endpoint: The animals will be euthanized for tissue collections and also for histological analysis at the designated time points previously described.

Early Endpoint: Any of the following will represent a reason for early euthanasia: inability to ambulate or reach food or water, self-mutilation, continuous circling, or persistent labored respiration or gasping, loss of 20% of weight below baseline (weight taken on alternate days), prostration/inactivity for up to 24 hours. These signs, if observed by animal facility personnel and no study personnel can be reached, may be taken by the veterinarian as cause for euthanasia.

V.4.6. Euthanasia: Some animals in each group will be euthanized by decapitation following injection of a ~75-100 mg/kg dose of pentobarbital based euthanasia solution. Others will be euthanized by transcardial perfusion following euthanasia solution administration (Fatal Plus, 75-100mg/kg or other pentobarbital based euthanasia solution, Intraperitoneal, 200-300µl volume, 25 gauge needle).

Transcardial perfusion will be done as described in our publications (Ariayannur et al, 2010; Arun et al, 2010 b; Mathew et al, 2005; Madhavarao et al, 2009). Briefly, animals will be deeply anesthetized with Fatal Plus (75-100 mg/kg), and the heart will be exposed by opening up the thoracic cavity after confirming that the animal is fully under anesthesia. To monitor the depth of anesthesia we will test whether the animal has lost its toe pinch (pedal withdrawal) reflex. The animals will be perfused with either 10% neutral buffered formalin or 4% freshly depolymerized paraformaldehyde through the left ventricle using a peristaltic pump. The right atrium will be cut and approximately 50-75 ml of fixative solution will be passed through the circulatory system. Following the perfusion, tissues will be removed to a container of fresh fixative solution prior to histopathological analysis.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs.

V.5.1.1. Study Room: CCI-TBI will be conducted in LAM's surgery room or CNRM facilities.

Building(s) (b)(6) Room Number(s) (b)(6) (b)(6)

V.5.1.2.

Special Husbandry Provisions: No separate housing required after surgery

Food Restriction: Yes _____ No X

Fluid Restriction: Yes _____ No X

V.5.1.3. Exceptions: N/A

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care: The animals will be observed daily according to LAM SOPs.

V.5.2.2. Emergency Veterinary Medical Care: All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: Except as indicated below, all animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents.

V.5.3.2. Enrichment Restrictions: N/A

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
Intragastric administration	(b)(6)	Ph.D. 8 years exp. in mice Ph.D., 2 years exp. in mice	Investigator training, 2003, Rodent handling class, 2003 Investigator training, 2014, Rodent handling class,2014
IP injection		Ph.D., 2 years exp. in mice M.Sc., 3 years exp. in mice	Investigator training, 2014, Rodent handling class,2014 Investigator training, 2013, Rodent handling class, 2013
decapitation		Ph.D., 2 years exp. in mice M.Sc., 3 years exp. in mice	Investigator training, 2014, Rodent handling class,2014 Investigator training, 2013, Rodent handling class, 2013
transcardial perfusion		Ph.D., 2 years exp. in mice	Investigator training, 2014, Rodent handling class,2014

CCI		Ph.D. 8 years exp. in mice	Investigator training, 2003, Rodent handling class, 2003
HS		M.D., to be trained by our collaborator at WRAIR.	awaiting investigator and rodent handling trainings

VII. BIOHAZARDS/SAFETY: Gowns, gloves, and masks will be used for personal protection and sharp items will be disposed of in separate containers as per safety rules. The volatile anesthetic agents will be properly closed and removed from the procedure area. Chemicals and hazardous waste used in this protocol will be handled in accordance with all applicable state and federal guidelines, regulations, and standing operating procedures. Waste anesthetic gas (isoflurane) will be scavenged passively and exposure to investigators will be minimized using the set up used in the LAM operating room since the surgeries will be done in one of those operating rooms.

A. Zoonotic Disease:None
B. Safety Hazards:None
C. Isoflurane:Yes
D. Isoflurane Exposure: Minimal exposure
E. Sharp Instruments: Yes
F. Infectious Agents that do not cause Zoonoses: None

VIII. ENCLOSURES: References

IX. EXTRAMUAL COLLABORATION:

If there are any collaborations with outside entities, please explain here.

X. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

(b)(6) 4/14/2016

Principal Investigator Signature Date

G. Training: The following personnel will attend the next USUHS Investigator/Animal User Training Course:

H. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely,

"Responsibility" for implementing animal use alternatives where feasible and conducting humane and lawful research.

I. Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress ~~**WILL**~~ **or WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

XI. PROTOCOL ABSTRACT:

Hemorrhage is responsible for about 30-40% of all traumatic deaths and approximately 50% of battlefield deaths worldwide. Studies have suggested that the ability of tissues to deal with hemorrhage related problems such as hypoxia, hypercapnia and hypothermia, is critical and that robustness of this ability differs among individuals, suggesting involvement of genetic or epigenetic mechanisms. Recently it has been shown that acetylation of the transcription factor HIF-2α controls erythropoietin production during pathophysiological stress induced by oxygen deprivation. In earlier studies we have developed acetate supplementation using glyceryl triacetate (GTA), which generates acetate and glycerol on hydrolysis in vivo, to improve outcomes after traumatic brain injury. Based on these and other studies we have found that oral GTA administration is an effective way to increase acetate levels in all tissues and that GTA has no detectable toxic effects on chronic usage even at relatively high doses in animals and children. In subsequent studies, acetate supplementation using GTA has been shown to induce anti-inflammatory effects in multiple rat model systems. Histone deacetylase inhibitors including valproic acid and trichostatin, which increase protein acetylation status in general and histone acetylation status in particular, have anti-inflammatory and protective effects in hemorrhagic shock. This is due in part to the fact that patients who survive acute episodes of blood loss experience systemic inflammatory response syndrome (SIRS) triggered by ischemia-reperfusion injury and organ damage. Based on these earlier findings, we propose to develop oral acetate supplementation using GTA as a way to augment acetylation-based regulatory mechanisms involved in the response to and recovery from bodily injury, blood loss and reperfusion injury. Our immediate goal is to develop GTA treatment as an adjunct therapy for hemorrhagic shock and injury. We and others have shown that acetyl-coenzyme A synthetase-1 (enzyme name: AceCS1, gene: Acss2) is primarily involved in generating acetyl-coenzyme A (acetyl-CoA) for acetylation reactions, especially in cell nuclei, and we currently have an ongoing breeding colony of mice in which the Acss2 gene is knocked out for studying the related genetic mechanisms. Using this gene knockout model we plan to determine the genetic and epigenetic regulatory mechanisms involved in the acetylation-based regulation of stress responses to blood loss and injury, and the beneficial effects of GTA treatment on survival from hemorrhagic shock and injury. Subsequently, we plan to focus efforts on enhancing our understanding of such regulatory mechanisms in humans for improving survival from traumatic hemorrhage and associated shock, providing knowledge that will lead to genetically-informed personalized treatments. Our central hypothesis is that enhancing acetylation-based endogenous genetic/epigenetic mechanisms is an effective way to minimize chronic disability and death due to hemorrhagic shock. We propose to test this hypothesis using GTA-mediated acetate supplementation in a mouse model of hemorrhagic shock with concomitant injury and determine the associated genetic/epigenetic mechanisms using our Acss2 gene knockout mouse model. The long-term goal of the proposed studies is to improve survival for patients with traumatic hemorrhage and associated shock via regulation of genetic and epigenetic response mechanisms and to provide knowledge that will lead to genetically-informed personalized treatments.

PI NAME: (b)(6) Ph.D.
PROTCOL NUMBER: (b)(6)
DRUGS AND CONTROLLED SUBSTANCES

Please list ALL drugs and controlled substances that will be used under this protocol, indicating the DEA Schedule if known. Provide both the Approved Name and the Proprietary Name of each drug if known.

This list, once approved, will be used by the IACUC and the USU Pharmacy to determine which drugs and controlled substances can be supplied to the Principal Investigator. The Pharmacy will not dispense to the PI any drug that is not included in this list.

Drug Name (Please give both approved and Proprietary Names if possible)	DEA Schedule (I, II, III, or IV) (if known)
1. **Sodium pentobarbital (Fatal Plus)**	II
2.	

Date of Protocol Expiration Date: New Protocol

September 5, 2013

MEMORANDUM FOR DR. (b)(6) DEPARTMENT OF MEDICINE

SUBJECT: IACUC Approval of Protocol – Triennial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on September 5, 2013:

Animal Protocol Title: "Gene Therapeutic Approach for Tolerance Induction to Cognate Antigens and EAE in Mice"

USUHS Protocol Number: (b)(6)

Expiration Date: September 4, 2016

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. **NON-TECHNICAL SYNOPSIS:** Multiple sclerosis (MS) is an immune-mediated disease in which certain cells from the immune system attack and destroy parts of the central nervous system (CNS), in particular the myelin sheath that surrounds nerve fibers and aids in signal transduction and the nerve fibers themselves. This disruption of nerve impulses can be debilitating, with symptoms ranging from mild (limb numbness) to severe (paralysis/loss of vision). While the exact cause of MS is not known, it is believed that a number of factors play a role in disease development, among them an abnormal immune response. It is also believed that infections, genetics and environmental factors may be involved in triggering disease. Our lab has been interested in investigating the role that the immune system plays in MS. We have shown that when antigens are linked to protein, called an immunoglobulin "carrier", they can specifically inhibit the reactivity of the immune system (tolerance) to the linked protein antigens. In this protocol, we will use Experimental Allergic Encephalomyelitis (EAE), a mouse model which resembles MS. This is a well-established experimental model for multiple sclerosis that induces an impaired ability to walk and possibly can cause some muscle paralysis in the mice over a period of days to weeks. Mice will be injected with a protein from mouse brain together with an agent facilitating development of white blood cells (called T cells) that attack brain proteins, leading to tissue destruction. Treatments with modified immune cells from other mice will be tested to determine if such treatments might prevent or alleviate the impaired movement induced by the injection of brain proteins. We also are developing soluble fusion proteins built on the IgG scaffold to facilitate tolerance without cell transfer.

II. **BACKGROUND:**

II.1. Background: Our lab is interested in developing techniques to regulate (eliminate) the immune response to a variety of proteins that are being attacked by the body in autoimmunity. Our goal is to use a type of white blood cell, called B lymphocytes, which have been engineered to display parts of foreign or self materials to the immune system in such a way as to "trick" it into not responding, in order to control autoimmune (anti-self) diseases. We expect, and preliminary results have shown, that transferring these antigens to the blood B lymphocytes will lead to diminished responses to these proteins and curing of autoimmunity in animal models for multiple sclerosis.

Further studies show that we can also trick the immune system by transferring the antigens to the precursor form of B cells found in the bone, the bone marrow cell. The long-term objective is to understand and harness this process so that we can better prevent and reverse the autoimmune attack that occurs in diseases like diabetes or multiple sclerosis (MS). In this protocol, we will use Experimental Allergic Encephalomyelitis (EAE) as an autoimmune disorder resembling MS. It is characterized by a chronic relapsing, and remitting paralysis secondary to central nervous system (CNS) demyelination caused by T cells. Our hypothesis is that tolerance can be induced by our B-cell presentation of foreign or self proteins) delivered via our gene therapy procedure. This somehow tricks the immune system into a state of non-responsiveness (tolerance) and a reversal of autoimmunity. The objective is to optimize this process for future application.

II.2. Literature Search for Duplication:

II.2.1. Literature Source(s) Searched: Biomedical Research Database
RePORTER
Pubmed

II.2.2. Date of Search: July 23, 2013

II.2.3. Period of Search: 1990-2013 (BRD: 1998-2013 only)

II.2.4. Key Words and Search Strategy: Multiple sclerosis/EAE and alternatives to animal use; multiple sclerosis and alternatives to painful procedures; adjuvant alternatives;

II.2.5. Results of Search: No relevant hits; alternatives to footpad injection found and are incorporated. No other relevant hits nor do they represent duplication of work proposed. EAE is an autoimmune neurological disease that cannot be replicated in culture. Moreover, you cannot determine whether a therapy or immunization protocol will work in culture. Mice have been used for studies in immunology for several decades, and are the animal of choice due to extensive knowledge of their genetics, and of murine T and B cells and their interactions. In addition, mice provide useful models for human disease.

III. **OBJECTIVE\HYPOTHESIS:** Our goal is to use an animal model of Multiple Sclerosis (MS) to devise ways to prevent immune responses to nervous system proteins (like myelin). Our hypothesis is that tolerance can be induced by our B-cell presentation of foreign or self proteins) delivered via our gene therapy procedure. This somehow tricks the immune system into a state of non-responsiveness (tolerance) and a reversal of auto-immunity. The objective is to optimize this process for future application.

IV. **MILITARY RELEVANCE:** Autoimmune disorders such as multiple sclerosis (MS) can be severely debilitating. Moreover, there has been an increased incidence of certain autoimmune diseases in veterans of the ongoing wars. Understanding how to reverse these and other undesirable immune responses is important for the general health of the military population and their families. Our research is aimed at reversing the effects of autoimmune diseases and hence is relevant.

V. **MATERIALS AND METHODS:**

- C57Bl/6J (b)(4) male and female, 6-8 weeks of age. These mice are susceptible to MOG-induced EAE

- T-cell receptor transgenic 2D2 mice, are available from (b)(4) Male and female donors, 6-8 weeks of age. These mice possess transgenic T cells that are specific for MOG35-55, a target in EAE.
- Balb/c and DO11.10 are used in an experiment to follow the fate of specific T cells in a non-EAE model, and FoxP3-GFP mice to follow the role of T regulatory cells.

V.1. Experimental Design and General Procedures:

V.1.1. **Experiment 1**: To test whether memory B cells from immune mice are pathogenic or tolerogenic in our gene therapy protocol.

Goal and protocol: To determine whether tolerance to MOG-induced EAE can be induced with B cells from immunized mice, that is, can antigen-specific B cells be tolerogenic or immunogenic for CNS antigen. This is important because autoimmune patients will possess B cells specific for the CNS antigen. This will test the hypothesis that antigen-specific B cell may be tolerogenic or may contribute to pathogenesis whereas non-specific B cells are tolerogenic.

• Mouse strains needed/source: C57BL/6J, (b)(4) male and female, 6-8 weeks of age. These mice are susceptible to MOG-induced EAE (40 donors and 80 recipients per experiment; 360 mice total; JAX)

Experiment I: To determine whether tolerance to MOG-induced EAE can be induced with B cells from MOG-immunized donors; Age = 6-8 weeks

This experiment needs to be performed three times (original plus two repeats) for statistical significance based on the PI's experience with this model. We require:

Group 1: B cells from MOG immunized donors transduced with MOG-IgG (10 donors)
Group 2: B cells from MOG immunized donors transduced with OVA-IgG (10 donors) (specificity)
Group 3: B cells from naive donors transduced with MOG-IgG (10 donors) (tolerant)
Group 4: B cells from naïve donors transduced with OVA-IgG (10 donors) (specificity)

Day -30

Immunize 20 donors (groups 1 and 2) with MOG protein in alum intraperitoneally (i.p.) (10 micrograms in 0.2 ml, 27G needle)

~

Day -9

Prepare B cells from 20 normal C57BL/6J mice (normal polyclonal donors) or from 20 immunized donors, activate with LPS *in vitro*

~

Day -8

Culture activated B cells *in vitro* with MOG35-55 retroviral construct or control, e.g. OVA construct)

~

Day-7

Wash, mix and inject B cells (i.v.; tail; 27G, <0.2 ml) into 4 groups of 20 recipients (80 C57BL/6J)

~

Day 0

Immunization with antigen (MOG35-55) + Adjuvant (complete Freund's adjuvant (CFA)), flanks (s.q.) and base of tail (s.q.) (27G, 0.1 ml total)

~

Daily
Observe clinical symptoms

Day 28 All mice in groups 1-4 will have blood samples taken and will be euthanized to obtain tissues for T-cell proliferation*, record clinical symptoms. Mice are euthanized when they reach stage IV in this protocol if remission does not occur!
This experiment is repeated twice more.

**All euthanized mice are tested for T-cell proliferation in spleen and draining popliteal and inguinal lymph nodes.*

V.1.2. **Experiment 2:** To determine the fate of specific T cells in modulation of EAE (This experiment could not be done in our initial period due to commensals in facility affecting the tolerance protocol).

Goal and protocol: Same general protocol as Experiment 1. We will repeat this basic protocol with an injection of 2D2 T-cell receptor (TCR) transgenic T cells (labeled with carboxy-fluorescein succinimidyl ester, CFSE) into recipients in order to localize their migration under optimum tolerance conditions. In this variation of the basic experiment, MOG-specific TCR transgenic T cells (2D2) will be isolated, labeled with CFSE to trace them, and transferred into normal C57BL/6 recipient mice, which then receive tolerogenic B cells. At various time points during the experiment, mice from each group will be euthanized to obtain lymph node and spleen cells to assay for T cell responses to the test antigen in culture or followed for disease symptoms. The readout is EAE and flow cytometry.

Experiment 2

To determine whether the fate of T cells in tolerance to MOG-induced EAE

Mice;
Each experiment requires 48 C57BL/6 recipient mice, 24 C57BL/6 donor mice and 12 TCR transgenic 2D2 mice. Thus, 24 C57BL/6 donors and 48 recipients (x3) = 216; 12 2D2 donors per expt. (x3=36). Male and female, age 6-8 weeks.

This experiment needs to be performed three times (original plus two repeats) for statistical significance based on the PI's experience with this model.

Day -9
Prepare B cells from 24 normal C57BL/6 mice (normal polyclonal donors), activate with LPS *in vitro*
~

Day -8
Culture activated B cells *in vitro* with MOG35-55 retroviral construct or control, e.g. OVA construct
Day-8
Inject TCR transgenic 2D2 T cells (12 donors) i.v. (27G, <0.2 ml) labeled with CFSE into two groups of 12 recipients; 24 recipients do not receive 2D2 T cells
~

Day-7
Wash and inject B cells into 4 groups of 12 recipients

Group 1: B cells from naive donors transduced with MOG-IgG (plus 2D2 T cells)
Group 2: B cells from naïve donors transduced with OVA-IgG (plus 2D2 T cells)
Group 3: B cells from naive donors transduced with MOG-IgG (tolerant)
Group 4: B cells from naïve donors transduced with OVA-IgG (specificity)

~

Day 0

Immunization with Antigen (MOG35-55) + Adjuvant (CFA), flank (s.q.) and base of tail (s.q.) (27G, 0.1 ml total)

~

Day 3, 7, 14, 21

On days 3,7,14, and 21, three mice per group will be euthanized and spleens removed. Spleen cells will be examined for presence of CFSE-labeled T cells (to follow fate of T cells), both in numbers and for amount of proliferation.

Mice are observed for clinical symptoms on days 7-21 and are euthanized when they reach stage IV in this protocol if remission does not occur!

V.I.3. **Experiment 3:** To determine the fate of specific T cells in B-cell delivered gene therapy for a non-CNS-derived antigen

- Mice needed and source: Balb/c (216) and D011.10 (36), from (b)(4) are used for experiment 3 to follow the fate of specific T cells in a non-EAE model.

Goal and protocol: Same general protocol as Experiment 2. We will repeat this basic protocol with an injection of D011.10 TCR transgenic T cells (CFSE labeled) into recipients in order to localize their migration under optimum tolerance conditions with a non-CNS antigen. To follow the fate of the T cells, Ovalbumin-specific DO11.10 TCR transgenic T cells will be isolated, labeled with CFSE to trace them, and transferred into normal Balb/c recipient mice, which then receive tolerogenic B cells. At various time points during the experiment, mice from each group will be euthanized to obtain lymph node and spleen cells to assay for T cell responses to the test antigen in culture and antibody to OVA.

Experiment 3
To determine whether the fate of specific T cells in tolerance induced by OVA expressing B cells
Mice: Number per expt. Total Balb/c, (b)(4) male and female 72 donors and 144 recipients = 216.
Age =6-8 weeks
TCR transgenic DO11.10 mice 12x3=36 donors; Male and female, age 6-8 weeks.
This experiment needs to be performed three times (original plus two repeats) for statistical significance based on the PI's experience with this model.

Day -2

Prepare B cells from 24 normal Balb/c mice, activate with LPS *in vitro*

~

Day -1

Culture activated B cells *in vitro* with OVA-IgG retroviral construct or control, e.g. OVA construct) or control (MOG or other irrelevant antigen)

~

Day 0

Inject transduced B cells i.v. (27G, <0.2 ml) into Balb/c recipients

~

Day 1

Inject (i.v.) TCR transgenic DO11.10 T cells (12 donors) labeled with CFSE into 2 groups of 12 recipients; 24 mice do not receive DO11.10 T cells as controls

~

Day 3, 7, 14 and 28

Isolate spleen cells from 3 mice per group and examine for presence of CFSE-labeled T cells (to follow fate of T cells), both in numbers and for amount of proliferation. We already know this protocol leads to tolerance to OVA peptides, which is validated by T-cell proliferation to OVA peptide *in vitro*.

V.1.4. **Experiment 4:** To determine the role of FoxP3 T regulatory cells in B-cell delivered gene therapy. Same general protocol as Experiment 3. We will repeat the basic protocol except that DO11.10-FoxP3-GFP donors are used to follow the role of T regulatory cells in tolerance. The rationale is that these donor DO11.10-FoxP3-GFP, a marker of Tregs, will appear green when activated. These mice then receive tolerogenic B cells. At various time points during the experiment, mice from each group will be euthanized to obtain lymph node and spleen cells to assay for the increase in T regulatory (GFP+) cells.

• Mice needed and source: Balb/c [(D)(4)] and DO11.10-FoxP3-GFP (USU), are used as in experiment 3 to follow the role of specific T cells in a non-EAE model.

Experiment 4

To determine the role of regulatory T cells in tolerance

This experiment is repeated once

Day -2

Prepare B cells from 24 normal *Balb/c* mice, activate with LPS *in vitro*

~

Day-l

Culture activated B cells *in vitro* with OVA-Ig retroviral construct or control (e.g. MOG or other irrelevant antigen)

~

Day 0

Inject transduced B cells i.v. (27G, <0.2 ml) into 48 recipients + DO11.10-FoxP3-GFP TCR transgenic to trace Tregs into 24 recipients

~

Day 3, 7, 14 and 28

Isolate spleens from 3 mice per group and check for CFSE staining by flow cytometry (we already know this protocol leads to tolerance to OVA peptides, which is validated by T-cell proliferation to OVA peptide *in vitro*.

Experiment 5

GOAL: To determine whether fusion IgG's we have developed can induce tolerance to MOG-induced EAE

Mice;
Each experiment requires 40 C57BL/6 recipient mice (120 total)
This experiment needs to be performed three times (original plus two repeats) for statistical significance based on the PI's experience with this model.

Day-7
Wash and inject fusion IgG cells into 4 groups of 10 recipients (all injections i.v. 27G, <0.2 ml)

Group 1: Inject with scCD20 IgG MOG (10 micrograms)
Group 2: Inject with scCD20 IgG OVA (10 micrograms)
Group 3: Inject with scCD20 IgG MOG (50 micrograms)
Group 4: Inject with scCD20 IgG OVA (50 micrograms)

~

Day 0
Immunization with antigen (MOG35-55) + Adjuvant, flanks (s.q.) and base of tail (s.q.) (27G, 0.1 ml total)

~

Daily
Observe clinical symptoms

~

Day 28
Sample bleed and/or euthanize to obtain tissues for T-cell proliferation*, record clinical symptoms. Mice are euthanized when they reach stage IV in this protocol if remission does not occur!
This experiment is repeated twice more.

**All euthanized mice are tested to T-cell proliferation in spleen and draining popliteal and inguinal lymph nodes.*

V.2. Data Analysis: The significance of the responses will be analyzed by students' t test when appropriate sized groups or distributions are observed. In other cases, a statistician will be invited to examine the data.

V.3. Laboratory Animals Required and Justification: All of our studies require animals with an intact immune system and therefore cannot be replicated *in vitro*. Mice have been used for studies in immunology for several decades, and are the animal of choice due to extensive knowledge of their genetics, and of murine T and B cells and their interactions. In addition, mice provide useful models for human disease. Indeed, immunization of mice with myelin proteins mimics the symptoms of multiple sclerosis in humans. Thus, these mice are an excellent model for MS. We use mice that express T -cell receptor transgenes in order to examine the role of specific T cells in tolerance, and the fate of the latter in 2 different models, CNS-specific or non-CNS (OVA) reactive.

We also use mice that express a Green Fluorescent Protein (GFP) when a gene for FoxP3 (involved in regulation of immune responses) is expressed. These mice will allow us to follow the consequences of our treatment protocols on the development of regulatory T cells, and importantly will enable us *to* isolate and studies these T cells.

V.3.1. Non-animal Alternatives Considered: The ability to form antibodies or develop autoimmune responses requires *in vivo* immunization. *In vitro* experiments cannot address the questions. *There are NO non-animal alternatives to address these questions.*

V.3.2. Animal Model and Species Justification: Mice have been used for studies in immunology for several decades, and are the animal of choice due to extensive knowledge of their genetics, and of murine T and B cells and their interactions. In addition, mice provide useful models for human disease. Indeed, immunization of mice with myelin proteins mimics the symptoms of multiple sclerosis in humans. Thus, these mice are an excellent model for MS

V.3.3. Laboratory Animals

		Species #1
V.3.3.1.	Genus & Species:	Mouse (*Mus musculus)*
V.3.3.2.	Strain/Stock:	See Table below
V.3.3.3.	Source/Vendor:	See below
V.3.3.4.	Age:	6-12 weeks
V.3.3.5.	Weight:	20-25 g
V.3.3.6.	Sex:	M and F
V.3.3.7.	Special Considerations:	See below

V.3.4. Number of Animals Required (by Species):

Species	Strain	Weight/Age	Sex	Total # *(for 3 yrs)*
Mice	C57BL/6	25g/>6 wks	M/F	**696**
Mice	Balb/c	25g/>6 wks	M/F	**264**
Mice	DO11.10 (Balb/c) TCR transgenics	25g/>6 wks	M/F	**36**
Mice	*DO11.10/FoxP3-GFP knockin	25g/>6 wks	M/F	**96**
Mice	2D2 TCR transgenic	25g/>6 wks	M/F	**36**

V.3.5. Refinement, Reduction, Replacement (3 Rs):

V.3.5.1. Refinement:
All of our studies require animals with an intact immune system and therefore cannot be replicated *in vitro*. Mice have been used for studies in immunology for several decades, and are the animal of choice due to extensive knowledge of their genetics, and of murine T and B cells and their interactions. In addition, mice provide useful models for human disease. Indeed, immunization of mice with myelin proteins mimics the symptoms of multiple sclerosis in humans. Thus, these mice are an excellent model for MS. Appropriate anesthesia will be used when performing retro-orbital blood collection in an effort to reduce pain and distress. Soft bedding, enrichment pads, and gel nourishment will be used in all EAE related experiments. Analgesia is not recommended in our

experiments, as it may strongly influence the fate of T-cell subsets studied in our experiments. Analgesics may interfere with these studies since they are known to modulate the immune response. For example, see Carrigan KA, Saurer TB, Ijames SG and Lysle DT, 2004. Buprenorphine produces naltrexone reversible alterations of immune status *Internat. Immunopharmacol.* 4:419-28 for details and for additional citations. One refinement we intend to incorporate into this protocol is to inject antigen/adjuvant into the flanks and base of tail (SQ) as an alternative to footpad injection.

V.3.5.2. **Reduction:** Our experiments require tissue donors of bone marrow-derived B cells (LPS activated B cells), which will be harvested and retrovirally transfected for transfer. Based on experience, each experimental group needs to have 10-12 mice for statistical and biologic relevance (see references below). To estimate sample size of recipients needed to reach a statistical significance with 95% confidence using a two-tailed method where beta is 0.20, a computer program was used. Mean and standard deviation values from previous experiments performed under this protocol were used in the program. As part of these studies, we need to establish the role of regulatory T cells (and specific T cells) in tolerance.

We use one donor for every 2 recipients, and transfer B cells transduced with viral vectors for Ig fusions proteins with MOG or OVA (control) that are target antigens in MS (as well as control constructs). Therefore, groups of at least 20-24 mice are needed as recipients, and 10-12 mice as donors, and each experiment is repeated for statistical significance. The experiment is repeated for statistical significances based on the PI's experience with this model and precedence in the field.

The estimated total number of mice is based on the principal investigator's extensive experience in this experimental system, the requirement to repeat experiments for validation and to obtain significance. We have requested this annual total of mice as determined by many years of prior experience in this and similar experimental systems (historical justification; see references below). The mice will be used in a series of linked studies that involve the induction of tolerance via gene therapy of transplanted B cells, the fate of target T cells and the role of regulatory T cells, and the assessment of clinical symptoms and immune responses. While it is impossible to detail the outcome of all experiments and to predict the specific fate of any single experimental group ahead of time as experiments are planned based on ongoing results, a typical set of experiments is delineated below. Every effort is made to ensure the scientific utility of data derived from each animal used in this study by monitoring, evaluating and modifying group size as needed to obtain clear and consistent data. Every effort will be made to minimize the numbers of mice used without compromising research results.

V.3.5.3. **Replacement:** No computer or *in vitro* simulation is available as replacement.

V.4. **Technical Methods:** Tissue Harvest: Mice whose tissues will be used as donor will be euthanized via CO_2 asphyxiation as described in Section V.4.6. Spleens and/or lymph nodes are removed aseptically, and B cells are purified using magnetic beads (positive selection) or antibody + complement (negative selection), then stimulated *in vitro* with Lipopolysaccharide (LPS) for retroviral transduction. Retroviral vectors containing the CNS proteins (or OVA) fused to IgG heavy chain are used to transduce the cells via standard procedures. These B cells are then adoptively transferred into naïve or immunized mice of each strain to test our tolerogenic protocol.

Monitoring of EAE: Experimental Allergic Encephalomyelitis (EAE) is an autoimmune disorder characterized by a chronic relapsing, and remitting paralysis secondary to central nervous system (CNS) demyelination caused by T cells, and mice can go into remission even after development of stage III disease. Animals are monitored daily and investigators will inform the animal care staff of

the condition of the animals so that they can be carefully monitored. Mice will be monitored by the above investigators for disease daily and EAE will be scored as follows: (I) flaccid tail, (II) partial paralysis of 1 or 2 limbs or flaccid tail with ataxia, (III) total paralysis of 2 limbs, (IV) paralysis of more than 2 limbs, (V) moribund. All mice will be weighed at stage III of EAE, when paralysis

has developed in both hind limbs, we will start putting paper bedding in the cages (a much softer bedding the conventional one). At this stage, we will also provide saturated gel so that the mice don't become dehydrated. Hydration will be monitored by physical examination. Moreover, at this stage III, the animal will be relocated to a separate cage if there are signs of injury by other animals. Food pellets will also be put on the cage floor for easier access. In animals at grade III or IV, the urinary bladders will be expressed daily by the investigators. Heat supplementation will be provided if necessary.

Note that due to the apparent severity of symptoms relative to access to food, water, urine and possibly fecal retention, we will continue to fully document each animals grade classification with daily observations and performance of functions, i.e., body weight, hydration, evidence that food has been accessed, urine expression, etc. These records will be monitored periodically by a consulting veterinarian, and the IACUC.

Alternative Endpoints: (b)(4)

(b)(4)

(b)(4) Additionally, if animals show continued lack of mobility and access to food or become moribund (i.e. display ruffled fur, immobility using front paws, dehydration, 20% weight loss) they will be euthanized. In order to determine weight loss, mice will be weighed at the time of immunization and then monitored periodically after that.

*This period is based on the fact that a number of mice can recover within this period of time, and that in many cases, additional analysis of the phenotype of cells in the peripheral blood may need to be followed to understand mechanisms (rise in suppressor T cells, cytokine profiles, etc.). Note that the paralysis per se is painless, so that the main issue is access to food and water, which we provide daily. Under other circumstances, however, mice are euthanized at 60 days after immunization.

See below for further details.

Euthanasia & Tissue Harvest: Mice will be euthanized via C02 asphyxiation followed by cervical dislocation. The following tissues will be harvested: spleen and draining lymph nodes (popliteal and inguinal chain):

V.4.1. Pain / Distress Assessment:

V.4.1.1. APHIS Form 7023 Information:

V.4.1.1.1. Number of Animals: 1164

		Species: Mus musculus #1 (C57BL/6)	Species: Mus musculus #2 (Balb/c)

V.4.1.1.1.2.	Column D:		
V.4.1.1.1.3.	Column E:		

V.4.1.2. Pain Relief / Prevention:

Experimental Allergic Encephalomyelitis (EAE) is an autoimmune disorder characterized by a chronic relapsing, and remitting paralysis secondary to central nervous system (CNS) demyelination caused by T cells, and mice can go into remission even after development of stage III disease. Animals are monitored daily and investigators will inform the animal care staff of the condition of the animals so that they can be carefully monitored. **At stage III of EAE, when paralysis has developed in both hind limbs, we will start putting paper bedding in the cages (a much softer bedding the conventional one). At this stage, we will also provide saturated gel so that the mice don't become dehydrated. Hydration will be monitored by physical examination. Moreover, at stage III, the animal will be relocated to a separate cage if there are signs of injury by other animals. Food pellets will also be put in the bedding to make easy access to food. In animals at grade III or IV, the urinary bladders will be expressed daily by the investigators. Heat supplementation will be provided if necessary.**

Note: due to the apparent severity of symptoms relative to access to food, water, urine and possibly fecal retention, we will continue to fully document each animals grade classification with daily observations and performance of functions, i.e., body weight, hydration, evidence that food has been accessed, urine expression, etc. These records will be available to be monitored periodically by a LAM veterinarian, and the IACUC.

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization: General anesthesia (isoflurane) and topical anesthesia (tetracaine) will be used for retro-orbital bleeding. The procedure for isoflurane anesthesia is as follows: Mice will be anesthetized with isoflurane + 100% oxygen, 500-1000ml/min (0.5-4% induction, 0.5-3% maintenance). Isoflurane will be delivered using a precision vaporizer via a rodent anesthesia machine. Induction will occur in an appropriately-sized clear viewing chamber. Following induction, mice will be moved to the stereotaxic device and maintained via nose cone. Lack of paw-pinch reflex will be used to ensure adequate depth of anesthesia prior to beginning procedure. Waste anesthetic gases will be passively scavenged using a charcoal filter. Topical anesthetic eyedrops will be applied directly to the eye. Analgesia is not recommended in our experiments, as it may strongly influence the fate of T-cell subsets studied in our experiments. Analgesics may interfere with these studies since they are known to modulate the immune response. For example, see Carrigan KA, Saurer TB, Ijames SG and Lysle DT, 2004. Buprenorphine produces naltrexone reversible alterations of immune status *Internat. Immunopharmacol.* 4:419-28 for details and for additional citations. Euthanasia of mice does not require monitoring for pain as the CO2 euthanasia is a non-painful procedure. Collection of blood from the vein tail is a minimal distressful procedure that will take less than 1 min per mouse.

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions: After tail snips (for genotyping), ear punching (for identification), blood withdrawal, and injections mice will be observed for a period of time to be certain they are not experiencing excessive pain and/or distress or bleeding. For procedures that require it, silver nitrate and/or clean gauze/paper towel will be used to stop any bleeding that occurs. During the course of experiments involving EAE, animals will be observed daily to monitor any paralysis and to ensure that the animals have access to food and water.

V.4.1.2.3. Paralytics: N/A

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures:

V.4.1.3.1. Sources Searched: Animal Welfare Information Center (AWIC), PubMed, Agricola

V.4.1.3.2. Date of Search: July 29, 2013.

V.4.1.3.3. Period of Search: 1990-2013

V.4.1.3.4. Key Words of Search: Animal testing, Multiple Sclerosis/EAE animal alternatives, mice, multiple sclerosis, pain, alternatives to complete Freund's adjuvant, alternatives tc footpad immunization, alternatives to painful or distressful procedures in mice

V.4.1.3.5. Results of Search: 3 references, one relevant. For example: Rodrigues DH, Sachs D, Teixeira AL. Mechanical hypernociception in experimental autoimmune encephalomyelitis. Arq Neuropsiquiatr. 2009 Mar;67(1):78-81. Footpad injections replaced by flank and base of tail (SubQ).

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification: Injections of adjuvants (complete Freund's adjuvant, CFA) are necessary to obtain significant immune responses to some of our experimental proteins. See V.4.1.2.

V.4.2. Prolonged Restraint: N/A

V.4.3. Surgery: N/A

V.4.3.1. Pre-surgical Provisions: N/A

V.4.3.6. Multiple Major Survival Operative Procedures: N/A

V.4.3.6.1. Procedures: N/A

V.4.3.6.2. Scientific Justification: N/A

V.4.4. Animal Manipulations:

V.4.4.1. Injections: Intravenous (i.v.) Tail Vein Injections: Under constant surveillance, mice will be placed in a clean cage under a heat lamp for 1-3 minutes, so that tail veins will dilate. One at a time, the mice will be removed from the cage, placed in the Mouse Tail Vein Illuminator device (Braintree Scientific) for restraint, tail wiped with a 70% ethanol soaked gauze pad, and using a 27G

needle attached to a 0.5cc syringe injected with 100-200µl cells or fusion constructs diluted in sterile saline depending on the experiment.

Intravenous (i.v.) Retro-Orbital Injection (alternative to tail vein): The animal is anesthetized with isoflurane/tetracaine and placed on a clean paper towel on the bench top with eye to be injected facing up. Using the thumb and forefinger, gently retract the skin around the eye so that the eyeball protrudes slightly. Using a 27G needle attached to either a 0.5cc or 1cc syringe, insert the needle bevel up into the medial canthus until it hits the orbital bone and pull back slightly. The needle should be at a 45 degree angle to the nose. Inject 100-200µl. Slowly remove the needle and apply light pressure with sterile gauze to control any bleeding that may occur. Care should be taken to avoid applying too much pressure around the trachea, which may result in cutting off the animal's airway. Also, avoid inserting the needle too far into the retro-orbital space as this may puncture the orbital bone behind the eye, causing the agent to be injected into the skull. Finally, care must be taken to prevent movement of the needle once it is inserted to avoid rupturing the blood vessels behind the eye. A minimum of one day between injections is required and no more than two injections per mouse (one per eye) will be given. This procedure is well tolerated by the animals and is routinely used in many laboratories.

Intraperitoneal (i.p.) Injections: All i.p. injections will use a 27G needle attached to either a 0.5cc or 1cc syringe in a volume of 200µl. Prior to injection, site will be swabbed with 70% ethanol. Sterile saline will be used as a diluent. (experiment 1, MOG + Alum is ip)

Subcutaneous (s.c.) Injections: All s.c. injections will use a 27G needle attached to a 0.5cc or 1cc syringe. Total volume injected will not exceed 100µl. Prior to injection, site will be swabbed with 70% ethanol.

Blood Collection: Blood collection will occur through the retro-orbital sinus. The procedure is as follows:

Mice are placed in the chamber of the isoflurane vaporizing machine until they are sufficiently anesthetized. Mice are then removed from the chamber by the base of tail and placed on their side on a clean surface. The mice are then grasped by the scruff of the neck using the thumb and index finger. A clean capillary tube is then placed near the posterior portion of the eye and then slowly inserted into the retro-orbital sinus and gently rotated between the fingers until blood flow commences. No more than 200µl shall be collected. Once the capillary tube is removed, gentle pressure will be applied to the eye with a clean gauze pad/towel. Mice will be observed for a sufficient period of time post bleed to confirm bleeding has stopped.

V.4.4.2. Biosamples: Blood collection: 0.2mL blood collected with mouse under anesthesia (isoflurane). Frequency of bleeds is listed within each experiment.

Tissue collection: Draining lymph nodes and spleen will be removed after euthanasia.

V.4.4.3. Adjuvants: Complete Freund's Adjuvant (CFA), Alum

Our lab is interested in developing techniques to regulate (eliminate) the immune response to a variety of proteins that are being attacked by the body in autoimmunity. We are researching ways to tolerize the immune system to prevent destruction of the body's own cells. Specifically, we are studying a mouse model of multiple sclerosis known as EAE. This is a well-established model that requires the use of complete Freund's adjuvant (CFA) to elicit a robust immune response. We have attempted to use alternative adjuvants in the past, however we have found that they do not sufficiently stimulate the immune system.

In our study, the use of CFA will be limited to the initial immunization with antigen. The route of administration will be subcutaneous into the flank and base of tail (0.05mL/site). Prior to immunization, the injection site will be clipped of fur and swabbed with betadine and alcohol. Post injection, animals will be monitored daily for any adverse reactions. If necessary, the injection site will be disinfected and bandaged. If the animal is observed to be in pain/distress and that pain/distress cannot be alleviated, euthanasia will be employed.

V.4.4.4. Monoclonal Antibody (MAbs) Production: N/A

V.4.4.5. Animal Identification: Ear Clip: mice will be restrained by hand and ear(s) will be punched using a commercially available ear punch for identification purposes. Alternatively, mice may have numbered tags attached to their ears.

V.4.4.6. Behavioral Studies: N/A

V.4.4.7. Other Procedures: N/A

V.4.4.8. Tissue Sharing: N/A

V.4.5. Study Endpoint: Euthanasia. Euthanasia is allowed for veterinary staff if animals appear moribund and PI staff informed.

V.4.6. Euthanasia: Using a compressed gas cylinder containing CO_2 and a flow rate of > 2 liters per minute, introduce 100% CO_2 into the cage containing the mice. Within two minutes the mice should be unconscious. Observe mice for a period to confirm that they have stopped breathing. Remove mice from the cage and ensure death by cervical dislocation.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol.

V.5.1.1. Study Room:
Building(s) (b)(6) Room Number(s) (b)(6)

V.5.1.2. Special Husbandry Provisions:

Food Restriction:	Yes		No	X
Fluid Restriction:	Yes		No	X

V.5.1.3. Exceptions: N/A

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care: Monitor animals on a daily basis for unexpected illness/injury.

V.5.2.2. Emergency Veterinary Medical Care: All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: Except as indicated below, all animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents.

V.5.3.2. Enrichment Restrictions: N/A

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)

VII. BIOHAZARDS/SAFETY:

VIII. ENCLOSURES:

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. **Animal Use:** The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. **Duplication of Effort:** I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. **Statistical Assurance:** I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. **Biohazard\Safety:** I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. **Training:** I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. **Training:** I verify that I have attended the USUHS Investigator/Animal User Training Course.

G. (b)(6) _____ 08/01/13

Principal Investigator Signature — Date

G. **Training:** The following personnel will attend the next USUHS Investigator/Animal User Training Course:

_____ _____

_____ _____

H. **Responsibility:** I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely, "Responsibility" for implementing animal use alternatives where feasible and conducting humane and lawful research.

I. (b)(6) _____ 08/01/13

Principal Investigator Signature — Date

Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL or WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

E. Funding: NIH/NIAID

I. **F. Objective and Approach:** Multiple sclerosis (MS) is an immune-mediated disease in which certain cells from the immune system attack and destroy parts of the central nervous system (CNS), in particular the myelin sheath that surrounds nerve fibers and aids in signal transduction and the nerve fibers themselves. This disruption of nerve impulses can be debilitating, with symptoms ranging from mild (limb numbness) to severe (paralysis/loss of vision). While the exact cause of MS is not known, it is believed that a number of factors play a role in disease development, among them an abnormal immune response. Our lab has been interested in investigating the role that the immune system plays in MS. We have shown that when antigens are linked to protein, called an immunoglobulin "carrier", they can specifically inhibit the reactivity of the immune system (tolerance) to the linked protein antigens. In this protocol, we will use Experimental Allergic Encephalomyelitis (EAE), a mouse model which resembles MS. This is a well-established experimental model for multiple sclerosis that induces an impaired ability to walk and possibly can cause some muscle paralysis in the mice over a period of days to weeks. Mice will be injected with a protein from mouse brain together with an agent facilitating development of white blood cells (called T cells) that attack brain proteins, leading to tissue destruction. Treatments with modified immune cells from other mice will be tested to determine if such treatments might prevent or alleviate the impaired movement induced by the injection of brain proteins. We also are developing soluble fusion proteins built on the IgG scaffold to facilitate tolerance without cell transfer.

MEMORANDUM FOR DR. (b)(6) DEPARTMENT OF MEDICINE

SUBJECT: IACUC Approval of Protocol – Initial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on June 19, 2013:

Animal Protocol Title: "T Cell Trafficking and Retention in an Autoimmune Mouse Model"

USUHS Protocol Number: (b)(6)

Expiration Date: June 18, 2016

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. NON-TECHNICAL SYNOPSIS: Autoimmune diseases are extremely complex disorders that result from the immune system attacking its own tissues. Autoimmune diseases, including multiple sclerosis (MS), affect approximately 10 million individuals in the United States alone. Here we will study one of the more prevalent autoimmune diseases, MS, a disease that can result in severe and chronic disability. MS is an autoimmune disease in which the immune system attacks the myelin sheath that is essential for transduction of nerve impulses in neurons. MS is a progressive disease which can initially cause multiple neurological symptoms and ultimately leads to paralysis, disability and death. The immune processes leading to autoimmunity in MS is initiated and coordinated by T lymphocytes, a type of white blood cell that also directs healthy immune responses. T lymphocytes that are specific for endogenous products (autoantigens) become activated and traffic to the central nervous system (CNS) or brain in the case of MS. The goal of this study is to understand the mechanisms T cells use to traffic to and be retained within the CNS using a mouse model of MS. We will analyze the extrinsic and intrinsic signals that control T cell migration and retention within the CNS during neuroinflammatory disease.

II. BACKGROUND:

II.1. Background:. In these studies, multiple techniques will be utilized to determine how T cell migrate through tissue in the steady state and during inflammation, and their fate following induction of inflammatory lesions. Analysis of the role of T cells in autoimmune disease requires the use of animal models and there are well-characterized models of autoimmune diabetes and MS in mice. For induction of autoimmunity in mice, we will use established models for experimental autoimmune encephalomyelitis (EAE) (the mouse model for MS). To generate a population of autoreactive T cells that can be analyzed and tracked, we will utilize adoptive transfer techniques for induction of EAE. This system will utilize an *in vivo* priming/adoptive transfer method to allow introduction of pathogenic T-cells without the potential experimental complications associated with direct induction of disease. This adoptive transfer model will be utilized to assess the phenotype and functional capabilities associated with T-cell trafficking to the central nervous system, the site of pathogenesis for MS. Further, we will examine the importance of recognized adhesion molecules,

including VLA-4 and LFA-1 and effector functions including interleukin 17 (IL-17) and interferon gamma (IFN-γ) to the pathogenesis of EAE. (b)(4)

(b)(4)

We hypothesize that the experiments outlined in this proposal will allow us to identify the signals and properties of T cells that invade tissues in autoimmune disease and determine their fate once tissue destruction in achieved. These findings will also allow us to identify specific T-cell components necessary for disease induction. Ultimately, the information found through the proposed study would demonstrate novel targets for therapeutic treatment of autoimmune diseases such as MS. All of the animal studies and experiments described in this protocol are supported by either a grant from the (b)(4) or Institutional Start-up Funds.

II.2. Literature Search for Duplication:

II.2.1. Literature Source(s) Searched: DOD Biomedical Research Database, NiH Reporter, PubMed

II.2.2. Date of Search: 03/29/2013 (DOD BRD, NiH Reporter), 5/22/13 (PubMed)

II.2.3. Period of Search: 1990-2013

II.2.4. Key Words and Search Strategy: "Multiple Sclerosis T cells trafficking, Multiple Sclerosis T cells retention, EAE T cells retention" for NIH reporter and DOD BRD, Rodentia"[Mesh] AND (migration OR trafficking OR retention) AND ("Multiple Sclerosis"[Mesh] OR "Encephalomyelitis, Autoimmune, Experimental"[Mesh]) AND "T-Lymphocytes"[Mesh] for PubMed

II.2.5. Results of Search: 242 hits, none duplicative. No relevant results were found. our studies will be describing currently unknown pathogenesis pathways relating to T cell retention within the brain and spinal cord. At this time we are the leading edge of this topic of inquiry. .

III. OBJECTIVE\HYPOTHESIS: Our objective is to use an animal model of Multiple Sclerosis (MS) to identify vital components of nervous system inflammation in order to target these components for therapeutic intervention in humans. Our hypothesis is that T cell retention is a requisite component for induction of autoimmune lesions in the brain and spinal cord. We expect that disruption of the processes utilized by T cells to remain within the nervous system would prevent or even reverse the associated inflammation and clinical symptoms.

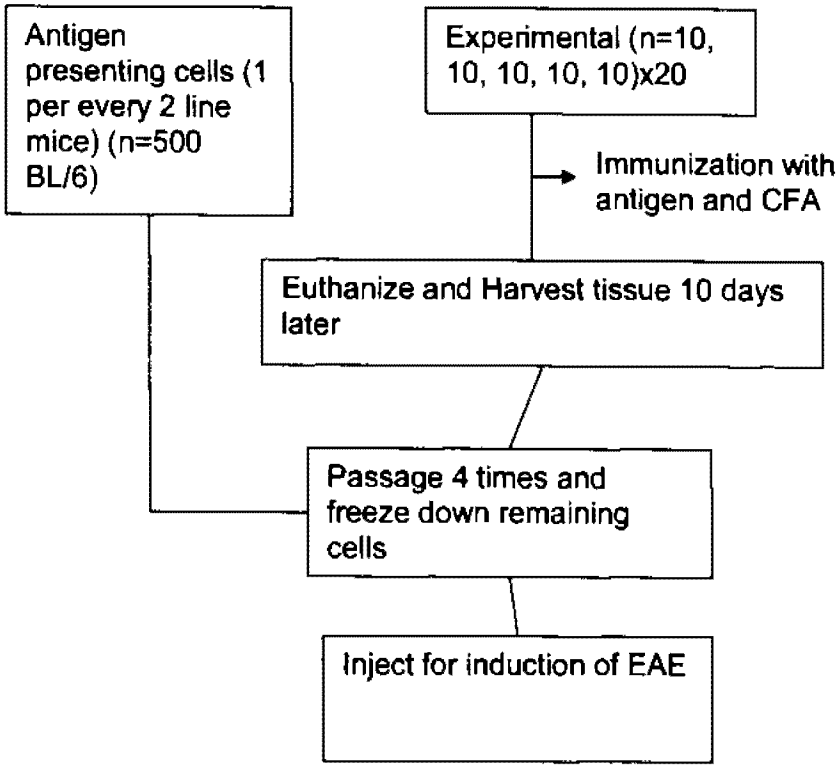
IV. MILITARY RELEVANCE: Multiple sclerosis (MS) can be debilitating and is one of the most common causes of disability in non-elderly adults. Our research is aimed at modulating the effects of neuroinflammation. Understanding how to reverse

neuroinflammatory states such as those found in MS is relevant to the general health of the military population and their families.

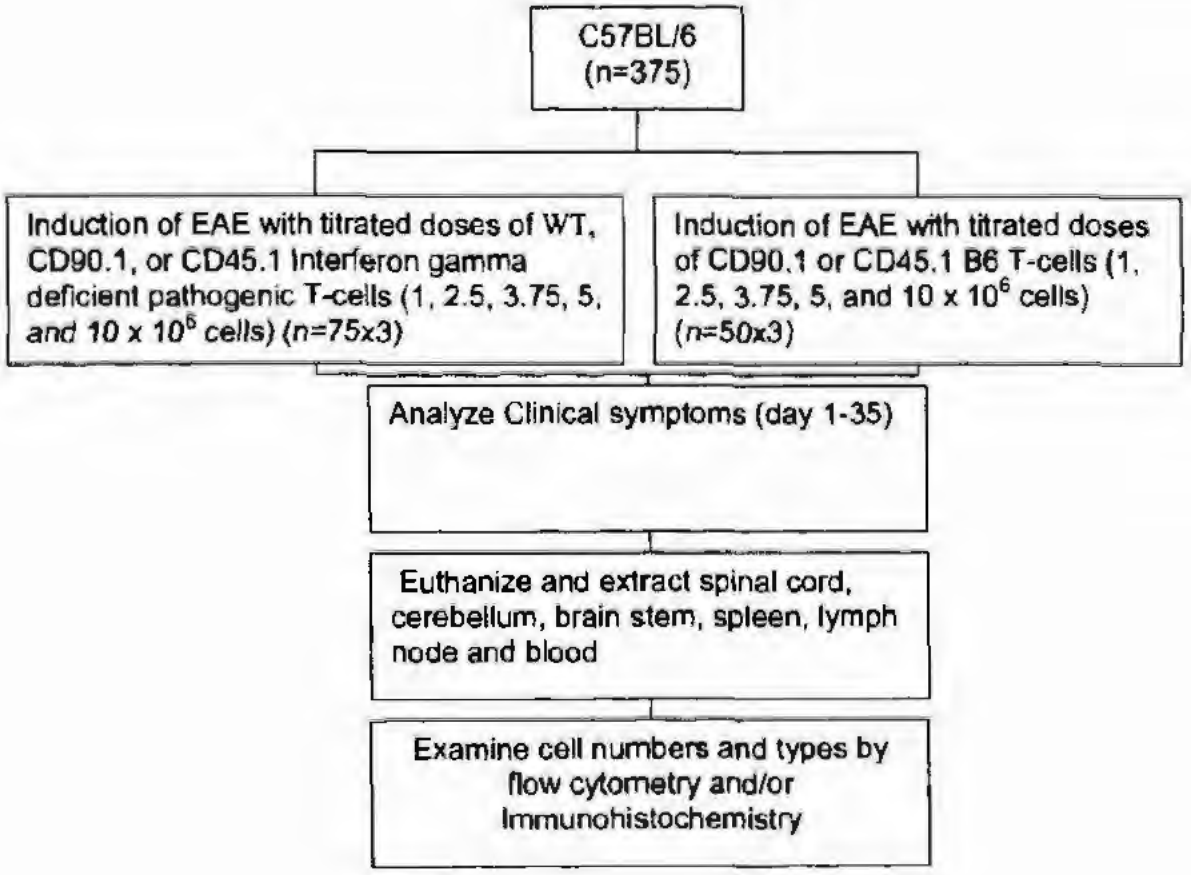
V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures:

V.1.1. Experiment 1: The objective of this experiment is to generate T cells specific for myelin proteins and control T cells specific for a non-self-antigen (ovalbumin). These T cells will be further propagated by *in vitro* culture to produce pathogenic T cells lines that will subsequently be used for induction of EAE by adoptive transfer *in vivo*. We will generate these T cells in 5 different mouse strains: two different B6 congenic mouse strains that express a T cell-specific marker allele (CD45.1 and CD90.1), in a mouse strain that is deficient in IFN-γ production (IFN-γ KO mice), and in CD45.1 and CD90.1 congenic IFN-γ deficient mice to define the mechanisms of IFN-γ action in EAE induction, maintenance, and resolution. For each line 10 mice (CD90.1, CD45.1, IFN-γ KO, CD45.1 IFN-γ KO, or CD90.1 IFN-γ KO) will be immunized with antigen and adjuvant as described below. Following immunization mice will be rested for 10 days. then euthanized by CO2 asphyxiation/cervical dislocation as described below. Axillary lymph nodes and the spleen will be recovered and treated with peptide, cytokines, and irradiated spleen cells recovered from naive C57BL/6 mice in standardized sterile practices necessary to produce T-cell lines specific for the immunizing antigen. We estimate 20 lines from each group will be required to fulfill the experiments described below. In total we will need 500 C57BL/6 (treated as Category C), and 200 CD90.1, 200 CD45.1, 200 IFN-γ KO, 200 CD90.1 IFN-γ KO, and 200 CD45.1 IFN-γ KO all treated as Category E mice.



V.1.2. Experiment 2: The purpose of these experiments is to determine the relative capacity of the cell lines developed in Experiment 1 to induce EAE *in vivo*. T cell lines specific for myelin proteins will be generated from WT or IFN-γKO congenic mice as described in Experiment 1, and transferred into healthy C57BL/6 host mice, and the induction of EAE will be monitored by analyzing the behavior and clinical signs of EAE as described below to determine whether Classical or Atypical EAE is induced. 5 mice per group will be injected with 1 of 5 titrated doses of pathogenic EAE inducing T-cells (1, 2.5, 3.75, 5, and 10 x 10^6 cells) derived from cell lines established in Experiment 1; Mice will be examined for clinical symptoms as described below. After 35 days (corresponding to classical EAE disease induction, peak, and resolution) mice will be perfused and euthanized as described to allow histochemical analysis of the brain and spinal cord. Experiment will be repeated 3 times to insure adequate representation of the data. This group of experiments will require 375 C57BL/6 mice all treated as Category E mice.

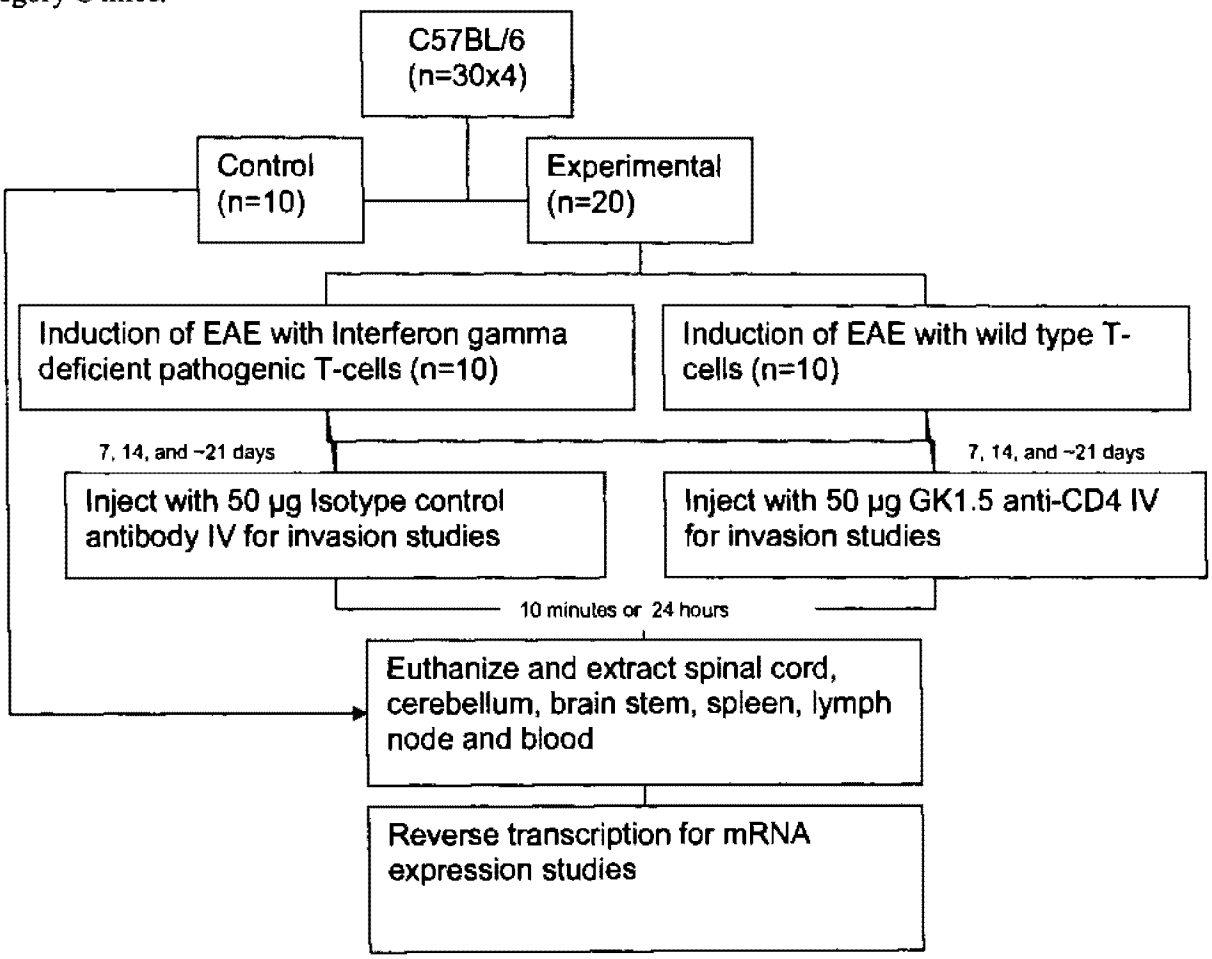


V.1.3. Experiment 3: The purpose of this experiment is to analyze the gene expression pattern in the brain and CNS following induction of the two forms of EAE (classical and atypical forms). Mice will be injected with optimal doses (as determined by experiment 2) of pathogenic T cells derived from either WT or Interferon gamma deficient mice as shown in Experiment 1.

(b)(4)

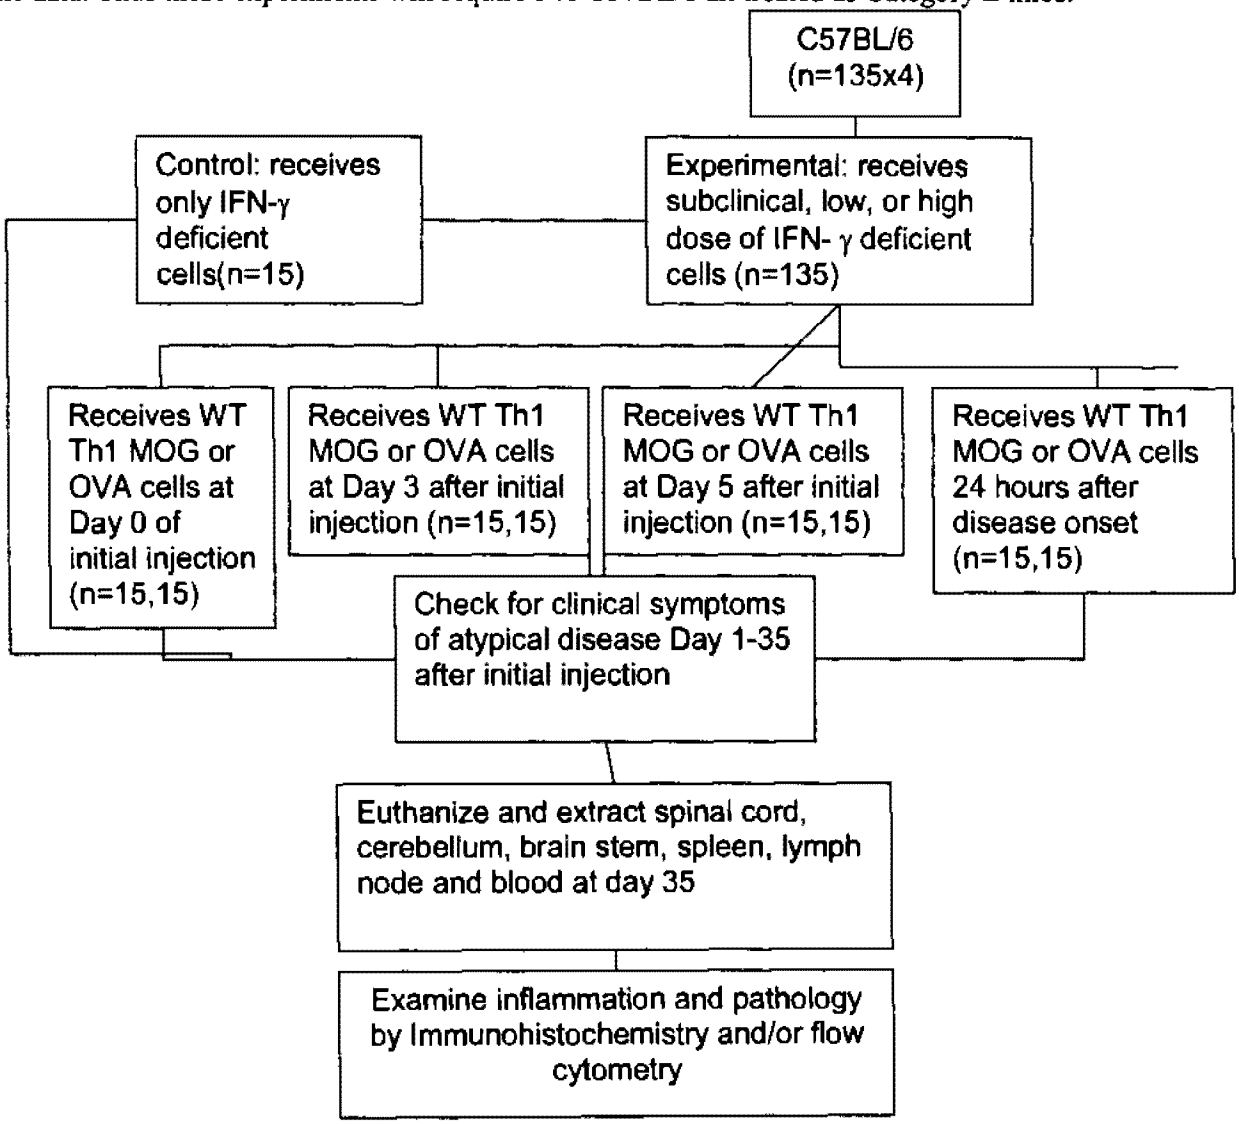
(b)(4) then euthanized and perfused as described in section V.4.6. Harvested tissue will then be utilized for mRNA examination. Experiment will be repeated 4 times to insure adequate representation of the data. This group of experiments will require 120 C57BL/6 mice with 80 treated as Category E mice and 40 as

Category C mice.



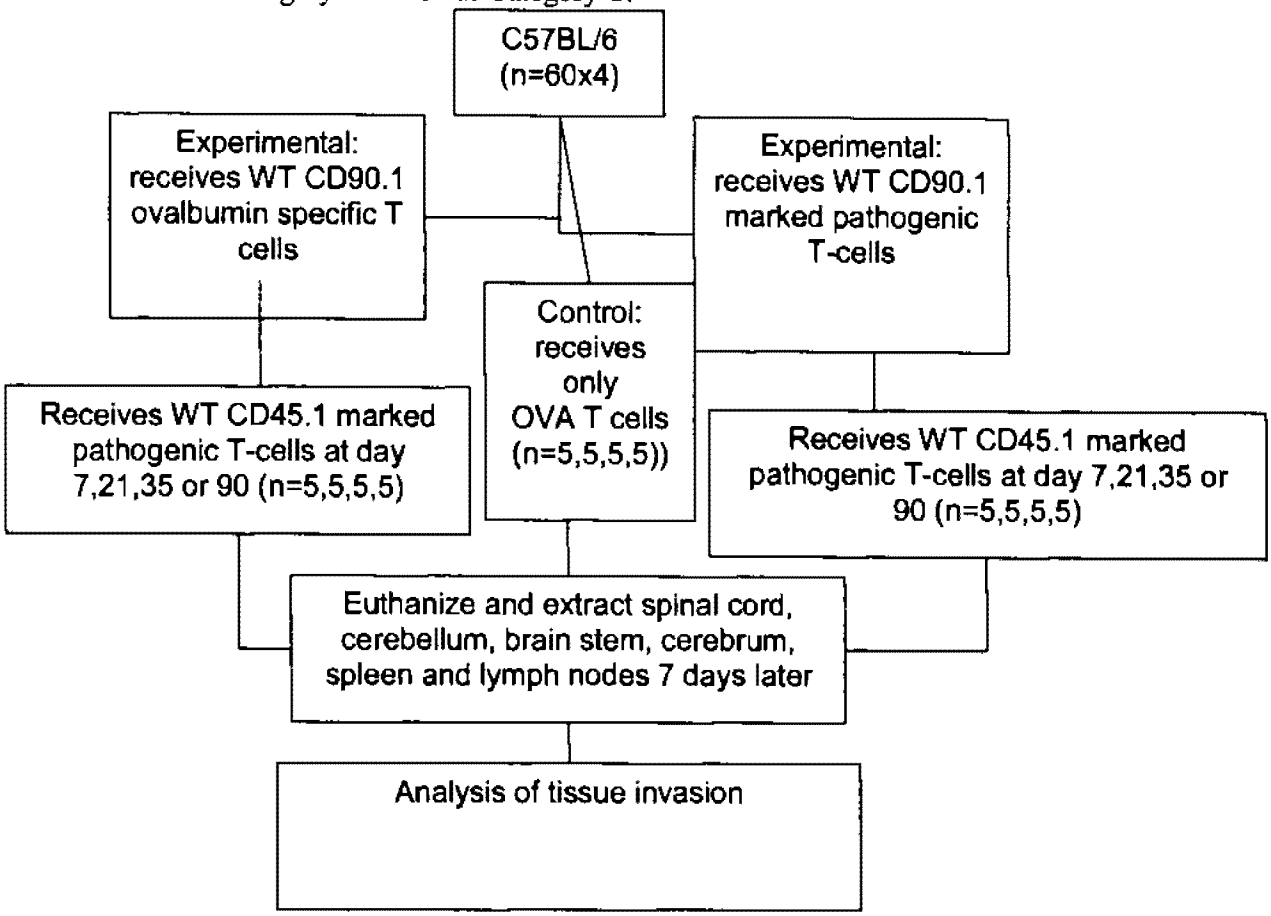
V.1.4. <u>Experiment 4:</u> The objective of the experiment will be to determine the effect lesions induced by IFN-γ deficient effector cells will have on CNS cell expression patterns at various times following induction of the atypical EAE. 5 mice per group will be injected with various doses (subclinical, low disease (peak clinical scores of ~2), high disease (peak clinical scores of 3-4) inducing doses) of pathogenic EAE inducing T-cells derived from Interferon gamma deficient mice in Experiment 1. Mice will then be injected with WT EAE inducing T cells or control T cells at various time points after the initial injection (Day 0, 1, 3, or 5 days after disease onset in control mice). Mice will then be examined for disease symptoms as described below before being euthanized 35 days later. Harvested tissue will be utilized for flow cytometric and histological examination. Experiment will be repeated 4 times to insure adequate representation

of the data. Thus these experiments will require 540 C57BL/6 all treated as Category E mice.



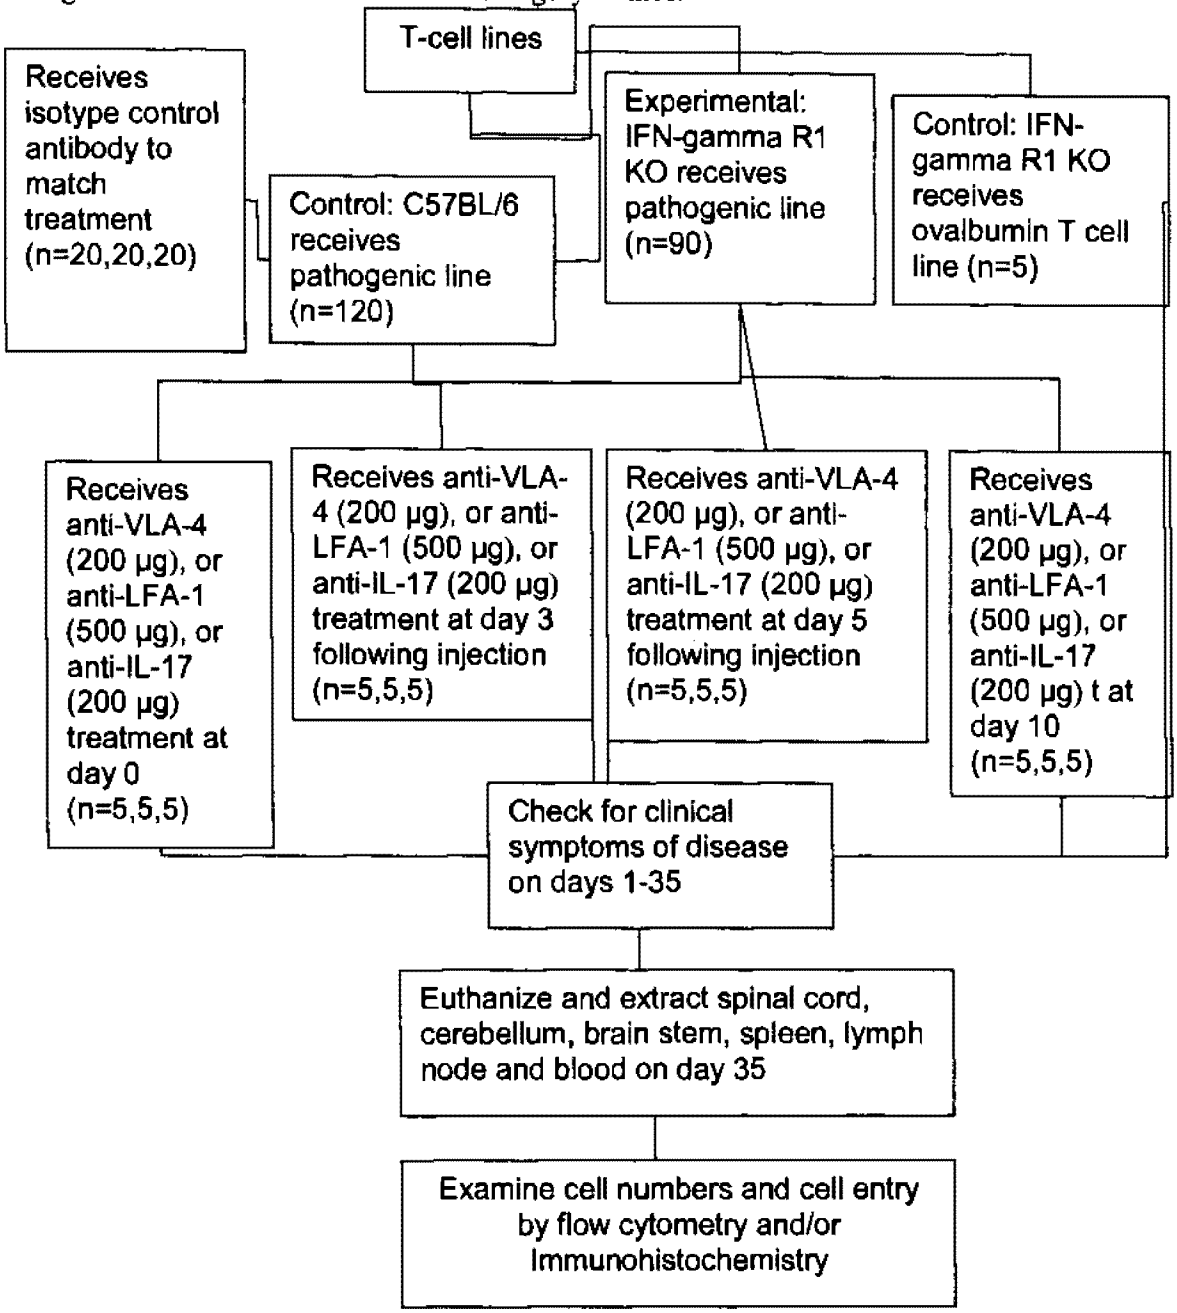
V.1.5. <u>Experiment 5:</u> The objective of this experiment is to determine how prior classical EAE CNS lesion development influence secondary EAE lesion localization within the brain and spinal cord. 5 mice per group will be injected with pathogenic EAE inducing T-cells or ovalbumin specific cells derived from CD90.1 WT mice. Mice will then be injected with WT CD45.1 EAE inducing T-cells 7 days, 21 days, 35 days, and 90 days after the initial injection. Mice will be perfused and euthanized as described in section.4.6 7 days later. Harvested tissue will be utilized for histology and flow cytomtery. Experiment will be repeated 4 times to insure adequate representation of the data. Thus, these experiments will require 240 C57BL/6 mice

with 160 treated as Category E and 80 as Category C.



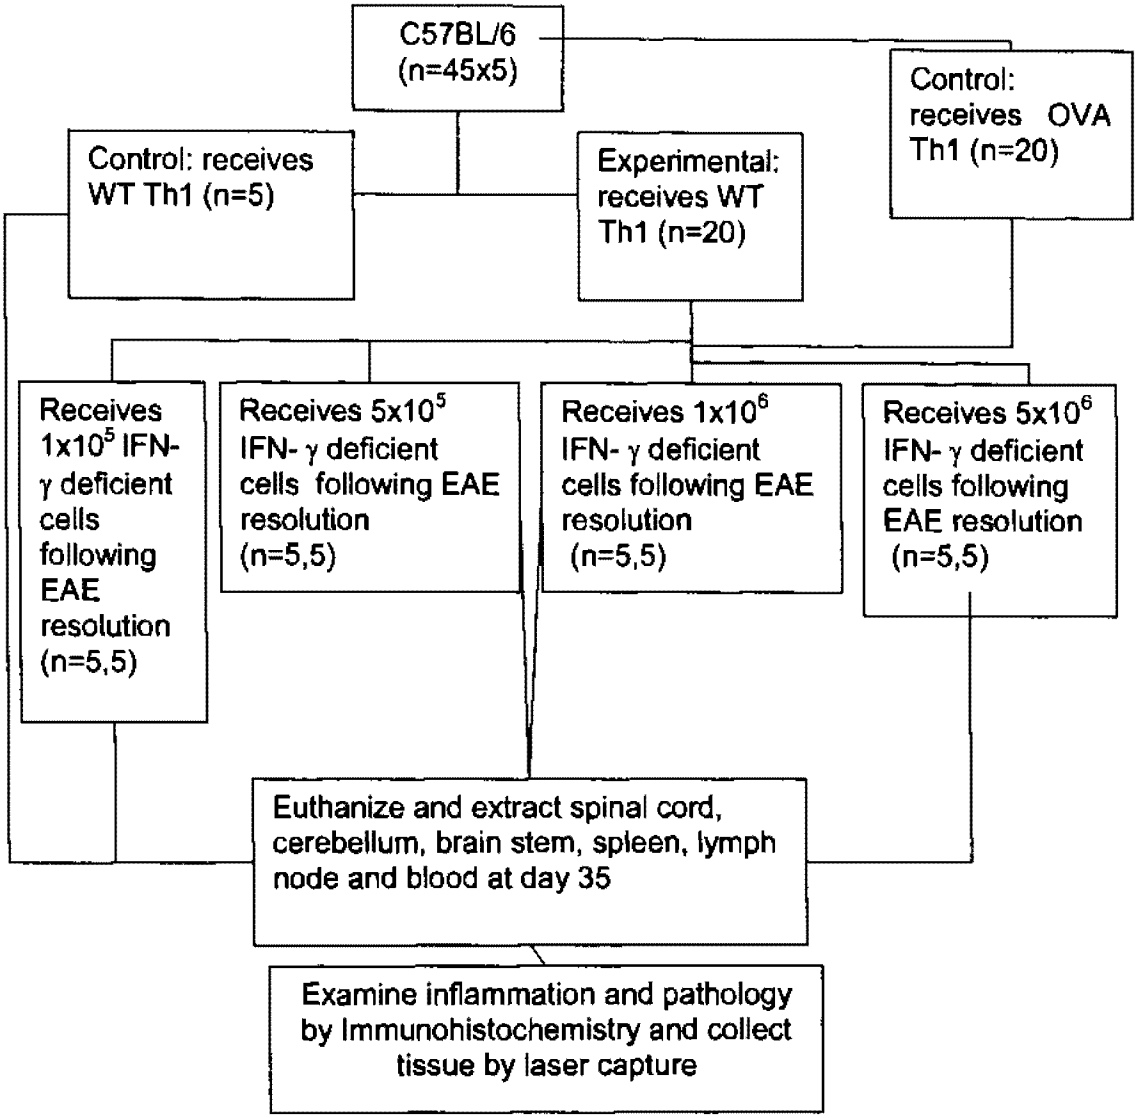
V.1.6. <u>Experiment 6:</u> the objective of this experiment is to determine if induction of atypical EAE disease requires similar molecular markers to those previously reported to be required for induction of typical EAE. Both WT and IFN-γ R1 KO mice will be injected with an optimal dose of pathogenic EAE inducing T-cells derived from WT mice or a control line specific for ovalbumin generated in Experiment 1. 2 days before or after 0, 3, 5, or 10 days mice will be injected with purified antibody specific for a T-cell marker or a control antibody with the same immunoglobulin isotype then perfused and euthanized as described below. Harvested tissue will then be utilized for flow cytometry and/or histological examination. These experiments will be

repeated 4 times for each antibody. These experiments will require 460 C57BL/6 mice and 380 IFN-gamma R1 KO mice all treated as Category E mice.



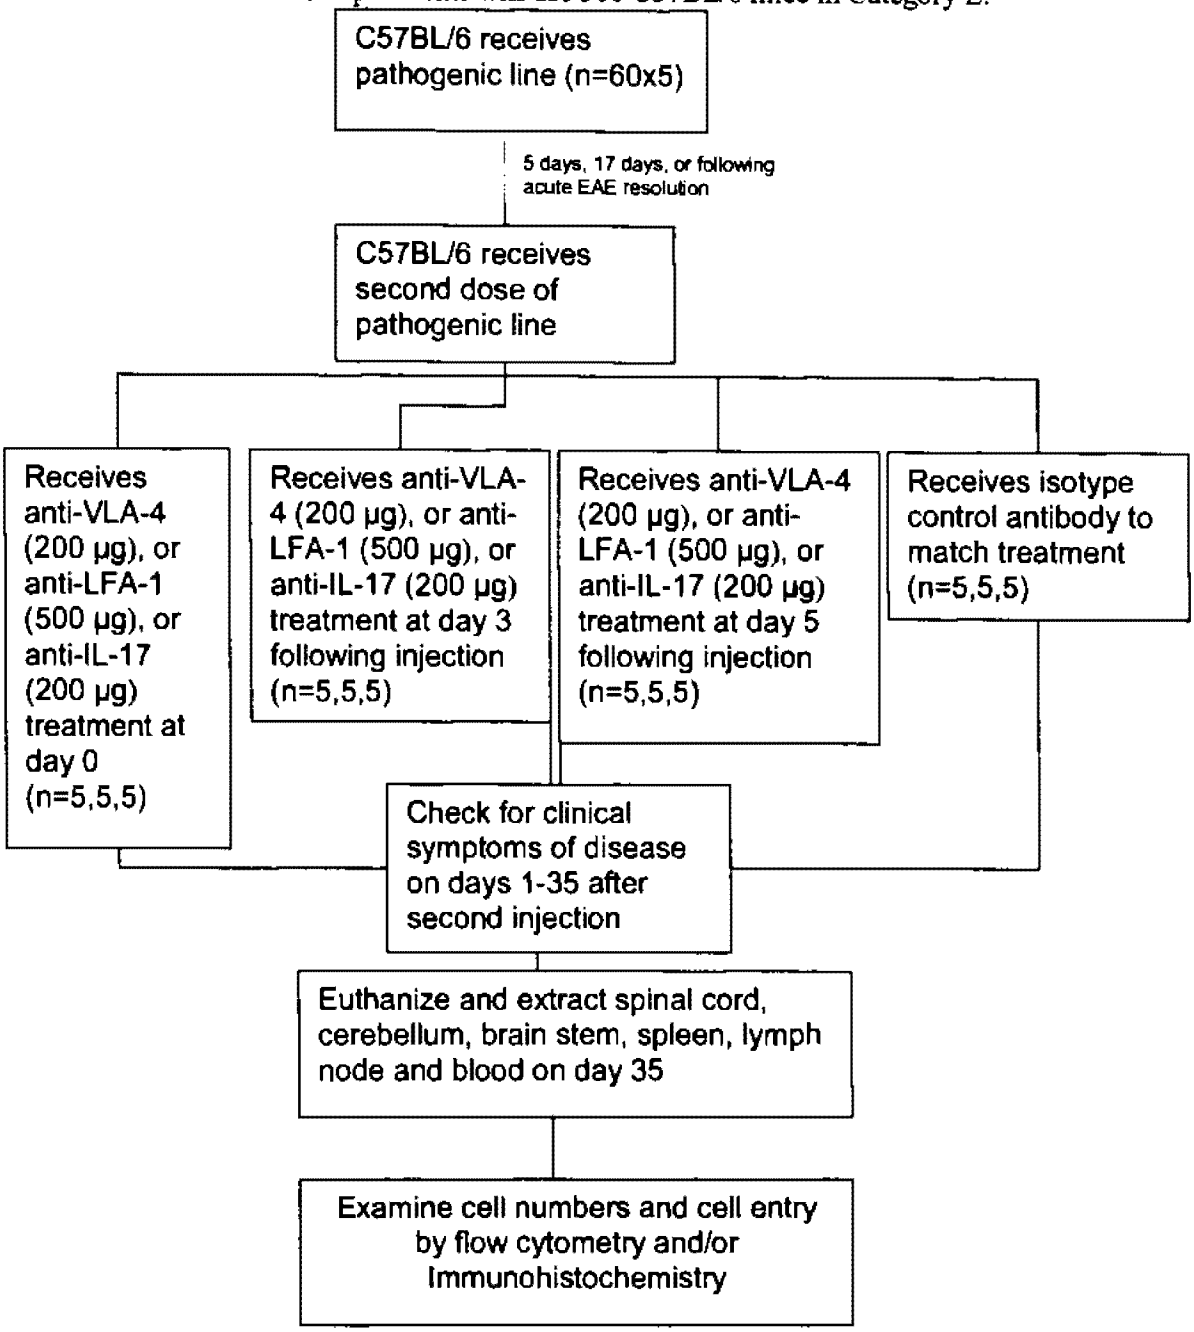
V.1.7. Experiment 7: The objective of this experiment is to determine if IFN-γ deficient effector cells are capable of exacerbating disease directly in lesions already formed by IFN-γ sufficient effector cells or form new lesions. Mice will be injected with pathogenic EAE inducing T-cells or ovalbumin specific T cells derived from CD90.1 or CD45.1 WT mice generated in Experiment 1. Mice will be examined for the development and resolution of EAE. After EAE resolution mice will then be injected with additional doses of pathogenic EAE inducing T-cells derived from Interferon gamma deficient mice. Mice will be examined for

relapse of disease. At the peak of relapse mice will be perfused and euthanized. Harvested tissue will be utilized for histology. Experiment will be repeated 5 times to insure adequate representation of the data. These experiments will require 225 C57BL/6 mice all treated as Category E mice.



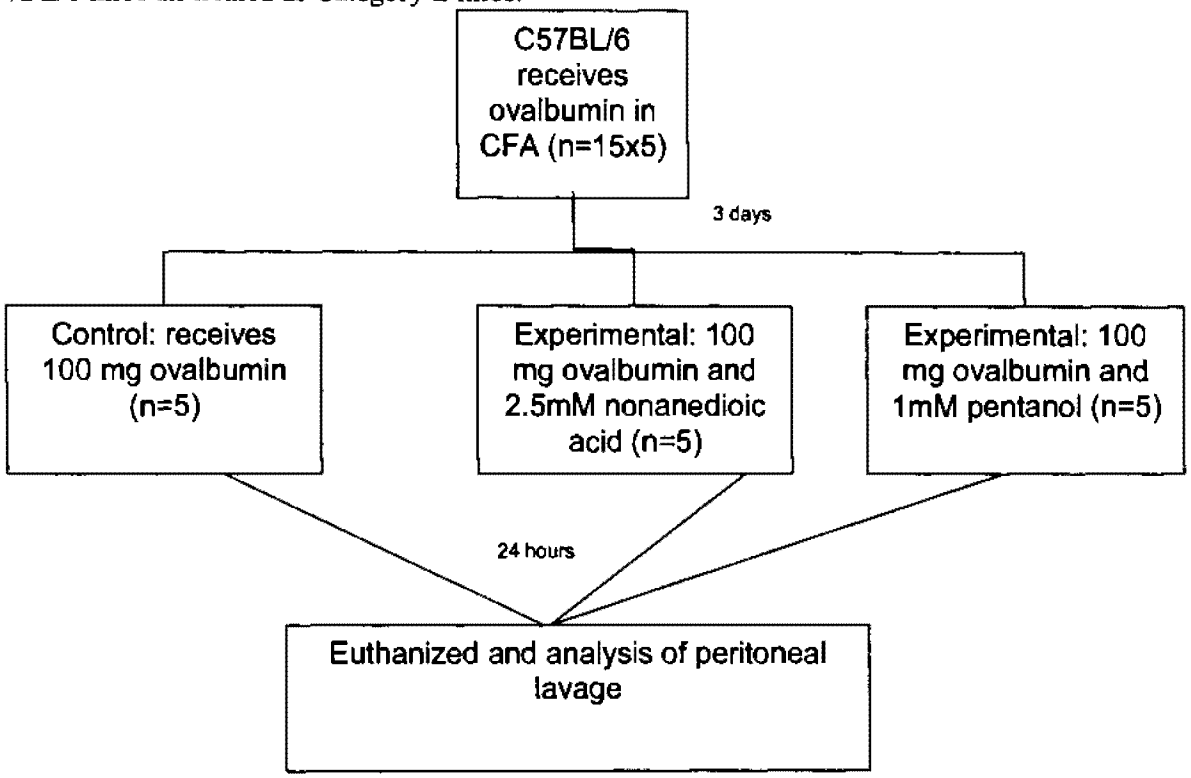
V.1.8. Experiment 8: The objective of this experiment is to determine if induction of secondary EAE disease requires similar molecular markers to those previously reported to be required for induction of typical EAE. C57BL/6 mice will be injected with an optimal dose of pathogenic EAE inducing T cells derived from WT mice. After 5 days (preclinical), 17 days (peak), or following resolution of acute EAE disease mice will receive a second dose of MOG specific EAE inducing cells. Concurrently or on days 3 and 5 after the second encephalitogenic cell dose mice with be injected with purified antibody specific for a T-cell marker or a control antibody with the same immunoglobulin isotype, then perfused and euthanized. Harvested tissue will then be utilized for flow cytometry and/or histological examination. These experiments will

be repeated 5 times. As such these experiments will use 300 C57BL/6 mice in Category E.



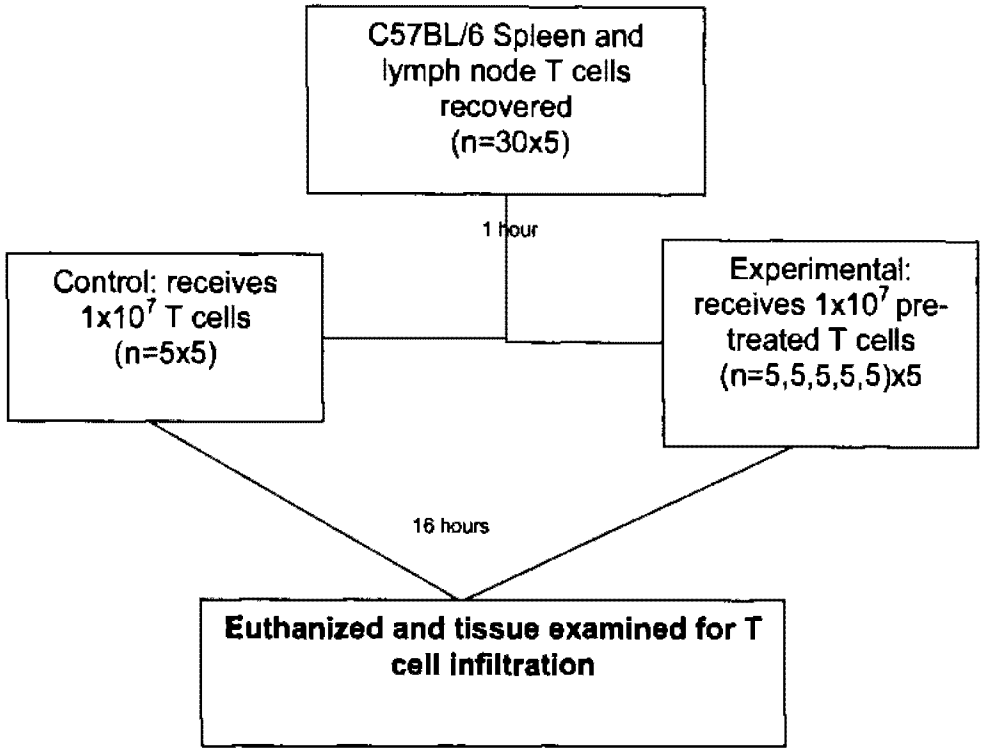
V.1.9. Experiment 9: The objective of this experiment is to determine if administration of nonanedioic acid is sufficient to block antigen specific T cell entry into an inflammatory site. C57BL/6J mice will be immunized subcutaneously (SQ) with 100 mg chicken ovalbumin (Sigma) in complete Freund's adjuvant in two 50 ul volumes as described below in section V.4.4.1 in compliance with USUHS IACUC policy #2 regarding the use of complete Freund's adjuvant. Then, 3 d later, ovalbumin-primed mice will be challenged by intraperitoneal injection of 100 mg ovalbumin dissolved in 250 ul double-distilled water with or without 2.5 mM nonanedioic acid or 1 mM pentanol. After 24 hours these mice will be euthanized by CO2 asphyxiation/cervical dislocation and peritoneal lavage with 5 ml PBS will be done with direct

visualization of the peritoneal sac and its contents to avoid peripheral blood contamination. Harvested lavage will be counted and examined by flow cytometry. Experiment will be repeated 5 times to insure adequate representation of the data. Thus, these experiments will require 75 C57BL/6 mice all treated as Category E mice.



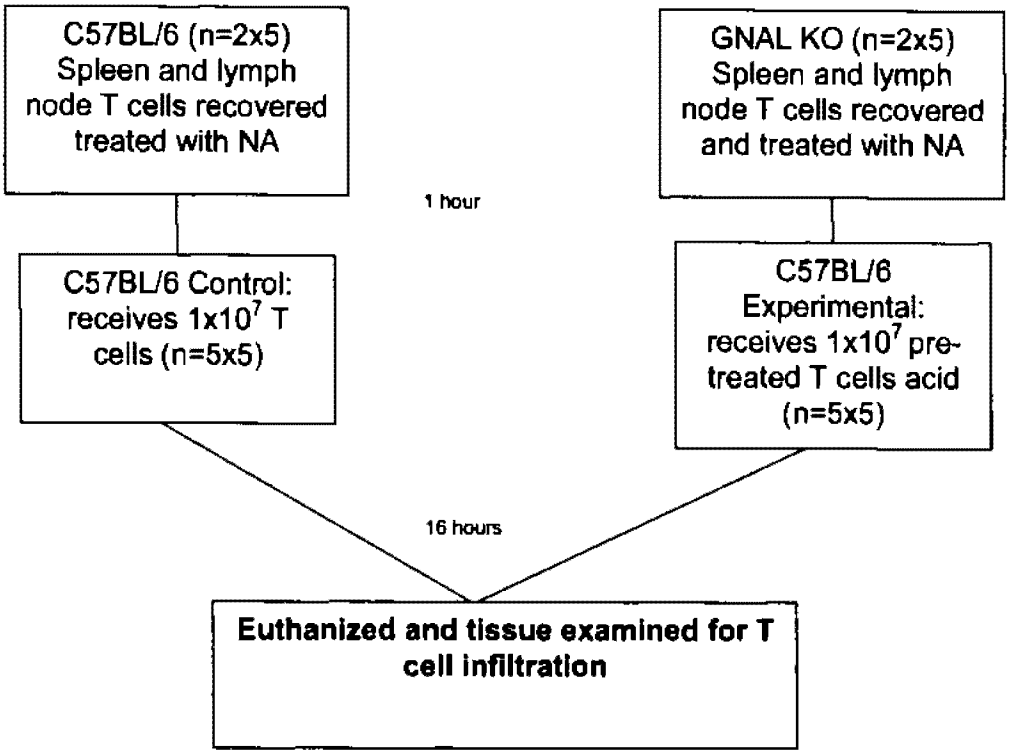
V.1.10. <u>Experiment 10</u>: Objective: To determine if various in vitro treatments are sufficient to block T cell recirculation from peripheral tissue to the lymphoid compartment.. C57BL/6J mice will be euthanized and naïve T cells separated from spleen and lymph nodes. Separated T cells will be incubated in sterile conditions for 1 hour with or without 2.5 mM nonanedioic acid, 1mM pentanol, 10 um sp-5,6-cBIMPS, 10 uM RP-CMAPs, or 1uM FTY720. Cells will then be transferred to mice via subcutaneous injection into the footpad. After 16 hours these mice will be euthanized by CO2 asphyxiation/cervical dislocation and spleen, contra and ipsilateral popliteal, inguinal, and axillary lymph nodes recovered and examined for T cell accumulation. Recovered T cells will be counted and examined by flow cytometry. Experiment

will be repeated 5 times to insure adequate representation of the data. Thus, these experiments will require 300 C57BL/6 mice, with 150 considered Category E and 150 Category C.



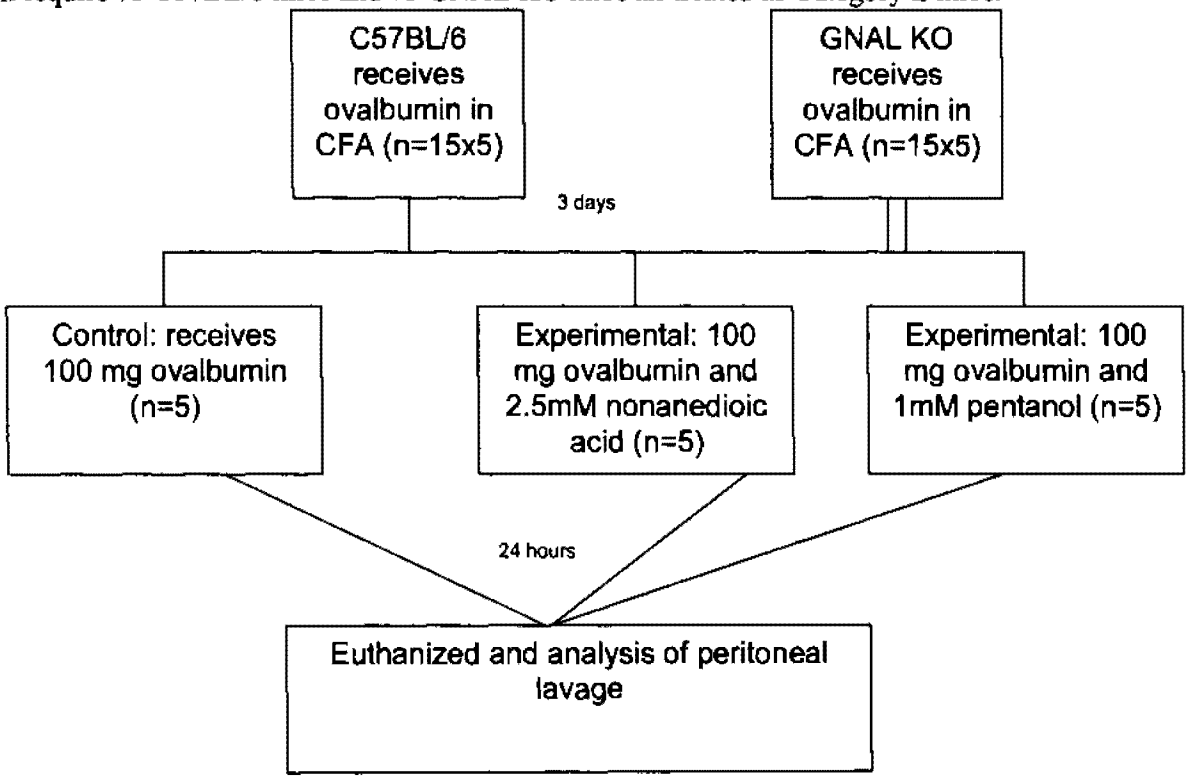
V.1.11. **Experiment 11** the objective of this experiment is to determine if various in vitro treatments are sufficient to block T cell recirculation from peripheral tissue to the lymphoid compartment. C57BL/6J of GNAL KO mice will be euthanized and naïve T cells separated from spleen and lymph nodes. Separated T cells will be incubated in sterile conditions for 1 hour with 2.5 mM nonanedioic acid (NA). Cells will then be transferred to mice via subcutaneous injection into the footpad. After 16 hours these mice will be euthanized by CO2 asphyxiation/cervical dislocation and spleen, contra and ipsilateral popliteal, inguinal, and axillary lymph nodes recovered and examined for T cell accumulation. Recovered T cells will be counted and examined by flow cytometry. Experiment will be repeated 5 times to insure

adequate representation of the data, thus,these experiments will require 60 C57BL/6 mice (10 Category C and 50 Category E) and 10 GNAL KO mice all Category C.



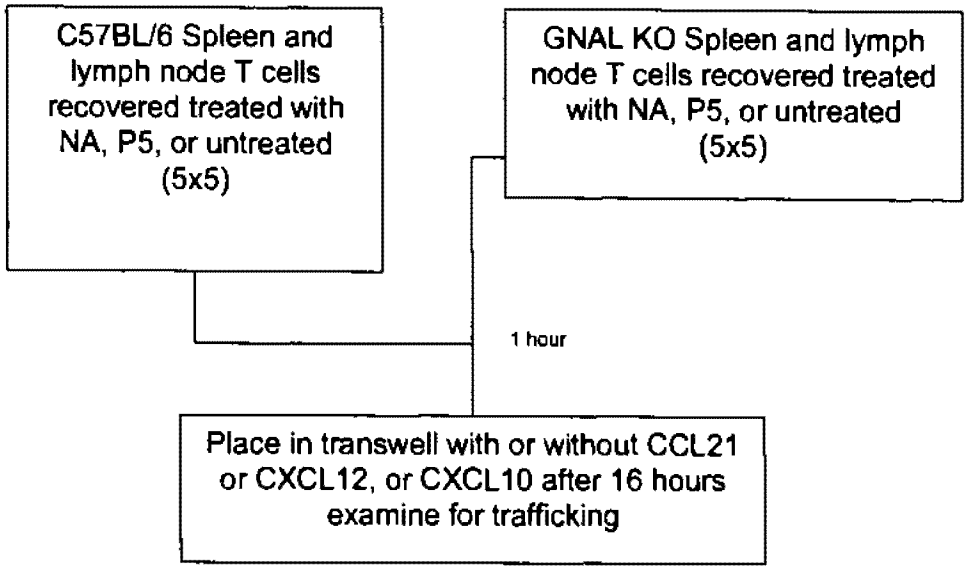
V.1.12. **Experiment 12:** The objective of this experiment is to determine if administration of nonanedioic acid is sufficient to block antigen specific T cell entry into an inflammatory site in the absence of GNAL. C57BL/6J or GNAL KO mice will be immunized subcutaneously (SQ) with 100 mg chicken ovalbumin (Sigma) in complete freunds adjuvant in two 50 ul volumes as described in section V.4.4.1. Then, 3 d later, ovalbumin-primed mice will be challenged by intraperitoneal injection of 100 mg ovalbumin dissolved in 250 ul double-distilled water with or without 2.5 mM nonanedioic acid or 1 mM pentanol. After 24 hours these mice will be euthanized by CO2 asphyxiation/cervical dislocation and peritoneal lavage with 5 ml PBS will be done with direct visualization of the peritoneal sac and its contents to avoid peripheral blood contamination. Harvested lavage will be counted and examined by flow cytometry. Experiment will be repeated 5 times to insure adequate representation of the data. Thus, these experiments

will require 75 C57BL/6 mice and 75 GNAL KO mice all treated as Category E mice.



V.1.13. **Experiment 13**: The objective of this experiment is to determine if administration of nonanedioic acid is sufficient to block T cell entry responses to chemokines in the absence of GNAL. C57BL/6J or GNAL KO mice will be euthanized by CO2 asphyxiation/cervical dislocation. Harvested spleen cells will be examined for trafficking capacity to CCL21, CXCL12, or CXCL10 following treatment with or without 2.5 mM nonanedioic acid (NA) or 1 mM pentanol (P5). Experiment will be repeated 5 times to insure adequate representation of the data. Thus, these experiments will require 25 C57BL/6 mice and 25 GNAL KO mice all treated

as Category C mice.



V.2. **Data Analysis**: All statistical tests will be performed using Prism GraphPad. The significance of the responses will be analyzed by students' t test or analysis of variance (including tukey's subtests) tests as appropriate given the numbers of groups utilized (t test for experiment 11, ANOVA for all others). To determine the appropriate number of mice tested for each experiment we utilized a web based power calculator (http://homepage.stat.uiowa.edu/~rlenth/Power/index.html) and our prior knowledge of the variability within the system and to determine appropriate sample sizes. We set our alpha error rate to correspond with the literature standard of 0.05. We set our beta error rate to the conservative literature standard rate of 0.10. We set the influence of random effects to be within 1.33 standard deviations and the minimal detectable difference to be a 0.8 unit contrast in the observed clinical scores. We made our assumptions based on previously observed variability of EAE clinical scores.

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered: Alternative methods for studying autoimmune disease outside of *in vivo* approaches do not currently exist. The studies supported by this protocol specifically examine in vivo autoimmune pathogenesis, a phenomena without an in vitro equivalent. Further, our studies will be describing currently unknown pathogenesis pathways. The complex and unknown *in vivo* factors regulating pathogenesis preclude use of current in vitro or computer based models.

V.3.2. Animal Model and Species Justification:

Mice were chosen based on the similarities between the models utilized and human autoimmune disease. In addition, mice are a very well characterized model system, with a multitude of immunologically relevant mouse specific tools available. No smaller, less sentient mammalian species with appropriate genetic components and inflammatory responses are readily available for studying these aspects of autoimmunity. Examination in non-mammalian species is problematic as the autoimmune disease modeled is only known to occur in higher vertebrate species. Current *in vitro* systems do not recapitulate the complex interactions between the cells and extracellular components necessary to model the interactions of T-cells with the target organs of interest. *In silico* models are insufficient for dissection of pathogenic T-cell interactions with target tissues due to the vast number of still unknown players that play a role in the examined processes.

The C57BL/6 (B6) background was chosen for the EAE studies due to the similarities between the disease model and autoimmune mediated CNS disease in humans. The B6 model provides a well described system that has been used in many published studies for examination of mechanisms involved in autoimmune mediated CNS diseases such as MS. Information gained from this system has already proven translatable to improved treatment of human disease. In addition, the B6 background is widely used for production of genetically altered mouse strains providing vital reagents for examination of molecular mechanisms of pathogenesis. As such the reagents necessary for these studies are readily available.

V.3.3. Laboratory Animals

		Species #1
V.3.3.1.	**Genus & Species:**	Mus Musculus
V.3.3.2.	**Strain/Stock:**	See table
V.3.3.3.	**Source/Vendor:**	See table
V.3.3.4.	**Age:**	6-24 weeks
V.3.3.5.	**Weight:**	20-27 g
V.3.3.6.	**Sex:**	Male and Female

V.3.3.7. Special Considerations: N/A

V.3.4. Number of Animals Required (by Species): Mice-4785

Strain	Source	Sex	Total # *(for 3 yrs)*
C57BL/6/CR	(b)(6)	M	3295
IFN-gamma KO		M	200
IFN-gamma KO-CD45.1	*	M/F	100/100
IFN-gamma KO-CD90.1	*	M/F	100/100
IFN-gamma R1 KO	(b)(6)	M	380
C57BL/6-Ly5.2/CR (Called CD45.1 here)		M	200
C57BL/6J-CD90.1		M	200
GNAL KO	*	M/F	55/55

V.3.5. Refinement, Reduction, Replacement (3 Rs):

V.3.5.1. Refinement: All animals with EAE are observed daily for advanced disease. If advanced disease is detected food and water sources on the floor of the cage will be provided. In addition animals will be euthanized if they meet any of the alternate endpoint criteria outlined in section V4.5. Analgesics were considered but cannot be used to relieve pain due to their effects on the immune and neuronal cells being tested.

V.3.5.2. Reduction: The estimated total number of mice is based on a power analysis utilizing the principal investigator's extensive experience in this experimental system, as well as the requirement to repeat experiments for validation of results. Every effort is made to ensure the scientific utility of data derived from each animal used in this study by monitoring, evaluating and modifying group size as needed to obtain clear and consistent data. Every effort will be made to minimize the numbers of mice used without compromising research results.

V.3.5.3. Replacement: All of our studies require animals with an intact immune system, and therefore can not be replicated *in vitro*. For details please see the literature seach for alternatives, the description of data analysis, etc...

V.4. Technical Methods:

V.4.1. Pain / Distress Assessment:

V.4.1.1. APHIS Form 7023 Information:

V.4.1.1.1. Number of Animals:

	Species #1	C57BL/6/CR	γ KO	γ KO CD45.1	γ KO CD90.1	γR1 KO	CD45.1	CD90.1	GNAL KO
V.4.1.1.1.1. Column C:	640	805	0	0	0	0	0	0	35
V.4.1.1.1.2. Column D:									
V.4.1.1.1.3. Column E:	3945	2490	200	200	200	380	200	200	75

V.4.1.2. Pain Relief / Prevention:

- **V.4.1.2.1. Anesthesia/Analgesia/Tranquilization:** Anesthesia will be used for terminal procedures (500 mg/kg 2% avertin). Avertin is used in terminal procedures to prevent disturbance of the T cell and nervous tissue cell subsets studied in our experiments that can occur with other anesthetic methods. Compounding of avertin will occur as follows (2% PBS mixture will be Sterile filtered with a 0.2 micron filter then stored and used under sterile conditions. Compounded Avertin will be kept at 4^0C in dark containers to prevent photodegredation. Soultion color (clear) and pH (>5) will be checked before each use. All solutions will be labeled with date of manufacture and discarded after 4 months.)

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions:

Monitoring of EAE: Experimental Allergic Encephalomyelitis (EAE) is an autoimmune disorder characterized by a chronic relapsing, and remitting paralysis secondary to central nervous system (CNS) demyelination caused by T cells, and mice can go into remission even after development of stage III disease. Ordinarily, animals will be monitored for clinical symptoms daily and weighed every other day to determine weight loss associated with autoimmune disease. Any mouse that has a clinical score of 4 or an inability to express urine will monitored twice daily until the symptoms have resolved below a clinical score of 4, to functional capacity to void the bladder, or the animal is euthanized. We and other labs have devised a system for classification of disease severity in both atypical and classical EAE. (b)(4) (b)(6),(b)(4) Clinical symptoms will be graded and recorded daily using the following scales:

Classical EAE symptoms

1- Flaccid Tail
2- Delay in righting reflex, hind limb weakness
3- Flaccid paralysis in 1 hind limb
4- Flaccid paralysis in both hind limbs
5- Moribund

Atypical EAE symptoms
1- Tail Rigor
2- Wide stance, leaning, or directed locomotion to a single side, mild ataxia
3- Continual turning to a single side, rigor in a single limb, moderate ataxia
4- Rolling, rigor in multiple limbs, severe ataxia
5- Moribund

Ataxia symptoms
1- Mild ataxia (stumbling)
2- Moderate ataxia (weaving)
3- Severe ataxia (moribund)

Mice will be considered moribund if they are found to be incapable of directed mobility at will. Specifically, mice with paralysis, rigor, or weakness in three or more limbs will be considered moribund. Additionally any mouse that is found to be incapable of directed continuous (lasting longer than 1s) movement due to vertigo or ataxia will be defined as moribund. Any mice with scores higher than a 2 on any EAE disease score scale will be provided with moistened food and transport gel on the cage floor to insure access to food and water. Hydration will be monitored by physical examination. If animals show signs of injury or difficulty ambulating they will be relocated to a separate cage to protect them from potential negative interactions with cagemates. Mice with distended bladders that do not urinate upon handling will be considered incapable of self-elimination and the bladder will be expressed twice daily until symptoms subside or the mouse is euthanized. Skin lesions and ulcers are expected in many of the mice after complete CFA administration. Lesions will be monitored for pus-like discharge. If such a discharge occurs mice will be euthanized.

V.4.1.2.3. Paralytics: N/A

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures:

V.4.1.3.1. Sources Searched: AGRICOLA, PubMed

V.4.1.3.2. Date of Search: 04/04/13

V.4.1.3.3. Period of Search: All available.

V.4.1.3.4. Key Words of Search: Alternatives to EAE, Alternatives to encephalomyelitis, Pain EAE
V.4.1.3.5. Results of Search: Agri (0), Pubmed (74) None relevant.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification: Some mice used under this proposal will develop EAE following treatment. The neurological symptoms associated with EAE will be experienced without relief for the remainder of the time described in individual experiment descriptions. The induction and development of EAE is vital to all major scientific questions addressed in this proposal. As analgesics work by modulation of neuronal and inflammatory processes treatment with analgesics could compromise our

neuroimmunological findings. It is my belief that the utilization of the EAE system will allow us to address unique questions relating to neuroinflammation that may in turn provide significant human benefit, thus justifying the moderate and temporary pain and distress the animals may experience.

V.4.2. Prolonged Restraint: N/A

V.4.3. Surgery:

V.4.3.1. Pre-surgical Provisions: N/A

V.4.3.2. Procedure: N/A

V.4.3.3. Post-surgical Provisions: N/A

V.4.3.4. Location: N/A

V.4.3.5. Surgeon: N/A

V.4.3.6. Multiple Major Survival Operative Procedures: N/A

V.4.3.6.1. Procedures: N/A

V.4.3.6.2. Scientific Justification: N/A

V.4.4. Animal Manipulations:

V.4.4.1. Injections: IP injection - A 27 gauge needle will be used to inject sterile 2% Avertin (Tribromoethanol)/PBS (for anesthesia prior to exsanguination via cardiac puncture), or MOG peptide or Ovalbumin/PBS (for recovery of peritoneal leukocytes), or400 ng of pertussis toxin in PBS (for active induction of EAE) into the recipient mice. All IP injections will be done with 200 ul of volume. IV injection- into lateral tail vein will be done using a 27 gauge needle to adoptive transfer encephalitogenic or control T cells, or to administer purified monoclonal antibodies in PBS. For all IV injections no more than 0.2mls per injection will be administered. SQ injection- For induction of EAE and development of antigen specific cell lines , subcutaneous injections of CFA/PBS emulsion containing MOG peptide or ovalbumin will be done using a 25G needle into the upper trunk ~2cm caudal and ventral to each forelimb in a total volume of 50 µl per site.

Treatment (concentration)	Dose	Frequency	Route	Site	Volume	Needle size
Avertin (2 % in PBS)	500 mg/kg	Once	IP	abdomen	0.2 mL	27 ga ½in
Pertussis Toxin (2 ug/mL)	20 mg/kg	Once	IP	abdomen	0.2 mL	27 ga ½ in
MOG peptide (0.5 mg/ml in	100ug/mouse	Once	IP	abdomen	0.2 mL	27 ga ½ in

PBS)						
Ovalbumin (0.5 mg/ml in PBS)	100ug/mouse	Once	IP	abdomen	0.2 mL	27 ga ½in
T cells (in PBS)	.5-10 x10^6 cells/mouse	up to 2	IV	Lateral tail vein	0.2 mL	26 ga ¾ in
Purified monoclonal antibody (1-100 ug/ml)	1-100 mg/kg	once	IV	Lateral tail vein	0.2 mL	26 ga ¾ in
MOG peptide (0.5 mg/ml in CFA/PBS emulsion)	50ug/mouse	Once	SQ	Upper trunk	0.1mL	25 ga 1in
Ovalbumin (8 mg/ml in CFA/PBS emulsion)	800ug/mouse	Once	SQ	Upper trunk	0.1mL	25 ga 1in

V.4.4.2. Biosamples:

Once mice are euthanized, we will perform aseptic removal of liver, lung, lymph node (LN), pancreas, spleen, and CNS tissue for *in vitro* analysis and T-cell separations using standard techniques. For removal of the spleen an incision will be made near the left flank of the mouse, the spleen lifted up with a forceps and cut away from the tissue fascia with surgical scissors. Lymph nodes (LN) will be removed from the intestines (mesenteric lymph node (MLN)), from peripheral sites such as the popliteal LN (PLN) in the legs, from the upper torso (axillary lymph node (ALN)) and from the pancreatic area (PLN). The central nervous system will be removed in multiple sections, separating the cerebellum and brainstem, the remaining brain, and the spinal cord. Each portion of the CNS will be removed whole following perfusion. The brain will be exposed by removal of skin and the cranium with scissors. The spinal cord will be removed as a piece following removal of the dorsal side of each vertebra using scissors. The lungs, liver, and pancreas will be also be removed following perfusion.

We will obtain mouse peripheral blood for screening of peripheral T cells in mice. For obtaining peripheral blood, mice will be immobilized using a table top cone mouse immobilizerand a sterile 27 gauge needle will be used to prick the tale over a vein. ~20 ul of blood will be removed via tail bleeding into a heparinized capillary tube. Blood will then be stained and examined by flow cytometry. If mice do not immediately stop bleeding following collection pressure will be applied to the site of puncture with a sterile gauze strip until hemostasis is achieved. Each mouse will be screened via blood sampling no more than twice, once for screening purposes and once to examine T cell populations.

I am very experienced with mouse bleeding (13 years' experience), and these procedures are performed efficiently, minimizing discomfort to the mouse. For screening mice, bleeding will be done between 4 and 8 weeks of age. For quality control, transgenic mice will routinely be screened once every month, (or up to once weekly as necessary).

V.4.4.3. Adjuvants: Freund's adjuvant has been commonly used for decades in immunologic studies in mice and while multiple adjuvants are sufficient to induce EAE in rats, CFA is thought to be uniquely capable of reliably generating autoimmunity in mice (Stromnes and Goverman 2006). As such for these studies, no adequate substitute is available. Mice will be treated with CFA containing either the MOG immunodominant peptide or the protein control ovalbumin. We will utilize subcutaneous injections of CFA/PBS emulsion containing MOG peptide or ovalbumin will be done using a 25G needle into the upper trunk ~2cm caudal and ventral to each forelimb in a total volume of 50 µl per site. Mice will be watched for development of adverse reactions and subsequent euthanasia as described in section V.4.5.

V.4.4.4. Monoclonal Antibody (MAbs) Production: N/A

V.4.4.5. Animal Identification: Within each experimental iteration mice will be identified through use of ear punch as outlined below (V.4.4.7). Using a location code for punch placement we can identify up to 99 mice/experiment.

V.4.4.6. Behavioral Studies: N/A

V.4.4.7. Other Procedures: Mice will be restrained by hand and an ear punch will be utilized to produce specific marks. Prior to use of the ear punch the area to be marked and the punch will be treated with 70% isopropanol. Mice will be marked immediately prior to use and as such mouse age will depend on the age (4-8 weeks)at time of usage.

V.4.4.8. Tissue Sharing: Unused tissues will be available after termination of experimental procedures with the understanding that mice have been manipulated and may have disease-associated tissue inflammation.

V.4.5. Study Endpoint: Euthanasia at pre-determined time. Alternatively mice will be euthanized if they are judged to be moribund or display any of the following criteria associated with EAE development:

i. total weight loss exceeding 20% of body weight at start of experiment.
ii. Inability to rest.
iii. Hunched posture, head tucked into abdomen, lethargy lasting for >24 hours.
iv. Any condition that interferes with fecal or urinary elimination.

or development of other issues sometimes found in the mouse population:

v. Formation of multiple sores on tail.
vi. Diarrhea, if debilitating or prolonged over 3 days.
vii. Spreading alopecia that covers ~25% or more body surface area.
viii. Excessive scratching with associated scabbing
ix. Persistent coughing, labored breathing, or nasal discharge.

x. Jaundice.
xi. Bleeding from any orifice and/or prolapse.
xii. Pus-like discharge from sores.

V.4.6. Euthanasia: In general mice will be euthanized with CO2 from a regulated tank with input at .5-1 liters/minute (10-30% volume displacement per minute) until respiratory arrest is clear followed by cervical dislocation as recommended by the 2013 AVMA Guidelines for the Euthanasia of Animals. For experiments that require harvesting tissue used in determination of mRNA expression the long timing and induction of anoxia associated with CO2 asphyxiation is problematic and so mice will be euthanized by cervical dislocation following high dose (500mg/kg) avertin anesthesia. Mice will be tested for deep anesthesia as evidenced by a lack of response to foot pressure prior to dislocation. Finally, because cervical dislocation disrupts the architecture of the spinal cord, it cannot be utilized as a primary method of euthanasia when intact spinal cords are required. As such, for all studies that utilize CNS tissue, mice will be euthanized by exsanguination via cardiac perfusion under high dose (500mg/kg) avertin anesthesia injected intraperitoneally followed by perfusion with ice cold PBS.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol.

V.5.1.1. Study Room:

Building(s) _____ Room Number(s)LAM Procedure room

V.5.1.2. Special Husbandry Provisions:

Food Restriction:	Yes	_____	No	X
Fluid Restriction:	Yes		No	X

V.5.1.3. Exceptions: None _____ _____

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care: Animals will be cared for by LAM personnel according to LAM SOPs. We will also monitor daily and weigh every other day following development of EAE clinical symptoms. Food and water sources will be placed on the floor of the cage as needed for animals that may have difficulty accessing the normal feed and water sources.

V.5.2.2. Emergency Veterinary Medical Care All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary

technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: Except as indicated below, all animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents.

V.5.3.2. Enrichment Restrictions: None

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
Colony management, genotyping, animal observation, injections, tissue sampling, euthanasia	(b)(6) PhD	13 years experience with mouse maintenance and handling including previous experience in all procedures listed in the protocol	(b)(6) IACUC Training 1999 (b)(6) (b)(6) IACUC Training 2004, (b)(6) IACUC rodent handling and investigator training, 2008, USUHS IACUC training 4/4/13

VII. BIOHAZARDS/SAFETY: We will follow all regulations on handling mice as per instructions received during the USUHS IACUC courses. Routine PPE (lab coat, mask, gloves) will be worn when working with animals to reduce the potential exposure to animal allergens. Blood withdrawal and spleen collection (after euthanasia) will be handled in a sterile hood in LAM facility. Sharps will be disposed of as instructed by EHS policy.

VIII. ENCLOSURES: None

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

_____ _____

Principal Investigator Signature Date

G. Training: The following personnel will attend the next USUHS Investigator/Animal User Training Course:

_____ _____

_____ _____

H. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely, "Responsibility" for implementing animal use alternatives where feasible and conducting humane and lawful research.

I. Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL or WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

X. PROTOCOL ABSTRACT:

A. Animal Protocol Number:

B. Animal Protocol Title: T cell trafficking and retention in an autoimmune mouse model

C. Principal Investigator: (b)(6) PhD, Department of Medicine

D. Performing Organization: Uniformed Services University of the Health Sciences

E. Funding: ~$50,000

F. Objective and Approach: The long-term objective is to understand and identify the necessary components involved in T cell mediated autoimmune attack that occurs in neuroinflammatory diseases like multiple sclerosis (MS). In this protocol, we will use Experimental Allergic Encephalomyelitis (EAE) as a demyelinating autoimmune disorder resembling MS. Our hypothesis is that discrete molecular components will be required to retain T cells long term within the CNS. This long term population appears to be involved in the continuation and/or reactivation of lesions within the brain and spinal cord. The objective is to identify vital components of this T cell retention future for future therapeutic targeting. Previous work within the model used here have been shown that information gained in the mouse system is uniquely applicable to multiple sclerosis treatment. However deleterious effects associated with established treatment limit their utility. AS such there is a great need for new and better therapeutics.

MEMORANDUM FOR DR. (b)(6) DEPARTMENT OF MEDICINE

SUBJECT: IACUC Approval of Protocol – Initial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Full Committee Review on May 21, 2014:

Animal Protocol Title: "Generation of Therapeutic Human anti-Influenza Virus Antibodies (HAIVA) using DRAG mice"

USUHS Protocol Number: (b)(6)

Expiration Date: May 20, 2017

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

TECHNICIANS(S):

I. **NON-TECHNICAL SYNOPSIS:** Influenza viral vaccination using mixtures of egg-cultured virus strains isolated from the lungs of recently infected people can provide protection to 60-70% of individuals. Thus, conventional flu vaccines require yearly preparation due to seasonal changes in the structure of viral proteins (antigen drift or shift) that lead to immune evasion that result in a less efficiency of a previous year vaccine preparation. The preparation process and testing of a new flu vaccine requires 6-8 months. The vaccine is less efficient in elderly, immunocompromised individuals, and children due to a poor and respectively, immature immune system. Some 3,000 deaths occurred between the years 1986-87 and around 50,000 in the year between 2003-04 by non-endemic, seasonal influenza infection in USA according to the CDC reports(Centers for Disease & Prevention, 2010). Furthermore, current therapeutic procedures for patients with acute flu pulmonary infection rely mostly on palliative treatment that does not address viral clearance from the system, and their efficacy depends greatly on the antiviral resistance to the drug and the immune status of each individual to clear the infection.

Our proposal aims at designing of a new class of anti-viral therapeutics, Human Anti-influenza Virus Antibodies (HAIVA prep) for critical conditions like acute pulmonary infection (with different types of flu viruses), and for vaccination purposes in imminent flu endemics. HAIVA prep consists of a cocktail of "fully human" antibodies able to neutralize a large number of influenza virus strains regardless the seasonal antigen drift and the immune status of an individual. Generation of HAIVA preps relies on our newly developed humanized DRAG mouse (Danner et al., 2011) (patent recently licensed by Jacksons Labs) and our preliminary data showing the possibility of generating fully human antibodies against flu and malaria. HAIVA preparation is designed for human use and to lack the side effects of conventional flu vaccines, ex. Allergy to egg, cardiovascular and kidney complications, joints inflammatory syndrome, etc. HAIVA shelf-life is expected to be several years and highly efficient regardless the seasonal mutations of the virus and the patient immune status. HAIVA-like preparations may greatly impact the way acute flu infections are treated in both the military and civilian populations. They may also represent a novel platform to generate 'universal' vaccines for other types of infections and pathogens of bioterrorism threat.

GRANT TITLE (if different from above):

USUHS PROJECT NUMBER: (b)(6)

CO-INVESTIGATOR(S): Dr (b)(6)

TECHNICIANS(S):

NON-TECHNICAL SYNOPSIS:

Currently, the pre-clinical animal models that are used to test approaches that target the immune system (i.e., vaccines) are imperfect. Development of humanized mouse models able to generate a surrogate human immune system is a highly pursued goal for investigating human immunology and testing human vaccines prior to clinical trial. Under this protocol we will investigate the immunogenicity and protective efficacy of human malaria vaccines generated in our lab using NMRC genetically engineered, humanized mice. We have demonstrated that genetically modified mice expressing human protein (HLA, and CD80) and that are knockout for mouse immune system (RAG KO, Il2R KO), namely DRAG mice, developed a functional human immune system upon infusion of human hematopoietic stem cells from umbilical cord blood. Our results also indicated that the humanized mice sustain infection with *Plasmodium falciparum* as they also develop human hepatocytes and erythrocytes –the restriction elements for human malaria infection.

To demonstrate the protective efficacy of two different human monoclonal antibodies generated previously in the lab that are specific for Pf CSP (Ab1 and Ab2), we will vaccinate wild type mice that self-cure malaria infection (BALB/c and C57BL/6 mice) as well as our four strains of humanized mouse strains (HLA-DR4, RAG2KO, IL2RgcKO, CD80, NOD mice, HLA-DR4, A2, RAG2KO, IL2RgcKO, NOD mice, HLA-DR4, A2, RAG2KO, AbbKO, C57 mice, and HLA-DR4, AbbKO, NOD) with human monoclonal antibodies Ab1 and Ab2, and further infect these mice with a mouse specific malaria strain, *Plasmodium Yoelii* (a strain that infects the mice but not humans). The P. Y strain has the *Plasmodium Falciparum* CSP transgene (Py-Pf CSP transgene) from *Plasmodium Falciparum* CSP known to infect humans.The Py-Pf CSP transgenic strain does not infect humans, but it does infect mice. The rationale of using human monoclonal antibodies as protective agents against infections has been overtly demonstrated. The use of Ab1 and Ab2 preparations in these mice is to test their protective efficacy against Py malaria carrying Pf CSP transgene. We expect that binding Ab1 and/or Ab2 to the sporozoites will impair their ability to reach the liver. BALB/c and C57BL/6 mouse strains are used as control infectivity. The use of humanized mice is to find out the role of various human immune molecules (see human transgenes expressed in these mice) on the Py infectivity as well as how these

human molecules interfere with Py infection upon Ab treatment.

A number of 70 mice from each strain (BALB/c and C57BL/6 mice as well as HLA-DR4, RAG2KO, IL2RgcKO, CD80, NOD mice, and HLA-DR4, A2, RAG2KO, IL2RgcKO, NOD mice, and HLA-DR4, A2, RAG2KO, AbbKO, C57 mice, and HLA-DR4, AbbKO, NOD) will be used in the experiments as described in Table 1.

In a parallel experiment we will vaccinate the same strains of mice as mentioned above with four different protein fragments from Pf CSP, namely the NH2 terminus of Pf CSP (Ag1), or COOH terminus of Pf CSP (Ag2), or COOH-repeat of Pf CSP (Ag3), or the intact Pf CSP (Ag4). The rationale of using these CSP fragments is to delineate the most immunogenic part of CSP that can induce protective antibodies upon immunization. CSP is known as an immunogenic protein, but mapping the immunogenic sites is still a major challenge. The use of humanized mice will provide insights into the role of each of these human immune molecules (see human transgenes expressed in these mice) on the immunogenicity and protection against malaria infection.

The proposed study is part of a peer-reviewed award "(Development of malaria vaccines for military, of $ 680,000) by MIDRP to the Malaria group from NMRC. Dr (b)(6) project has been assigned as a collaborator sub-award to this main project.

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

January 14, 2014

MEMORANDUM FOR DR (b)(6) DEPARTMENT OF MILITARY EMERGENCY MEDICINE

SUBJECT: IACUC Approval of Protocol – Triennial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on January 14, 2014:

Animal Protocol Title: ""Biomarkers for Detection of Heat Intolerance in Mice

USUHS Protocol Number: (b)(6)

Expiration Date: January 13, 2017

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. NON-TECHNICAL SYNOPSIS:

Heat injury continues to be a significant problem confronting the military, particularly during recruit training, and remains a common cause of preventable non-traumatic related death. Identifying these heat-vulnerable individuals is important for reducing heat-related injuries in outdoor constructions and military operations. The overall goal of this project is to determine the biomarkers that can be used to detect heat intolerance. In this protocol, we will continue our previous work to test the effects of two antioxidants, quercetin and curcumin, on the heat stress responses of key organs, which play an important role in maintaining thermal homeostasis, of heat-tolerant versus heat-intolerant mice.

II. BACKGROUND:

II.1. Background:

Prolonged exposure to high temperatures may cause heat-related illnesses, such as cramps, syncope, exhaustion or even stroke in some individuals. Heat-related injuries remain a threat to the health and operational effectiveness of military personnel [1]. Heat injury victims experience long-term complications that may include multi-system organ (liver, kidney, muscle) and neurologic damage, as well as reduced exercise capacity and heat intolerance. Animal and human research suggest late or untreated heat injury may result in organ damage that continues for weeks to months and possibly even after clinical symptoms or biomarkers have returned to normal. Current military return-to-duty guidelines are based on "best guess" estimates and clinical anecdotes, rather than valid biomarkers of recovery and scientific evidence. Thus, the predictive and prognostic biomarkers, which can be used to identify heat-intolerant individuals and to determine recovery after heat injury, will improve military force readiness. Our previous work showed that heat-intolerant (INT) mice were associated with altered regulation of tissue heat shock proteins (HSPs) at translational and transcriptional levels compared to heat-tolerant (TOL) mice [2, 3]. In this protocol, we will further assess the role of HSPs in key organs, including heart, liver and skeletal muscles, in regulating heat tolerance in mice fed a diet containing quercetin (Que) and curcumin (Cur). Both Que and Cur are plant-derived natural products and have antioxidant/anti-inflammatory properties. Oxidative stress and inflammation have been implicated in heat stress.

Importantly, it has been shown that Que [4] inhibits but Cur [5] enhances induction of HSPs by heat acclimation (HA).

II.2. Literature Search for Duplication:

II.2.1. Literature Source(s) Searched:
Biomedical Research Database; RePORT; PubMed
II.2.2. Date of Search: 10|22|2013
II.2.3. Period of Search:
all available years
II.2.4. Key Words and Search Strategy:
"heat" AND (tolerance" OR "intolerance" OR "stress") AND ("antioxidant" OR "flavonoid" OR "quercetin" OR curcumin")
Results include work done in rodents relevant to regulation of heat shock proteins (HSP).
BRD 0 hit; RePORT 0 hit; PubMed 407 hits

II.2.5. Results of Search:
No previous studies were found that duplicate the proposed studies. Heat intolerance has been shown to be associated with hypothalamo-pituitary-adrenocortical axis impairment in rats [6]. The effects of quercetin on heat acclimation and HSP content in blood cell has been examined in humans [4]. Peripheral organs such as liver, heart and skeletal muscles are known to play an important role in maintaining thermal homeostasis during heat stress. Little information is available on how an antioxidant intervention influences the responses of these organs to heat stress.

III. OBJECTIVE\HYPOTHESIS:
The objective of the proposed studies is to establish key biomarkers that can be used to identify mice that are heat intolerant. We hypothesize that heat intolerance is associated with inflammation and oxidative stress that induce hyperthermia and tissue injury during heat stress. Heat exposure should cause greater metabolic activities and stress-related changes in INT mice, compared to TOL mice. Anti-inflammatory or antioxidant therapy should reduce hyperthermia and tissue stress in response to heat shock. Thus, we propose to establish the biomarker profile of heat-intolerance and test the hypothesis by comparing heat-induced functional and/or biochemical changes in INT and TOL mice in the absence and presence of antioxidants. The proposed studies in this protocol will continue our work about the effects of selected dietary antioxidants, Que and Cur, on heat tolerance in mice.

IV. MILITARY RELEVANCE:
Heat related injury remains a threat to the health and operational effectiveness of military personnel who are heat-intolerant. Heat injury victims experience long-term complications. In this project, we will examine various biomarkers that can be potentially used to identify heat-intolerance. The information from this project will help develop strategies to detect heat-susceptible individuals and to improve military force readiness.

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures:
The experiments will be conducted using adult male C57BL/6J mice (b)(4) (b)(4) All animals will be housed in the USUHS LAM facility and allowed free access to water and food. We previously reported that INT mice were characterized by increased cardiovascular activities; and activation of heat shock proteins (HSPs) and glucocorticoid receptor in multiple organs in response to heat exposure. The proposed studies will test the effects of Que and Cur on heat stress in control (**Experiment 1**) and heat-acclimated mice (**Experiment 2**). Both Que and Cur are natural plant extracts and commonly present in fruits and vegetables. The proposed doses of Que and Cur (oral administration) in mice are comparable to the relatively low amount used in human studies, in which, for example, supplemental quercetin intake ranges from 1,000 mg (~14 mg/kg/day for a 70 kg person) [7] to 2,000 mg (~28 mg/kg) [4]. Neither Que nor Cur is listed as an ingredient in lab animal diets (Harlan Laboratories).

Animals. Mice will be surgically implanted with a temperature transponder (G2 E-Mitter, Mini Mitter Corp, Bend, OR) in abdominal cavity and a pressure transmitter (PA-C10, Data Science International, St. Paul, MN) (catheter placed into the left carotid artery and the transmitter body tunneled subcutaneously to a small pouch along the right ventral flank) under anesthesia (1.5-2% isoflurane). At least 2 weeks will be allowed for recovery. The body weight of the animals will be recorded 2-3 times each week. To be included in experimentation, mice will have to regain pre-surgical body weight. Their heat tolerance will be determined through a heat tolerance test described below. Mice with a peak core temperature of >= 42.0 °C during the test will be considered "INT" while those with a peak core temperature of <= 41.0 °C, "TOL" [2, 3].

V.1.1. Experiment 1: Effects of Que and Cur on heat tolerance
As illustrated in Figure 1, each mouse will undergo two heat tolerance tests separated by at least 10 days. The study includes three groups of mice that will receive regular food (control) or foods containing Que or Cur between the two heat tests. Spirometry measurements will be performed on control mice within 24 hrs before and 2 hrs after heat test. Each group requires 15 INT mice. Our previous studies showed ~31% of C57BL/6J mice are INT. **Total for Exp 1: mice = 45 x 3 groups = 135**

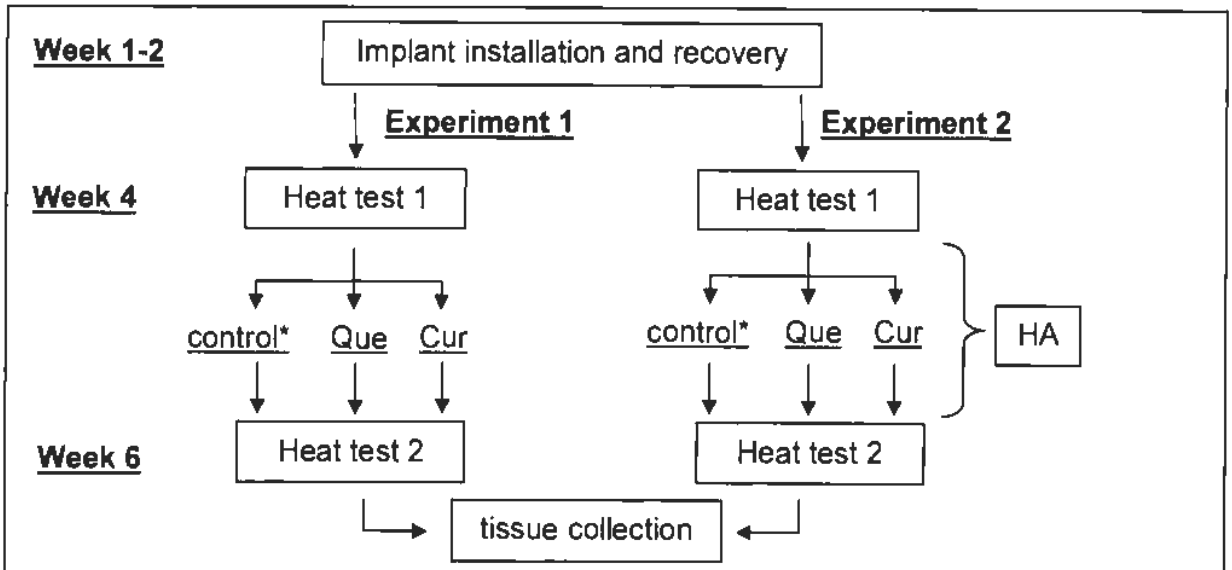

Figure 1. Experimental groups and procedures. Animals in each experiment will undergo two heat tests (an interval of at least 10 days). All mice will be placed on normal diet (control) or diet containing Que or Cur and mice in Experiment 2 will receive heat acclimation training (HA) between the two tests. *spirometry before and after heat test

Heat tolerance test. The test will be performed in an environmental chamber (Thermo Forma 3950, Marietta, OH). All mice will be placed in the chamber (in their regular cages with both food and water) overnight before each heat test. All heat tests will be conducted in the morning (0830-1200). As soon as a stable baseline measurement is obtained, heat will be turned on. The chamber temperature will gradually rise until it reaches the preset temperature, 39.5 °C (this heating process takes ~1 hr). Heat exposure will continue until whichever comes first, core temperature ≥42.4 °C or 3 hours (including chamber heating).

Dietary treatments. Mice will be placed on regular chow or chow containing Que or Cur. We estimate that, on average, mice eat approximately 2.5 grams of mouse chow per day. We prepare dried mouse chow pellets containing 0.6% Que or Cur (in weight), resulting in a daily dose of ~1.5 mg/mouse/day (60 mg/kg body wt/day). The pellets will be prepared by mixing Que or Cur with powdered mouse chow in a blender. Water will be added to make a thick paste sheet that is cut into squares and dried in an oven at 85° F until it returns to original weight.

Spirometry. Each mouse will be placed in an airtight polypropylene chamber (iWorx). The mouse chamber air is circulated (open loop) via a pump at a rate of ~250 ml/min during acclimation, which allows rapid temperature equilibration between the mouse and environmental chambers and sufficient fresh air supply (mouse resting minute ventilation: ~23 ml). The chamber (1.4L) provides a comfortable room that permits animals to calm down quickly and changes in gas concentration can be effectively detected. We will allow animals sufficient time (usually <20 min) to acclimate in the chamber. Closed-flow respirometry (~15 min) will be used to measure VO_2 and carbon dioxide release (VCO_2) at a flow rate of ~150 ml/min. Excurrent O_2 and CO_2 will be recorded continuously.

V.1.2. Experiment 2: Effects of Que and Cur on heat acclimation
The experimental groups and measurements are similar to Experiment 1 (Figure 1). In addition, mice will receive HA training between the two heat tests. Similarly, each group requires 15 INT mice. About ~31% of mice are expected to be INT. **Total for Exp 2: mice = 45 x 3 groups = 135**

HA training. Mice will be subjected to an ambient temperature of 33 °C in the environmental chamber (in their regular cages with foods and water) for 5 hrs daily for 10 consecutive days. This HA is considered mild. Higher temperatures and longer exposure (24hrs daily for 30 days) have been used in rodent studies.

Upon completion of each experiment, animals will be euthanized for collection of arterial blood (via the right carotid artery), urine, heart, liver kidneys and soleus and gastrocnemius muscles under isoflurane anesthesia.

V.2. Data Analysis:
Based on our experience, the number of mice requested is necessary to accomplish the research goals. Two-way ANOVA with repeated measures will be used to evaluate the differences among groups in each Experiment. Post hoc subgroup comparisons will be performed after significant effects. Using reasonable estimations of the variance of each of the measurements based on previous studies, we determined the proposed sample sizes to have an 80% power to detect a difference in mean variables of 1.2 standard deviations with a significant level of 0.05 (two-tailed).

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered:
Heat tolerance in a living animal is a result of the complex interaction involving multiple organs/systems. This cannot be sufficiently modeled in a non-living system (i.e. computer modeling) or simple living unit (i.e. cultured cells) and thus, requires the use of in vivo model system.

V.3.2. Animal Model and Species Justification:
Rodents have been commonly used in heat stress studies. It is desirable to characterize heat intolerance in a mouse model of heat stress, which offers an additional advantage due to the ability to use genetic engineering, an important tool to study the mechanisms for heat tolerance in the future.

V.3.3. Laboratory Animals

	Species #1	Species #2
V.3.3.1. Genus & Species:	Mus musculus	
V.3.3.2. Strain/Stock:	C57 BL/6J	
V.3.3.3. Source/Vendor:	(b)(4)	
V.3.3.4. Age:	2-3month	
V.3.3.5. Weight:	20-30g	

V.3.3.6. Sex: M

V.3.3.7. Special Considerations: none

V.3.4. Number of Animals Required (by Species):

Mice 270

V.3.5. Refinement, Reduction, Replacement (3 Rs):

V.3.5.1. Refinement:

Possible pain and distress will be reduced by the use of an implanted device to record temperature and blood pressure. Alternatives (i.e. rectal probe for temperature) would be more stressful. All the procedures (i.e. installation of telemetry probes, terminal blood or tissue collection) that cause pain will be completed under anesthesia. Pain reliever will be administered to animals following surgeries.

V.3.5.2. Reduction:

We design experiments and prepare tissue samples in a way that allows us to conduct several physiological measurements in a given animal and multiple assays in a given tissue rather than adding animals.

V.3.5.3. Replacement:

Ex vivo studies, tissue culture methods, and computer simulations were considered but rejected since they are not suitable techniques to address the goals of the project. These techniques cannot replicate the complexity of in vivo temperature regulation mechanisms.

V.4. Technical Methods:

V.4.1. Pain / Distress Assessment:

V.4.1.1. APHIS Form 7023 Information:

V.4.1.1.1. Number of Animals:

	Species #1	Species #2
V.4.1.1.1.1. Column C:		
V.4.1.1.1.2. Column D:		
V.4.1.1.1.3. Column E:	270	

V.4.1.2. Pain Relief / Prevention:

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization:

Isoflurane (4% induction, 2% maintenance) will be used during surgeries and terminal tissue collections. Analgesic will be given for the first 24 hrs post surgery and longer if needed. Buprenorphine will be administered subcutaneously between the shoulders blades or along the back at a dose of 0.05-0.1mg/kg (0.01 ml/mouse) q12hr using a 27-29 gauge needle in a 1 cc syringe.

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions:

Animals will be continuously monitored for their activity after heat tests. They will be transferred back to their housing unit once they return to normal activity.

V.4.1.2.3. Paralytics:

none

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures:

V.4.1.3.1. Sources Searched:

PubMed, Altweb

V.4.1.3.2. Date of Search:

10/22/2013

V.4.1.3.3. Period of Search:

All available dates

V.4.1.3.4. Key Words of Search:

Pubmed: heat stress OR exposure AND mice

Altweb: body temperature measurement

V.4.1.3.5. Results of Search:

No alternative procedure or method, which results in less pain or stress, was available.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification:

The proposed study will expose conscious mice to high ambient temperature (39.5 ± C) for up to 180 min including ~1hr chamber heating. This process is needed to investigate heat tolerance that cannot be effectively assessed under anesthesia or analgesia. Our preliminary results show that majority of the animals remained fully active during entire heat exposure and core temperatures rapidly returned to baseline levels following heat exposure. The discomfort caused by this process should be very limited.

V.4.2. Prolonged Restraint:

none

V.4.3. Surgery:

V.4.3.1. Pre-surgical Provisions:

The skin of the incision sites will be prepared (shaving, hair removal) and treated with betadine and alcohol. The surgeon will follow all aseptic procedures (wear a lab coat and gloves and use sterilized instruments). The animal's body temperature will be maintained at ~37 °C with a heating pad.

V.4.3.2. Procedure:

Animals will be periodically tested for absence of a response to toe pinch to ensure the appropriate depth of anesthesia during the surgical operation. The following procedures will be performed during a single surgery.

Blood pressure telemetry probe installation: A midline incision will be made on the anterior neck area. The left carotid artery will be carefully isolated and freed from the muscle and tissue around the trachea. The implantable catheter of the telemetry probe (Data Science International, St. Paul, MN) will be securely installed into the carotid artery. The telemetry probe body (weight: 1.4 gm) will be implanted into a subcutaneous pocket in the right flank. The incision will be closed with sutures wound clips.

Body temperature telemetry probe installation: A midline incision will be made to access to abdominal cavity under anesthesia after the area is shaved/cleaned/sterilized. A telemetry probe for temperature and heart rate (weight: 1.1 g. Respironics, Inc) will be

placed in the cavity before closing the incision with absorbable suture (muscle) and wound clips (skin).

V.4.3.3. Post-surgical Provisions:
Animals will be carefully monitored following the implant surgery. They will return to their housing unit after they become awake and fully mobile. Animals will be surveyed for signs of infection or pain twice a day for two days after the surgery.

V.4.3.4. Location:
G-175

V.4.3.5. Surgeon:
(b)(6)

V.4.3.6. Multiple Major Survival Operative Procedures:
none

V.4.3.6.1. Procedures:
N/A

V.4.3.6.2. Scientific Justification:
N/A

V.4.4. Animal Manipulations:

V.4.4.1. Injections:
none

V.4.4.2. Biosamples:
Upon completion of the studies, we will collect blood via a carotid catheter, urine via a bladder puncture and tissues/organs (hindlimb muscle, liver, kidneys and heart, etc) under terminal anesthesia.

V.4.4.3. Adjuvants:
none

V.4.4.4. Monoclonal Antibody (MAbs) Production:
none

V.4.4.5. Animal Identification:
Tail tattoo (will be performed under anesthesia at the time of surgical implantation). Cage cards

V.4.4.6. Behavioral Studies:
none

V.4.4.7. Other Procedures:
none.

V.4.4.8. Tissue Sharing:
none

V.4.5. Study Endpoint:
The endpoint for mice in Experiments 1 and 2 will be up to 5 weeks following surgical implantation. Although not expected, any animals that are in poor health (i.e. inactive, sign of persistent pain or stress, body weight loss >15%) will be euthanized upon the suggestion of or in consultation with the LAM veterinary staff.

V.4.6. Euthanasia:
Upon completion of experiments, animals will be anesthetized with isoflurane. Euthanasia will be accomplished by exsanguination under deep anesthesia for terminal blood and tissue collection. The euthanasia procedure is in compliance with the 2013 AVMA Guidelines on Euthanasia.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations:
Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol.

V.5.1.1. Study Room:
Building(s) (b)(6) Room Number(s) (b)(6)

V.5.1.2. Special Husbandry Provisions:

Food Restriction: Yes _____ No √

Fluid Restriction: Yes _____ No √

V.5.1.3. Exceptions:
none

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care:
Animals will be observed and cared for by the Center for LAM personnel according to USUHS Center for LAM SOPs.

V.5.2.2. Emergency Veterinary Medical Care: All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: Except as indicated below, all animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents; balls, toys and food enrichment treats for large animal species.

V.5.3.2. Enrichment Restrictions:
none

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
all protocol procedures	(b)(6)	15 yrs research experience using rodents	attended USUHS Investigator Training Course in March 2008
recovery assessment		>10 yrs experience in rodent research	attended USUHS Investigator Training Course in 1982?
all protocol		3 yrs experience in	attended USUHS

procedures	(b)(6)	rodent research	Investigator Training Course in July 2010.

VII. BIOHAZARDS/SAFETY:

All personnel handing animals will wear protective gloves, lab coat and mask at all times to minimize exposure to allergens. During surgical procedures, isoflurane vapor will be scavenged by a canister that connects to mouse anesthesia mask.

VIII. ENCLOSURES:

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

F. Objective and Approach:

Heat-related injuries remain a threat to the health and operational effectiveness of military personnel. The objective of the proposed research is to establish key biomarkers that can be potentially used to identify individuals susceptible (heat intolerance) to heat stress. The proposed studies will determine the biomarkers of heat intolerance by comparing the physiological and biochemical changes of heat-tolerant and -intolerant mice in response to heat exposure. Our previous studies have shown that heat exposure causes stress-related changes in multiple organs of heat-intolerant mice. In this protocol, we will determine if these changes are associated with oxidative stress by testing the effects of selected dietary antioxidants on heat tolerance and acclimation in mice. Specifically, we will examine the effects of heat exposure and acclimation on mice fed a normal food or food containing quercetin or curcumin. The proposed research will provide information useful for developing strategies to detect and protect individuals susceptible to heat injury

MEMORANDUM FOR DR. (b)(6) DEPARTMENT OF MILITARY EMERGENCY MEDICINE

SUBJECT: IACUC Approval of Protocol - Initial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on October 2, 2015:

Animal Protocol Title: "Application of Low Dose Inhaled Carbon Monoxide to Attenuate Diet-Induced Obesity and Insulin Resistance in Rats (Rattus Norvegicus)"

USUHS Protocol Number: (b)(6)

Expiration Date: October 1, 2018

Supporting Grant(s) Number: TBD

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. NON-TECHNICAL SYNOPSIS:

The prevalence of obesity in the U.S. general population and military continues to increase. Obesity increases the risk of developing insulin resistance, diabetes, and cardiovascular disease. Dysregulated mitochondrial function and altered structure have been reported to be associated with obesity related conditions. Diet and exercise are recommended in the prevention and treatment of obesity and resulting diseases, but are not reversing the trend. The use of alternative prevention and treatment strategies, in conjunction with exercise, may be required to slow the rise in obesity and diseases. Low dose inhaled carbon monoxide (CO) has successfully been used to increase the production of new mitochondria, thus may protect against the onset of obesity associated diseases. The overall goal of this project is to determine whether low dose inhaled CO is efficacious in preventing diet-induced obesity and insulin resistance in rats by preserving mitochondrial structure and function.

II. BACKGROUND:

II.1. Background:

In the U.S., the prevalence of overweight and obesity combined is approximately 70%, and the prevalence of obesity is approximately 35%, rates that have more than doubled from 1976-1980 (1). In the U.S. Military, the combined prevalence of overweight and obesity is 60.5% and the prevalence of obesity is 12.9%, a 2.5 fold increase in obesity from 1990 (18). While there is a genetic component to the pathology of obesity and associated diseases, much of the cause can be attributed to excess energy intake and insufficient physical activity. Diet-induced obesity is associated with an increase in fat accumulation within visceral adipocytes, chronic low-grade inflammation, an increase in plasma free fatty acids that leads to ectopic fat accumulation and dysregulated lipid and glucose oxidation in the liver and skeletal muscle, and insulin resistance (17). The underling etiology of insulin resistance or prediabetes has been reported to be attributed to an increase in mitochondrial reactive oxygen species (ROS) and a reduction in the cellular antioxidant defenses (3, 5). If unabated, the increase in ROS may lead to impaired regulation of mitochondrial morphology, a reduction in mitochondrial biogenesis and a reduction in respiratory capacity, all of which have been linked to the

development of type 2 diabetes (6, 10, 12, 13). Although lethal at high concentrations, low-dose carbon monoxide (CO) may provide a safe, relatively non-invasive treatment option for obesity and its associated metabolic diseases. By stimulating the production of antioxidant enzymes (heme oxygenase-1 (HO-1) and mitochondrial superoxide dismutase (SOD2)), and hydrogen peroxide, CO serves to protect against oxidative damage and inflammation, and stimulates mitochondrial biogenesis (14, 21). The proposed work is expected to identify how CO alters mitochondrial dynamics in skeletal muscle of rats fed a high-fat diet for 10 weeks. The results from this work will advance our understanding of diet-induced obesity and mitochondria dysfunction. Perhaps most intriguing will be the therapeutic potential that may be afforded by CO.

II.2. Literature Search for Duplication:

(("Mitochondria"[Mesh] OR mitochondria) AND ("Carbon Monoxide"[Mesh] OR "inhaled carbon Monoxide" OR "inhaled CO")) OR (("Insulin Resistance"[Mesh] OR "Diabetes Mellitus"[Mesh] OR "Overweight"[Mesh] OR "insulin resistance" OR overweight OR obesity OR obese OR diabetes) AND ("Carbon Monoxide"[Mesh] OR "inhaled carbon Monoxide" OR "inhaled CO")) AND ("Rodentia"[Mesh] OR rats OR rat OR rattus)

Biomedical Research Database 0 hit; RePORT 0 hit; MEDLINE/PubMed 151 hit

II.2.5. Results of Search:
No previous studies were found that duplicate the proposed research. Only one study has examined the efficacy of inhaled CO on diet-induced obesity in mice (7). By exposing mice to 28 parts per million (ppm) or 200 ppm daily for 30 weeks, CO was determined to be effective in attenuating diet-induced obesity and improving glycemia in the first 10 weeks, but not with continued high-fat feeding. In this study, an exercise component was not included, and mitochondria morphology and respiratory capacity measures were not performed. Furthermore, CO was administered every day vs. intermittently, thus this amount over this duration could have in fact lead to ROS production, inflammation and mitophagy, masking any protection that may exist in the long-term.

III. OBJECTIVE\HYPOTHESIS:

The overall objective of this research is to explore the potential use of low dose inhaled CO on attenuating the development of diet-induced obesity and insulin resistance in rats, with and without exercise since moderate-intensity aerobic and high-intensity interval training increases mitochondria number and quality, respiratory capacity and whole body oxygen consumption (VO_2) (8, 15, 20, 23). The central hypothesis is that

CO will protect against diet-induced obesity and insulin resistance by preserving mitochondrial morphology, mitochondrial biogenesis, and respiratory capacity.

IV. MILITARY RELEVANCE:

Obesity related illnesses are likely to increase in the military with rising obesity rates. This will impact operational readiness, both fitness to perform and equipment requirements, e.g., the racks on ships will be too small for the girth of a sailor. In addition, the number of available healthy recruits that meet body fat and fitness standards will become fewer, impacting force readiness. Finally, Tricare and the VA system will be affected by the financial burden of treating obesity associated diseases. Research aimed at understanding the molecular mechanisms of obesity, and potential adjunct prevention and treatment options are, therefore, warranted.

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures:

Animals: The experiments will be conducted using male obese prone Sprague Dawley (OP-CD) rats aged 8-9 weeks old (b)(4) All animals will be doubly housed in the USUHS LAM facility on a reverse 12 h light and 12 h dark schedule, and allowed free access to water and food. Animals will be randomized to 1 of 5 groups after pre-study testing **(Figure 1)**: sedentary (CON), high-fat sedentary (HF), high-fat exercise training (HF-EX), high-fat sedentary carbon monoxide (HF-CO), or high-fat exercise training + carbon monoxide high-fat (HF-EXCO).

Exercise: Seven days upon arrival, all rats will be habituated to endurance exercise on a 4 lane rodent motorized treadmill (Columbus Instruments). The lanes are 43.8 cm in length and 12 cm wide with the dividers between lanes 12.7 cm in height. The rats will perform 3 practice sessions to condition them to run on the treadmill. The sessions will consist of the rats being placed on the lanes with the speed increased to 9 m/min, a very slow pace, for 10 min at an incline of 0° (19). On the back of each treadmill lane, there is an electrical shock grid (11.4 x 12 cm) that can produce a stimulus current of 0 – 1.5 mA (adjustable), a voltage of 163V, at a repetition rate (adjustable) of 1, 2 or 3 Hz. Since electrical stimulation can yield significant stress on the animal, the current will not exceed 0.5 mA and the rate will not exceed 1 Hz over a period of 5 sec. If the animals fail to run for a period of 5 sec, then the exercise session will be terminated. To circumvent reliance on negative reinforcement, chocolate will be provided following all exercise sessions which will positively condition the animals to perform the treadmill exercise. Following the 3 familiarization sessions, rats will undergo a test to determine the animals maximal aerobic exercise capacity (VO_2 max) using a modular enclosed metabolic treadmill (Columbus Instruments). The only difference between this unit and the regular treadmills is that the treadmill is enclosed in Plexiglas for determination of oxygen uptake (VO_2) and carbon dioxide production (VCO_2) using open circuit spirometry. The animals will be placed into this unit for 5-10 min to determine basal steady state VCO_2 and VO_2, followed by a 15 min warm-up at 40-50% of the estimated VO_2 max, which has been reported to correspond to a treadmill speed of 12-14 m/min at an incline of 25° (24). The belt speed will be increased by 1.8 m/min every 2 min until VO_2 levels-off (generally 8-15 min), or the animal refuses to run for 5 sec. The total testing time will be ≤ 45 min, including the time needed to establish steady state VCO_2

and VO_2. Since 10-15% of rats refuse to run on a treadmill (11), this pre-study familiarization and VO_2 max testing will be used to randomize the animals into the exercise training (HF-EX and HF-EXCO) and non-exercise (CON, HF and HF-CO) groups. During the 10 week protocol, the HF-EX and HF-EXCO groups will undergo aerobic exercise training three times/week, consisting of an 18 min warm-up at 40-50% of the animals measured VO_2 max, followed by 6 alternating intervals of 4 min at 85-90% and 2 min at 50% of the animals VO_2 max, serving as an active recovery period (9). Should the animals fail to complete this protocol, adjustments will be made to the intensity so that the volume of work performed is similar amongst the animals, i.e., lower speed, longer duration. In addition, a VO_2 max test will be performed in the HF-EX and HF-EXCO groups every 2 weeks with the training workload adjusted for subsequent training sessions. After each training session and VO_2 max test, the animals will receive a small piece of chocolate as positive reinforcement (24). The rats in the CON, HF and HF-CO groups will perform a weekly 10 min treadmill training session at 9 m/min and 0° incline to maintain treadmill familiarity.

Diet: All animals will consume a low-fat control diet upon arrival until the start of the 10 week protocol. After all pre-study testing is complete and the animals have been randomized to CON, HF, HF-EX, HF-CO and HF-EXCO groups, the CON group will continue to receive the low-fat control diet, whereas the HF, HF-EX, HF-CO and HF-EXCO groups will be fed a high-fat diet comprised of 43% carbohydrates, 42% fat, and 15% protein ad libitum until the completion of the study.

Body mass: Weights will be recorded for all animals weekly using a calibrated scale.

Resting whole body oxygen consumption (VO_2) and carbon dioxide production (VCO_2): Prior to, at week 5, and following the 10 week protocol (after an overnight fast), conscious rats will be placed in the modular enclosed metabolic treadmill for 30 min for continuous recording of VO_2 and VCO_2. These values will be used to calculate the respiratory exchange ratio (VCO_2/VO_2) and energy expenditure (kcal/h) (4).

Intraperitoneal glucose tolerance test (IPGTT): Prior to and following the 10 week protocol, and after an overnight fast, approximately 5-10 µL of blood will be collected from the tail vein (time 0) from conscious, restrained rats. The rats will be placed in a rat restrainer and the tail will be swabbed with alcohol to expose the blood vessel. Finger pressure will be applied approximately 5 cm from the tip of the tail, and a 21-23 gauge butterfly needle will be inserted into the tail vein with blood collected into microvette tube. The total time of restraint will be approximately 1-3 min. Next, 2 g of glucose/kg body weight (99.5% glucose from Sigma-Aldrich dissolved in distilled water) will be administered intraperitoneally via a 1-2 mL syringe with a 21 gauge needle. The same blood collection procedure will be repeated 15, 30, 60, 90 and 120 min post-glucose injection for determination of blood glucose using reagent strips and an automated handheld glucometer. The rats will be placed back in their cages, without access to food, in-between blood collection over the 2 h IPGTT.

Baseline and post-study blood collection for serum lipids and insulin: Prior to and following the 10 week protocol, and after an overnight fast, approximately 400 µL of blood will be collected from the lateral saphenous vein into a 500 µL microvette for later

analysis of serum lipids (total cholesterol, triglycerides, high density and low density lipoproteins) and insulin. This sample will be collected at the same time as the first tail vein blood draw (time 0) for the IPGTT to avoid an additional day of fasting and stress. The rats will be placed in a restrainer; the lower limb will be shaved with an electric razor and swabbed with alcohol to expose the vein prior to puncturing with a 21-23 gauge needle.

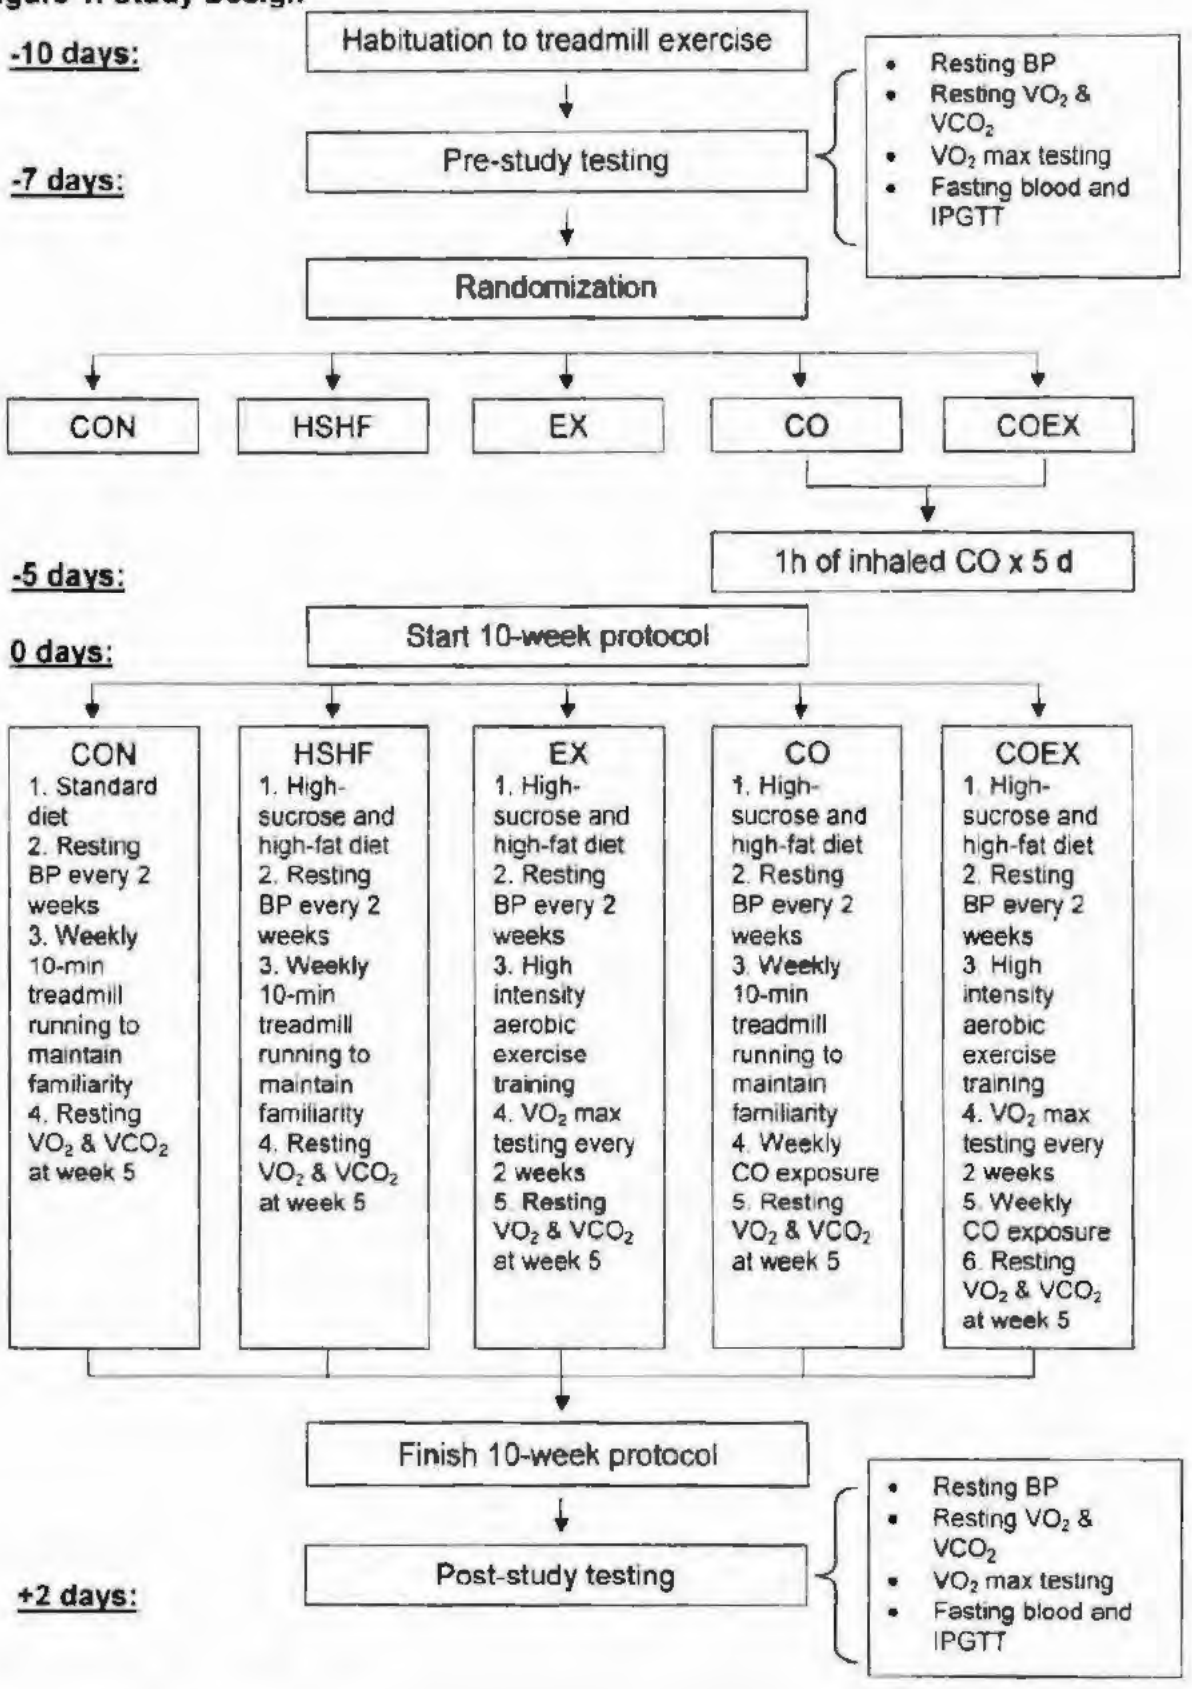
Carbon monoxide (CO) exposure: Two rat cages containing 2 rats in each will be placed in an enclosed plastic box that will be placed underneath a ventilated hood. Carbon monoxide (250 ppm balance air) will be supplied to the enclosed box via an inlet port for 1 h x 5 consecutive days before the 10 week protocol, and once per week for 1 h during the 10 week protocol. An outlet port with tubing will be ventilated into the hood. A portable CO analyzer will be placed inside the enclosed box to verify that the CO is maintained at 250 ppm for 1 h. A carbon monoxide concentration of 250 ppm has previously been reported to raise carboxyhemoglobin (HbCO) levels to ~13% in rats (22), with levels <20% considered to be safe (2). Only animals in the HF-CO and HF-EXCO groups will receive the CO treatment.

Carboxyhemoglobin levels: Of the animals that receive CO (HF-CO and HF-EXCO), before and after a CO treatment, approximately 100 μL of blood will be collected from the tail vein in a subset of animals (n = 6-8), as described above, in order to determine the concentration of carboxyhemoglobin in whole blood.

Resting blood pressure: Before the 10 week protocol, during weeks 2, 4, 6, 8 and following the 10 week protocol, resting blood pressure will be measured in all of the rats using a rat tail-cuff system (Kent Scientific). Rat tail-cuff blood pressure monitoring is considered non-invasive and has been extensively used by researchers, i.e., > 1000 PubMed hits. Rats will be placed in a restrainer that are appropriate for body mass with the tails exposed and placed on a heating pad to maintain tail temperature between 32-35° C for 15 min, which will be monitored with an infrared thermometer. Next, an occlusion cuff will be placed near the base of the tail and a volume pressure-recording sensor cuff will be placed distal to the occlusion cuff. Once the cuffs are secure, inflation-deflation cycles will commence with the first 5 serving as acclimation cycles, followed by 5 measurements used for data analysis. The total time of restraint is approximately 20-25 min. Once the measurements are complete, the animals will be immediately placed back into their housing cages with the appropriate food and water.

Tissue and blood collection: Upon collection of all post-study data, animals will be euthanized in an induction box using isoflurane. The animals will not be in contact with gauze dampened with isoflurane. Blood from the left ventricle and tissues (skeletal muscle, bone, heart, lung, liver and brain, and epidydmal fat pads) will be harvested for later analyses.

Figure 1. Study Design



V.2. Data Analysis:
A two factor repeated measures ANOVA will be used to determine whether inhalation of low dose CO is as effective as aerobic exercise training in attenuating diet induced obesity and insulin resistance. Since this experiment is novel, sample size estimates are based off of studies that explored the effects of a high-fat diet on obesity and metabolic dysregulation in rats (16, 25). From these studies, we anticipate that 10 weeks on a high-fat diet will result in a mean difference in weight gain of ~100 ± 55 g (SD) compared to rats fed standard chow, requiring a minimum of 9 rats per group to achieve 80% power with a 0.05 significance level (two-tailed). Since not all rats are trainable (~10-15%), and to ensure that there is sufficient tissue available for mitochondrial morphology, respiratory capacity and biogenesis measures, and for preliminary CO exposure and exercise testing, we estimate that approximately 15 animals in each group will be needed to complete this study.

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered:
Obesity and the metabolic sequela is complex, involving multiple organs/systems. This cannot be sufficiently modeled in a non-living system (computer models) or cultured cells and thus, requires the use of in vivo model system.

V.3.2. Animal Model and Species Justification:
Rats are a good species to explore the effects of diet-induced obesity, specifically because this outcome and metabolic complications are observed within a short period of time, i.e., 5-12 weeks. While these changes also occur in mice, the skeletal muscles that are preferentially recruited during aerobic exercise training are too small in mice for all of the proposed, necessary, measurements. Only males will be used for this research to avoid the potential confounding effects of estrogen and progesterone on energy homeostasis.

V.3.3. Laboratory Animals

	Species #1	Species #2
V.3.3.1. Genus & Species:	*Rattus norvegicus*	
V.3.3.2. Strain/Stock:	Sprague Dawley (OP-CD); strain code: 463	
V.3.3.3. Source/Vendor:	(b)(4)	
V.3.3.4. Age:	8-9 weeks	
V.3.3.5. Weight:	~250-300 g	
V.3.3.6. Sex: Females will not be used in this pilot study due to the role that estrogen and progesterone play in regulating	M	

glucose and lipid metabolism, and insulin sensitivity, serving to protect from diet-induced obesity. However, once we characterize the effects of CO on obesity and insulin resistance in male rats, we will then consider studying females, but this will be several years down the road. Furthermore, the entire study design would have to be changed, lengthened, to ensure that a high proportion of the female rats become obese and insulin resistant.

V.3.3.7. Special Considerations: None

V.3.4. Number of Animals Required (by Species): Rats 75

V.3.5. Refinement, Reduction, Replacement (3 Rs):

V.3.5.1. Refinement:

Possible pain and distress will be reduced by habituation to the rodent treadmill and the blood pressure tail-cuff system. There is no pain or discomfort associated with inhaling 250 ppm of CO balanced with room air. The animals will be restrained during blood collection to minimize distress.

V.3.5.2. Reduction:

The proposed experiments are designed to maximize the number of measurements that can be made to support the objectives. In addition, we will collect additional organs not intended for study in this research (brain, heart and lung), but quite possibly for future experiments which will ultimately reduce the number of animals required for those protocols. Since this research has not previously been carried out, reducing the number of animals, or use of animals, is not possible.

V.3.5.3. Replacement:

In vitro models were considered, but deemed inappropriate to test the proposed hypothesis since the objectives are to examine in vivo diet-induced obesity.

V.4. Technical Methods:

V.4.1. Pain / Distress Assessment:

V.4.1.1. APHIS Form 7023 Information:

V.4.1.1.1. Number of Animals:

	Species #1	Species #2

V.4.1.1.1.1. Column C:

V.4.1.1.1.2. Column D:

V.4.1.1.1.3. Column E: 75

V.4.1.2. Pain Relief / Prevention:

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization:
None

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions:
Animals will be monitored for 30 min following tail-vein blood collection. Following blood pressure tail-cuff monitoring, resting VO_2 and VCO_2 monitoring, CO exposure and treadmill exercise, animals will be immediately returned to their housing units. Since the electrical shock grid can induce redness and bleeding to the tails, all of the rat tails will be monitored. Although unlikely, in the event that a tail becomes necrotic, the rat will be removed from the study and euthanized using isoflurane.

V.4.1.2.3. Paralytics:
None

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures:

V.4.1.3.1. Sources Searched:
PubMed, Altweb

V.4.1.3.2. Date of Search:

V.4.1.3.4. Key Words of Search:
(treadmill* OR forced running) AND ("Rodentia"[Mesh] OR rats OR rat OR rattus) AND (alternative OR substitute OR replace* OR allev*) AND (pain OR distress OR stress OR shock OR motivation)
PubMed 43 hit; Altweb 38 hit

V.4.1.3.5. Results of Search:
No alternative procedure or method, which results in less pain or stress, was available. Habituation and positive-reinforcement are the best approaches for alleviating stress.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification:
High-intensity aerobic exercise training and VO_2 max testing. During the 10 week protocol, the HF-EX and HF-EXCO groups will undergo aerobic exercise training three times/week, consisting of an 18 min warm-up at 40-50% of the animals measured VO_2 max, followed by 6 alternating intervals of 4 min at 85-90% and 2 min at 50% of the animals VO_2 max, serving as an active recovery period (9). This intensity is high, but

serves to reduce the frequency by which the animals need to perform exercise training (i.e., 3 days per week vs. 5 days per week) and still obtain the benefits. Should the animals fail to complete this protocol, the intensity will be reduced (lower speed) and the duration will be increased so that the volume of work performed is similar between all animals. Although not anticipated to occur, if the intensity does need to be reduced, the exercise session will never last longer than 90 min including the warm-up period. Moreover, if the animals fail to run for 5 consecutive sec with electrical stimulation provided (0.5 mA at a frequency of 1 Hz) the exercise session will be terminated. When performing VO_2 max testing (all animals), as described in section V.1., if the animals VO_2 plateaus, or they fail to run for 5 consecutive sec with electrical stimulation, same as above, the test will be terminated. Therefore, whenever an animal cannot perform, the exercise session or test will be terminated.

V.4.2. Prolonged Restraint:
None

V.4.3. Surgery:
V.4.3.1. Pre-surgical Provisions:
No surgeries will be performed.

V.4.3.2. Procedure:

V.4.4. Animal Manipulations:

V.4.4.1. Injections:
Prior to and following the 10 week protocol, and after an overnight fast, 2 g of 99.5% glucose/kg body weight (dissolved in distilled water) will be administered intraperitoneally via a 1-2 mL syringe with a 21 gauge needle.

V.4.4.2. Biosamples:
For the IPGTT conducted before and after the 10 week protocol, 5-10 µL of blood will be collected from the tail vein (time 0) from conscious, restrained rats. The rats will be placed in a restrainer and the tail will be swabbed with alcohol to expose the blood vessel. Finger pressure will be applied approximately 5 cm from the tip of the tail, and a 21-23 gauge butterfly needle will be inserted into the tail vein with blood collected into microvette tube. The total time of restraint will be approximately 1-3 min. For serum lipids, 400 µL of blood will be collected from the lateral saphenous vein into a 500 µL microvette. This sample will be collected at the same time as the first tail vein blood draw (time 0) for the IPGTT to avoid an additional day of fasting and stress. The rats will be placed in a restrainer for no ≥ 5 min; the lower limb will be shaved with an electric razor and swabbed with alcohol to expose the vein prior to puncturing with a 21-23 gauge needle. Upon completion of the protocol, we will collect blood from the left ventricle and tissues (skeletal muscle, brain, heart, lung, liver, brain and epidydmal fat pads) under terminal anesthesia.

V.4.4.3. Adjuvants:
None

V.4.4.4. Monoclonal Antibody (MAbs) Production:
None

V.4.4.5. Animal Identification:
Ear tags and cage cards

V.4.4.6. Behavioral Studies:
None

V.4.4.7. Other Procedures:
None

V.4.4.8. Tissue Sharing:
None

V.4.5. Study Endpoint:
The endpoint for all animals will be up to 10 days following the 10 week protocol to ensure that all post-study data is collected. Although not expected, any animals that are in poor health (i.e., inactive, sign of persistent pain or stress, body weight loss >15%) will be euthanized upon the suggestion of or in consultation with the LAM veterinary staff.

V.4.6. Euthanasia:
Upon completion of experiments, animals will be euthanized with isoflurane for terminal tissue collection.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol. The animals will be housed 2 per cage.

V.5.1.1. Study Room:
Building(s) (b)(6) Room Number(s) (b)(6)

V.5.1.2. Special Husbandry Provisions:

Food Restriction: Yes ___X___ No _____

Fluid Restriction: Yes _____ No ___X___

In order to assess the animal's ability to transport and oxidize glucose, measure fasting serum lipids, and assess resting energy expenditure, the animals must be fasted during their light phase. This will occur on two occasions before, and after the 10 week protocol. On one occasion, blood collection and the IPGTT will be performed, and on the other occasion, resting VO_2 and VCO_2 measurements will be collected. The test diets produced by Harlan (TD.08485 and TD.88137) will be procured by LAM, and provided by the investigators throughout the study. Animals will be housed on a reverse light cycle in order for the investigators to conduct exercise testing and training.

V.5.1.3. Exceptions: N/A

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care:
Animals will be observed and cared for by the Center for LAM personnel according to USUHS Center for LAM SOPs.

V.5.2.2. Emergency Veterinary Medical Care: All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: Except as indicated below, all animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples may include tunnels and nylabones for rats.

V.5.3.2. Enrichment Restrictions:
None

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or	Name of person	Qualifications of person	Specific training in this

procedure (e.g., tail vein injections, euthanasia)	performing activity	performing activity (e.g., research technician, 2 yrs experience)	activity or procedure (e.g., rodent handling class, 1999)
All protocol procedures	(b)(6)	6 yrs experience in rodent research	Attended USUHS investigator training course in 2015
All protocol procedures		>20 yrs experience in rodent research	Attended USUHS investigator training course in 2008
All protocol procedures		>20 yrs experience in rodent research	attended USUHS investigator training course in 2014
IPGTT, blood collection, tail-cuff blood pressure monitoring, exercise training, tissue collection		4.5 yrs experience in rodent research.	Attended USUHS animal handling class and investigator training course in 2011
IPGTT, blood collection, tail-cuff blood pressure monitoring, exercise training, tissue collection		None. Will be trained by the PI and (b)(6)	Attended USUHS animal handling class and investigator training course in 2015
IPGTT, blood collection, tail-cuff blood pressure monitoring, exercise training, tissue collection		None. Will be trained by the PI and (b)(6)	Attended USUHS animal handling class and investigator training course in 2015

VII. BIOHAZARDS/SAFETY:

All personnel handing animals will wear protective gloves, lab coat and mask at all times to minimize exposure to allergens. Personnel will follow universal sharps procedures to reduce risk of injury.

VIII. ENCLOSURES:

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

(b)(6) _____ 14 AUG 2015

Principal Investigator Signature Date

G. Training: The following personnel will attend the next USUHS Investigator/Animal User Training Course:

_____ _____

_____ _____

H. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely, "Responsibility" for implementing animal use alternatives where feasible and conducting humane and lawful research.

(b)(6) _____ 14 AUG 2015

Date

I. Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL or WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

X. PROTOCOL ABSTRACT:

A. Animal Protocol Number:

B. Animal Protocol Title:
Application of low dose inhaled carbon monoxide to attenuate diet-induced obesity and insulin resistance

C. Principal Investigator:
(b)(6)

D. Performing Organization:
Uniformed Services University of the Health Sciences

E. Funding:
USUHS Office of Research (Start-up) and JPC-5 (CANDS)

F. Objective and Approach:
The prevalence of obesity in the U.S. general population and military continues to increase. Obesity increases the risk of developing insulin resistance, diabetes, and cardiovascular disease. Dysregulated mitochondrial function and altered structure have been reported to be associated with obesity related conditions. Low dose inhaled carbon monoxide (CO) has successfully been used to increase the production of new mitochondria, thus may protect against the onset of obesity associated diseases. Obese-prone Sprague Dawley rats will be fed a high-fat diet for 10 weeks and subjected to low dose inhaled CO (250 ppm), high-intensity aerobic exercise training, or both. Measures will include fasting lipids, insulin, and glucose tolerance, blood pressure, resting VO_2 and VCO_2, and VO_2 max testing. Moreover, indicators of skeletal muscle mitochondrial biogenesis and morphology, and respiratory function will be determined. Data will be analyzed using a two-way repeated measures ANOVA. The novelty of this experiment precludes the alternative use of cell culture or simulated models. This research will determine whether low dose inhaled CO is efficacious in preventing diet-induced obesity and insulin resistance in rats by preserving mitochondrial structure and function.

G. Indexing Terms (Descriptors):
Inhaled carbon monoxide, animals, rats, exercise, diet-induced obesity, insulin resistance, skeletal muscle, mitochondrial

MEMORANDUM FOR DR. (b)(6) DEPARTMENT OF MICROBIOLOGY

SUBJECT: IACUC Approval of Protocol – Triennial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on July 12, 2012:

Animal Protocol Title: "Pathogenicity of Shiga Toxin-Producing E.coli and Ricin Intoxication (Mice)"

USUHS Protocol Number: (b)(6)

Expiration Date: July 11, 2015

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. **NON-TECHNICAL SYNOPSIS:** Shiga toxin (Stx)-producing Escherichia coli (STEC) are the causative agent of "hamburger disease" because they are often transmitted through undercooked hamburgers. STEC O157:H7 are food- and water-borne bacteria that are the most common infectious cause of bloody diarrhea in the United States. The hemolytic uremic syndrome (HUS), which can occur as a result of STEC infection, is the most frequent cause of acute kidney failure in U.S. children. The STEC make one or more Stxs (Stx1, Stx2 or variant of those) that are key factors in the development of the HUS. The genes that encode the Stxs are present on bacteriophages, which are viruses that infect *E. coli*; these viruses can infect other bacteria and transfer the toxin genes. Evidence that such transmission may occur became evident in 2011 when a large food-borne outbreak of bloody diarrhea and HUS occurred in Germany. The outbreak isolate was an enteroaggregative *E. coli* strain that had most likely acquired the stx_2 phage from a more typical STEC. Stxs act to halt protein synthesis in the target cell, which causes the cell to die. The goals of the studies described here are as follows: 1) evaluate the potency of different Stxs; 2) determine if the *stx* phage can be transferred from one bacterial strain to another in the intestines; 3) study the role of Stx2 in the unusual disease caused by the German outbreak strain; 4) investigate the systemic effects of ricin; 5) identify host factors that play a role in Stx or *E. coli* disease; and 6) determine if antibodies against Stxs or ricin can protect against exposure to the respective toxin. All of the mouse studies described herein will be performed in full accordance with the Institutional Animal Care and Use Committee at USUHS.

II. BACKGROUND:

II.1. Background: Our experience with Shiga toxins (Stxs), STEC-infection animal models, and ricin that led to this proposal will be briefly reviewed.

Escherichia coli O157:H7 and other Stx-producing E. coli (STEC) cause food- and water-borne outbreaks and sporadic cases of intestinal disease manifest as diarrhea and/or hemorrhagic colitis (bloody diarrhea). About 5-10% of children infected with these agents subsequently develop a sequela called the hemolytic uremic syndrome (HUS) that is characterized by hemolytic anemia, thrombocytopenia, and kidney dysfunction and/or failure. The capacity of STEC to cause bloody diarrhea and HUS derives from the activity of the Stxs. There are two major types of Stxs expressed by *E. coli* associated with human disease: Stx1 and Stx2 (or variants thereof). These cytotoxins block eukaryotic translation and are structurally similar; however, Stx1 and Stx2 differ in relative toxicity both for Vero cells and for mice. Stx2 and its variants are more toxic than Stx1 when injected in pure form into mice or when STEC is fed orally to mice pre-treated with streptomycin (str) to reduce facultative bowel flora or gavaged into mice with an intact commensal flora. We have found that STEC strains that produce a particular variant of Stx2, called Stx2dact, are exquisitely virulent in the str-treated mouse oral challenge model. Furthermore, Stx2dact exhibits increased cytotoxicity or "activation" after incubation with crude mucus isolated from mice or humans or with purified elastase.

We are interested in the contribution of Stx type to disease and will test strains that produce more than one toxin type for virulence in mice and then evaluate the pathogenesis of derivatives of those strains that are mutated in one toxin type. Additionally, the potency of Stx subtypes can be measured by oral gavage or by intraperitoneal or intravenous injection into mice. Studies to determine the relative potency of toxin subtypes are important to estimate the potential virulence of STEC strains in humans. We will examine the virulence of human outbreak strains such as the German O104:H4 isolate in our mouse models to directly ask about the pathogenicity of such isolates. Furthermore, because the O104:H4 strain likely acquired the capacity to produce Stx2 through lysogeny with an stx_2-encoding phage, we will examine if the O104:H4 phage can be transmitted to other bacterial strains within the intestines of mice or if a phage cured derivative of O104:H4 can become lysogenized again with the toxin-encoding phage *in vivo*.

We found that Stx2 has the capacity to enhance STEC colonization in tissue culture and in mice. Stxs bind to globotriaosylceramide (Gb3) on the surface of host cells. In addition, we demonstrated that eukaryotic cells treated with Stx2 exhibit an increase in cell-surface localized nucleolin (a host factor that interacts with intimin, a common STEC adhesin). In the proposed studies, we will characterize the capacity of Stx1 to augment STEC colonization in a manner similar to that of Stx2. In addition, we will address our hypothesis that nucleolin plays a role in the Stx-mediated enhancement of colonization by STEC strains in mice.

Previous studies in our laboratory and others showed that Gb3 expression on host cells is elevated in the presence of butyrate, a metabolite produced by some commensal gut flora. We found that a high fiber diet (10% guar gum) causes an increase in intestinal butyrate levels, which may lead to increased cell surface Gb3 and enhanced Stx binding and transit through the gut. Therefore we will examine the effect

of alterations in the amount of fiber in the mouse diet on susceptibility to toxin alone or to infection with STEC strains.

Our studies in mice have largely been restricted to the outbred CD-1 and inbred BALB/c and C57BL/6 strains. Recently a large number of BXD mouse strains (parental mice = C57BL/6J and DBA/2J) were established that can be used to determine genetic markers that correlate with susceptibility to infection or intoxication. Although many investigators believe that there must be host genetic factors involved in the development of the HUS, we have not previously had a model to ask questions about what those host factors might be. In these studies we plan to assess the relative susceptibility of the BXD mice to intoxication by Stx1 or Stx2, or to colonization by O157 strains that produce either Stx1 or Stx2.

Ricin is a plant toxin that has the same mode of action as the Stxs. No vaccine is currently licensed to protect individuals from infection or disease caused by STEC or from intoxication with ricin. We have begun to develop and test anti-ricin and anti-Stx therapeutics that rely on a) the conjugation of antibody fragments to the cell-binding domain of ricin or Stx; or, b) small molecule inhibitors of ricin (obtained from a collaborator); or, c) morpholino compounds that are either anti-bacterial or will suppress toxin expression from STEC strains. We will examine the protective capacity of the inhibitors in tissue culture and mice.

II.2. Literature Search for Duplication:

II.2.1. Literature Source(s) Searched: Pubmed, Biomedical Research Database, NIH RePORTER

II.2.2. Date of Search: 6-7 May 2012

II.2.3. Period of Search: Pubmed: 1948-present, English filter
Biomedical Research Database: 1998-2009
NIH RePORTER: 1998-2012 active projects

II.2.4. Key Words and Search Strategy:
1. "Shiga toxin OR Verotoxin" AND "mouse OR mice" AND "infection OR intoxication"
2. "Ricin" AND "mouse OR mice" AND "intoxication"

II.2.5. Results of Searches:

Pubmed: "Shiga toxin OR Verotoxin" AND "mouse OR mice" AND "infection OR intoxication"
Results: A total of 150 publications were found. Ten publications are from our laboratory. The remaining studies focused on diagnostics and detection (5 reports), pathogenesis of STEC and Stx (33), host response and interactions with host cells (24), therapeutics (22), antibiotic treatment of STEC infection (12), vaccine development (19), the use of probiotics as alternative therapies (6), epidemiology (1), and topics not relevant to the search (13). Of particular interest are 20 publications that discuss various mouse models to assess STEC infection or Stx intoxication. Two papers investigated the use of *Citrobacter rodentium* strains that cxpress Stx as a means to study the role of Stx in infection. Five of the twenty papers are from our laboratory.

They describe the streptomycin-treated CD-1 mouse model that we use to investigate morbidity and mortality caused by STEC, the intact commensal flora BALB/c mouse model that we use to study the capacity of EHEC strains to colonize the gut, and the CD-1 mouse model of Stx intoxication. An additional six publications used various mouse models to emulate the hemolytic uremic syndrome that is a sequel in humans. Several publications, at least three of which are from our laboratory, demonstrated the capacity of antibodies that neutralize Stx activity to protect against STEC infection. These studies provide a strong foundation to support our studies in Experiment V.1.6., which utilize neutralizing antibodies as components of potential therapies to counter STEC disease.

Pubmed: "Ricin" AND "mouse OR mice" AND "intoxication"
Results: A total of 34 publications were identified, none of which are from our laboratory. The studies focused on vaccines (4), anti-ricin therapeutics (9), detection of ricin (3), ricin toxicity (4), the host response to ricin (3), the mechanism of action of ricin (5), and topics not relevant to the search (5). None of the reports investigated the mechanisms by which ricin transits throughout the body or the novel liposome-receptor-antibody approach that we will test as a therapeutic.

Biomedical Research Database: "Shiga toxin OR Verotoxin" AND "mice OR mouse"
Results: A total of 29 projects were identified and all of them are from our laboratory.

Biomedical Research Database: "Ricin" AND "mouse or mice"
Results: A total of 72 projects were identified in this search, of which four are from our laboratory. The studies focused on bioassays and detection (12), toxicology of ricin (4), a skin patch vaccine (8), recombinant ricin subunit vaccines (18), vaccines that protect against multiple bioweapons (2), and therapeutics and countermeasures to treat ricin exposure (18). Six were deemed irrelevant to the topic of the search. The projects identified in this search do not overlap with our proposed experiments.

NIH RePORTER: "Shiga toxin OR Verotoxin" AND "mice OR mouse"
Results: A total of 22 projects were identified in this search, of which 5 are not relevant. The remaining projects addressed therapeutics (5), innate immunity (2), diagnostics (1), Stx-encoding phage (1), EHEC pathogenesis (5), and animal models of STEC disease (3). None of these projects overlap with our proposed experiments.

NIH RePORTER: "Ricin" AND "mouse or mice"
Results: Ten studies were returned in this search and six were deemed irrelevant to the studies proposed here. Two addressed therapeutics, one related to innate immunity, and one was focused on diagnostics. Our proposed studies do not overlap with the studies identified here.

III. OBJECTIVE\HYPOTHESIS: The goals of the studies outlined in this protocol are 1) to characterize the roles of Shiga toxins in the pathogenesis of EHEC disease; 2) to determine the level of nucleolin expression in the intestine in response to EHEC infection; 3) to assess the contribution of specific diets to the pathogenesis of STEC, 4)

to identify host biomarkers of EHEC disease using advanced recombinant inbred (ARI) mice with defined genotypes; and 5) to measure the safety and efficacy of therapeutic compounds designed to ablate the lethal effects of Stx or ricin.

IV. MILITARY RELEVANCE: *E. coli* O157:H7 and *E. coli* O104:H4 have the potential to simultaneously infect large numbers of people who ingest as few as 100 organisms in common source food- or water-borne outbreaks (examples: July 1996 outbreak in Japan that affected ~10,000 people, 2006 outbreak in the U.S. linked to spinach, 2011 outbreak in Germany linked to fenugreek seeds). In addition, the rate of secondary transmission of *E. coli* O157:H7 is high. Therefore, large-scale infection of soldiers with *E. coli* O157:H7 or another Shiga-toxin producing *E. coli* (STEC) isolate would likely result in an incapacitating illness among troops. Furthermore, Stx and other Stx family members are considered potential biological warfare/terrorist threats as highlighted by the CDC- and DoD-mandated select agent restrictions on use, storage and shipment of Stxs and Stx-expressing clones.

In addition to the Stxs, our laboratory studies ricin, a toxin derived from the castor bean. Ricin is also select agent and is considered to be a potential bioterrorism weapon. Our laboratory has designed potential therapeutics against ricin and will need to test the safety and efficacy of these treatments.

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures: For the majority of the studies proposed here, we will use one of the following mouse models of EHEC infection or Stx or ricin intoxication.

V.1.A. Infection with Enterohemorrhagic *E. coli* (EHEC) to assess virulence: Six- to eight-week-old mice will be given drinking water that contains streptomycin (str, 5 g/liter) or ampicillin (amp, 5-10 g/L) to reduce normal facultative flora. [**Note**: from published studies, we know that after 1 day of str or amp treatment, the number of facultative bacteria drops from about 10^8 to less than 10^2 CFU/g of feces, and the number of anaerobic bacteria remains constant at about 10^9 CFU/g of feces (3, 6).] Mice will then be fasted overnight. An overnight fast is needed to reduce the volume of the stomach contents so that the entire inoculum can be administered. In addition, we have found that mice fed by Pipetman or weigh boat are more likely to ingest the inoculum if they have been fasted. The next morning, groups of five mice will be fed 10^2 to 10^{10} CFU of the *E. coli* strain (str or amp resistant) to be tested in 25-100 µl of 20% sucrose. The oral infection will be accomplished either by holding the mice and allowing them to eat the material as delivered from a Pipetman tip, by placing weigh boats with the inocula in the cages of the animals, or by oral gavage with a 20 gauge, 1 ½" disposable gavage needle. The mice readily ingest the bacterial suspension which is prepared by harvesting the bacteria by centrifugation, washing the bacterial pellet twice in phosphate buffered saline (PBS, pH 7.4), and suspending the washed bacteria in 1 ml of sterile 20% (w/v) sucrose. After inoculation the animals will then be returned to their cages and permitted food and water containing 5 g/liter str or amp *ad libitum*. Mice will be weighed daily and any mice that lose more than 30% of their initial body weight will be euthanized. The endpoint for this study is extreme morbidity or mortality, as defined in Section V.4.5, and the experiment will be continued for 21-28 days. The timing of the

inoculations will be planned such that the majority of the illnesses will occur during normal business hours (0600-1900) to facilitate more frequent monitoring of the animals so as to permit euthanasia as soon as mice are extremely moribund. Death due to infection typically occurs 3-6 days post-inoculation, depending on the EHEC strain used. Inoculations will be done on the morning of the first day of the experiment so as to permit maximum monitoring during the times of day when we typically observe the most deaths. If we observe that more deaths occur between 1900 and 0600 in the experiments described here, we will change the inoculation time such that deaths will occur during the day and/or we will monitor the mice every 4-6 hrs between 1900 and 0600. Mice will be monitored for signs of extreme morbidity (see Section V.4.5 below for definition of extreme morbidity) as described in Section V.3.5.1. Any mice that exhibit extreme morbidity will be euthanized immediately by inhalational isoflurane overdose followed by cervical dislocation.

V.1.B. Infection with EHEC to monitor colonization. Six- to eight-week-old mice will be fasted overnight. An overnight fast is needed to reduce the volume of the stomach contents so that the entire inoculum can be administered. In addition, we have found that mice fed by Pipetman or weigh boat are more likely to ingest the inoculum if they have been fasted. The next morning, groups of five mice will be fed 10^8 to 10^{10} CFU of the *E. coli* strain to be tested in 25-100 µl of 20% sucrose. The oral infection will be accomplished either by holding the mice and allowing them to eat the material as delivered from a Pipetman tip, by placing weigh boats with the inocula in the cages of the animals, or by oral gavage with a disposable gavage needle. Once the mice are fed, they will be returned to their cages and allowed food and water *ad libitum*. Mice orally inoculated in this way may be further monitored in the following ways: 1) the morbidity due to O157 infection will be assessed through observation of physical symptoms (Section V.3.5.1), 2) the degree to which a given strain colonizes the intestine will be determined by the number of CFU that persist in the feces for up to 14 days after infection (mice will be placed individually into empty cages and approximately 1 g of feces will be collected, homogenized in 10 ml of 1% PBS, and 10-fold serial dilutions of the homogenate prepared and plated on agar media that contains the appropriate antibiotics); 3) bacteremia will be monitored by enumeration of bacteria in the blood (blood will be collected either once by tail vein bleed, or, if the mice are to be euthanized for tissue collection, blood will be collected immediately after the mice are euthanized); and/or 4) specific sites of colonization and/or toxin localization will be determined by examining tissues collected from infected animals. Mice will be weighed daily and any mice that lose more than 30% of their initial body weight will be euthanized. The endpoint for this study is euthanasia 7-21 days post-inoculation. While we do not anticipate significant morbidity or mortality in these mice, the mice will be monitored for signs of extreme morbidity (see Section V.4.5 below for definition of extreme morbidity) as described in Section V.3.5.1. Any mice that exhibit extreme morbidity will be euthanized immediately by inhalational isoflurane overdose followed by cervical dislocation. Death due to infection in this model is uncommon, but occurs 3-6 days post-inoculation.

V.1.C. Intoxication with Stx or ricin. Six to eight week old male or female mice will be intoxicated by i.p. injection of Stx or ricin in sterile phosphate-buffered saline using a 26

gauge needle attached to a tuberculin syringe or by oral gavage with a 20 gauge 1.5" gavage needle. Mice will be weighed daily and any mice that lose more than 30% of their initial body weight will be euthanized. The endpoint for this study is extreme morbidity or mortality, and the experiment will be continued for 14-21 days. The timing of the inoculations will be planned such that the majority of the illnesses will occur during normal business hours (0600-1900) to facilitate more frequent monitoring of the animals so as to permit euthanasia as soon as mice are extremely moribund. Death due to intoxication typically occurs 2-3 days post-inotoxication. Inoculations will be done on the morning of the first day of the experiment so as to permit maximum monitoring during the times of day when we typically observe the most deaths. If we observe that more deaths occur between 1900 and 0600 in the experiments described here, we will change the inoculation time such that deaths will occur during the day and/or we will monitor the mice every 4-6 hrs between 1900 and 0600. Mice will be monitored for signs of extreme morbidity (see Section V.4.5 below for definition of extreme morbidity) as described in Section V.3.5.1. Any mice that exhibit extreme morbidity will be euthanized immediately by inhalational isoflurane overdose followed by cervical dislocation.

V.1.1. Experiment 1. Characterization of the roles of Shiga toxin variants in the pathogenesis of STEC disease. Our EHEC virulence (V.1.A) model and our EHEC colonization model (V.1.B) will be used to investigate the involvement of Stx variants in the pathogenesis of STEC-mediated disease.

V.1.1.1. Assessment of the impact of Stx2dact versus Stx2c on STEC virulence when the toxins are expressed in otherwise isogenic backgrounds. We previously demonstrated that STEC B2F1, a strain that produces Stx2dact, exhibits enhanced virulence in our mouse model of STEC infection. Stx2dact is the most potent form of Stx2, and we theorize that the increased activity of this toxin variant is due to the fact that it is activated by intestinal mucus. One hypothesis that we will test in aim #2 of our NIH grant is whether a derivative of strain B2F1 that produces Stx2c (Stx2c is less potent than Stx2dact on tissue culture cells), rather than Stx2dact, is attenuated in str-treated CD-1 mice. Our second mouse virulence study will compare EHEC strain 86-24 (Stx2+) to 86-24 making Stx2dact. *These latter studies, in which 86-24 producing Stx2dact will be tested for virulence in mice, will be done in the ABSL-3 Suite once the Suite is available, as requested by the Division of Select Agents and Toxins at the CDC* (see attached letter, enclosure 2).

These studies will be performed exactly as described in V.1.A above.

V.1.1.1.1: Investigation of contribution of Stx2c to B2F1 virulence.
Group 1: 5 mice at 10^1 CFU B2F1
Group 2: 5 mice at 10^2 CFU B2F1
Group 3: 5 mice at 10^4 CFU B2F1
Group 4: 5 mice at 10^6 CFU B2F1
Group 5: 5 mice at 10^1 CFU B2F1 making Stx2c only
Group 6: 5 mice at 10^2 CFU B2F1 making Stx2c only
Group 7: 5 mice at 10^4 CFU B2F1 making Stx2c only

Group 8: 5 mice at 10^6 CFU B2F1 making Stx2c only
Group 9: 5 mice at 10^8 CFU B2F1 making Stx2c only
Group 10: 5 mice at 10^{10} CFU B2F1 making Stx2c only

5 mice/group x 10 groups x 4 iterations = 200 CD-1 mice

V.1.1.1 2: Investigation of contribution of Stx2dact to 86-24 virulence.
Group 1: 5 mice at 10^8 CFU 86-24
Group 2: 5 mice at 10^{10} CFU 86 24
Group 3: 5 mice at 10^2 CFU 86-24 making Stx2dact only
Group 4: 5 mice at 10^4 CFU B2F1 making Stx2dact only
Group 5. 5 mice at 10^6 CFU B2F1 making Stx2dact only
Group 6: 5 mice at 10^8 CFU B2F1 making Stx2dact only
Group 7: 5 mice at 10^{10} CFU B2F1 making Stx2dact only

5 mice/group x 7 groups x 4 iterations – 140 CD-1 mice

Total number of mice (V.1.1): 200 + 140 = 340 CD-1 mice

V.1.1.2. Feeding of novel Stx2dact-producing strains to mice. Our laboratory is involved in an ongoing characterization of STEC isolates identified in California or locally. When we identify an isolate that makes Stx2dact, the IACUC will be notified. We will assess the virulence of that isolate in male CD-1 mice at doses of 10^4 to 10^{10} CFU/mouse. We may receive up to 5 such strains/year. CD-1 mice will be inoculated orally with each strain as described in V.1.A.

Group 1: 5 mice at 10^4 CFU
Group 2: 5 mice at 10^6 CFU
Group 3: 5 mice at 10^8 CFU
Group 4: 5 mice at 10^{10} CFU

5 mice/group x 4 groups x 5 strains/year x 3 years = ***300 CD-1 mice***

V.1.1.3. Assessment of virulence of STEC outbreak isolates. Our laboratory is uniquely poised to rapidly characterize the virulence of STEC isolates recovered during outbreaks with our currently approved procedures or modifications thereof. In studies approved as a major modification to (b)(6) we recently developed a new mouse model of infection for the unique *E. coli* O104:H4 strain (C227 11) that caused a serious STEC outbreak linked to contaminated fenugreek seeds that occurred in Germany in May 2011. When we receive a new outbreak isolate, we will assess the virulence of that isolate in our str treated male CD-1 mouse model (V.1.A) and we will investigate the capacity of the strain to colonize the gut in our ICF BALB/c mouse model (V.1.B). In our extensive experience with these models, we have found that a minimum of four experiments with each mouse model is necessary to accurately compare the virulence of each outbreak strain to that of our prototype STEC strains 86-24 or B2F1. Additional

studies will be necessary to characterize the role of Stx(s) in the capacity of each strain to colonize the gut and to cause disease. We may receive up to 3 such strains/year.

V.1.1.3.1: Infection of str-treated CD-1 mice with outbreak strain to assess virulence.
Group 1: 10 mice infected with 10^{10} CFU 86-24 or 10^{6} CFU B2F1
Group 2: 10 mice infected with 10^{6} CFU outbreak strain
Group 3: 10 mice infected with 10^{8} CFU outbreak strain
Group 4: 10 mice infected with 10^{10} CFU outbreak strain

10 mice/group x 4 groups x 4 iterations x 3 strains/year x 3 years = 1440 male CD-1 mice

V.1.1.3.2: Infection of str-treated CD-1 mice with Stx- derivative(s) of outbreak strain to assess contribution of Stx to virulence.
Group 1: 10 mice infected with lethal dose of outbreak strain identified above
Group 2: 10 mice infected with same dose of Stx-negative derivative of outbreak strain

10 mice/group x 2 groups x 4 iterations x 3 strains/year x 3 years = 720 male CD-1 mice

V.1.1.3.3: Infection of ICF BALB/c mice with outbreak strain to assess colonization of the gut.
Group 1: 10 mice infected with 10^{10} CFU 86-24 or 10^{6} CFU B2F1
Group 2: 10 mice infected with 10^{10} CFU outbreak strain

10 mico/group x 2 groups x 4 iterations x 3 strains/year x 3 years = 720 BALB/c ***mice***

V.1.1.3.4: Infection of ICF BALB/c mice with Stx- derivative(s) of outbreak strain to assess the contribution of Stx to colonization of the gut.
Group 1: 10 mice infected with 10^{10} CFU outbreak strain
Group 2: 10 mice infected with 10^{10} CFU of Stx-negative derivative of outbreak strain

10 mice/group x 2 groups x 4 iterations x 3 strains/year x 3 years = 720 BALB/c ***mice***

Total number of mice (V.1.3)
1440 + 720 = 2160 male CD-1 mice
720 + 720 = 1440 female BALB/c mice

V.1.1.4. Characterization of roles of each Stx variant in STEC disease caused by strains that encode more than one Stx. Some STEC strains encode for and produce more than one Stx. To investigate the contribution of each Stx variant to colonization and pathogenesis, we will challenge mice with the parent strain or isogenic strains that do not produce one or both Stx variants. The strains that we will test in our str-treated CD-1 virulence model (V.1.A) and in our ICF BALB/c model (V.1.B) are as follows:

- 933 (Stx1, Stx2) and isogenic derivatives that are Stx1-Stx2+, Stx1+Stx2-, Stx1-Stx2-;
- B2F1 (Stx2dact1, Stx2dact2) and its isogenic derivatives that are Stx2dact1-Stx2dact2+, Stx2dact1+Stx2dact2-, Stx2dact1-Stx2dact2-;
- K3995 (Stx2, Stx2c) and its isogenic derivatives that are Stx2-Stx2c+, Stx2+Stx2c-, Stx2-Stx2c-

V.1.1.4.1. Infection of str-treated CD-1 mice to assess virulence of Stx-derivatives.
Group 1: 10 mice infected with lethal dose of parent strain
Group 2: 10 mice infected with same dose of parent strain missing one Stx
Group 3: 10 mice infected with same dose of parent strain missing the other Stx
Group 4: 10 mice infected with same dose of parent strain missing both Stxs

10 mice/group x 4 groups x 4 iterations x 3 parent strains = ***480 male CD-1 mice***

V.1.1.4.2: Infection of ICF BALB/c mice to assess capacity of Stx- derivative(s) to colonize the gut.
Group 1: 10 mice infected with parent strain
Group 2: 10 mice infected with same dose of parent strain missing one Stx
Group 3: 10 mice infected with same dose of parent strain missing the other Stx
Group 4: 10 mice infected with same dose of parent strain missing both Stxs

10 mice/group x 4 groups x 4 iterations x 3 parent strains = ***480 BALB/c mice***

V.1.1.4.3: Infection of ICF BALB/c mice to determine the site of colonization of parent strain and Stx- derivatives.
Group 1: 10 mice infected with parent strain
Group 2: 10 mice infected with same dose of parent strain missing one Stx
Group 3: 10 mice infected with same dose of parent strain missing the other Stx
Group 4: 10 mice infected with same dose of parent strain missing both Stxs

10 mice/group x 4 groups x 2 iterations x 3 parent strains = ***240 BALB/c mice***

Total number of mice (V.1.1.4)
480 male CD-1 mice
480 + 240 = 720 female BALB/c mice

Total number of mice for V.1.1:
340 + 300 + 2160 + 480 = 3280 male CD-1 mice
1440 + 720 = 2160 female BALB/c mice

V.1.2. Experiment 2: Investigation of the role of a high fiber diet in STEC pathogenesis. Previous studies in our laboratory and others showed that the receptor for Stxs *in vitro* and *in vivo* is Gb3, which is on the surface of host cells in the intestines and kidney. Gb3 expression on host cells is elevated in the presence of butyrate, a metabolite produced by some commensal gut flora. We recently found that a high fiber diet (10% guar gum) causes an increase in intestinal butyrate levels, which may lead to increased cell surface Gb3 and enhanced Stx binding and transit through the gut. To test this hypothesis, we will employ a modified version of our BALB/c ICF model (V.1.B). Fourteen days prior to challenge with 86-24 (produces Stx2) or its isogenic Stx2-derivative TUV86-2, mouse chow will be changed from the standard diet provided by LAM (3.5% plant fiber) to custom diets from (b)(4) that contain either 2% guar gum (low fiber) or 10% guar gum (high fiber) as the sole fiber source. In some experiments, 5 µM butyrate will be co-injected with the inoculum (EHEC or Stx). In other experiments, mice will be challenged with derivatives of 86-24 and TUV86-2 that express green fluorescent protein (GFP) or red fluorescent protein (RFP) to permit *in vivo* imaging with our Carestream Multispectral FX Pro *in vivo* imaging system. The Carestream Multispectral FX Pro has a large dynamic range and a highe signal:noise ratio for fluorescence; in addition, it has x-ray capability that permits more accurate signal localization. At each time point, up to five mice will be anesthetized with isoflurane and placed on a heated platform within the imaging box of the Carestream Multispectral FX Pro for imaging as described in Section V.4.1.2.1.

V.1.2.1: Infection of mice fed custom diets to assess colonization, adherence, Gb3 expression, and/or Stx binding, and to characterize the mouse intestinal microbiome. Female BALB/c mice will be fed a low fiber or a high fiber diet for 14 days prior to challenge by oral gavage with 86-24 or TUV86-2 as described in V.1.B above. In some studies, colonization of the gut will be assessed daily for up to 14 days by bacterial enumeration of homogenized fecal samples. In other studies, mice will be euthanized at specific times post-challenge and intestines and kidneys will be harvested for immunohistochemistry and/or fluorescent microscopy.

V.1.2.1.1: Intestinal colonization of mice fed custom diets and challenged with EHEC.
Group 1: 10 mice, low fiber diet, 86-24 challenge
Group 2: 10 mice, high fiber diet, 86-24 challenge
Group 3. 10 mice, low fiber diet, TUV86-2 challenge
Group 4: 10 mice, high fiber diet, TUV86-2 challenge

10 mice/group x 4 groups x 3 iterations = 120 female BALB/c mice

V.1.2.1.2: Harvest of tissues from mice fed custom diets and challenged with EHEC. Mice will be fed one of the two diets for 14 days, challenged with 86-24 or TUV86-2 (or their GFP-expressing derivatives), and euthanized 6 h, 24 h, 48 h, 72 h, 96 h, 120 h, and 168 h post-inoculation. Intestines and kidneys will be harvested and prepared for immunohistochemistry.

Group 1: 5 mice, low fiber diet, 86-24 challenge
Group 2: 5 mice, high fiber diet, 86-24 challenge
Group 3: 5 mice, low fiber diet, TUV86-2 challenge
Group 4: 5 mice, high fiber diet, TUV86-2 challenge

10 mice/group x 4 groups x 7 time points x 2 iterations = 560 female BALB/c mice

V.1.2.1.3: Characterization of the mouse intestinal microbiome in mice fed custom diets and challenged with STEC. We will use Illumina sequencing of fecal 16S rDNA from mice fed high or low fibers diets to assess the effects of diet and STEC on the microbiome. Fecal samples will be collected from mice daily for 14 days prior to and 14 days after challenge with 86-24 or sterile saline
Group 1: 8 mice, low fiber diet, sterile saline challenge
Group 2: 8 mice, high fiber diet, sterile saline challenge
Group 3: 8 mice, low fiber diet, 86-24 challenge
Group 4: 8 mice, high fiber diet, 86-24 challenge

8 mice/group x 4 groups x 2 iterations = 64 female BALB/c mice

Total number of mice (V.1.2.1) = 120 + 560 = 64 = 744 female BALB/c mice

V.1.2.2. Use of an intestinal loop model to assess EHEC adherence to intestinal epithelium, Stx binding to Gb3, Stx transit through the intestinal epithelium, nucleolin redistribution to the epithelial cell surface, and Stx-mediated induction of apoptosis. An intestinal loop model will be used to investigate direct interactions between EHEC, Stx, and the intestinal epithelium. The procedure that we will use is a modification of a protocol that was described by (b)(6) *et al.* for analysis of the effects of *Clostridium perfringens* epsilon toxin on different segments of the intestines (2). The procedure is described in detail in Section V.4.3.2. In brief, female BALB/c mice will be anesthetized and their peritoneal cavities will be exposed. The intestines will be removed and loops will be formed. EHEC, Stx, and/or butyrate will be injected into the loops, the intestines will be placed back into the peritoneum, and the incision will be closed with sutures. Topical and general analgesia will be provided during the 6 hour time course of the study. All procedures will be conducted in a certified Biosafety Cabinet in our satellite animal room. (b)(6) At the study endpoint, mice will be euthanized by an overdose of inhaled isoflurane followed by cervical dislocation and intestines will be harvested for further analysis.

1.2.2.1. Inoculation of intestinal loops with EHEC strains 86-24 or TUV86-2. Each group will include 5 mice inoculated with 86-24, 5 mice inoculated with TUV86-2, and 2 mice inoculated with sterile saline in a particular intestinal site, for a total of 12 mice per ligature site.

Group 1: 12 mice with loop in duodenum/jejunum
Group 2: 12 mice with loop in ileum
Group 3: 12 mice with loop in cecum

Group 4: 12 mice with loop in ascending colon
Group 5: 12 mice with loop in distal colon

*12 mice/group x 5 groups x 3 iterations = **180 female BALB/c mice***

1.2.2.2: Inoculation of intestinal loops with Stx1 or Stx2. Each group will include 5 mice inoculated with 500 ng Stx1, 5 mice inoculated with 500 ng Stx2, and 2 mice inoculated with sterile saline in a particular intestinal site, for a total of 12 mice per ligature site.

Group 1: 12 mice with loop in duodenum/jejunum
Group 2: 12 mice with loop in ileum
Group 3: 12 mice with loop in cecum
Group 4: 12 mice with loop in ascending colon
Group 5: 12 mice with loop in distal colon

*12 mice/group x 5 groups x 3 iterations = **180 female BALB/c mice***

1.2.2.3: Inoculation of intestinal loops with butyrate and EHEC strain 86-24. Each group will include 5 mice inoculated with 86-24, 5 mice inoculated with 5 µM butyrate diluted in sterile saline + 86-24, and 2 mice inoculated with 5 µM butyrate diluted in sterile saline in a particular intestinal site, for a total of 12 mice per ligature site.

Group 1: 12 mice with loop in duodenum/jejunum
Group 2: 12 mice with loop in ileum
Group 3: 12 mice with loop in cecum
Group 4: 12 mice with loop in ascending colon
Group 5: 12 mice with loop in distal colon

*12 mice/group x 5 groups x 3 iterations = **180 female BALB/c mice***

1.2.2.4: Inoculation of intestinal loops with butyrate and Stx1 or Stx2. Each group will include 5 mice inoculated with 500 ng Stx1 or Stx2, 5 mice inoculated with 5 µM butyrate diluted in sterile saline + 500 ng Stx1 or Stx2, and 2 mice inoculated with 5 µM butyrate diluted in sterile saline in a particular intestinal site, for a total of 12 mice per ligature site.

Group 1: 12 mice with loop in duodenum/jejunum
Group 2: 12 mice with loop in ileum
Group 3: 12 mice with loop in cecum
Group 4: 12 mice with loop in ascending colon
Group 5: 12 mice with loop in distal colon

*12 mice/group x 5 groups x 2 toxins x 3 iterations = **360 female BALB/c mice***

Total number of mice (V.1.2.2) = 180 + 180 + 180 + 360 = 900 female BALB/c mice

Total number of mice (V.1.2) = 744 + 900 = 1644 female BALB/c mice

V.1.3. Experiment 3: Acute intoxication with Stxs. We recently optimized our mouse models of acute Stx intoxication after i.p. or oral administration of purified toxin. We will intoxicate mice via the i.p. or oral routes to confirm our preliminary LD_{50} observations. In addition, we will intoxicate mice with fluorescently-labeled Stx and use *in vivo* imaging to monitor Stx transit through the mouse after oral intoxication.

V.1.3.1. Intraperitoneal administration of Stx variants to calculate LD_{50} values. Stx variants will be administered to BALB/c mice via i.p. injection with a 26 gauge needle attached to a tuberculin syringe. Mice will be closely monitored for morbidity and mortality, and any mice that exhibit two or more signs of morbidity will be euthanized by isoflurane overdose followed by cervical dislocation. We will determine the i.p. LD_{50} for Stx2c, buffer-treated (BT)-Stx2dact, and elastase-treated (ET)-Stx2dact. One group of mice intoxicated with 5 LD_{50} of Stx2 (5 ng) will serve as the positive control group in each experiment. The LD_{50} will be calculated with Probit analysis.

V.1.3.1.1: Intraperitoneal administration of Stx2 and Stx2c

Group 1: 5 mice at 10 ng Stx2
Group 2: 5 mice at 0.5 ng Stx2c
Group 3: 5 mice at 1 ng Stx2c
Group 4: 5 mice at 2 ng Stx2c
Group 5: 5 mice at 5 ng Stx2c
Group 6: 5 mice at 10 ng Stx2c
Group 7: 5 mice at 20 ng Stx2c
Group 8: 5 mice at 50 ng Stx2c

5 mice/group x 8 groups x 2 iterations = 80 BALB/c mice

V.1.3.1.2: Intraperitoneal administration of Stx2, BT-Stx2dact, and ET-Stx2dact.

Group 1: 5 mice at 10 ng Stx2
Group 2: 5 mice at 0.5 ng BT-Stx2dact
Group 3: 5 mice at 1 ng BT-Stx2dact
Group 4: 5 mice at 2 ng BT-Stx2dact
Group 5: 5 mice at 5 ng BT-Stx2dact
Group 6: 5 mice at 10 ng BT-Stx2dact
Group 7: 5 mice at 0.5 ng ET-Stx2dact
Group 8: 5 mice at 1 ng ET-Stx2dact
Group 9: 5 mice at 2 ng ET-Stx2dact
Group 10: 5 mice at 5 ng ET-Stx2dact
Group 11: 5 mice at 10 ng ET-Stx2dact

5 mice/group x 11 groups x 2 iterations = 110 BALB/c mice

Total number of mice (V.1.3.1) = 80 + 110 = 190 female BALB/c mice

V.1.3.2. Oral gavage of Stx variants to calculate LD_{50} values. Stx variants will be administered via oral gavage as in V.1.A above and mice will be closely monitored for morbidity and mortality. Any mice that exhibit two or more signs of morbidity will be euthanized by isoflurane overdose followed by cervical dislocation. We will determine the oral LD_{50} for Stx2c, buffer-treated (BT)-Stx2dact, and elastase-treated (ET)-Stx2dact. One group of mice intoxicated with 5 LD_{50} of Stx2 (17 µg) will serve as the positive control group in each experiment.

V.1.3.2.1: Oral gavage of Stx2 and Stx2c
Group 1: 5 mice at 17 µg Stx2
Group 2: 5 mice at 5 µg Stx2c
Group 3: 5 mice at 10 µg Stx2c
Group 4: 5 mice at 20 µg Stx2c
Group 5: 5 mice at 50 µg Stx2c
Group 6: 5 mice at 100 µg Stx2c

5 mice/group x 6 groups x 2 iterations = 60 BALB/c mice

V.1.3.2.2: Oral gavage of Stx2, BT-Stx2dact, and ET-Stx2dact.
Group 1: 5 mice at 17 µg Stx2
Group 2: 5 mice at 2 µg BT-Stx2dact
Group 3: 5 mice at 5 µg BT-Stx2dact
Group 4: 5 mice at 10 µg BT-Stx2dact
Group 5: 5 mice at 20 µg BT-Stx2dact
Group 6: 5 mice at 50 µg BT-Stx2dact
Group 7: 5 mice at 2 µg ET-Stx2dact
Group 8: 5 mice at 5 µg ET-Stx2dact
Group 9: 5 mice at 10 µg ET-Stx2dact
Group 10: 5 mice at 20 µg ET-Stx2dact
Group 11: 5 mice at 50 ng ET-Stx2dact

5 mice/group x 11 groups x 2 iterations = 110 BALB/c mice

Total number of mice (V.1.3.2): 60 + 110 = 170 BALB/c mice

V.1.3.3: *in vivo imaging of BALB/c mice orally intoxicated with Stx2.* We hypothesize that Stx2 travels from the stomach to the small intestine, where it can transit across the epithelium and enter the bloodstream. Once in the circulation, Stx2 travels to the kidney and binds to its receptor Gb3 on the surface of kidney cells. Intoxication studies with fluorescently-labeled Stx2 are needed to investigate the sites in the body to which the toxin travels and the mechanism by which Stx2 binds to and transits through the gastrointestinal epithelium. Female BALB/c mice will be orally intoxicated with 1 LD_{50} Stx and imaged throughout the course of the study in our Carestream Multispectral FX Pro *in vivo* imaging system. At specific time points, mice will be euthanized and organs will be imaged *ex vivo* prior to harvest and fixation for immunohistochemistry and immunofluorescence.

Group 1: 5 mice, 1 LD_{50} Stx2, euthanize 4 h post-intoxication
Group 2: 5 mice, 1 LD_{50} Stx2, euthanize 8 h post-intoxication
Group 3: 5 mice, 1 LD_{50} Stx2, euthanize 12 h post-intoxication
Group 4: 5 mice, 1 LD_{50} Stx2, euthanize 24 h post-intoxication
Group 5: 5 mice, 1 LD_{50} Stx2, euthanize 48 h post-intoxication
Group 6: 5 mice, 1 LD_{50} Stx2, euthanize 72 h post-intoxication
Group 7: 5 mice, 1 LD_{50} Stx2, euthanize 96 h post-intoxication

5 mice/group x 7 groups x 3 iterations = 105 female BALB/c mice

Total number of mice (V.1.3) = 190 + 170 + 105 = 465 female BALB/c mice

V.1.4. Experiment 4: Characterization of the virulence of C227-11, an O104:H4 STEC outbreak strain. C227-11 is an enteroaggregative *E. coli* (EAEC) strain that acquired the *stx2* phage. EAEC strains typically form biofilms in the host intestines and cause mild to moderate colitis. Acquisition of the *stx2* phage and subsequent expression of Stx2 conferred upon C227-11 unique properties of both EAEC and STEC strains. In studies approved as a major modification to (b)(6) we developed a mouse model of C227-11 virulence in which C57BL/6 mice are inoculated by oral gavage and treated with ampicillin (amp) in their water beginning 4 h after challenge (C227-11 is naturally amp-resistant). Infected mice lose up to 25% of their body weight throughout the 28 day infection, though only ~50% succumb to the infection. In the studies proposed here, we will identify the site of C227-11 colonization in the mouse gut, assess the virulence of phage-cured and *stx2*- derivatives of C227-11, and determine whether transmission of *stx*-encoding phages occurs *in vivo*. All of the studies in Experiment 4 will be conducted as described in V.1.A above with two modifications. Six to eight week-old female C57BL/6 mice will be used in place of male CD-1 mice. In addition, mice will be treated with 10 g/L amp rather than str, and the amp-water treatment will commence 4 hrs after challenge rather than the day before.

V.1.4.1. Oral infection of C57BL/6 mice with C227-11 to determine the site of colonization in the gut. Five mice per group will be challenged by oral gavage with C227-11. One group of mice each will be euthanized at 3 h, 6 h, 12 h, 24 h, 48 h, 72 h, 96 h, and 120 h. Intestines will be harvested and bacteria in each compartment will be enumerated.
Group 1: 5 mice, euthanized at 3 h
Group 2. 5 mice, euthanized at 6 h
Group 3: 5 mice, euthanized at 12 h
Group 4. 5 mice, euthanized at 24 h
Group 5: 5 mice, euthanized at 48 h
Group 6. 5 mice, euthanized at 72 h
Group 7: 5 mice, euthanized at 96 h
Group 8: 5 mice, euthanized at 120 h

*5 mice/group x 8 groups x 2 iterations = **80 female C57BL/6 mice***

V.1.4.2. Assessment of the contribution of Stx2 to the pathogenesis of C227-11. The intensity of infection and the frequency of HUS in the 2011 C227-11 outbreak suggest that Stx2 contributed significantly to the severity of disease. To test this hypothesis, we will infect 6 to 8 week-old C57BL/6 mice orally by gavage or pipet feeding with C227-11, a phage-cured derivative of C227-11, or a *stx2* deletion mutant of C227-11. Colonization will be monitored by bacterial enumeration of homogenized fecal samples collected daily. Morbidity and mortality will be monitored regularly and mice that exhibit two or more signs of morbidity will be euthanized by isoflurane overdose and cervical dislocation.
Group 1: 10 mice inoculated with C227-11
Group 2: 10 mice inoculated with phage-cured C227-11
Group 3: 10 mice inoculated with *stx2* deletion mutant of C227-11

10 mice/group x 3 groups x 4 iterations = ***120 female C57BL/6 mice***

V.1.4.3. Transmission of *stx2* phages *in vivo*. Evolutionary studies of EAEC strains suggest that the *stx2* phage in C227-11 (ΦO104) was acquired from an O157 EHEC strain that contains a *stx2* phage (ΦO157). To test the transmissibility of the phages *in vivo*, we will infect C57BL/6 mice with one of the following three pairs of strains in which the phage contains a gene the encodes kanamycin (kan) resistance (donor first, recipient second): amp-resistant C227-11 and str-resistant *E. coli* K-12, amp-resistant C227-11 and phage-cured str-resistant 86-24, and str-resistant 86-24 and phage-cured amp-resistant C227-11. The experiments will be conducted with and without a dose of ciprofloxacin (cipro) that is sublethal to the bacteria. A sublethal dose of cipro, which is a dose of cipro that will kill some but not all of the bacteria, has been shown to induce excision of the phage from the bacterial chromosome and formation of new virions that could be transferred to other bacteria. A dose of 40 µg cipro or saline will be administered i.p. in a volume of 0.1 ml with a 26 gauge needle attached to a tuberculin syringe on days 2, 3, 4, and 5 post-inoculation (7). Fecal samples will be collected daily and plated on media selective for the donor, the recipient, and any kan-resistant recipients (indicates transmission of the phage from donor to recipients).

V.1.4.3.1: Transmission of ΦO104 from C227-11 to E. coli K-12.
Group 1: 5 mice inoculated with C227-11, treated with saline
Group 2: 5 mice inoculated with *E. coli* K-12, treated with saline
Group 3: 10 mice inoculated with equal doses of C227-11 and *E. coli* K-12, treated with saline
Group 4: 5 mice inoculated with C227-11, treated with cipro
Group 5: 5 mice inoculated with *E. coli* K-12, treated with cipro
Group 6: 10 mice inoculated with equal doses of C227-11 and *E. coli* K-12, treated with cipro

[(5 mice/group x 4 groups) + (10 mice/group x 2 groups)] x 3 iterations = 120 female C57BL/6 mice

V.1.4.3.2. Transmission of ΦO104 from C227-11 to phage-cured 86-24
Group 1: 5 mice inoculated with C227-11, treated with saline
Group 2: 5 mice inoculated with phage-cured 86-24, treated with saline
Group 3: 10 mice inoculated with equal doses of C227-11 and phage-cured 86-24, treated with saline
Group 4: 5 mice inoculated with C227-11, treated with cipro
Group 5: 5 mice inoculated with phage-cured 86-24, treated with cipro
Group 6: 10 mice inoculated with equal doses of C227-11 and phage-cured 86-24, treated with cipro

[(5 mice/group x 4 groups) + (10 mice/group x 2 groups)] x 3 iterations = 120 female C57BL/6 mice

V.1.4.3.3. *Transmission of ΦO157 from 86-24 to phage-cured C227-11.*
Group 1: 5 mice inoculated with 86-24, treated with saline
Group 2: 5 mice inoculated with phage-cured C227-11, treated with saline
Group 3: 10 mice inoculated with equal doses of 86-24 and phage-cured C227-11, treated with saline
Group 4: 5 mice inoculated with 86-24, treated with cipro
Group 5: 5 mice inoculated with phage-cured C227-11, treated with cipro
Group 6: 10 mice inoculated with equal doses of 86-24 and phage-cured C227-11, treated with cipro

[(5 mice/group x 4 groups) + (10 mice/group x 2 groups)] x 3 iterations = 120 female C57BL/6 mice

Total number of mice (V.1.4.3) = 120 + 120 + 120 = 360 female C57BL/6 mice

Total number of mice (V.1.4): 80 + 120 + 360 = 560 C57BL/6 mice

V.1.5. Experiment 5: Identification of host biomarkers that play a role in STEC and/or Stx-mediated disease. The purpose of these studies is to identify potential host factors that are involved in the pathogenesis of STEC infections. We will use 49 strains of advanced recombinant inbred (ARI) mice for detailed and high throughput systems genetics and systems biology studies of host interactions with STEC. These mice offer the most robust and practical means to identify networks of genes and pathways involved in regulating the host response. The mice, called BXD mice, result from crosses of C57BL/6 and DBA2/J mice for several generations, then backcrosses of the progeny to generate genetic mosaic mice. The genome sequences of the parent strains are known, as are the locations of the crossovers for each strain of BXD mice. Thus, this panel of mice can be used to identify specific traits that are linked to host susceptibility to Stx intoxication and/or EHEC infection. The BXD mice to be used in these studies will be obtained from Dr. (b)(6) at the (b)(6) or from (b)(4) In addition, we will continue our studies to investigate the role of Carcinoembryonic Antigen (CEA) in the pathogenesis of STEC infection. CEA is a protein expressed by human mucosal epithelial cells; the gene that encodes CEA is not present in mice. CEA Tg mice are more susceptible to colonization of mucosal

surfaces by bacteria. The increased susceptibility occurs because CEA suppresses exfoliation of mucosal epithelial cells, which are the site of attachment for mucosal pathogens, including *E. coli* O157:H7. We hypothesize that CEA Tg mice will be colonized more efficiently by *E. coli* O157:H7 because the mucosal cells to which the bacteria have attached will not be exfoliated as much as mucosal cells from wild-type mice.

V.1.5.1. Initial screen to identify host biomarkers involved in colonization of the gut with EHEC. We tested colonization in 25 strains of BXD mice as part of MIC-09-137. A minimum of 30 strains of mice need to be infected before quantitative trait loci (QTL) linked to colonization can be identified. Groups of 3 C57BL/6J, DBA/2J, or different strains of BXD mice will be infected orally with 86-24 ($Stx2^+$) or TUV86-2. Colonization of the intestines will be monitored daily by collection of feces and enumeration of the CFU present in the feces. In addition, mice will be monitored for bacteremia 7 days post-inoculation by blood collection from the tail vein followed by enumeration of bacteria in the blood. We do not expect to find bacteremia; however, one group reported that EHEC-infected mice may become septicemic, a finding that we have not duplicated.

V.1.5.1.1. Final preliminary experiments to generate sufficient data for QTL mapping. A minimum of 10 mice from each BXD strain need to be infected prior to QTL mapping, and we have not reached that threshold with some strains of BXD mice. We anticipate the need to conduct 5 additional experiments, described below, to complete our initial screen.

Group 1: 3 C57BL/6J mice
Group 2: 3 DBA/2J mice
Groups 3-7: 3 mice from each of 5 different BXD strains

3 mice/group x 7 groups/experiment x 5 experiments = 105 mice

V.1.5.1.2. Second round of screening to identify host biomarkers involved in colonization of the gut with EHEC. Once BXD strains that exhibit a different colonization phenotype than the parent strains have been identified, a second round of colonization experiments will be conducted to confirm the results of the initial screen. Groups of 5 BXD mice each will be infected with 86-24 or TUV86-2 and monitored for colonization and bacteremia as above. Groups of 3 C57BL/6J and DBA/2J mice will serve as controls. Every attempt will be made to combine experiments such that control mice can be used for multiple experimental groups of BXD mice. Up to 12 BXD strains will be tested in the second round of screening.

Group 1: 3 C57BL/6J mice
Group 2: 3 DBA/2J mice
Groups 3-5: 5 mice from each of 3 different BXD strains

21 mice/experiment x 4 experiments x 2 iterations = 168 mice

V.1.5.2. Second round of screening to identify host biomarkers involved in Stx2 intoxication. In studies conducted under MIC-09-137, we identified a region of chromosome 12 that contains a QTL that is involved in the number of days of survival after systemic Stx2 intoxication. The studies here will take advantage of BXD strains that are genetic mosaics for the parental strains in the region of chromosome 12 that contains the QTL. Groups of 5 BXD mice each will be intoxicated with Stx2 and monitored for symptoms of intoxication as in Section V.4.5. Groups of 3 C57BL/6J and 3 DBA/2J mice will serve as controls. Every attempt will be made to combine experiments such that control mice can be used for multiple experimental groups of BXD mice. A total of 6 BXD strains will be tested in the second round of screening. We anticipate that 2-4 strains of BXD can be tested in a particular experiment; however, many BXD strains do not breed well, so simultaneous availability of multiple strains is not always achievable.

Group 1: 3 C57BL/6J mice
Group 2: 3 DBA/2J mice
Groups 3-4: 5 mice from each of 2 different BXD strains

16 mice/experiment x 3 experiments x 2 iterations = 96 mice

V.1.5.3: Characterization of the involvement of CEA in the pathogenesis of STEC infection. CEA Tg mice were generated on the C57BL/6J background, so C57BL/6J mice will serve as the control in this experiment. Mice will be treated with str-water prior to and during the experiment, which will be carried out as described in V.1.A. Fecal samples will be collected daily to assess intestinal colonization and to quantify epithelial cell shedding.

Group 1: 10 CEA Tg mice inoculated with 86-24
Group 2: 10 C57BL/6J mice inoculated with 86-24

Total number of mice = (10 CEA Tg mice + 10 C57BL/6J mice) x 5 iterations = ***50 CEA Tg mice and 50 C57BL6/J mice***

Total number of mice (V.1.5):
15 + 24 + 18 + 50 = 107 C57BL/6J mice
15 + 24 + 18 = 57 DBA/2J mice
75 + 120 + 60 = 255 BXD mice
50 CEA Tg mice

V.1.6: Experiment 6: Measurement of the efficacy of therapeutic compounds designed to ablate the lethal effects of Stx. The objective of these studies is to test the efficacy of therapeutics designed to inactivate Stxs after entry into the gut or more distal target cells. We will engineer toxin-neutralizing antibodies or toxin inhibitors that can be selectively delivered into toxin-sensitive cells. The first approach involves administration of toxin-neutralizing monoclonal antibodies after infection or intoxication. Secondly, we theorize that conjugation of StxB1 or StxB2 to the exterior of liposomes

will target and deliver liposome-encapsulated inhibitory RNA molecules (iRNAs) to the cytoplasm of toxin-sensitive cells. The iRNAs will be designed to block the enzymatic activity of the toxins inside the cell. Finally, we hypothesize that peptide-linked phosporodiamidate morpholino oligos (morpholinos), which bind specific RNA sequences in the region of the translational start site and block translation, can be used to inhibit growth of and/or Stx production by STEC strains *in vivo*. The efficacy of these inhibitors will be tested in mice once their efficacy has been demonstrated in tissue culture cells. We anticipate testing up to 9 compounds over the next 3 years.

V.1.6.1: Determination of capacity of monoclonal antibodies against Stx2 to rescue mice from systemic intoxication with Stx2 variants or from infection with STEC strains that produce one or more Stx2 variants. We have previously shown that mouse monoclonal antibody 11E10 anti-Stx2 has the capacity to rescue Stx2-intoxicated and 86-24- or B2F1-infected CD-1 mice from morbidity and mortality. In the current studies, we will test the capacity of 11E10 to rescue male CD-1 mice from intoxication with Stx2c and Stx2dact and from infection with K3995 (Stx2, Stx2c) and C227-11 (Stx2).

V.1.6.1.1: Monoclonal antibody-mediated rescue from mortality of male CD-1 mice intoxicated with Stx2c or Stx2dact. Groups of five male CD-1 mice will be intoxicated with 5 LD_{50} each of Stx2 (10 ng, positive control), Stx2c, BT-Stx2dact, or ET-Stx2dact via i.p. inoculation with a 26 gauge needle connected to a tuberculin syringe. Twice in the first 96 hrs post-intoxication, 1 µg 11E10 will be administered via i.v. injection with a 26 gauge needle connected to a tuberculin syringe. In previous studies, we have found that the time points for administration of 11E10 are dependent upon the toxin or strain used as the inoculum. As such, the time points will be determined through experimentation. Mice will be monitored for morbidity and mortality, and any mice that exhibit 2 or more symptoms of morbidity will be euthanized by isoflurane overdose followed by cervical dislocation.

Group 1: 10 ng Stx2, no 11E10
Group 2: 10 ng Stx2, 11E10 administered twice
Group 3: 5 LD_{50} Stx2c, no 11E10
Group 4: 5 LD_{50} Stx2c, 11E10 administered twice
Group 5: 5 LD_{50} BT-Stx2dact, no 11E10
Group 6: 5 LD_{50} BT-Stx2dact, 11E10 administered twice
Group 7: 5 LD_{50} ET-Stx2dact, no 11E10
Group 8: 5 LD_{50} ET-Stx2dact, 11E10 administered twice

5 mice/group x 8 groups x 10 iterations = 400 male CD-1 mice

V.1.6.1.2: Monoclonal antibody-mediated rescue from mortality of male CD-1 mice infected with STEC. Groups of ten male CD-1 mice will be orally infected with 10 LD_{50} each of B2F1 (positive control), K3995, or C227-11 as described in V.1.B. Twice in the first 96 hrs post-infection, 1 µg 11E10 will be administered via i.v. injection with a 26 gauge needle connected to a tuberculin syringe. In previous studies, we have found that the time points for administration of 11E10

are dependent upon the toxin or strain used as the inoculum. As such, the time points will be determined through experimentation. Mice will be monitored for morbidity and mortality, and any mice that exhibit 2 or more symptoms of morbidity will be euthanized by isoflurane overdose followed by cervical dislocation.

Group 1: 10 mice infected with B2F1, no 11E10
Group 2: 10 mice infected with B2F1, 11E10 administered twice
Group 3: 10 mice infected with K3995, no 11E10
Group 4: 10 mice infected with K3995, 11E10 administered twice
Group 5: 10 mice infected with C227-11, no 11E10
Group 6: 10 mice infected with C227-11, 11E10 administered twice

10 mice/group x 6 groups x 10 iterations = 600 male CD-1 mice

Total number of mice (V.1.6.1) = 400 + 600 = 1000 male CD-1 mice

V.1.6.2: Assessment of efficacy of liposome-encapsulated iRNAs. Groups of 5 male CD-1 mice will be administered 5xLD_{50} of Stx2 (i.p. using a 26 gauge needle attached to a tuberculin syringe) followed by or given simultaneously with a dose of the therapeutic compound that neutralizes the toxin for tissue culture cells administered by i.v. injection. Control groups will receive a similar dose of toxin and diluent, or control liposomes, as appropriate. An additional control group will have the toxin and therapeutic agent mixed prior to i.p. injection. In previous studies, we have found that the time points for administration of anti-Stx therapeutics are dependent upon the toxin used as the inoculum. As such, the doses and time points will be determined through experimentation. The mice will be monitored for signs of extreme morbidity (see V.4.5 for definition) for 14 days post-intoxication. Any mice that exhibit signs of extreme morbidity will be euthanized immediately by inhalational isoflurane overdose and cervical dislocation.

Group 1: 5 mice, 10 ng Stx2, sterile saline
Group 2: 5 mice, 10 ng Stx2, liposome-iRNA, low tissue culture dose
Group 3: 5 mice, 10 ng Stx2, liposome-iRNA, high tissue culture dose
Group 4: 5 mice, sterile saline, liposome-iRNA at low tissue culture dose
Group 5: 5 mice, sterile saline, liposome-iRNA at high tissue culture dose
Group 6: 5 mice, 10 ng Stx2 pre-mixed with liposome-iRNA at low tissue culture dose
Group 7: 5 mice, 10 ng Stx2 pre-mixed with liposome-iRNA at high tissue culture dose

5 mice/group x 7 groups x 10 iterations = ***350 male CD-1 mice***

V.1.6.3: Determination of capacity of morpholinos to rescue infected mice from STEC disease. Groups of 5 mice will be challenged orally with STEC as described in V.1.A. Morpholinos will be administered orally by gavage (0.1-0.2 ml in sterile saline) and/or pipet feeding (25-50 µl in sterile 20% sucrose) or systemically by intravenous injection (0.1 ml in sterile saline) two to five times after infection. The optimal number of doses

and time points for morpholino administration will be determined experimentally. Previous studies with other types of *E. coli* strains showed that the effective and nontoxic dose range is 50-300 µg administered two to four times in the first 48 hrs after inoculation. Our preliminary studies with B2F1-infected CD-1 mice suggest that a minimum of two daily doses of therapeutic will be needed and that three to five doses may be more optimal. The mice will be monitored for signs of extreme morbidity (see V.4.5 for definition) for 14 days post-intoxication. Any mice that exhibit signs of extreme morbidity will be euthanized immediately by inhalational isoflurane overdose and cervical dislocation.

V.1.6.3.1: Infection of str-treated CD-1 mice with B2F1 and treatment with morpholinos.

Group 1: 5 mice, B2F1, sterile saline
Group 2: 5 mice, B2F1, 200 µg morpholino #1 administered twice
Group 3: 5 mice, B2F1, 200 µg morpholino #2 administered twice
Group 4: 5 mice, B2F1, 200 µg morpholino #3 administered twice
Group 5: 5 mice, B2F1, 200 µg morpholino #4 administered twice
Group 6: 5 mice, B2F1, 200 µg morpholino #1 administered four times
Group 7: 5 mice, B2F1, 200 µg morpholino #2 administered four times
Group 8: 5 mice, B2F1, 200 µg morpholino #3 administered four times
Group 9: 5 mice, B2F1, 200 µg morpholino #4 administered four times

5 mice/group x 9 groups x 10 iterations = 450 male CD-1 mice

V.1.6.3.2: Infection of BALB/c mice with 86-24 and treatment with morpholinos.

Group 1: 5 mice, 86-24, sterile saline
Group 2: 5 mice, 86-24, 200 µg morpholino #1 administered twice
Group 3: 5 mice, 86-24, 200 µg morpholino #2 administered twice
Group 4: 5 mice, 86-24, 200 µg morpholino #3 administered twice
Group 5: 5 mice, 86-24, 200 µg morpholino #4 administered twice
Group 6: 5 mice, 86-24, 200 µg morpholino #1 administered four times
Group 7: 5 mice, 86-24, 200 µg morpholino #2 administered four times
Group 8: 5 mice, 86-24, 200 µg morpholino #3 administered four times
Group 9: 5 mice, 86-24, 200 µg morpholino #4 administered four times

5 mice/group x 9 groups x 10 iterations = 450 female BALB/c mice

V.1.6.3.3: Infection of C57BL/6 mice with C227-11 and treatment with morpholinos.

Group 1: 5 mice, C227-11, sterile saline
Group 2: 5 mice, C227-11, 200 µg morpholino #1 administered twice
Group 3: 5 mice, C227-11, 200 µg morpholino #2 administered twice
Group 4: 5 mice, C227-11, 200 µg morpholino #3 administered twice
Group 5: 5 mice, C227-11, 200 µg morpholino #4 administered twice
Group 6: 5 mice, C227-11, 200 µg morpholino #1 administered four times
Group 7: 5 mice, C227-11, 200 µg morpholino #2 administered four times
Group 8: 5 mice, C227-11, 200 µg morpholino #3 administered four times
Group 9: 5 mice, C227-11, 200 µg morpholino #4 administered four times

5 mice/group x 9 groups x 10 iterations = 450 female C57BL/6 mice

V.1.6.3.4. Systemic inoculation and therapeutic delivery. If we fail to observe a therapeutic effect of the morpholinos in our STEC infection models, we will determine if the morpholinos have the capacity to reduce the effects of systemic infection with STEC. To do so, we will first need to do three pilot studies to determine the LD_{50}s for B2F1, 86-24, and C227-11 administered i.p to male CD-1 mice. Each strain will be diluted to the appropriate density in sterile saline, and the inoculum (in 200 µl) will be administered i.p. with a 26 gauge, ½" needle. The first experiment with each strain will utilize 3 mice/group and multiple doses that are predicted to fall on either side of the LD_{50}. We will then refine the experiment to utilize 5 mice/group and a narrower range of doses; this experiment will be done twice to confirm the results. Although the endpoint of this assay is mortality, mice that are extremely moribund, as defined in Section V.4.5, will be euthanized by laboratory personnel using isoflurane inhalation overdose and cervical dislocation. Surviving mice will be euthanized by LAM personnel with CO_2 inhalation followed by cervical dislocation.

V.1.6.3.4.1. Pilot experiment: estimation of LD_{50} for STEC strains administered i.p.
Group 1: 3 mice, 10^2 CFU
Group 2: 3 mice, 10^3 CFU
Group 3: 3 mice, 10^4 CFU
Group 4: 3 mice, 10^5 CFU
Group 5: 3 mice, 10^6 CFU
Group 6: 3 mice, 10^7 CFU

6 doses x 3 mice/dose x 3 strains: 54 CD-1 mice

V.1.6.3.4.2. Dose response: i.p. inoculation with STEC strains
Group 1: 5 mice, 100X predicted LD_{50}
Group 2: 5 mice, 10X predicted LD_{50}
Group 3: 5 mice, 1X predicted LD_{50}
Group 4: 5 mice, 0.1X predicted LD_{50}

4 doses x 5 mice/dose x 3 strains x 2 iterations: 120 CD-1 mice

V.1.6.3.4.3. Infection of CD-1 mice with STEC strains and treatment with morpholinos. CD-1 mice will be challenged via i.p. inoculation with 10xLD_{50} of B2F1, 86-24, or C227-11 and treated via i.p. or i.v. injection with 0.1 ml morpholino in sterile saline at various times post-infection. The optimal number of doses and time points for morpholino administration will be determined experimentally.

Group 1: 5 mice, sterile saline
Group 2: 5 mice, 50 µg morpholino 1 twice
Group 3: 5 mice, 50 µg morpholino 2 twice
Group 4: 5 mice, 50 µg morpholino 3 twice
Group 5: 5 mice, 50 µg morpholino 4 twice
Group 6: 5 mice, 300 µg morpholino 1 twice
Group 7: 5 mice, 300 µg morpholino 2 twice
Group 8: 5 mice, 300 µg morpholino 3 twice
Group 9: 5 mice, 300 µg morpholino 4 twice

5 mice/group x 9 groups x 10 iterations x 3 strains = 1350 male CD-1

Total number of mice (V.1.6.3):
450 + 54 + 120 + 1350 = 1974 male CD-1 mice
450 female BALB/c mice
450 female C57BL/6 mice

Total number of mice (V.1.6):
1000 + 350 + 1974 = 3324 male CD-1 mice
450 female BALB/c mice
450 female C57BL/6 mice

Experiment 1.7: Isolation of mouse intestinal mucus. The focus of aim #2 of the NIH grant is the mucus-activatable Stx2dact toxin found in several non-O157 strains. We will address why that particular Stx2 variant is so toxic compared to Stx2. For these studies, we will need mouse mucus to demonstrate the activatable phenotype of this toxin.

Intestinal mucus will be isolated from groups of 5 adult male CD-1 mice. Mice will be administered str in their drinking water, and, simultaneously, food will be withheld from the mice for about 18 h prior to mucus isolation. Although we have found that treatment of mice with str is not required for mouse mucus to activate Stx2dact, we have shown that such treatment reduces bacterial contamination of the mucus sample. Moreover, mucus obtained from animals administered the antibiotic, in principle, more closely resembles the mucus in the gut of the str-treated, orally-infected mouse than mucus from untreated mice. Food is withheld to reduce the amount of fecal matter in the intestines and also so that the mucus is isolated from mice treated in the same way as the orally-infected mouse model. Within 18 hours after str administration and food removal, mice will be euthanized by inhalational isoflurane overdose followed by cervical dislocation. The intestines will be removed and fecal material expelled from intestinal segment. The mucus will be pushed out of the intestines into HEPES buffer, pH 7.4, diluted in HEPES buffer and used immediately or frozen at -70°C for future use. Based on current rates of mucus usage, we anticipate the need for 20 CD-1 mice for this purpose per year.

20 mice/year x 3 years = ***60 male CD-1 mice***

Experiment 1.8. Studies to assess ricin intoxication, transit of ricin throughout the body, and anti-ricin therapeutics. In these experiments, we will identify the LD_{50} for a new lot of ricin, use *in vivo* imaging of mice to visualize transit of fluorescently-labeled ricin throughout the body, and test the efficacy of therapeutics to rescue mice from acute ricin intoxication. All of these experiments will be conducted in six to eight week-old male CD-1 mice according to V.1.C above.

V.1.8.1: Identification of LD_{50} of ricin administered via oral gavage or i.p. injection. We will use historical data from previous lots of ricin and current data on Vero cell cytotoxicity of the new lot of ricin to determine the dose range of ricin to administer to identify the LD_{50}s for new lots of ricin. We anticipate that we will produce up to three new lots of toxin in the three years of this protocol.

V.1.8.1.1: Oral gavage
Group 1: 5 mice, 5 LD_{50}s old lot of ricin in sterile saline
Groups 2-7: 5 mice, five two-fold dilutions of ricin in sterile saline

5 mice/group x 7 groups x 2 iterations x 3 lots of ricin = 210 male CD-1 mice

V.1.8.1.2: Intraperitoneal injection
Group 1: 5 mice, 5 LD_{50}s old lot of ricin in sterile saline
Groups 2-7: 5 mice, five two-fold dilutions of ricin in sterile saline

5 mice/group x 7 groups x 2 iterations x 3 lots of ricin = 210 male CD-1 mice

Total number of mice (V.1.8.1) = 210 + 210 = 420 male CD-1 mice

V.1.8.2: *in vivo imaging of CD-1 mice orally intoxicated with ricin.* Our previous studies demonstrated that, after oral gavage into the stomach, ricin travels through the gastrointestinal tract and is excreted in the feces or across the gastrointestinal tract and into the bloodstream. We have observed ricin in the kidneys, spleen, liver and brain in these preliminary studies. Further studies are needed to investigate the sites in the body to which ricin travels and the mechanism by which ricin binds to and transits through the gastrointestinal epithelium. Mice will be orally intoxicated and imaged throughout the course of the study in our Carestream Multispectral FX Pro *in vivo* imaging system. At specific time points, mice will be euthanized and organs will be imaged *ex vivo* prior to harvest and fixation for immunohistochemistry and immunofluorescence.

Group 1: 5 mice, 1 LD_{50} ricin, euthanize 4 h post-intoxication
Group 2: 5 mice, 1 LD_{50} ricin, euthanize 8 h post-intoxication
Group 3: 5 mice, 1 LD_{50} ricin, euthanize 12 h post-intoxication
Group 4: 5 mice, 1 LD_{50} ricin, euthanize 24 h post-intoxication
Group 5: 5 mice, 1 LD_{50} ricin, euthanize 48 h post-intoxication
Group 6: 5 mice, 1 LD_{50} ricin, euthanize 72 h post-intoxication

5 mice/group x 6 groups x 3 iterations = ***90 male CD-1 mice***

V.1.8.3: Measurement of the efficacy of therapeutic compounds designed to ablate the lethal effects of ricin. The first approach involves administration of toxin-neutralizing monoclonal antibodies after intoxication. We will use a well-characterized monoclonal antibody, R70, that neutralizes the activity of the A (catalytic) subunit of ricin (RtxA) *in vitro*. In our second approach, we will administer liposome-encapsulated R70 anti-ricin antibody after intoxication. The cell binding domain of ricin (RtxB) will be conjugated to the exterior of the liposomes, which are vesicles composed of an outer lipid bilayer that forms around an aqueous solution (anti-RtxA antibody in sterile saline) when the two components are mixed together. We theorize that conjugation of RtxB to the exterior of liposomes will target and deliver liposome-encapsulated R70 anti-ricin antibody to the cytoplasm of toxin-sensitive cells. We have shown that treatment of ricin-intoxicated tissue culture cells with R70 anti-ricin alone or liposome-encapsulated R70 anti-ricin neutralizes the cytotoxicity of ricin in a dose-dependent manner.

V.1.8.3.1: Monoclonal antibody-mediated rescue from mortality of male CD-1 mice intoxicated with ricin. Groups of five male CD-1 mice will be intoxicated with 5 LD_{50} each of ricin in sterile saline via oral gavage. Twice in the first 96 hrs post-intoxication, 1 µg R70 anti-ricin in sterile saline will be administered via i.v. injection with a 26 gauge needle connected to a tuberculin syringe In previous studies, we have found that the time points for administration of monoclonal antibodies are dependent upon the toxin used as the inoculum. As such, the time points will be determined through experimentation. Mice will be monitored for morbidity and mortality, and any mice that exhibit 2 or more symptoms of morbidity will be euthanized by isoflurane overdose followed by cervical dislocation.

Group 1: 5 mice, 5 LD_{50} ricin, no R70
Group 2: 5 mice, 5 LD_{50} ricin, low dose R70 administered twice
Group 3: 5 mice, 5 LD_{50} ricin, high dose R70 administered twice

5 mice/group x 3 groups x 10 iterations = 150 male CD-1 mice

V.1.8.3.2: Assessment of efficacy of liposome-encapsulated R70 anti-ricin. Groups of 5 male CD-1 mice will be administered 5xLD_{50} of ricin in sterile saline by oral gavage, followed by or given simultaneously with a dose of the liposome-encapsulated R70 anti-ricin that neutralizes the toxin for tissue culture cells; the liposome-antibody conjugated will be diluted in sterile saline and administered by i.v. or i.p. injection. Control groups will receive a similar dose of toxin and diluent, or control liposomes without antibody and/or RtxB, as appropriate. An additional control group will have the toxin and therapeutic agent mixed prior to i.v. or i.p. injection. In previous studies, we have found that the time points for administration of anti-ricin therapeutics are dependent upon the route of ricin inoculation and the route of therapeutic administration. As such, the doses and time points will be determined through experimentation. The mice will be monitored for signs of extreme morbidity (see V.4.5 for definition) for 14 days post-intoxication. Any mice that exhibit signs of extreme morbidity will be

euthanized immediately by inhalational isoflurane overdose and cervical dislocation.

Group 1: 5 mice, 5xLD_{50} ricin, sterile saline
Group 2: 5 mice, 5xLD_{50} ricin, liposome-R70 anti-ricin, low tissue culture dose
Group 3: 5 mice, 5xLD_{50} ricin, liposome-R70 anti-ricin, high tissue culture dose
Group 4: 5 mice, sterile saline, liposome-R70 anti-ricin at low tissue culture dose
Group 5: 5 mice, sterile saline, liposome-R70 anti-ricin at high tissue culture dose
Group 6: 5 mice, 5xLD_{50} ricin pre-mixed with liposome-R70 anti-ricin at low tissue culture dose
Group 7: 5 mice, 5xLD_{50} ricin pre-mixed with liposome-R70 anti-ricin at high tissue culture dose

5 mice/group x 7 groups x 10 iterations = 350 male CD-1 mice

Total number of mice (V.1.8.3) = 150 + 350 = 500 male CD-1 mice

Total number of mice (V.1.8) = 420 + 90 + 500 = 1010 male CD-1 mice

V.2. Data Analysis: A sample size of 5-10 animals per condition will have 80% power to detect a difference of 1.3 - 1.8 standard deviations based on a t test for independent samples with a 5%, two-sided significance level. A sample size of 15 animals per group will have 80% power to compare two proportions (i.e. survival data) based on a t test for independent samples with a 5%, two-sided significance level. These are the smallest differences that would be considered clinically meaningful for this type of study. Lethal dose 50% will be estimated by the method of Reed and Muench (5) or calculated by Probit analysis using 95% confidence intervals if the data allow it. For protection studies, ANOVA will be used to compare the mean time-to-death between groups and Chi-square tests with 95% confidence intervals will be used to compare the percentages of deaths between groups.

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered: Whenever possible, we will test the toxicity of Stx preparations on Vero cells rather than in animals. All of our initial assessments and comparative assessments of cytotoxicity are done on Vero cells rather than mice. The use of the Vero cell assays does allow us to reduce the range of toxin doses that we subsequently administer to mice. Additionally, historical data allow us to approximate an LD_{50} rather than the more usual range of at least 10 doses. Unfortunately, some of the differences in toxicity among Stx family members are only evident in the whole animal (*e.g.*, Stx2c versus Stx2dact). Further, the proposed studies to assess the efficacy of therapeutics require systemic responses that are not possible to achieve in tissue culture systems. No other alternatives to the use of animals were identified for this proposal.

V.3.2. Animal Model and Species Justification: The long term goals of this project are to define the pathogenic mechanisms by which STEC and ricin cause disease and to develop strategies for the prevention and treatment of STEC-mediated HUS and ricin intoxication. Humans are the most appropriate model with which to assess the virulence of STEC. However, humans cannot be used for logistical as well as ethical reasons, *i.e.*, a volunteer fed an STEC strain might develop HUS, a life-threatening condition. Instead, we use mice in four types of mouse assays developed in my laboratory. All of the mouse strains are used for specific experiments for historical reasons. We use male CD-1 mice for our str-treated model of STEC-mediated lethality because they are sensitive to infection with STECs and they exhibit toxin-mediated renal tubular necrosis when fed those STEC strains. In our initial studies more than twenty years ago, we found that outbred male CD-1 mice were susceptible to infection with STECs in the presence of str; their continued susceptibility to STEC and their low cost make them the strain of choice for our ongoing studies. We use female BALB/c for our intact commensal flora (ICF) model because we found that these mice are highly likely to be colonized by STEC when normal gastrointestinal flora are present. Female mice are used in this model because they are highly colonized more consistently than are males. We use female C57BL/6 mice for our amp-treated model, which is specific for C227-11. C227-11 was isolated from an outbreak in Germany in May 2011 and is a hybrid between enteroaggregative (FAEC) and enterohemorrhagic *E. coli* strains; the only published mouse model for EAEC utilized C57BL/6 mice. Females are used because they are more susceptible to infection than males. We use BALB/c and CD-1 mice for toxicity assays because we have found that these strains of mice are susceptible to Sbxs (BALB/c, CD-1) and ricin (ricin) administered orally or systemically in these strains of mice. Some Stxs exhibit greater toxicity in inbred mice (BALB/c) and some in outbred mice (CD-1). In addition, other groups routinely use CD-1 mice for ricin toxicity studies. Our observations that ricin and some of the Sbxs are toxic by oral and systemic routes have important implications for ricin and STEC pathogenesis.

All of the mouse assays will be used in conjunction with tissue culture assays to further dissect the virulence characteristics of these organisms and toxins. While *in vitro* cell-based assays can provide an estimate of toxin potency, they do not accurately reflect the multitude of effects of toxins on complex living systems and so cannot be used to replace the testing in animals. The interactions between EHEC and the plethora of cell types within the gastrointestinal tract, circulation, and kidneys cannot be mimicked in tissue culture systems. Unfortunately mice do not completely mimic STEC-mediated disease because diarrhea and glomerular damage are notably absent in infected animals. The most accurate endpoint to assess the virulence of an EHEC strain or the potency of Stxs and ricin is lethality. All published studies of EHEC, Stx, and ricin pathogenesis of which we are aware utilize mice, rabbits, or primates to determine the local and systemic effects of the organisms and toxins. At this time mice are the least sentient species we can use to test certain aspects of STEC and ricin pathogenesis and to evaluate potential therapies. With respect to the number of animals required for each experiment, we have used the minimal number of animals required for biological and statistical significance. If we establish in our preliminary protection studies that the therapeutic(s) under investigation do in fact reduce or prevent morbidity or mortality, the pain category for these animals will be changed from category E to category C.

V.3.3. Laboratory Animals

	Species #1	Species #2	Species #3	Species #4	Species #5	Species #6
V.3.3.1. Genus & Species	*Mus musculus*	*Mus musculus*	*Mus musculus*	*Mus musculus*	*Mus musculus*	*Mus musculus*

V.3.3.5. Weight:	14-25 grams	12-25 grams	10-20 grams	10-20 grams	10-20 grams	10-20 grams
V.3.3.6. Sex	Male	Female	Both	Both	Both	Both
V.3.3.7. Special Considerations	N/A	N/A	N/A	N/A	N/A	N/A
V.3.4. Number of Animals Required (by Species)	7674	4719	1117	57	255	50

V.3.5. Refinement, Reduction, Replacement (3 Rs):

V.3.5.1. Refinement: For certain experiments death will be the study endpoint; however, we will carefully monitor the animals and euthanize those that appear moribund because it is our experience that these animals will ultimately succumb to Stx intoxication after inoculation or infection with a virulent strain. Investigators will carefully monitor intoxicated animals and euthanize those that appear to be extremely moribund. We define extremely moribund as when a mouse exhibits 2 or more of the following symptoms: ruffled fur, lethargy, hunched posture, impaired ambulation that prevents the animals from reaching food and water, >25% weight loss, difficult or labored breathing, and the inability to remain upright. Death due to intoxication typically occurs 2-3 days post-injection and death due to infection typically occurs 3-6 days post-inoculation. Mice will be inspected every 4 h during normal working hours (0600-1900) and every 7-8 h during non-business hours. All inspections will be noted on cage cards so that LAM personnel are aware that the mice are being monitored.

As part of (b)(6) we investigated the possible use of weight loss as a surrogate endpoint for the Stx or ricin intoxication and STEC infection experiments. Our studies

demonstrated that a positive correlation between ≥ 25% weight loss at 4 days post-challenge and lethality exists. However, only about 50% of the mice that lost 25% of their body weight by day 4 succumbed to intoxication or infection. All mice that lost 30% of their body weight by day 4 were humanely euthanized prior to death because we found that the mice would have succumbed within another 24 hrs. We will continue to monitor weight loss in intoxicated or infected animals, and animals will be humanely euthanized when they are extremely moribund.

V.3.5.2. **Reduction**: As many of our experiments involve infected animals or tissues, we do not participate in any shared tissue and or control groups with other investigators. To reduce the number of mice required, the studies with BXD mice will be done using a single dose of toxin or STEC, and only one iteration will be used for the first round of screening. In theory, we could use up-down dosing to determine the oral LD_{50} for Stxs and ricin. However, the amount of toxin that is needed for these studies prohibits this type of study. Instead, we will do one to two traditional LD_{50} studies with small numbers of mice in each group so as to reduce the amount of the Select Agent toxins that are needed.

V.3.5.3. **Replacement**: Whenever possible, we will test the toxicity of Shiga toxin preparations/constructs on Vero cells rather than in animals. Unfortunately, some of the differences in toxicity among Stx family members are only evident in the whole animal. We will also routinely assess the capacity of anti-intimin sera to block STEC adherence to tissue culture cells rather than test the sera for blocking activity in animals.

V.4.1.2. Pain Relief / Prevention:

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization: Administration of isoflurane gas prior to intoxication or infection will be done in one of two ways: 1) via a Gas Anesthesia System that delivers isoflurane gas to a 5-port anesthesia manifold, or 2) by soaking gauze with liquid isoflurane in the bottom of a bell jar in a chemical hood and placing the mice on a metal rack above the gauze. When using the Gas Anesthesia System, animals will be placed into an induction chamber and anesthetized with isoflurane (3-4%) with oxygen as the carrier gas. The induction chamber will be set to deliver isoflurane at a constant rate. The manifold also provides waste gas scavenging ports to help prevent gas from entering the surrounding work environment. A built-in vacuum system helps ventilate waste gas away from researchers and into disposable isoflurane-absorbing filters. We use the bell jar method rather than the gas anesthesia system when mice are extremely moribund because 1) the fume hood is closer to our animal room than is the anesthesia system, and 2) the bell jar can be set up more quickly than the gas anesthesia system, which results in less suffering for moribund mice. Once anesthetized using either method, the depth of anesthesia will be assessed by the onset and maintenance of slow, shallow breathing as well as the loss of toe pinch response in the animals.

For experiment V.1.2.2 (intestinal loop model), mice will be anesthetized by i.p. injection of ketamine (100 mg/kg) and xylazine (10 mg/kg) immediately before the surgical procedure. Once anesthetized, the depth of anesthesia will be assessed by the onset and maintenance of slow, shallow breathing as well as the loss of toe pinch response in the animals. At the end of the survival surgery, a few drops of liquid bupivacaine (0.5%) will be placed on the incision site to provide post-surgical wound anesthesia. In addition, buprenorphine (0.1 mg/kg) will be administered once by s.c. injection to provide post-surgical systemic analgesia. Mice will be euthanized 6 hrs after surgery, which is prior to the time at which the bupivacaine and buprenorphine effects are expected to wear off, and mice will be monitored during this period.

For *in vivo* imaging studies, isoflurane has the advantage of maintaining the mice under anesthesia during the imaging procedure while permitting the animals a quick recovery time. The anesthetized mice will be placed on a warm platform and fluorescence and x-ray images will be captured over a 5 min period at 0.5, 1, 3, 6, 12, 24, 48, and/or 72 h post intoxication. To anesthetize the mice and secure their immobility during imaging with the Carestream Multispectral *in vivo* imaging system, we will follow the following procedures. Administration of isoflurane gas will be done via a Gas Anesthesia System that delivers isoflurane gas to a 5-port anesthesia manifold housed in the imaging chamber of the *in vivo* imaging system. Animals will be initially placed into an induction chamber and anesthetized with isoflurane (3-4%) with oxygen as the carrier gas. Once the animals are properly sedated, they will be swiftly moved to nose cones on the 5-port anesthesia manifold housed in the imaging chamber and maintained at 1.5-3.0% isoflurane. Any unused manifold ports will be closed off. Sufficient time will be given to allow the anesthetic gas to reach the manifold nose cones prior to removing the animals from the induction chamber. Both the induction chamber and manifold will be set to deliver isoflurane at a constant rate. The manifold also provides waste gas scavenging

ports to help prevent gas from entering the surrounding work environment. A built-in vacuum system helps ventilate waste gas away from researchers and into disposable isoflurane-absorbing filters.

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions: Only mice that appear to be in good health will undergo anesthesia. We define good health as clean unruffled fur, alert demeanor and no obvious signs of sickness. Mice recovering from anesthesia will be placed into a clean cage with external heat applied, through either the use of an overhead heat lamp or a heating pad placed under the recovery cage, to prevent mice from undergoing a rapid loss in body temperature. Once the mice have roused from anesthesia and appear to be moving in an alert manner, they will be placed back into a clean cage with their cagemates. Mice injected with toxin or infected with *E. coli* will be monitored by laboratory personnel up to 6 times daily following the procedure as well as twice daily observation by LAM staff.

V.4.1.2.3. Paralytics: N/A

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures:

V.4.1.3.1. Sources Searched: Pubmed and AGRICOLA

V.4.1.3.2. Date of Search: 16 May 2012

V.4.1.3.3. Period of Search: All available

V.4.1.3.4. Key Words of Search: Pain AND (alleviation OR alleviate OR alternative OR reduction) AND (mouse OR mice); add AND (toxin OR bacteria) for Pubmed search

V.4.1.3.5. Results of Search:

PubMed: Search of Pain AND (alleviation OR alleviate OR alternative OR reduction) yielded 39252 hits. Limiting these to (mouse OR mice) yielded 1015 hits. Further limiting these results to (toxin OR bacteria) yielded 76 hits. Of those 76 references, only three dealt with alternatives to mouse assay for intoxication or infection. The three references suggest the use of hen egg approaches that would not work with Shiga toxins or STEC. One additional article conducted and reviewed studies that used opioids as analgesics in *in vivo* immunological experiments (4). (b)(5) *et al.* concluded that the opioid analgesics fentanyl and buprenorphine affected the immune system in such a way as to alter the outcome of the experiments.

AGRICOLA: Search Request. Search = (Pain OR alleviation OR reduction OR alternatives) AND (mouse OR mice) yielded 25 hits. Only one article dealt with alternatives to or reduction of pain in mouse intoxication or infection experiments. The investigators assessed the effect of buprenorphine on *Toxoplasma gondii* studies in mice, and concluded that buprenorphine does not affect the outcome of 28 day *T. gondii* infections in mice (1).

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification: Our justification for the use of the mouse model to study toxin mediated STEC disease is

that tissue culture systems used to evaluate toxin production cannot always discriminate between animal-virulent and animal-attenuated strains. Examples of the importance of using animals rather than Vero cells for assessing relative toxicity of Stxs or virulence of STEC strains are as follows. First, we discovered that Stx2 is at least 100-fold more toxic than Stx1 for mice and that observation led to an experiment by Dr. Tom Obrig in which he demonstrated that Stx2 is a 1000-fold more toxic for human renal capillary endothelial cells than is Stx1. Moreover, with the recognition that animals and primary human renal cells (that are extremely difficult to obtain and maintain) are more susceptible to Stx2 than Stx1 came an understanding of the basis for the epidemiological observation that infection with Stx2-producing STEC strains more frequently leads to HUS in children than does infection with an Stx1-only producing strain. Secondly, we would not have recognized the fact that Stx2dact is activated by intestinal mucus without feeding the strain producing the toxin to str-treated CD-1 mice. Lastly, the str-treated mouse model (renal tubular necrosis) is one of two (the rabbit is the other) small animal models available for studying the systemic delivery of Stx from the intestinal tract and for identifying methods to prevent or neutralize the effect of that toxin and/or STEC-mediated disease. We further minimize distress during the studies by careful cage-side monitoring of the animals to determine if an animal should be euthanized. Signs indicating that euthanasia should be implemented would include an inability to reach food and water, labored breathing, excessive weight loss, and inability to remain upright.

No analgesics will be given to STEC-infected animals for the following two reasons. First, inflammation and/or the inflammatory response are key components of both STEC-mediated hemorrhagic colitis (inflammation of the colon and neutrophilic infiltrate) and STEC-mediated HUS. Pro-inflammatory cytokines are believed to play a role in HUS potentially by up-regulating toxin receptor expression or by exacerbating Stx-mediated damage. Because we will be using these animal models to study both the pathogenesis of disease and possible treatment therapies, we believe that the use of non-steroidal anti-inflammatory drugs (NSAIDs) could confound or possibly mask the extent of STEC-mediated damage that we will be evaluating by histological examination or toxicity. Secondly, the use of opioids as analgesics has the potential to exacerbate symptoms rather than eliminate pain since peristalsis would be reduced. Opium compounds have been used in several animal models for gastroenteritis to **increase** the likelihood of establishing and/or maintaining bacterial infection. Additionally, anti-motility agents are not recommended for patients with suspected STEC-mediated diarrhea because this treatment may increase the risk of progression to HUS.

V.4.2. Prolonged Restraint: N/A

V.4.3. Surgery: Intestinal Loop Model

V.4.3.1. Pre-surgical Provisions: Only mice that appear to be in good health will undergo anesthesia. We define good health as clean unruffled fur, alert demeanor and no obvious signs of sickness. The mice will be fasted for 18 h prior to surgery. Mice will be anesthetized by i.p. injection of ketamine (100 mg/kg) and xylazine (10 mg/kg) immediately prior to the surgical procedure.

V.4.3.2. **Procedure:** The procedure that we will use is a modification of a protocol that was described by (b)(6) *et al.* for analysis of the effects of *Clostridium perfringens* epsilon toxin on different segments of the intestines (2). BALB/c mice will used in this study. All procedures will be conducted in a certified Biosafety Cabinet in our satellite animal room, (b)(6)

The mice will be fasted for 18 h prior to surgery. An overnight fast is needed to reduce the volume of the stomach contents so that the entire inoculum can be administered. In addition, we have found that mice fed by Pipetman or weigh boat are more likely to ingest the inoculum if they have been fasted. Mice will be anesthetized by i.p. injection of ketamine (100 mg/kg) and xylazine (10 mg/kg) immediately prior to the surgical procedure. The abdominal area will be shaved with clippers. A 3-4 cm midline abdominal incision will be performed with a pointed scalpel and the stomach, the small intestine or the large intestine will be partially externalized. Prior to ligation, the intestinal segments will be flushed with 1ml of warm sterile saline to remove the lumenal contents. For the proximal portion of the small intestine, a segment of 4 cm of intestine including duodenum and jejunum will be ligated with Prolene 3-0 just below the pylorus. The middle portion of the small intestine will be ligated 1 cm distal the ligament of Treitz and 5 cm down to the ileum. For the distal portion, the ileum will be ligated approximately 5 and 1 cm before the ileocecal valve, respectively. For the colonic loops, a ligature will be placed at the cecocolonic junction and a second ligature will be placed on the colon immediately before the opening to the rectum. Care will be taken that the ligatures are tight enough to prevent the flow of liquids into and from the ligated intestinal segments but not too tight to cause damage to the tissues involved. *E. coli* O157:H7 (enterohemorrhagic *E. coli* or EHEC) will be diluted in warm sterile saline, which will also serve as the control. Bacterial or saline preparations will be administered using 1-ml tuberculin syringes with a 27-gauge needle by oblique insertion of the needle in the intestinal segment, always in distal direction, with care being taken to avoid intestinal blood vessels. After administration of test solutions, the organs will be gently repositioned and the abdominal incisions will be sutured in two planes using 3-0 Prolene to close the abdominal incision and tissue glue to close the skin layer. Topical bupivacaine ointment will be placed on the incision site after suturing to provide post-surgical wound analgesia. Buprenorphine (0.1 mg/kg, subcutaneous) will be used as a post-surgical analgesic. Injection volumes will be kept constant at 300 µl per animal regardless of the site of administration. The surgical procedure is predicted to last approximately 7-10 min per animal. Mice will be euthanized by isoflurane overdose and cervical dislocation 6 hrs after inoculation and tissues will be collected for bacterial enumeration and histological examination.

V.4.3.3. **Post-surgical Provisions:** Topical bupivacaine drops will be placed on the incision site after suturing to provide post-surgical wound analgesia. Buprenorphine (0.1 mg/kg, subcutaneous) will be used as a post-surgical analgesic and will be administered by s.c. injection prior to recovery from anesthesia. Mice will be observed hourly after the survival surgery. Any mice that appear to be extremely moribund, as described in V.3.5 above, will be euthanized by isoflurane overdose and cervical

dislocation. In addition, all mice will be euthanized 6 hrs after inoculation and tissues will be collected for bacterial enumeration and histological examination.

V.4.3.4. Location: (b)(6)

V.4.3.5. Surgeon: The procedure will be performed by Dr. (b)(6) who is a postdoctoral fellow in our laboratory. Dr. (b)(6) was trained by MAJ (b)(6) (b)(6) DVM.

V.4.3.6. Multiple Major Survival Operative Procedures:

V.4.3.6.1. Procedures: N/A

V.4.3.6.2. Scientific Justification: N/A

V.4.4. Animal Manipulations:

V.4.4.1. Injections:

Intraperitoneal:
V.1.C, V.1.2.2, V.1.4.3, V.1.6.2, V.1.8.3: Mice will receive i.p. injections of Stxs, ricin, ketamine/xylazine, or anti-Stx or anti-ricin therapeutics diluted in 0.1-0.2 ml sterile saline or sterile PBS. All will be injected i.p. using a 26 gauge needle attached to a tuberculin syringe. The dose of toxins and therapeutics will be determined in the experiments. Doses of 100 mg/kg ketamine and 10 mg/kg xylazine diluted in 0.1-0.2 ml sterile saline will be administered for anesthesia in V.1.2.2. In V.1.4.3, a dose of 40 µg of cipro will be diluted in 0.1 ml sterile saline and administered by i.p. injection on days 2, 3, 4, and 5 post-inoculation.

Intravenous:
V.1.6.1, V.1.6.3., V.1.8.3: Mice will receive anti-Stx or anti-ricin therapeutics i.v. via the tail vein or retro-orbital sinus in a volume of 100 or 25 µl PBS, respectively, using a 30 gauge 0.5 inch needle attached to a tuberculin syringe.

Intestinal injection:
V.1.2.2: Mice will receive an injection of STEC or Stx diluted in 0.3 ml sterile saline directly into an intestinal loop with a 27 gauge needle attached to a tuberculin syringe.

Subcutaneous:
V.1.2.2: Mice will receive 0.1 mg/kg buprenorphine in 0.1 ml sterile saline via s.c. injection into the right flank with a 26 gauge, ½" needle attached to a tuberculin syringe. Buprenorphine will be administered only to mice that have undergone survival surgery.

V.4.4.2. Biosamples:
Mucus: We collect mucus from the small intestine of mice treated with str and fasted for 18 h. An overnight fast is needed to reduce the volume of the stomach contents so that the entire inoculum can be administered. In addition, we have found that mice fed by Pipetman or weigh boat are more likely to ingest the inoculum if they have been fasted.

The mice are euthanized by inhalational isoflurane overdose and cervical dislocation prior to mucus collection.

Sera: Blood will be collected from the mice in sections V.1.A, V.1.B and V.1.C by tail vein bleed or retro-orbital bleed immediately prior to or by exsanguination upon euthanasia. Retro-orbital bleeds will be performed using sterile fine-bore Pasteur pipets or micro-capillary tubes. Mice will be lightly anesthetized with isoflurane. No more than 0.1 ml of blood will be collected by placing the pipet or micro-capillary tube against the capillary bed immediately to the right or left of the eye and applying slight pressure to stimulate blood flow. A single mouse will be bled no more frequently than once every 3-4 days and mice will be bled from alternating eyes if they are bled more than once.

Feces: approximately 1 gram obtained by pellet collection.

Tissues: Intestines, kidneys, livers, spleens, hearts, brains will be collected after inhalational isoflurane overdose and cervical dislocation.

V.4.4.3. Adjuvants: N/A

V.4.4.4. Monoclonal Antibody (MAbs) Production: N/A

V.4.4.5. Animal Identification: Mice will be identified by cage cards and ear tags or ear punch.

V.4.4.6. Behavioral Studies:

V.4.4.7. Other Procedures:
Streptomycin and ampicillin in V.1.A will be administered orally in the drinking water at a dose of 5 g/L str or 10 g/L amp. Antibiotic-containing water will be changed every 1-2 days.
Oral gavage of 0.1-0.3 ml STEC, Shiga toxin, or ricin in sterile saline will be performed using a 18-20 gauge feeding needle. Anesthesia is not required for this procedure.
Custom diets that contain 2% or 10% guar gum as the sole source of fiber will be used in V.1.2. We have fed mice these diets in the past and have observed no negative impact.

V.4.4.8. Tissue Sharing: N/A

V.4.5. Study Endpoint: The experimental question is answered by determining the number of mice that survived or succumbed to STEC or toxin. See Table 4.5.1 below for a description of the study outcome for each experiment. Investigators will carefully monitor intoxicated animals and euthanize those that appear extremely moribund because it is our experience that these animals will ultimately succumb to intoxication. We define extremely moribund as when a mouse exhibits 2 or more of the following symptoms: ruffled fur, lethargy, hunched posture, impaired ambulation that prevents the animals from reaching food and water, excessive weight loss (>25% of initial weight), difficult or labored breathing, and the inability to remain upright.

Mice will be weighed daily and those that lose more than 25% of their initial body weight by day 4 post-inoculation will be euthanized. During the first 5-10 days after infection or first 2-5 days after intoxication (range depends upon the model and agent), mice will be inspected every 4 h during normal working hours (0600-1900) and every 7-8 h during non-business hours. After day 5-14 (endpoint of increased monitoring depends upon the model and the agent), mice will be inspected twice per day because few additional deaths are expected. We carry out the experiments for 7-28 days because we occasionally observe symptoms that range from mild morbidity to death until the endpoint noted in Table 4.5.1 below. All inspections will be noted on cage cards so that LAM personnel are aware that the mice are being monitored. Surviving mice will be euthanized by LAM personnel by CO_2 overdose and cervical dislocation.

Table 4.5.1. Study endpoints and predicted outcomes

Study number	Pain Category C	Pain Category D	Pain Category E	Study Outcome
V.1.1.1.1			200	Death or euthanasia on day 21
V.1.1.1.2			140	Death or euthanasia on day 21
V.1.1.2			300	Death or euthanasia on day 21
V.1.1.3.1			1440	Death or euthanasia on day 21
V.1.1.3.2			720	Death or euthanasia on day 21
V1.1.3.3			720	Death or euthanasia on day 7 or 14
V1.1.3.4			720	Death or euthanasia on day 7 or 14
V1.1.4.1			480	Death or euthanasia on day 7 or 14
V1.1.4.2			480	Death or euthanasia on day 7 or 14
V1.1.4.3			240	Death or euthanasia on day 7 or 14
V1.2.1.1			120	Death or euthanasia on day 7 or 14
V1.2.1.2			560	Death or euthanasia on day 7 or 14
V1.2.1.3	32		32	Death or euthanasia on day 14
V1.2.2.1		180		Death or euthanasia at hr 6
V1.2.2.2		180		Death or euthanasia at hr 6
V1.2.2.3		180		Death or euthanasia at hr 6
V1.2.2.4		360		Death or euthanasia at hr 6
V1.3.1.1			80	Death or euthanasia on day 14
V1.3.1.2			110	Death or euthanasia on day 14
1.3.2.1			60	Death or euthanasia on day 14
1.3.2.2			110	Death or euthanasia on day 14
1.3.3			105	Death or euthanasia at 4, 8, 12, 24, 48, 72, 96 hrs
1.4.1			80	Death or euthanasia at 3, 6, 12, 24, 48, 72, 96, 120 hrs
1.4.2			120	Death or euthanasia on day 28
1.4.3.1			120	Death or euthanasia on day 28
1.4.3.2			120	Death or euthanasia on day 28
1.4.3.3			120	Death or euthanasia on day 28
1.5.1.1			105	Death or euthanasia on day 14
1.5.1.2			168	Death or euthanasia on day 14
1.5.2			96	Death or euthanasia on day 14
1.5.3			100	Death or euthanasia on day 14
1.6.1.1			400	Death or euthanasia on day 14
1.6.1.2			600	Death or euthanasia on day 14
1.6.2	100		250	Death or euthanasia on day 14

Study number	Pain Category C	Pain Category D	Pain Category E	Study Outcome
1.6.3.1			450	Death or euthanasia on day 21
1.6.3.2			450	Death or euthanasia on day 21
1.6.3.3			450	Death or euthanasia on day 28
1.6.3.4.1			54	Death or euthanasia on day 14
1.6.3.4.2			120	Death or euthanasia on day 14
1.6.3.4.3	150		1200	Death or euthanasia on day 14
1.7	60			Euthanize immediately
1.8.1.1			210	Death or euthanasia on day 14
1.8.1.2			210	Death or euthanasia on day 14
1.8.2			90	Death or euthanasia at 4, 8, 12, 24, 48, 72, 96 hrs
1.8.3.1			150	Death or euthanasia on day 14
1.8.3.2	100		250	Death or euthanasia on day 14

V.4.6. Euthanasia: Mice will be euthanized by either isoflurane overdose (3-4% concentration) within the isoflurane induction chamber of our Gas Anesthesia System, which is connected to a waste disposal system, or within a bell jar containing isoflurane-saturated gauze, or by CO_2 overdose. Cervical dislocation will be done on deeply anesthetized mice to confirm euthanasia. CO_2 will be delivered from a compressed gas cylinder via a regulated rate of flow in accordance with the 2007 AVMA Guidelines on Euthanasia. For euthanasia using CO_2, all procedures will be performed by LAM personnel. Investigative staff will perform isoflurane euthanasia followed by cervical dislocation.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol. Mice will be housed in USUHS room (b)(6) that is maintained as a dedicated ABSL2 room. Before the start of the experiment, LAM personnel will be responsible for routine animal observations and cage maintenance and provide food and water as detailed in the LAM Husbandry SOP. During the experiment the investigator will be responsible for animal observations (up to 4 times daily) and provide all care for the animals. For animals in Experiment V.1.1.1 that are housed in the ABSL-3 facility once it is completed, all husbandry will be performed by the investigator.

V.5.1.1. Study Room:

Building(s)	(b)(6)	Room Number(s)	(b)(6)	

V.5.1.2. Special Husbandry Provisions:

Food Restriction:	Yes x (some mice will be fasted overnight)
Fluid Restriction:	No

V.5.1.3. Exceptions: None

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care:
Untreated animals will be observed and cared for by the Center for LAM personnel according to USUHS Center for LAM SOPs. Immunized, infected or intoxicated animals will be checked regularly by laboratory personnel working on these projects. Moribund mice will be euthanized.

V.5.2.2. Emergency Veterinary Medical Care: All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: Except as indicated below, all animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents.

V.5.3.2. Enrichment Restrictions: None

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING: Dr (b)(6) who will not do these "hands on" experiments herself, has 35 years experience working with mice in microbicidal assays and has been involved with the mouse anthrax model since 2002.

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
Oral inoculations	(b)(6)	Senior technician, 20 yrs experience	Investigator training, 1995, Trained by Dr. (b)(6) rodent handling class, Walter Reed, 2000
Oral inoculations		Research Associate Professor, 20 yrs experience	Investigator training, 1995, Trained by Dr. (b)(6)
Oral inoculations		Associate Professor, 17 yrs experience	Investigator training, 1995, Trained by Dr. (b)(6)
Oral inoculations		Research Technician, 7 yrs experience	Investigator training, 2004, Trained by Dr (b)(6)
Oral Inoculations		Graduate student, 5 yrs experience	Investigator training, 2007, Rodent handling course, 2007, Trained by Dr (b)(6)
Oral Inoculations		Graduate student, 3 yrs experience	Investigator training, 2008, Rodent handling course, 2008; trained by Dr (b)(6)
Oral Inoculations		Research Technician, 1 yr experience	Investigator training, 2011, trained by M (b)(6)

Ear tag / Ear punch		Postdoctoral Fellow, 1 yr experience	Investigator training, 2008, trained by Mr. (b)(6)

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
Intestinal Loop surgery	(b)(6)	Postdoctoral fellow, 2 yrs experience	Investigator training, 2009. Rodent handling course, 2009, trained by MAJ (b)(6)

VII. **BIOHAZARDS/SAFETY**: A detailed risk assessment was completed at the request of the Division of Select Agents and Toxins (DSAT) at the Centers for Disease Control and Prevention. All animal handling procedures meet or exceed the requirements of the DSAT and the Biosafety in Microbiological and Biomedical Laboratories, Fifth Edition, for ABSL2 experiments. The mice are housed under biocontainment conditions (ABSL2). Mice infected with STEC or intoxicated with Stx or ricin will be isolated from non-infected animals. Gloves, lab coats, and surgical masks must be worn by all personnel when handling mice. N95 masks are required when mice are inoculated with ricin, Stxs, or C227-11. In addition, all inoculations with C227-11 will be conducted in a certified Type II Biosafety Cabinet. Survival surgery will be conducted in a certified Type II Biosafety Cabinet. Bedding may be contaminated with fecal pellets that contain STEC; therefore, all bedding and all animal carcasses should be treated as infectious and must be autoclaved and/or burned. All cages will be changed in a certified Biosafety Cabinet in Room (b)(6). All needles and scalpels will be disposed of in dedicated Sharps containers that are decontaminated and incinerated as Regulated Medical Waste.

All procedures that involve the use of isoflurane will be performed in either a chemical fume hood (bell jar) or with a gas anesthesia system with waste-scavenging charcoal filters (both located in Dr (b)(6) laboratory). All personnel who use isoflurane are aware of its associated safety hazards and have been properly trained in its transport, use, and storage.

VIII. **ENCLOSURES**:

1. Registration Certificate for use of Select Agents from the Division of Select Agents and Toxins, Centers for Disease Control and Prevention

2. Letter of approval for Experiment V.1.1.1 from Division of Select Agents and Toxins, Centers for Disease Control and Prevention

3. (b)(6) from NIAID, "Pathogenicity of Shiga Toxin-Producing *E. coli*"

4. (b)(6) Administrative Supplement to (b)(6) from NIAID, "Pathogenicity of Shiga Toxin-Producing *E. coli*"

5. (b)(6) from NIAID, "Shiga toxin and ricin interaction with enterocytes and rescue of target cells"

6. (b)(6) from DTRA, "Antibacterial and Anti-Shiga Toxin Expression Activities of Morpholino Compounds against EHECO104:H4 and Related Prokaryotes"

7. (b)(6) from USUHS, "Susceptibility of Recombinant Inbred Mice to Shiga Toxins and *E. coli* O157:H7"

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

A. **Training:** I verify that I have attended the USUHS Investigator/Animal User Training Course

B. (b)(6) [redacted]

Principal Investigator Signature | Date

A. **Training:** The following personnel will attend the next USUHS Investigator/Animal User Training Course: All personnel are current on their training

H. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely, "Responsibility" for implementing animal use alternatives where feasible and conducting humane and lawful research.

(b)(6)	
Principal Investigator Signature	Date 5/17/2022

I. Painful Procedure(s): I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL or WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

Principal Investigator Signature	Date 5/17/22

X. PROTOCOL ABSTRACT:

A. **Animal Protocol Number:** (b)(6)

B. **Animal Protocol Title:** Pathogenicity of Shiga toxin-producing *E. coli* and ricin intoxication (mice)

C. **Principal Investigator:** (b)(6) Ph.D.

D. **Performing Organization:** USUHS

E. **Funding:** NIAID, DTRA, USUHS

F. **Objective and Approach:** Shiga toxin (Stx)-producing Escherichia coli (STEC) are known as the causative agent of "hamburger disease" because they are often transmitted through undercooked hamburgers. STEC are food- and water-borne pathogens that are the most comroon infectious cause of bloody diarrhea in the United States. The hemolytic uremic syndrome (HUS), which can occur as a result of STEC infection, is the most frequent basis for acute kidney failure in U.S. children. The STEC make one or more Stxs (Stx1, Stx2 or variant of those) that are key factors in the development of the HUS. The Stxs are generally encoded within bacteriophage genomes that lysogenize *E. coli*, and can therefore be transmitted among susceptible bacteria. Evidence that such transmission may occur became evident in 2011, when a large food-borne outbreak of bloody diarrhea and HUS due to an unusual O104:H4 *E. coli* strain that produced Stx2 occurred in Germany. The outbreak isolate was an enteroaggregative *E. coli* that had most likely acquired an *stx*$_2$-encoding phage from a more typical STEC. The mechanism of action of the Stxs is the same of that of the plant toxin ricin: they both halt protein synthesis in the target cell. The specific aims of this project are to: 1.) evaluate the properties of certain Stx family members either in purified form or as produced from STEC strains that make them more toxic for mice and human kidney cells than other family members; 2.) determine if an O157:H7 strain that produces Stx2dact is virulent in mice, and, conversely, if the Stx2dact-producing mouse virulent strain B2F1 is rendered less virulent when Stx2dact is mutated to Stx2; 3.) determine the effect of alterations in dietary fiber on the susceptibility of mice to the Stxs or to STEC; 4.) assess if Stx1 or Stx2 enhances the colonization capacity of STEC strains; 5.) evaluate the protective capacity of anti-bacterial or anti-toxin morpholino compounds in STEC-infected mice; 6.) measure the protective properties of anti-Stx or anti-ricin therapeutic conjugates in tissue culture or in mice; 7.) evaluate the susceptibility of advanced recombinant inbred (ARI) mice to Stx1 or Stx2; and, 8.) measure differences in the capacity of STEC strains that produce Stx1 or Stx2 to colonize BXD mice.

G. **Indexing Terms (Descriptors):** STEC, Shiga toxin-producing *E. coli*, Shiga toxin, animal model, mice, hemorrhagic colitis, hemolytic uremic syndrome, ricin, morpholino, antibody

MEMORANDUM FOR DR. (b)(6) DEPARTMENT OF MICROBIOLOGY

SUBJECT: IACUC Approval of Protocol – Triennial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via designated member review on January 25, 2012:

Animal Protocol Title: "New Therapies and Vaccines Against Bacillus Anthracis"

USUHS Protocol Number: (b)(6)

Expiration Date: January 24, 2015

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. **NON-TECHNICAL SYNOPSIS:** *Bacillus anthracis*, the bacterium responsible for anthrax, persists in the environment as a dormant, well-protected spore that is resistant to damage and drying. Disease occurs when the spores are inhaled, ingested, or enter wounds in the skin. Once in the body, the dormant spores germinate, or lose their protective coating, and expand into rod-shaped bacteria that multiply and produce toxins that lead to often fatal disease in the patient. Spores of *B. anthracis* have long been considered potential biological weapons. During October, 2001 in the US there were 22 cases of anthrax that resulted from such a deliberate exposure, 11 of which had the most lethal inhalational disease form. Indeed, the aggressive use of quinolones and other antibiotics coupled with the early recognition of disease resulted in the survival of 6 of the 11 patients. Nonetheless, hundreds of other individuals potentially exposed to anthrax spores required an extended course of antibiotic therapy due to the concern that they still carried spores in their lungs that could germinate after the conclusion of their antibiotic treatment. Our overarching goals are to 1) develop a vaccine that is safe and effective for prevention of anthrax disease, and 2) develop therapies that prevent the first stage of disease, specifically germination of the spores. Two ways to block such germination are to 1) administer antibodies against the spores before or immediately after exposure; or, 2) immunize at-risk individuals (such as soldiers) with a vaccine that contains spore-surface (also known as exosporium) proteins. Our experiments will be done with *B. anthracis* Sterne, a strain that does not cause disease in humans and is not considered a bioweapon. We will determine if mice immunized with exosporium proteins of *B. anthracis* or inactivated spores from an avirulent *B. cereus* strain are protected against an otherwise lethal dose of spores introduced into the nose, the skin, or the bloodstream. In addition, we will test chemical compounds that alter germination of spores in lab cultures for their capacity to prevent disease in mice infected with spores. Another aim is to study how certain traits of *B. anthracis* influence disease production. Identification of these traits, or virulence factors, will illuminate which are important targets for antimicrobials and vaccines. We will measure the outcome of infection in mice exposed to the Sterne strain versus that seen when mice are infected with strains mutated (deficient) in those traits. Likewise, we will investigate the very closely-related bacterium *B. cereus* that causes self-limiting

gastrointestinal or ocular diseases in healthy people but which is responsible for illnesses like sepsis, meningitis, and endocarditis in immunocompromised persons. We hope to determine the bacterial properties (some likely shared with *B. anthracis*) that lead to disease with *B. cereus*.

II. BACKGROUND:

II.1. Background: Our studies will continue to investigate two highly related species from the genus *Bacillus*: *B. anthracis* and *B. cereus*. The infectious form of *B. anthracis* and *B. cereus* for animals and humans is the spore. To cause systemic disease, the spore must germinate and undergo outgrowth to the vegetative rod. Although the pathogenesis of inhalational, cutaneous, and gastrointestinal anthrax likely involves the same general steps, the morbidities and mortalities differ significantly. After introduction of spores into the host via inhalation, ingestion, or wound contamination, the spores are rapidly phagocytosed by resident macrophages (MΦs). We and others have shown through *in vivo* imaging studies that the spores germinate in the MΦs, either at the site of inoculation or after the MΦs have migrated to the regional lymph nodes (7, 9, 10, 19). The spores germinate to form encapsulated vegetative rods, which replicate in the MΦs and produce toxins that kill the MΦs. The extracellular bacilli then disseminate within the host and express the full constellation of virulence factors.

The two principal toxins produced by the vegetative bacteria are Edema Toxin (ET) and Lethal Toxin (LT). Edema Factor (EF) and Lethal Factor (LF) interact with and are delivered to the cell interior by the same binding subunit, called the Protective Antigen (PA). PA is the principal component of the licensed anthrax vaccine (Biothrax®). ET is comprised of PA and EF and LT is comprised of LF and PA. ET is a calmodulin-dependent adenylate cyclase that converts ATP to cAMP within its target cells. Lethal toxin is a zinc-metalloprotease that cleaves mitogen-activated protein kinase kinases (MAPKK) within MΦs, which can lead to apoptosis of the MΦ and release of vegetative cells and toxins into the surrounding milieu. In addition to the toxins, all strains of *B. anthracis* and some strains of *B. cereus* that cause disease in humans produce one or more capsules. The capsules protect the vegetative bacteria from phagocytosis by macrophages and neutrophils, particularly during dissemination through the lymph and blood to distal sites.

The majority of animal models of anthrax disease mimic inhalational or subcutaneous anthrax in humans [see (20) for review of animal models of anthrax disease]. Inhalational models have been used most often, despite the relatively low frequency of inhalational anthrax (compared to the other routes of inoculation), because aerosolized spores have the potential to be used as bioweapons. Like humans, non-human primates and rabbits are particularly susceptible to the effects of LT and ET, a characteristic that makes these animal models particularly useful for studies of late stage anthrax disease as well as vaccines and therapeutics. Mice and guinea pigs can be used to model both the infection (early) and toxemia (late) stages of disease. Mice have been used most extensively due to their low cost, ease of handling, and genetic diversity. Mouse models of anthrax disease are used to mimic inhalational (aerosol, intranasal, intratracheal inoculation), cutaneous (subcutaneous inoculation), and gastrointestinal (oral inoculation) forms of human anthrax, and all of these models are useful for studies of infection and toxemia. In addition, challenge by intraperitoneal or

intravenous routes can be useful for investigations of the roles of capsules and toxins in *Bacillus* pathogenesis.

All of our *B. anthracis* animal studies are conducted with *B. anthracis* Sterne, an attenuated strain that does not produce capsule and that is used as a vaccine for cattle. *B. anthracis* Sterne is fully virulent in A/J mouse models of anthrax disease. The genes that encode the toxin components in *B. anthracis* (*pag, lef, cya*) are located on the pXO1 megaplasmid. The pXO2 megaplasmid, which is not present in *B. anthracis* Sterne, encodes the genes required for production of a poly-D-glutamic acid capsule. Our studies of *B. cereus* virulence are conducted with *B. cereus* G9241, a strain that was isolated from the blood and sputum of a welder who had anthrax-like pneumonia (11). *B. cereus* G9241 is unique among *B. cereus* strains for the following reasons: 1) *B. cereus* typically causes mild gastroenteritis rather than anthrax-like pneumonia in humans; and 2) the strain contains two megaplasmids, pBCXO1 and pBC218. The pBCXO1 megaplasmid is 99% identical to pXO1 in *B. anthracis*. One key difference between the two megaplasmids is that the *hasACB* operon on pBCXO1 is intact, which provides *B. cereus* G9241 with the tools necessary to produce a hyaluronic acid capsule (16). The *hasACB* operon on the *B. anthracis* pXO1 contains a frameshift mutation that renders the operon non-functional. In addition, pBC218 contains a second functional capsule operon and a homolog of the gene that encodes PA (*pag*). A third toxin, Certhrax, that functions as an ADP-ribosyltransferase is encoded on pBC218 as well (8); the role of this toxin in *B. cereus* disease will be investigated in the studies described in this protocol.

Despite the prominent role of the toxins in anthrax disease, we propose that if spores can be blocked from germination, the vegetative cells that express these toxins will not be formed. We hypothesize that antibodies against spore surface components could prevent germination, possibly via opsonization of the spores to facilitate phagocytic cell uptake and subsequent killing. We have previously demonstrated that intraperitoneal (i.p.) immunization of A/J mice with a sublethal dose of PA followed by the spore proteins BclA, BxpB, and/or p5303 protects mice from subsequent subcutaneous (s.c.) challenge with *B. anthracis* Sterne (6). We also vaccinated A/J and BALB/c mice with formalin-inactivated *B. cereus* G9241 pBCXO1- pBC218- spores (DC FIS); DC FIS are non-viable due to formalin-inactivation and do not contain toxin components. All A/J mice vaccinated intranasally (i.n.) or s.c. with DC FIS were protected from subsequent *B. anthracis* Sterne challenge via i.n. or s.c. routes. When our collaborators at USAMRIID vaccinated BALB/c mice with DC FIS i.p., they saw 60% protection from i.n. challenge and 80% protection from i.p. challenge with the fully virulent *B. anthracis* Ames. These data provide strong evidence for our hypothesis that spore surface components are effective immunogens for generation of antibodies that protect against *B. anthracis* infection.

We also theorize that administration of a small molecule that inhibits germination as a post-challenge therapeutic will protect mice from anthrax disease. The small molecule 6-thioguanine (6-TG), an analog of known *in vitro* germinants inosine and alanine, was previously shown to inhibit germination of *B. anthracis* spores *in vitro* and in MΦs (1). We have screened 3722 small molecules to identify compounds that have the capacity to alter germination of *B. anthracis* Sterne spores in a high-throughput *in vitro* assay. We have discovered 20 potential lead compounds (molecules that inhibit the germination rate by at least 2/3), as well as 65 additional compounds classified as "moderate inhibitors" that reduce the germination rate to between 1/3 and 2/3 of the

positive control. These 85 compounds will be further tested *in vitro* and in MΦ phagocytosis and killing assays. Small molecules that inhibit germination in all of the *in vitro* assays will be tested in our A/J mouse models of *B. anthracis* disease.

II.2. Literature Search for Duplication:

II.2.1. Literature Source(s) Searched: DoD Biomedical Research Database (BRD), NIH Research Portfolio Online Reporting Tools (RePORT), and PUBMED

II.2.2. Date of Search: 12 December 2011

II.2.3. Period of Search: BRD Database [FY1998 to FY2009 (most recent)], NIH RePORT (FY2002 - FY2012), PUBMED (Available – December 2011, English only)

II.2.4. Key Words and Search Strategy: *Bacillus* AND (spores OR capsule OR germination OR dissemination OR immunization) AND (mouse OR mice)

II.2.5. Results of Search:
RESULTS FROM BRD: Search of the BRD database using *Bacillus* AND *anthracis* AND spores resulted in 102 hits, of which 40 were unique and 7 were from my laboratory. Other studies utilized guinea pigs, rabbits, and monkeys to ascertain *B. anthracis* virulence properties. Fourteen documents were from our collaborators at USAMRIID and outlined our joint studies to investigate spore proteins as vaccine candidates and the roles of antibodies against spores in inhibition of germination and growth. An additional document was from another collaborator and resulted in a joint publication between our laboratories (23).
Five of the studies were focused on development of vaccines against anthrax disease that are based on PA and LF and five were focused on multivalent vaccines against two or more organisms considered to be high bioterrorism threats (*B. anthracis*, *Yersinia pestis*, *Burkholderia spp*). Finally, the use of antibodies against PA and/or LF as post-exposure prophylaxis was the subject of two studies. None of the studies identified in the BRD database overlap with the studies proposed here, except those outlined in proposals from my laboratory.

RESULTS FROM NIH RePORT: A total of 102 unique awards were identified in NIH RePORT using *Bacillus* AND (spores OR capsule OR germination OR dissemination OR immunization) AND mouse, of which two were from my laboratory. Awards to my collaborators include two to Dr. (b)(6) two to Dr. (b)(6) and one was a program project on which I was an investigator (awarded to Dr. (b)(6) (b)(6) Of these, 5 proposed the use of various spore coat components as vaccine antigens; however, they were focused on different spore antigens than those we propose to study. A search using *Bacillus* and mouse and germination resulted in 28 awards, including 1 from my laboratory, 1 from the Middle Atlantic Regional Center of Excellence (b)(6) and 2 from our collaborator Dr. (b)(6) Of these, 11 were focused on various vaccine strategies using spores or spore components; again, none directly overlap with our studies. A search of NIH RePORT for *Bacillus* and immunization and mouse yielded 203 hits. Most immunization strategies are focused on PA and/or LF. Two focused on the use of capsule as a

vaccine candidate. Three others targeted proteins on the surface of the *Bacillus* spore coat, but the focus of those awards was different than our focus in Experiment 5 below.

RESULTS FROM PUBMED: A search of the Pubmed database using *Bacillus* AND (spores OR capsule OR germination OR dissemination OR immunization) AND mouse resulted in 318 relevant articles, of which 6 were published by our laboratory. Fifteen of these articles describe vaccination strategies using various antigens from the spore surface, but none directly overlap with the studies proposed here because we are using different antigens and/or different immunization or challenge methods. An additional 75 articles include those that describe the use of *Bacillus* spores as vaccine platforms (21), the efficacy of vaccines against PA (26), multivalent vaccines that target multiple organisms (2), and vaccines that use other toxin components than PA as the primary immunogen (4). A total of 33 papers describe the development of therapeutics against *B. anthracis* infection; 11 discuss the use of post-exposure antibody administration, 12 present possible antibiotic therapies, and 10 use alternate approaches. None of these papers demonstrates the utility of small molecule inhibitors of germination. A total of 92 papers focus on the host response to *B. anthracis* infection; 36 focus on macrophages, neutrophils or epithelial cells and 22 investigate the contributions of components of the inflammasome.

III. **OBJECTIVE/ HYPOTHESIS**: One way to increase the likelihood that individuals who are exposed to aerosolized *B. anthracis* spores remain disease free is to prevent germination of the infectious dormant spores into active vegetative cells that can produce potentially lethal toxins. Our findings that rabbit antiserum against *B. anthracis* spores or spore proteins decreases spore germination *in vitro*, taken with the fact that FIS can serve as a protective vaccine against anthrax in guinea pigs and mice, led us to the following **hypothesis**. Vaccine candidates that contain spore surface components will elicit antibodies that block or reduce spore germination *in vivo* or render spores more susceptible to phagocytosis and ultimately killing by macrophages. Based on this theory, our **goals** are to characterize spore surface components as potential targets for incorporation into a second-generation PA-based vaccine and to identify small molecules that inhibit germination *in vivo* for post-exposure prophylaxis. The specific aims are to:

1. Assess the virulence of *B. anthracis* Sterne or *B. cereus* G9241 strains in which a particular virulence trait has been deleted;
2. Administer *B. cereus* G9241 toxin components to assess their activity *in vivo*;
3. Monitor the location and kinetics of germination, vegetative outgrowth, and dissemination of fluorescent derivatives of *B. anthracis* Sterne and *B. cereus* G9241 in the mouse with an *in vivo* imaging system;
4. Characterize the *in vivo* efficacy of small molecules to inhibit germination of *B. anthracis* Sterne spores; and
5. Immunize A/J mice with a sublethal dose of recombinant PA (rPA) followed by spore antigens alone or in combination and/or with exosporium protein preparations, then challenge with *B. anthracis* to assess the protective efficacy of the vaccine candidates.

IV. **MILITARY RELEVANCE**: The potential use of *B. anthracis* as a weapon of biowarfare was brought to the forefront in the aftermath of the terrorist attacks of September 11th, 2001. From October to December 2001, a total of 22 cases of

confirmed or suspected bioterrorism-related anthrax occurred in the United States. Eleven of these cases were inhalational (the most lethal form of the infection) and resulted in the death of 6 individuals. In light of these events, the development of therapeutic agents against *B. anthracis* infection is paramount for the protection of both deployed military personnel and civilians who may come into contact with sabotaged contaminated materials.

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures:

1. Three general types of experiments will be conducted in the studies outlined in this protocol.

A. Mice will be inoculated with *B. anthracis* or *B. cereus* spores or with purified toxin components by intranasal (i.n.), intratracheal (i.t.), subcutaneous (s.c.), or intraperitoneal (i.p.) administration and monitored for morbidity and mortality with death as an endpoint. The purpose of these studies is to determine 1) if isogenic mutant strains that lack a particular virulence factor are attenuated for virulence when compared to the parent strain, 2) if the toxins produced by *B. cereus* G9241 exhibit similar activity *in vivo* as do their *B. anthracis* counterparts, or 3) the *in vivo* location(s) of *B. anthracis* and *B. cereus* strains that fluoresce at a particular stage in growth (germination, vegetative outgrowth, dissemination).

B. Mice will be vaccinated with formalin-inactivated spores (FIS), viable spores of an avirulent *B. cereus* strain, purified spore proteins (alone or in combination), or crude exosporium protein preparations, then they will be challenged with a lethal dose of *B. anthracis* Sterne, *B. cereus* G9241, or fluorescent derivatives thereof. The purpose of these studies is to further develop a potential second-generation vaccine strategy to prevent anthrax disease.

C. Mice will be challenged with *B. anthracis* Sterne spores and treated one hour post-challenge with small molecules known to inhibit germination *in vitro*. The purpose of these studies is to determine whether the small molecule(s) could be used as post-exposure prophylaxis to prevent germination and subsequent vegetative outgrowth in the host.

2. For all of the mouse studies outlined in this protocol, 6-8 week old female A/J or C57BL/6 mice will be challenged by one of four routes (i.n., i.t., s.c., i.p.) with *Bacillus anthracis* Sterne spores, *B. cereus* G9241 spores, or purified toxin components (i.p. only). Moribund mice will be anesthetized by isoflurane overdose and sacrificed by cervical dislocation. We define moribund as when the mouse is crouched down or lying in the bottom of the cage with little movement, even when gently prodded. Other nonspecific signs that will be used are ruffled fur, lethargy, hunched posture, decreased alertness, weight loss, and difficulty breathing.

A. For i.n. inoculation, mice will be anesthetized with inhaled isoflurane delivered via a Xenogen XGI-8 gas anesthesia system or with i.p. ketamine (100 mg/kg) and xylazine

nostril). The mice will be held upright until the inoculum is inhaled (~1 min), then

(10 mg/kg). Once anesthesia is confirmed by non-response to toe pinch, mice will be inoculated i.n. by manually pipetting 50 µl spores in H_2O onto the nares (25 µl/per nostril). The mice will be held upright until the inoculum is inhaled (~1 min), then returned to their cages to recover from the anesthesia. Mice will remain in the laboratory for one hour after inoculation to permit careful monitoring of mice. The study endpoint will be either death (see section V.4.5) or euthanasia 14 days post-challenge. Obviously moribund animals will be euthanized using CO_2 inhalation or isoflurane inhalation followed by cervical dislocation (see section V.4.6).

B. For i.t. inoculation (conducted as described in Brown *et al.* (4)), A/J mice will be anesthetized by i.p. administration of ketamine (100 mg/kg) and xylazine (10 mg/kg). Once anesthetized (defined as no response to toe pinch), each mouse will be placed on its back on a flat surface that can be elevated 75°. Paper tape will be applied to each arm to gently adhere the arms to the flat surface. A hypodermic needle will be inserted into the flat surface ~5 cm from the top of the mouse's head. A rubber band will be looped over the needle and under the upper incisors of the open mouth of the mouse to tilt the neck backward and to hold the mouth open. The flat surface will be elevated to 75° such that the mouse's nose will face upward. The two flexible fiber-optic arms of a halogen light source will be placed on either side of the mouse's neck to provide transillumination of the trachea. The tongue will be held to one side of the mouth with forceps. A sterile 68.6 mm gel-loading pipette tip, which is tapered for 25 mm to a narrow tip, will be attached to a P-100 pipettor and the 50 µl inoculum will be aspirated into the tip. The tip will be inserted into the trachea and the inoculum will be delivered by gentle and constant depression of the pipettor plunger. The tip will be removed from the mouse, the rubber band will be removed from the teeth, and the mouse will remain elevated for ~1 min to allow the inoculum to flow into the lungs by gravity. The tape will then be removed from the arms and the mouse will be returned to its cage to recover from anesthesia. Mice will remain in the laboratory for one hour after inoculation to permit careful monitoring of mice. The study endpoint will be either death (see section V.4.5) or euthanasia 14 days post-challenge. Obviously moribund animals will be euthanized using CO_2 inhalation or isoflurane inhalation followed by cervical dislocation (see section V.4.6).

C. For s.c. inoculation, 100-200 µl heat-activated *Bacillus* spores will be administered to each mouse behind the foreleg, between the scapulae, or at the base of the tail using a tuberculin syringe attached to a 26 gauge 0.5 inch needle. Mice will remain in the laboratory for one hour after inoculation to permit careful monitoring of mice. The study endpoint will be either death (see section V.4.5) or euthanasia 14 days post-challenge. Obviously moribund animals will be euthanized using CO_2 inhalation or isoflurane inhalation followed by cervical dislocation (see section V.4.6).

D. For i.p. inoculation, 100-200 µl heat-activated *Bacillus* spores or purified toxin components will be administered to each mouse into the peritoneal cavity through the ventral abdominal wall using a tuberculin syringe attached to a 26 gauge 0.5 inch needle. Mice will remain in the laboratory for one hour after inoculation to permit careful monitoring of mice. The study endpoint will be either death (see section V.4.5) or euthanasia 14 days post-challenge. Obviously moribund animals will be euthanized

using CO_2 inhalation or isoflurane inhalation followed by cervical dislocation (see section V.4.6).

V.1.1. Assessment of virulence of *B. anthracis* Sterne and *B. cereus* G9241 and mutants. In these studies, we will address the contributions of several virulence factors to the pathogenesis of *B. anthracis* Sterne and/or *B. cereus* G9241 disease. The 50% lethal doses (LD_{50}) for *B. anthracis* Sterne administered i.n. and s.c. to A/J mice are 6.3×10^4 and 1.6×10^5, respectively and the LD_{50}s for *B. cereus* G9241 administered to A/J mice via i.n. and s.c. routes are 3.2×10^5 spores and 1.3×10^3 spores, respectively (23). Further, we and others have previously demonstrated that the *B. cereus* G9241 megaplasmids that encode the capsule operons and the toxin genes are required for virulence (23). We propose to investigate the virulence of *B. anthracis* Sterne or *B. cereus* G9241 mutants that do not produce certain capsules, toxins, spore proteins, or virulence regulators. We will test the virulence of these strains via s.c., i.t., and/or i.p. routes.

V.1.1.1. Identification of LD_{50} of *B. anthracis* Sterne and *B. cereus* G9241 delivered via i.t. or i.p. routes. We first need to determine the LD_{50}s of *B. anthracis* Sterne and *B. cereus* G9241 after delivery by each route because we have not used these routes of inoculation to any significant degree in the past. *B. anthracis* Sterne or *B. cereus* G9241 spores will be administered via i.t. or i.p. routes as described above. The i.t. experiment will be done twice with each strain, with a wide range of doses used in the first experiment and a narrow range of doses used in the second experiment to more accurately pinpoint the LD_{50}. A previous study with *B. anthracis* Ames showed that the LD_{50}s for spores administered i.n. and i.t. were 3.7×10^4 and 8.7×10^2, respectively (14), so we anticipate that the LD_{50}s for *B. anthracis* Sterne and *B. cereus* G9241 spores delivered i.t. will be lower than the i.n. LD_{50}s (6.3×10^4 and 3.2×10^5 spores, respectively). In a preliminary i.p. study, we found that a dose of 10^3 spores was lethal to all mice. However, another group determined that the LD_{50} for *B. cereus* G9241 delivered i.p. was 3.8×10^2 spores (16). Thus, we will do one additional study with a narrow range of doses that should permit us to calculate the i.p. LD_{50} for *B. cereus* G9241.

Intratracheal experiment 1
Group 1: 5 mice: 10^1 *Bacillus* spores in H_2O
Group 2: 5 mice: 10^2 *Bacillus* spores in H_2O
Group 3: 5 mice: 10^3 *Bacillus* spores in H_2O
Group 4: 5 mice: 10^4 *Bacillus* spores in H_2O
Group 5: 5 mice: 10^5 *Bacillus* spores in H_2O
Group 6: 5 mice: 10^6 *Bacillus* spores in H_2O
Group 7: 3 mice: H_2O
33 A/J mice

Intratracheal experiment 2
Remove two doses farthest from LD_{50} and increase to 10 mice/group = **43 A/J mice**

Total for intratracheal experiments: (33 mice + 43 mice) x 2 bacterial strains = 152 A/J mice

Intraperitoneal experiment 1 for B. anthracis Sterne
Group 1: 5 mice: 10^1 *Bacillus* spores in H_2O
Group 2: 5 mice: 10^2 *Bacillus* spores in H_2O
Group 3: 5 mice: 10^3 *Bacillus* spores in H_2O
Group 4: 5 mice: 10^4 *Bacillus* spores in H_2O
Group 5: 5 mice: 10^5 *Bacillus* spores in H_2O
Group 6: 3 mice: H_2O
28 A/J mice

Intraperitoneal experiment 2 for B. anthracis Sterne
Remove two doses farthest from LD_{50} and increase to 10 mice/group = **33 A/J mice**

Intraperitoneal experiment for B. cereus G9241
Group 1: 10 mice: 10^1 *B. cereus* spores in H_2O
Group 2: 10 mice: 10^2 *B. cereus* spores in H_2O
Group 3: 10 mice: 10^3 *B. cereus* spores in H_2O
Group 4: 10 mice: 10^4 *B. cereus* spores in H_2O
Group 7: 3 mice: H_2O
43 mice

Total for Intraperitoneal experiments = 28 + 33 + 43 = 104 A/J mice

Total mice for V.1.1.1 = 152 + 104 = 256 A/J mice

V.1.1.2. Identification of LD_{50} of *B. anthracis* Sterne or *B. cereus* G9241 mutants delivered via s.c. and i.t./i.n. routes. We will assess the contribution of several virulence factors to the pathogenesis of *B. anthracis* Sterne or *B. cereus* G9241 disease. These experiments are designed similarly to the LD_{50} analyses in V.1.1.1 above, except that a positive control group of mice that are infected with $10xLD_{50}$ of the parent strain (*B. anthracis* Sterne or *B. cereus* G9241) will be included for comparison purposes. Inasmuch as possible, more than one mutant strain will be tested in a given experiment so that negative (H_2O) and positive ($10xLD_{50}$ of the parent strain) control groups can be shared. The LD_{50} for each mutant strain will be determined as above with two experiments.

Intratracheal/intranasal experiment 1 for Bacillus mutants
Group 1: 5 mice: 10^1 *Bacillus* mutant spores in H_2O
Group 2: 5 mice: 10^2 *Bacillus* mutant spores in H_2O
Group 3: 5 mice: 10^3 *Bacillus* mutant spores in H_2O
Group 4: 5 mice: 10^4 *Bacillus* mutant spores in H_2O
Group 5: 5 mice: 10^5 *Bacillus* mutant spores in H_2O
Group 6: 5 mice: 10^6 *Bacillus* mutant spores in H_2O
Group 7: 5 mice: $10xLD_{50}$ *Bacillus* parent strain spores in H_2O
Group 8: 3 mice: H_2O
38 A/J mice

Intratracheal/intranasal experiment 2
Remove two doses farthest from LD_{50} and increase to 10 mice/group for mutant strains only = **48 A/J mice**

Total for intratracheal experiments: (38 mice + 48 mice) x 20 mutant strains = 1720 A/J mice

Subcutaneous experiment 1 for Bacillus mutants
Group 1: 5 mice: 10^2 *Bacillus* mutant spores in H_2O
Group 2: 5 mice: 10^3 *Bacillus* mutant spores in H_2O
Group 3: 5 mice: 10^4 *Bacillus* mutant spores in H_2O
Group 4: 5 mice: 10^5 *Bacillus* mutant spores in H_2O
Group 5: 5 mice: 10^6 *Bacillus* mutant spores in H_2O
Group 6: 5 mice: 10^7 *Bacillus* mutant spores in H_2O
Group 7: 5 mice: 10xLD_{50} *Bacillus* parent strain spores in H_2O
Group 8: 3 mice: H_2O
38 A/J mice

Subcutaneous experiment 2
Remove two doses farthest from LD_{50} and increase to 10 mice/group for mutant strains only = **48 A/J mice**

Total for subcutaneous experiments: (38 mice + 48 mice) x 20 mutant strains = 1720 A/J mice

Total mice for V.1.1.2 = 1720 + 1720 = 3440 A/J mice

Total mice for V.1.1 = 256 + 3440 A/J mice = 3696 A/J mice

V.1.2. Experiment 2: Determination of toxicity of putative *B. cereus* G9241 lethal toxin (LT), edema toxin (ET), and Certhrax. The purpose of these studies is to investigate the potential for each of these toxins to contribute to *B. cereus* G9241 disease. As mentioned in the Background, LT is composed of PA + LF and ET is composed of PA + EF. The activity of these toxins in *B. anthracis* has been characterized; in these studies, we propose to confirm that the *B. cereus* G9241 toxins exhibit the same *in vivo* activities as their *B. anthracis* homologs. Additionally, Certhrax is a *B. cereus* G9241-specific toxin that contains a PA binding domain and a functional ADP-ribosyltransferase domain; however, we do not yet know if PA is required for Certhrax activity *in vitro* or *in vivo*. Prior to initiation of LD_{50} studies in mice, we will confirm that each toxin is functional in *in vitro* systems.

The LD_{50} studies will be conducted in C57BL/6J mice according to established models of LT and ET toxicity. Female C57BL/6J mice will be injected i.p. with PA + LF (1:1 ratio) or with PA + EF (1:1 ratio) in sterile saline as described in V.1, section 2D above. Previous studies by other groups have shown that C57BL/6 mice inoculated i.p. with

100 µg PA +100 µg LF from *B. anthracis* typically die within 3 days after injection (13) and those inoculated i.v. with 25 µg PA + 25 µg EF from *B. anthracis* also die within 3 days after injection (12). Mice will be weighed daily to determine if a correlation between weight loss and eventual death exists. Mice will be carefully monitored as described in V.4.5 and euthanized as in V.4.6 if they are extremely moribund.

The published lethal doses for the *B. anthracis* toxins and the relative *in vitro* toxicities of the *B. cereus* G9241 toxins compared to the *B. anthracis* toxins will guide the dosing strategy for the first LD_{50} study for each *B. cereus* G9241 toxin.

Lethal Toxin Experiment 1
Groups 1-7 will be intoxicated with doses of the B. cereus G9241 toxin components that correspond with the published LD_{50}s for each B. anthracis toxin (i.e. for Group 1, mice will be intoxicated with doses of the B. cereus G9241 PA and LF that correspond to 20 LD_{50}s of the B. anthracis toxin components)
Group 8 will be intoxicated with B. anthracis Sterne toxin components (control)

Group 1: 5 mice: 20xLD_{50} *B. anthracis* PA + 20xLD_{50} *B. anthracis* LF
Group 2: 5 mice: 10xLD_{50} *B. anthracis* PA + 10xLD_{50} *B. anthracis* LF
Group 3: 5 mice: 5xLD_{50} *B. anthracis* PA + 5xLD_{50} *B. anthracis* LF
Group 4: 5 mice: 1xLD_{50} *B. anthracis* PA + 1xLD_{50} *B. anthracis* LF
Group 5: 5 mice: 0.5xLD_{50} *B. anthracis* PA + 0.5xLD_{50} *B. anthracis* LF
Group 6: 5 mice: 10xLD_{50} *B. anthracis* PA
Group 7: 5 mice: 10xLD_{50} *B. anthracis* LF
Group 8: 5 mice: 10xLD_{50} *B. anthracis* PA + 10xLD_{50} *B. anthracis* LF
40 C57BL/6J mice

Lethal Toxin Experiment 2
Groups 1-5 will be intoxicated with B. cereus G9241 toxin components
Group 6 will be intoxicated with B. anthracis Sterne toxin components (control)

Group 1: 5 mice: 20xLD_{50} *B. cereus* PA + 20xLD_{50} *B. cereus* LF
Group 2: 5 mice: 10xLD_{50} *B. cereus* PA + 10xLD_{50} *B. cereus* LF
Group 3: 5 mice: 5xLD_{50} *B. cereus* PA + 5xLD_{50} *B. cereus* LF
Group 4: 5 mice: 1xLD_{50} *B. cereus* PA + 1xLD_{50} *B. cereus* LF
Group 5: 5 mice: 0.5xLD_{50} *B. cereus* PA + 0.5xLD_{50} *B. cereus* LF
Group 6: 5 mice: 10xLD_{50} *B. anthracis* PA + 10xLD_{50} *B. anthracis* LF
30 C57BL/6J mice

Total for Lethal Toxin experiments: 40 mice + 30 mice = 70 C57BL/6J mice

Edema Toxin Experiment 1
Groups 1-7 will be intoxicated with doses of the B. cereus G9241 toxin components that correspond with the published LD_{50}s for each B. anthracis toxin (i.e. for Group 1, mice will be intoxicated with doses of the B. cereus G9241 PA and EF that correspond to 20 LD_{50}s of the B. anthracis toxin components)
Group 8 will be intoxicated with B. anthracis Sterne toxin components (control)

Group 1: 5 mice: 20xLD$_{50}$ *B. anthracis* PA + 20xLD$_{50}$ *B. anthracis* EF
Group 2: 5 mice: 10xLD$_{50}$ *B. anthracis* PA + 10xLD$_{50}$ *B. anthracis* EF
Group 3: 5 mice: 5xLD$_{50}$ *B. anthracis* PA + 5xLD$_{50}$ *B. anthracis* EF
Group 4: 5 mice: 1xLD$_{50}$ *B. anthracis* PA + 1xLD$_{50}$ *B. anthracis* EF
Group 5: 5 mice: 0.5xLD$_{50}$ *B. anthracis* PA + 0.5xLD$_{50}$ *B. anthracis* EF
Group 6: 5 mice: 10xLD$_{50}$ *B. anthracis* PA
Group 7: 5 mice: 10xLD$_{50}$ *B. anthracis* EF
Group 8: 5 mice: 10xLD$_{50}$ *B. anthracis* PA + 10xLD$_{50}$ *B. anthracis* EF
40 C57BL/6J mice

Edema Toxin Experiment 2
Groups 1-5 will be intoxicated with B. cereus G9241 toxin components
Group 6 will be intoxicated with B. anthracis Sterne toxin components (control)

Group 1: 5 mice: 20xLD$_{50}$ *B. cereus* PA + 20xLD$_{50}$ *B. cereus* EF
Group 2: 5 mice: 10xLD$_{50}$ *B. cereus* PA + 10xLD$_{50}$ *B. cereus* EF
Group 3: 5 mice: 5xLD$_{50}$ *B. cereus* PA + 5xLD$_{50}$ *B. cereus* EF
Group 4: 5 mice: 1xLD$_{50}$ *B. cereus* PA + 1xLD$_{50}$ *B. cereus* EF
Group 5: 5 mice: 0.5xLD$_{50}$ *B. cereus* PA + 0.5xLD$_{50}$ *B. cereus* EF
Group 6: 5 mice: 10xLD$_{50}$ *B. anthracis* PA + 10xLD$_{50}$ *B. anthracis* EF
30 C57BL/6J mice

Total for Edema Toxin experiments: 40 mice + 30 mice = 70 C57BL/6J mice

Certhrax Experiment 1

Group 1: 5 mice: 500 µg PA + 500 µg Certhrax
Group 2: 5 mice: 100 µg PA + 100 µg Certhrax
Group 3: 5 mice: 50 µg PA + 50 µg Certhrax
Group 4: 5 mice: 5 µg PA + 5 µg Certhrax
Group 5: 5 mice: 1 µg PA + 1 µg Certhrax
Group 6: 5 mice: 100 µg PA
Group 7: 5 mice: 100 µg Certhrax
35 C57BL/6J mice

Certhrax Experiment 2

Group 1: 5 mice: 20xLD$_{50}$ *B. cereus* PA + 20xLD$_{50}$ Certhrax
Group 2: 5 mice: 10xLD$_{50}$ *B. cereus* PA + 10xLD$_{50}$ Certhrax
Group 3: 5 mice: 5xLD$_{50}$ *B. cereus* PA + 5xLD$_{50}$ Certhrax
Group 4: 5 mice: 1xLD$_{50}$ *B. cereus* PA + 1xLD$_{50}$ Certhrax
Group 5: 5 mice: 0.5xLD$_{50}$ *B. cereus* PA + 0.5xLD$_{50}$ Certhrax
Group 6: 5 mice: 10xLD$_{50}$ PA
Group 7: 5 mice: 10xLD$_{50}$ Certhrax
35 C57BL/6J mice

Total for Certhrax experiments: 35 mice + 35 mice = 70 C57BL/6J mice

Total mice for V.1.2 = 70 + 70 + 70 mice = 210 C57BL/6J mice

V.1.3. Experiment 3: *In vivo* imaging of *B. anthracis* Sterne germination, outgrowth, and dissemination. Our previous *in vivo* imaging studies used *B. anthracis* Sterne derivatives that produced a luminescent signal when spores germinated or grew vegetatively in response to host signals (19). The luminescent signal was sufficient to provide information about the general location *in vivo* of a large bolus of spores or vegetative bacilli, but we were unable to visualize the less intense signal *in vivo*; instead, we used *ex vivo* imaging of organs post-necropsy at specific time points post-inoculation. To more accurately study the stages of *Bacillus* growth and the locations within the host in which these events occur, we will use a new *in vivo* imaging system that we recently purchased.

The Carestream Multispectral FX Pro has a larger dynamic range and a higher signal:noise ratio for fluorescence; in addition, it has x-ray capability that permits more accurate signal localization. Construction of fluorescent *B. anthracis* Sterne reporter strains that contain one of the Red Fluorescent Proteins (RFPs) mKate2, E2-Crimson, and FP650 is underway. These reporters will be controlled by germination, vegetative growth, or sporulation promoters and will be expressed episomally. In addition, we plan to label *B. anthracis* Sterne-RFP spores with an AlexaFluor label, which will allow us to monitor deposition and uptake of spores in the airway in a manner that does not require bacterial transcription, which is required for expression of RFP. The choice of Alexa-Fluor label and RFPs allow for simultaneous measurement of multiple fluorophores at once with the Multispectral unmixing functionality of our *in vivo* imaging system.

V.1.3.1. Virulence assessment of *B. anthracis* Sterne-RFP strains. Our earlier studies showed that the LD_{50} for *B. anthracis* Sterne-*sspB::lux* spores administered s.c. to A/J mice is higher than that of the wild-type *B. anthracis* Sterne spores ($1.5x10^4$ CFU vs. $2.3x10^3$ CFU, respectively). Similarly, the LD_{50} for the *B. anthracis* Sterne-*sspB::lux* administered i.n. to A/J mice is $1.4x10^6$ CFU, while the LD_{50} for wild-type *B. anthracis* Sterne is $6.7x10^4$ CFU. Since fluorescence is more intense than luminescence, complete deposition of the spores into the lungs is critical when mimicking inhalational anthrax. In previous studies, we found that i.n. inoculation under isoflurane anesthesia can lead to deposition of the spores into both the airways and the gastrointestinal tract. For this reason we will inoculate mice via the i.t. route to ensure that spores are deposited directly into the airway. In order to use the *B. anthracis* Sterne-RFP constructs to monitor the different stages of infection, we first need to establish the LD_{50} for these strains when delivered s.c. or i.t. As mentioned above, we will test the s.c. and i.t. virulence of three different *B. anthracis* Sterne-RFP constructs (mKate2, E2-Crimson, FP650) that are expressed by promoters that are active during germination, vegetative outgrowth, or sporulation.

Subcutaneous Inoculation Experiment 1
Group 1: 5 mice: H_2O or sterile saline
Group 2: 10 mice: 10^3 *B. anthracis* Sterne-RFP spores
Group 3: 10 mice: 10^4 *B. anthracis* Sterne-RFP spores
Group 4: 10 mice: 10^5 *B. anthracis* Sterne-RFP spores
Group 5: 10 mice: 10^6 *B. anthracis* Sterne-RFP spores
Group 6: 10 mice: 10^7 *B. anthracis* Sterne-RFP spores
Group 7: 10 mice: 10^8 *B. anthracis* Sterne-RFP spores
Group 8: 10 mice: 10xLD_{50} *B. anthracis* Sterne spores
75 A/J mice

Subcutaneous experiment 2
Remove two doses farthest from LD_{50} = **55 A/J mice**

Total for s.c. experiments = (75 + 55) x 3 RFP strains = 390 A/J mice

Intratracheal Inoculation Experiment 1
Group 1: 5 mice: H_2O or sterile saline
Group 2: 10 mice: 10^4 *B. anthracis* Sterne-RFP spores
Group 3: 10 mice: 10^5 *B. anthracis* Sterne-RFP spores
Group 4: 10 mice: 10^6 *B. anthracis* Sterne-RFP spores
Group 5: 10 mice: 10^7 *B. anthracis* Sterne-RFP spores
Group 6: 10 mice: 10^8 *B. anthracis* Sterne-RFP spores
Group 7: 10 mice: 10xLD_{50} *B. anthracis* Sterne spores
65 A/J mice

Intratracheal experiment 2
Remove two doses farthest from LD_{50} = **45 A/J mice**

Total for i.t. experiments = (65 + 45) x 3 RFP strains = 330 A/J mice

Total mice for V.1.3.1 = 390 + 330 = 720 A/J mice

V1.3.2. Assessment of deposition, uptake and dissemination using Alexa Fluor-labeled live or dead spores. We will label *B. anthracis* Sterne-RFP spores with an Alexa-Fluor (AF) conjugate, a fluorescent molecule that emits fluorescence when the spore is intact (before germination occurs), so that we can monitor deposition and uptake with the *in vivo* imaging system. We will monitor germination, outgrowth, dissemination, and sporulation through detection of the RFP signal (different excitation and emission wavelengths than the AF). Thus, we will be able to observe each step of inhalational *B. anthracis* disease. In addition, mice will be inoculated with non-viable spores to observe deposition and uptake of spores by host cells in the absence of germination and to determine the length of time that spores can persist in the airway. Epidemiological data from the human anthrax outbreak in Sverdlovsk, USSR in 1979 suggest that viable spores can persist in the airway for up to 45 days after exposure (15).

Female A/J mice will be inoculated i.t. or s.c. (described in V.1, sections 2B and 2C) with 10xLD_{50} AF-labeled *B. anthracis* Sterne-RFP spores (determined in V1.3.1) in H_2O. At 0.5, 1, 6, 12, 24, 48, 72 hrs, and 2 weeks post-inoculation, 5 mice will be

anesthetized with isoflurane and placed on a heated platform within the imaging box of the Carestream Multispectral FX Pro for imaging(~ 5 min). After whole animal imaging, each mouse will be sacrificed by isoflurane overdose and the body cavity will be opened and the organs exposed for *ex vivo* imaging, then the organs will be harvested and homogenized for enumeration of spores and vegetative bacilli. This experiment will be done twice with each of the three AF-*B. anthracis* Sterne-RFP strains.

V.1.3.2.1: Dissemination of Alexa Fluor-labeled B. anthracis Sterne-RFP spores after i.t. inoculation

Group 1: 5 mice sacrificed at 0.5 hr: 10xLD_{50} AF-*B. anthracis* Sterne-RFP spores
Group 2: 5 mice sacrificed at 1 hr: 10xLD_{50} AF-*B. anthracis* Sterne-RFP spores
Group 3: 5 mice sacrificed at 6 hrs: 10xLD_{50} AF-*B. anthracis* Sterne-RFP spores
Group 4: 5 mice sacrificed at 12 hrs: 10xLD_{50} AF-*B. anthracis* Sterne-RFP spores
Group 5: 5 mice sacrificed at 24 hrs: 10xLD_{50} AF-*B. anthracis* Sterne-RFP spores
Group 6: 5 mice sacrificed at 48 hrs: 10xLD_{50} AF-*B. anthracis* Sterne-RFP spores
Group 7: 5 mice sacrificed at 72 hrs: 10xLD_{50} AF-*B. anthracis* Sterne-RFP spores
Group 8: 5 mice sacrificed at 14 days: 10xLD_{50} AF-*B. anthracis* Sterne-RFP spores
40 mice x 3 *B. anthracis* strains x 2 iterations = 240 A/J mice

V.1.3.2.2: Dissemination of Alexa Fluor-labeled B. anthracis Sterne-RFP spores after s.c. inoculation

Group 1: 5 mice sacrificed at 0.5 hr: 10xLD_{50} AF-*B. anthracis* Sterne-RFP spores
Group 2: 5 mice sacrificed at 1 hr: 10xLD_{50} AF-*B. anthracis* Sterne-RFP spores
Group 3: 5 mice sacrificed at 6 hrs: 10xLD_{50} AF-*B. anthracis* Sterne-RFP spores
Group 4: 5 mice sacrificed at 12 hrs: 10xLD_{50} AF-*B. anthracis* Sterne-RFP spores
Group 5: 5 mice sacrificed at 24 hrs: 10xLD_{50} AF-*B. anthracis* Sterne-RFP spores
Group 6: 5 mice sacrificed at 48 hrs: 10xLD_{50} AF-*B. anthracis* Sterne-RFP spores
Group 7: 5 mice sacrificed at 72 hrs: 10xLD_{50} AF-*B. anthracis* Sterne-RFP spores
Group 8: 5 mice sacrificed at 14 days: 10xLD_{50} AF-*B. anthracis* Sterne-RFP spores
40 mice x 3 *B. anthracis* strains x 2 iterations = 240 A/J mice

V1.3.2.3. Persistence of AF-B. anthracis spores in the airway. We will investigate the number of days that non-viable AF-*B. anthracis* Sterne spores persist in the airways by daily imaging of mice inoculated with these spores. We predict that the spores will remain fluorescent until they are cleared by the mouse. The AF-*B. anthracis* Sterne spores will be inactivated by ultraviolet irradiation or fixation in 10% formalin for one week. Loss of viability will be confirmed by bacterial enumeration on agar plates. A/J mice will be inoculated i.t. with non-viable AF-*B. anthracis* Sterne spores and monitored by whole body *in vivo* and organ *ex vivo* imaging as described in V.1.3.2.1.

Group 1: 5 mice sacrificed at 0.5 hr: 10^7 AF-*B. anthracis* Sterne spores
Group 2: 5 mice sacrificed at 2 days: 10^7 AF-*B. anthracis* Sterne spores
Group 3: 5 mice sacrificed at 4 days: 10^7 AF-*B. anthracis* Sterne spores
Group 4: 5 mice sacrificed at 7 days: 10^7 AF-*B. anthracis* Sterne spores
Group 5: 5 mice sacrificed at 14 days: 10^7 AF-*B. anthracis* Sterne spores
Group 6: 5 mice sacrificed at 21 days: 10^7 AF-*B. anthracis* Sterne spores
Group 7: 5 mice sacrificed at 28 days: 10^7 AF-*B. anthracis* Sterne spores
Group 8: 5 mice sacrificed at 35 days: 10^7 AF-*B. anthracis* Sterne spores
Group 9: 5 mice sacrificed at 42 days: 10^7 AF-*B. anthracis* Sterne spores
Group 10: 5 mice sacrificed at 49 days: 10^7 AF-*B. anthracis* Sterne spores
Group 11 5 mice sacrificed at 56 days: 10^7 AF-*B. anthracis* Sterne spores
55 mice x 2 iterations = 110 A/J mice

Total mice for V.1.3.2 = 240 + 240 + 110 = 590 A/J mice

Total mice for V.1.3 = 720 + 590 = 1310 C57BL/6J mice

V.1.4. Experiment 4. Characterization of efficacy of small molecule inhibitors of germination. Small molecules that prevent both *B. anthracis* spore germination and macrophage killing will be tested in A/J mice for the capacity to prevent disease progression and death of animals challenged i.t. or s.c. with otherwise lethal doses of *B. anthracis* Sterne spores. Additionally, the capacity of selected compounds to block, reduce the extent, or delay spore germination *in vivo* will be evaluated i.t. or s.c. inoculation with *B. anthracis* Sterne-RFP and treatment with the compound of interest.

V.1.4.1. Assessment of efficacy of 6-Thioguanine (6-TG) in preventing anthrax disease. The small molecule 6-TG has been shown to inhibit spore germination *in vitro* (1). The studies described here are designed to 1) test the efficacy of 6-TG in prevention of spore germination and/or anthrax disease *in vivo*, and 2) act as a pilot study that allows us to investigate routes of inoculation with inhibitor and spores as well as the timing of inhibitor administration in preparation for the studies outlined in V.1.4.2 below. These kinetics studies should allow us to focus future studies involving additional inhibitors so that we use fewer mice.

V.1.4.1.1. Pilot study to identify a safe dose of 6-TG to use for subsequent experiments. The LD_{50} of 6-TG in mice is 50 mg/kg (2). In a very small pilot study approved under MIC-06-148, we injected A/J mice s.c. with 5 µg/kg of 6-TG and challenged with *B. anthracis* Sterne-*lux* spores. This dose was chosen because it inhibited spore germination following uptake by macrophages *in vitro*. We determined that this dose did not cause harm to the mice in the absence of spores, but, in a very small group of mice (n=3), it did not protect the mice from mortality. As such, we now propose a pilot dose study to identify a higher dose of 6-TG that is not toxic to the mice. To identify a safe dose of 6-TG for use in subsequent studies, 5 A/J mice per group with be injected s.c. with 0.1 ml of 6-TG in ≤5% DMSO as in V.1.2.C. The study endpoint for this experiment will be either a moribund state (see section V4.5) or euthanasia approximately 1 week post-injection. Thus, it is not an

LD_{50} study, so we will not use death as an endpoint. This experiment will be done once.

Group 1: 5 mice: ≤5% DMSO
Group 2: 5 mice: 5 µg/kg 6-TG in ≤5% DMSO
Group 3: 5 mice: 50 µg/kg6-TG in ≤5% DMSO
Group 4: 5 mice: 500 µg/kg 6-TG in ≤5% DMSO
Group 5: 5 mice: 5 mg/kg 6-TG in <5% DMSO
25 A/J mice

V.1.4.1.2. Assessment of efficacy of 6-TG treatment for inhibition of germination. Mice will be treated s.c. or i.n./i.t. with 6-TG in ≤5% DMSO 1 hr prior to, concurrent with, or 1 hr after inoculation with 10x LD_{50} *B. anthracis* Sterne spores (see Table 1.4.1 below for a description of each treatment condition and Section V.1.2 for description of the inoculation methods). For s.c. delivery of 6-TG, the 6-TG will be diluted in sterile ≤5% DMSO in sterile saline and 0.1 ml of the dose identified in V1.4.1.1 will be delivered s.c. with a 26 gauge, 0.5 inch needle attached to a tuberculin syringe 9 V.1, section 2C). For i.n. delivery of 6-TG, mice will be anesthetized by isoflurane inhalation and 0.05 ml of the dose identified in V1.4.1.1 of 6-TG will be delivered i.n. using a pipet tip attached to a pipette (V.1.2.A). For mice that are inoculated into the airway with *B. anthracis* Sterne spores and 6-TG concurrently, the 6-TG will be administered i.t. with the spores as in V.1.2.B. Mice will be imaged twice daily with the Carestream *in vivo* imaging system, and they will be monitored for morbidity and mortality for 2 weeks. In addition, mice will be weighed daily to determine if a correlation between weight loss and eventual death exists. Mice will be euthanized by isoflurane overdose followed by cervical dislocation to terminate the experiment.

Table 1.4.1. Groups of A/J mice to be challenged with germination inhibitor 6-TG

Number of mice	*Time of inhibitor delivery*	*Inhibitor*	*Challenge*
10	1 hr pre-challenge	6-TG	Water
10		6-TG	*B. anthracis* Sterne-RFP spores
10		≤5% DMSO	*B. anthracis* Sterne-RFP spores
10	Simultaneous with challenge	6-TG	Water
10		6-TG	*B. anthracis* Sterne-RFP spores
10		≤5% DMSO	*B. anthracis* Sterne-RFP spores
10	1 hr post-challenge	6-TG	Water
10		6-TG	*B. anthracis* Sterne-RFP spores
10		≤5% DMSO	*B. anthracis* Sterne-RFP spores

V.1.4.1.2a: Subcutaneous delivery of inhibitor and challenge with B. anthracis Sterne-RFP spores

10 mice/group x 9 groups x 2 iterations: 180 mice

V.1.4.1.2a: Intranasal delivery of inhibitor and challenge with B. anthracis Sterne-RFP spores

10 mice/group x 9 groups x 2 iterations: 180 mice

Total number of mice for V.1.4.1: 25 + 180 + 180 = 385 mice

V.1.4.2. Assessment of efficacy of additional small molecule inhibitors in prevention of spore germination and/or anthrax disease. The small molecule inhibitors of germination to be screened in this group of experiments will be identified for *in vivo* analysis as a result of *in vitro* screening of libraries of small molecule inhibitors. Each compound in the small molecule libraries will be screened *in vitro* for the ability to inhibit germination of *B. anthracis* Sterne in culture as well as in tissue culture. Up to 10 of the most effective germination inhibitors *in vitro* will be screened for efficacy *in vivo* as described below. The identity and composition of each molecule are known. As potential germination inhibitors are identified, we will conduct literature searches to identify studies in which the molecule has been used in mice to guide our further experimentation. If the results obtained with 6-TG (V1.4.1) give a clear idea of the most effective experimental conditions under which inhibitory effects can be seen, we will limit our screening experiments to those parameters. However, it may be necessary to screen inhibitors by all of the following experimental parameters: i.) s.c. administration before inoculation, ii.) simultaneous s.c. administration, iii.) i.n. administration before inoculation and iv.) simultaneous i.t. administration. A minor modification will be made to this protocol to describe the identity, potential toxicity, proposed solvent, route(s) of administration, and dose (or range of doses, see V1.4.2.1 below) of each compound prior to commencing *in vivo* studies.

V.1.4.2.1. Pilot study to identify a safe dose of each small molecule inhibitor to use for subsequent experiments. The purpose of this experiment is to identify the safest dose of each small molecule that can be given to the mouse without causing apparent morbidity. Thus, it is not an LD_{50} study, so we will not use death as an endpoint. We will use the outcome of the pilot study in V.1.4.1.1 above and a thorough search of the literature about each compound to guide the pilot dosing study for each new compound to be tested. To identify a safe dose of each small molecule inhibitor for use in subsequent studies, 5 A/J mice per group with be injected s.c. with 0.1 ml of 1 of 4 different doses of inhibitor in solvent or solvent alone using a 0.5 inch, 26 gauge needle. The study endpoint for this experiment will be either a moribund state (see section V4.5) or euthanasia approximately 1 week post-injection. Mice exhibiting symptoms of toxicity, including ruffled fur, lethargy, decreased activity, or unresponsiveness to external stimuli will be euthanized by isoflurane overdose followed by cervical dislocation (see section V.4.1.4.). Note: when possible, the safety of multiple inhibitors will be tested simultaneously (in

different mice) so that a single group of control animals (solvent injection only) can be used so as to reduce the number of mice needed.

Group 1: 5 mice: solvent
Groups 2-5: 5 mice each: 10-fold dilutions of molecule in solvent

5 mice/group x 5 groups/inhibitor x 10 inhibitors = 250 A/J mice

V1.4.2.2 Assessment of efficacy of small molecule inhibitors in prevention of spore germination and/or anthrax disease. All procedures in V.1.4.2.2. will be conducted as above for V.1.4.2.1.

Table 1.4.2.2A. Groups of mice to be challenged with small molecule inhibitors of germination.

Stage	*Control or experiment*	*Number of mice*	*Number of inhibitors*	*Challenge*	*Total mice*
First screen of 5 inhibitors	Control	5/inhibitor	5	Water	25
		10 total	Solvent	*B. anthracis* Sterne-RFP spores	10
	Experiment	10/inhibitor	5	*B. anthracis* Sterne-RFP spores	50
					85
Second screen of 5 inhibitors	Control	5/inhibitor	5	Water	25
		10 total	Solvent	*B. anthracis* Sterne-RFP spores	10
	Experiment	10/inhibitor	5	*B. anthracis* Sterne-RFP spores	50
					85
Confirmation of 2 best inhibitors	Control	5/inhibitor	2	Water	10
		10 total	Solvent	*B. anthracis* Sterne-RFP spores	10
	Experiment	10/inhibitor	2	*B. anthracis* Sterne-RFP spores	20
					40

Each inhibitor will be tested under 4 conditions:
Experiment 4.2a: i.n. administration of inhibitor 1 hr pre-challenge
Experiment 4.2b: i.t. administration of inhibitor simultaneous with challenge
Experiment 4.2c: s.c. administration of inhibitor 1 hr pre-challenge
Experiment 4.2d: s.c. administration of inhibitor simultaneous with challenge

Table 1.4.2.2B. Calculation of total number of mice for Experiment 1.4.2.2			
Stage	*Experiment*	*Number of mice*	*Total number of mice*
Screening of up to 10 candidate inhibitors (5 per experiment)	Expt 4.2.2a: s.c. inhibitor pre-challenge	170	680 200 Pain C 480 Pain E

Grand total number of mice			840 240 Pain C 600 Pain E

Total number of mice for V.1.4.2 = 250 + 840 = 1090 mice

Total number of mice for V.1.4 = 385 + 1090 = 1475 A/J mice

V.1.5. Experiment 5. Characterization of vaccine candidates to protect against *B. anthracis* disease. In our prior animal protocols, we assessed the immunogenicity of intact *B. cereus* G9241 spores and *B. anthracis* Sterne exosporium proteins, as well as the protective efficacy of antibodies against these exosporium components in mouse models of s.c. and i.n. anthrax disease. Our previous immunization studies and our proposed studies comprise a single immunization with a suboptimal dose of of the toxin component PA expressed recombinantly (rPA), followed by immunization with the antigen or antigens under investigation (3, 6). We previously demonstrated that a sublethal dose of rPA enhances the protective efficacy of vaccines comprised of spore proteins (3, 6). In the proposed studies, we will immunize A/J mice with rPA followed by rBclA, glycosylated BclA (Gly-BclA), BxpA, ExsE, and/or p2138. BclA is a glycoprotein of the exosporium that will be used as a control in these studies as (b)(6) *et al* previously demonstrated that immunization with rBclA (not glycosylated) in conjunction with rPA provides protection against murine anthrax disease (3). We will also test the protection afforded by immunization with the native glycosylated form of BclA, Gly-BclA. After immunization, mice will be challenged subcutaneously with *B. anthracis* Sterne spores.

V.1.5.1. Immunization of A/J and BALB/c mice with formalin-inactivated spores (FIS) to generate antisera for *in vitro* studies. As mentioned above, we showed that s.c. or i.n. immunization of A/J mice with a single dose of *B. cereus* G9241 pBCXO1- pBC218- (double-cured G9241 or DC-9241) live spores or FIS conferred 100% protection from subsequent s.c. or i.n. *B. anthracis* Sterne challenge. In addition, our collaborators at

USAMRIID demonstrated that immunization of BALB/c mice with a single dose of DC-G9241 FIS i.p. or i.n. protected 55-60% of the mice from subsequent challenge with the fully virulent *B. anthracis* Ames. Studies are underway in our laboratory to identify the protective immunogens on the surface of DC-G9241 using immunoproteomics methods. To conduct these studies, we will use antisera from A/J and BALB/c mice immunized with DC-G9241 or *B. cereus* 569, a related but avirulent environmental isolate of *B. cereus* that, when administered in FIS form i.p. or i.n., protects BALB/c mice from *B. anthracis* Ames challenge slightly less effectively than does DC-G9241.

To generate antisera against DC-G9241 or *B. cereus* 569, we will inject FIS of either strain into groups of 10 A/J and 10 BALB/c mice. Spores will be inactivated by fixation in 10% formalin for one week and extensive washing with water. Loss of viability will be confirmed by bacterial enumeration on agar plates. A dose of 10^7 spores (as enumerated prior to fixation) will be injected s.c. with or without Alhydrogel (139 µg aluminum/dose, Section 4.4.3) twice 14 days apart. On day 29, mice will be deeply anesthetized with inhaled isoflurane and exsanguinated by cardiac puncture to collect blood, then sacrificed by cervical dislocation. In previous studies approved under MIC-09-418, the mice exhibited no signs of morbidity after FIS administration. However, if two or more signs of morbidity, as defined in V.4.5, are observed, mice will be euthanized by isoflurane overdose and cervical dislocation as in V.4.6.

Group 1: 10 A/J mice immunized with DC-G9241 FIS
Group 2: 10 A/J mice immunized with *B. cereus* 569 FIS
Group 3: 10 BALB/c mice immunized with DC-G9241 FIS
Group 4: 10 BALB/c mice immunized with *B. cereus* 569 FIS
(20 A/J mice + 20 BALB/c mice) x 2 iterations = 40 A/J and 40 BALB/c mice

V.1.5.2. Dissemination of AF-*B. anthracis* Sterne spores after immunization of A/J mice with DC-G9241 spores. As mentioned above, a AF-*B. anthracis* Sterne spore emits a fluorescent signal only until germination occurs; as the spore germinates into a vegetative bacillus, the labeled spore coat is shed and the fluorescent signal is quenched. In a preliminary *in vivo* imaging experiment with only a few mice, we observed that AF-*B. anthracis* Sterne spores remained fluorescent and in the lungs of A/J mice that were immunized with DC-G9241, while the fluorescent signal from AF-*B. anthracis* Sterne spores introduced to naïve mice was quenched rapidly. We propose to repeat this experiment with additional mice in an effort to understand the mechanism behind the inhibition and germination and dissemination observed in immunized mice.

Groups of 18 A/J mice will be immunized with 10^7 DC-G9241 viable or formalin inactivated spores or sham-immunized with sterile saline by i.p. injection or i.n./i.t. administration as in V.1.5.1 above. On day 29, we will inoculate mice with $10xLD_{50}$ AF-*B. anthracis*-Sterne spores (determined in V.1.3.1) via s.c. or i.t. administration. We will lightly anesthetize mice with inhaled isoflurane as in V.1.4.2.1 below and image them 0.5, 2, 6, and 12 hrs, and 1, 2, 3, 4, and 7 days post-inoculation. Two mice per time point will be sacrificed by isoflurane overdose and the organs will be imaged *ex vivo*. Organs will be fixed in 10% formalin and processed to determine the location of spores and vegetative bacilli. The experiment will be conducted twice and the time points will be adjusted for the second experiment if necessary.

Group 1: 18 mice immunized with viable 10^7 DC-G9241 spores in sterile saline
Group 2: 18 mice immunized with 10^7 DC-G9241 FIS in sterile saline
Group 3: 18 mice sham immunized with sterile saline

54 mice x 2 iterations = 108 A/J mice

V.1.5.3. Immunization of A/J mice with candidate spore antigens and subsequent challenge with *B. anthracis* Sterne spores. A/J mice will receive 1 dose of either PBS, 10-25 µg exosporium antigen, or 50 ng rPA on day 1, then a dose of 10-25 µg of each exosporium antigen (alone or in combination with other exosporium antigens) on day 15. Antigens will be mixed with TiterMax Gold or Alhydrogel (139 µg aluminum/dose) (Section 4.4.3) in a final volume of 0.1 ml. We previously used TiterMax Gold with success. We may use Alhydrogel instead of TiterMax Gold as the adjuvant so as to better mimic the currently licensed Anthrax vaccine.

Blood will be collected by tail venipuncture every two weeks beginning with day 0 and processed to determine the specific antibody titer. Immunogens emulsified in adjuvant will be injected i.p. with a tuberculin syringe attached to a 26 gauge 0.5 inch needle on days 1, 15, 29, and 43 or until a specific antibody response is detected in the sera. On the 14th day after the last boost, mice will be challenged s.c. with 10-20xLD_{50} of *B. anthracis* Sterne spores delivered from a tuberculin syringe attached to a 26 gauge 0.5 inch needle. Mice will be monitored as described in section V4.5 following infection. Mice will be weighed daily to determine if a correlation between weight loss and eventual death exists. The study endpoint for this virulence experiment will be either death (see section V4.5) or euthanasia 2 weeks post-infection. Obviously moribund animals will be euthanized by CO_2 inhalation or isoflurane inhalation followed by cervical dislocation (see section V.4.1.4.).

The immunogens that we plan to test are listed in Table V.1.5.1 below. These proteins were shown to react with antisera from mice that had been immunized with a derivative of *B. cereus* G9241 that was cured of both virulence plasmids (double-cured *B. cereus* G9241 or DC-G9241). Each experiment will be done twice. Additional antigens will be added to the protocol as they are identified in *in vitro* studies.

Table V.1.5.1. Candidate antigens and antigen combinations

V.1.5. Grand total for 2 iterations of each experiment				***750 A/J mice***

Total number of mice for V.1.5 = 385 + 1090 = 1475 A/J mice

V.2. Data Analysis: A sample size of 5-10 animals per condition will have 80% power to detect a difference of 1.3 - 1.8 standard deviations based on a *t* test for independent samples with a 5%, two-sided significance level. These are the smallest differences that would be considered clinically meaningful for this type of study. Because mice have not been extensively used for work with *Bacillus* species, we need to establish the baseline virulence of the strains and the derivatives of those strains with which we are working. Furthermore, we are testing several vaccine candidates for protective efficacy in treatments that may eventually be used in humans.

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered: At this time, there are no non-animal alternatives for animal use that would achieve the objectives outlined in these studies. Our justification for the use of the mouse model to study *Bacillus* virulence is that tissue culture systems challenged with *Bacillus* spores cannot always discriminate between animal-virulent and animal-attenuated strains. *In silico* simulations and *In vitro* cell culture studies were considered but rejected because they cannot address the objectives of these studies.

V.3.2. Animal Model and Species Justification: Animal use will help develop prophylactic and therapeutic measures to counter *B. anthracis* spore exposure in humans. The major goals of this project are to identify *B. anthracis* spore antigens and small molecule compounds that act as anti-germination targets and to identify key virulence determinants in *B. cereus*. The use of murine animal models is essential to the evaluation of therapeutic and preventative strategies against disease caused by *Bacillus* spp. since no *In vitro* systems or models are currently available to predict the efficacy of such reagents. The mouse is one of three small animal models (rabbit and guinea pigs are others) available for studying *B. anthracis* and *B. cereus* virulence and the efficacy of agents that may mitigate the effects of that disease. Mice are the lowest animal on the evolutionary scale with which to perform virulence studies for *B. anthracis* and *B. cereus*.

Studies of pathogenesis and virulence of *Bacillus* spp. have historically been performed in female mice (3, 5, 9, 10, 17, 19, 21-23). Our laboratory has always used female mice for these studies, as have other laboratories who study *Bacillus* virulence. In addition, female mice are used to reduce the impact of fighting among the mice. Further, all of the mice in an experimental group can be housed in the same cage when female mice are used.

V.3.3. Laboratory Animals

		Species #1
V.3.3.1.	**Genus & Species:**	*Mus musculus*
V.3.3.2.	**Strain/Stock:**	A/J, C57BL/6J, BALB/c
V.3.3.3.	**Source/Vendor:**	(b)(4)
V.3.3.4.	**Age:**	6-8 weeks
V.3.3.5.	**Weight:**	15-25 g
V.3.3.6.	**Sex:**	*Female
V.3.3.7.	**Special Considerations:**	-

V.3.4. Number of Animals Required (by Species): 7629

V.3.3.6: Studies of pathogenesis and virulence of *Bacillus* spp. have historically been performed in female mice (3, 5, 9, 10, 17, 19, 21-23). Our laboratory has always used female mice for these studies, as have other laboratories who study *Bacillus* virulence. In addition, female mice are used to reduce the impact of fighting among the mice. Further, all of the mice in an experimental group can be housed in the same cage when female mice are used.

V.3.5. Refinement, Reduction, Replacement (3 Rs):

V.3.5.1. Refinement: Titermax Gold™ or Alhydrogel will be used instead of Freund's adjuvant (complete and incomplete). TiterMax Gold™ and Alhydrogel are adjuvants known to be less reactogenic than Freund's. Alhydrogel is the adjuvant in the currently FDA-approved human anthrax vaccine AVA® In addition, we will use small pilot studies to rapidly narrow the number of bacteria or amount of therapeutic to be administered in subsequent LD_{50} studies. These pilot studies will be done with the smallest number of mice that will provide the necessary information in a statistically significant manner. We further minimize distress during the studies by careful cage-side monitoring of the animals to determine if an animal should be euthanized as described in V4.1.4 and V4.5. Signs indicating that euthanasia should be implemented would include an inability to reach food and water, labored breathing, excessive weight loss, and inability to remain upright.

V.3.5.2. Reduction: As many of our experiments involve infected/spore-treated animals or tissues, we do not participate in any shared tissue and/or control group studies with other investigators. We have taken into consideration all information we have gleaned from 9 years of experience working with this anthrax model when proposing subsequent experiments as well as in the refinement of the total number of animals required for the proposed experiments. With respect to the number of animals

required for each experiment, we have used the minimal number of animals required for biological and statistical significance (generally 5 to 10 animals per group). Most experiments will be performed in duplicate to confirm the data. In these experiments, the two spore doses that are farthest from the LD_{50} of the strain in question will be eliminated in the second experiment in order to reduce the number of mice used.

V.3.5.3. Replacement: At this time, there are no replacements for animal use that would achieve the objectives outlined in these studies. Our justification for the use of the mouse model to study *Bacillus* virulence is that tissue culture systems challenged with *Bacillus* spores cannot always discriminate between animal-virulent and animal-attenuated strains. *In silico* simulations and *in vitro* cell culture studies were considered but rejected because they cannot address the objectives of these studies.

V.4. Technical Methods:

V.4.1. Pain / Distress Assessment:

V.4.1.1. APHIS Form 7023 Information:

V.4.1.1.1. Number of Animals: Animals are assigned to pain category E because we use death as an endpoint for the majority of our experiments. The symptoms on *Bacillus* infection, which will not be relieved using analgesics or antibiotics, are as follows: ruffled fur, lethargy, hunched posture, decreased alertness, weight loss, difficulty breathing, unresponsiveness to external stimuli, and trembling. Animals that are used as controls in each experiment (no spore inoculation) and animals that will be injected with small molecules during the studies outlined in V1.4 are assigned to pain category C because we do not expect them to suffer in any way from the control treatments.

Table V.4.1.1.1. Breakdown by study number of experimental and control animals for pain category assignment.

Experiment	*Total number of mice*	*Pain Category C*	*Pain Category E*
V.1.1.1	256	21	235
V.1.1.2	3440	240	3200
V.1.2	210	30	180
V.1.3.1	720	60	660
V.1.3.2.1	240	0	240
V.1.3.2.2	240	0	240

V.4.1.1.1.2. Column D:	-	-	-
V.4.1.1.1.3. Column E:	6135	180	0

V.4.1.2. Pain Relief / Prevention:

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization: We will use inhalation of isoflurane gas (1.5-3.0% in O_2) to anesthetize animals for *in vivo* imaging studies. We will use either an i.p. injection of ketamine-xylazine (100 mg/kg ketamine and 25 mg/kg xylazine) or inhalation of isoflurane gas (1.5-3.0% in O_2) to anesthetize animals for i.t. and i.n. inoculation. Animals used in s.c and i.p. challenge are not expected to endure anything more than momentary pain, so no analgesics will be necessary.

For imaging studies, isoflurane has the advantage of maintaining the mice under anesthesia during the imaging procedure while permitting the animals a quick recovery time. The anesthetized mice will be placed on a warm platform and monitored for bioluminescence for 5 min at 0.5, 1, 3, 6, 12, 24, 48, and/or 72 h post infection. To anesthetize the mice and secure their immobility during imaging with the Carestream Multispectral *in vivo* imaging system, we will follow the following procedures. Administration of isoflurane gas will be done via a Gas Anesthesia System that delivers isoflurane gas to a 5-port anesthesia manifold housed in the imaging chamber of the *in vivo* imaging system. Animals will be initially placed into an induction chamber and anesthetized with isoflurane (3-4%) with oxygen as the carrier gas. Once the animals are properly sedated, they will be swiftly moved to nose cones on the 5-port anesthesia manifold housed in the imaging chamber and maintained at 1.5-3.0% isoflurane. Any unused manifold ports will be closed off. Sufficient time will be given to allow the anesthetic gas to reach the manifold nose cones prior to removing the animals from the induction chamber. Both the induction chamber and manifold will be set to deliver isoflurane at a constant rate. The manifold also provides waste gas scavenging ports to help prevent gas from entering the surrounding work environment. A built-in vacuum system helps ventilate waste gas away from researchers and into disposable isoflurane-absorbing filters. In both anesthesia procedures, depth of anesthesia will be assessed by the onset and maintenance of slow, shallow breathing as well as the loss of toe pinch response in the animals.

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions: Only mice that appear to be in good health will undergo anesthesia. We define good health as clean unruffled fur, alert demeanor and no obvious signs of sickness. Mice recovering from anesthesia will be placed into a clean cage with external heat applied (a heating pad placed under the recovery cage) to prevent mice from undergoing a rapid loss in body temperature. Once the mice have roused from anesthesia and appear to be moving in an alert manner, they will be placed back into a clean cage with their cage mates. All mice will be monitored in the laboratory for at least one hour prior to their return to (b)(6)

V.4.1.2.3. Paralytics: N/A

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures:

V.4.1.3.1. Sources Searched: AGRICOLA and PUBMED databases were searched

V.4.1.3.2. Date of Search: 12 December 2011

V.4.1.3.3. Period of Search: AGRICOLA Database (1970 – December 2011), PUBMED Database (1966 – December 2011, English only)

V.4.1.3.4. Key Words of Search: Pain AND (alleviation OR alleviate OR alternative OR reduction) AND (mouse OR mice) AND (*Bacillus*)

V.4.1.3.5. Results of Search: The search for *Bacillus* and mouse and pain and alternative yielded no documents in AGRICOLA and two documents in PUBMED. The documents did not provide any methods for alleviation of pain or distress in mouse models that we use.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification: No analgesics will be given to *Bacillus*-infected animals for the following reasons. Inflammation and/or the inflammatory response are key components of *Bacillus*-mediated disease (macrophages play a key role in the dissemination of *Bacillus* spp). Because we will be using the mouse as a model to study both the pathogenesis of disease and possible treatment therapies, we believe that the use of non-steroidal anti-inflammatory drugs and opioids could confound or possibly mask the extent of *Bacillus*-mediated damage that we will evaluate by histological examination or toxicity (18).

Mice will be weighed daily to determine if a correlation between weight loss and eventual death exists. Investigator and staff will carefully monitor *Bacillus*-infected animals and euthanize those that appear moribund because it is our experience that these animals will ultimately succumb to *Bacillus* infection after inoculation. We define extremely moribund as when a mouse exhibits 2 or more of the following symptoms: ruffled fur, lethargy, hunched posture, impaired ambulation that prevents the animals from reaching food and water, excessive weight loss/emaciation, difficult or labored breathing, and the inability to remain upright. Death due to infection after i.n., i.t., s.c., or i.p. inoculation with *B. anthracis* and *B. cereus* typically occurs 3-5 days post-inoculation. During this time period, mice will be inspected every 4 h during normal working hours and every 8 h during non-business hours. All inspections will be noted on cage cards so that LAM personnel are aware that the mice are being monitored.

V.4.2. Prolonged Restraint: N/A

V.4.3. Surgery: N/A

V.4.3.1. Pre-surgical Provisions: N/A

V.4.3.2. Procedure: N/A

V.4.3.3. Post-surgical Provisions: N/A

V.4.3.4. Location: N/A

V.4.3.5. Surgeon: N/A

V.4.3.6. Multiple Major Survival Operative Procedures: N/A

V.4.3.6.1. Procedures: N/A

V.4.3.6.2. Scientific Justification: N/A

V.4.4. Animal Manipulations:

V.4.4.1. Injections: We will be giving i.p. and s.c. injections. All mouse injections are given with a 26 gauge 0.5 inch needle attached to a tuberculin syringe. All doses are given in a total volume of 0.1-0.2 ml.

For Immunization – for each mouse in this set of experiments, each recombinant exosporium protein or combination of proteins will be emulsified 1:1 with TiterMax (TiterMax, Norcross, Georgia 30092) or Alhydrogel and will be administered at a dosage of 25 µg protein (antigen) per animal. For spore immunization, 10^7 DC-G9241 viable or formalin inactivated spores will be administered by i.p. injection with or without Alhydrogel. Antigen/adjuvant will be administered by i.p. injection through the ventral abdominal wall with a tuberculin syringe attached to a 26 gauge 0.5 inch needle. Doses of antigen/adjuvant will be in a volume of 100 µl/animal. Control animals will receive 100 µl of saline- or PBS-adjuvant emulsion minus antigen. The injections will be done 10-14 days apart.

For Small Molecule Treatment – each mouse in the pilot experiments (to identify a non-toxic dose) will be injected s.c. between the scapulae, at the base of the tail, or behind the right foreleg with 0.1 ml of 1 of 4 different doses of the small molecule in water using a 0.5 inch, 26 gauge needle. Once a non-toxic dose of the small molecule is identified, each mouse in these experiments will be injected s.c. in the same location with 0.1 ml of that dose of small molecule in water using a 0.5 inch, 26 gauge needle.

For Spore Challenge or Toxin Administration – for each mouse in this set of experiments, heat-activated *Bacillus* spores will be administered via s.c. injection between the scapulae, at the base of the tail, or behind the right foreleg or via i.p. injection through the ventral abdominal wall using a tuberculin syringe attached to a 26 gauge 0.5 inch needle. Spores will be in a volume of 100-200 µl/animal. Toxin components will be injected i.p. through the ventral abdominal wall using a tuberculin syringe attached to a 26 gauge 0.5 inch needle.

For Anesthesia – for each mouse in this set of experiments, anesthesia will be induced by either by i.p. injection through the ventral abdominal wall of ketamine-xylazine (100 mg/kg ketamine, 25 mg/kg xylazine) in sterile phosphate buffered saline (PBS) using a tuberculin syringe attached to a 26 gauge 0.5 inch needle or inhalation of

isoflurane gas (1.5-3.0% in O_2) to anesthetize animals prior to imaging (see anesthesia section V.4.1.2.1).

V.4.4.2. **Biosamples:**

Blood samples from immunized mice will be obtained from the tail vein of mice using either a 26 gauge ½" needle or by nicking the tail with a sterile razor blade and collecting about 0.1 ml of whole blood into a sterile 1 ml tube. This will be done will be done 10-14 days apart prior to each subsequent boost. Exsanguination by terminal cardiac puncture will be conducted under deep isoflurane anesthesia. Once anesthetized, as confirmed by lack of toe-pinch response, each mouse will be placed on its back and a sterile 23 gauge ½" needle will be introduced directly into the heart through the chest cavity. The syringe plunger will be gently pulled to remove as much blood as possible from the mouse.

Lungs and other organs will be removed from the mice post-euthanasia as needed.

V.4.4.3. **Adjuvants**: TiterMax Gold contains the block copolymer CRL-8300, the metabolizable oil squalene, and a unique microparticulate stabilizer. Alhydrogel 2% is provided as a ready-to-use, sterile aluminium hydroxide wet gel (colloidal) suspension. TiterMax [1:1 (v/v)] will be resuspended with antigen in a total volume of 0.1 ml and will be given by i.p. injection. Alhydrogel 2% (139 µg Aluminum/dose) will be resuspended with antigen in a final volume of 0.1 ml and will be given by i.p. injection. The injections will be done 10-14 days apart with a tuberculin syringe attached to a 26 gauge 0.5 inch needle. Mice will be monitored daily after immunization. In the event of an adverse reaction to the adjuvant (injection site reaction), LAM veterinary staff will be consulted as to the proper course of action (alternative endpoint or veterinary treatment). Immunized mice that appear moribund will be sacrificed by isoflurane overdose and cervical dislocation.

V.4.4.4. **Monoclonal Antibody (MAbs) Production**: N/A

V.4.4.5. **Animal Identification:** Mice will be identified by cage cards and/or ear punch. Ear punches will be administered by (b)(6) staff (e.g. models EP-901 or EP-900, Braintree Scientific Inc., Braintree, MA 02185). (also see Section VI for staff qualifications).

V.4.4.6. **Behavioral Studies**: N/A

V.4.4.7. **Other Procedures:**

Inoculation or immunization by the intranasal route will take place under isoflurane anesthesia by the droplet method. Approximately 50 µl will be administered onto the nose of each mouse using a previously sterile pipet tip attached to a manual pipetman. The mouse will be allowed to inhale the droplet at will and then be returned to its cage.

Inoculation by the intratracheal route will take place under ketamine (100 mg/kg)-xylazine (10 mg/kg) anesthesia. Once anesthetized (defined as no response to toe pinch), each mouse will be placed on its back on a flat surface that can be elevated 75°. Paper tape will be applied to each arm to gently adhere the arms to the flat

surface. A hypodermic needle will be inserted into the flat surface ~5 cm from the top of the mouse's head. A rubber band will be looped over the needle and under the upper incisors of the open mouth of the mouse to tilt the neck backward and to hold the mouth open. The flat surface will be elevated to 75° such that the mouse's nose will face upward. The two flexible fiber-optic arms of a halogen light source will be placed on either side of the mouse's neck to provide transillumination of the trachea. The tongue will be held to one side of the mouth with forceps. A sterile 68.6 mm gel-loading pipette tip, which is tapered for 25 mm to a narrow tip, will be attached to a P-100 pipettor and the 50 µl inoculum will be aspirated into the tip. The tip will be inserted into the trachea and the inoculum will be delivered by gentle and constant depression of the pipettor plunger. The tip will be removed from the mouse, the rubber band will be removed from the teeth, and the mouse will remain elevated for ~1 min to allow the inoculum to flow into the lungs by gravity. The tape will then be removed from the arms and the mouse will be returned to its cage to recover from anesthesia.

Imaging of mice: Anesthetized mice will be placed on a warm platform within the Carestream Multispectral *in vivo* FX Pro imaging system and monitored for fluorescence for 5 min at a time at 0.5, 1, 3, 6, 12, 24, 48, and/or 72 h post-inoculation.

Photography: Mice may be photographed during inoculation procedures, during *in vivo* imaging, and post-mortem. Photos of inoculation procedures will only be used for teaching rodent handling techniques to new members of the laboratory. Photos from *in vivo* imaging will be used in seminars presented by approved users on this protocol and may be published in research articles. No photos will be taken of mice that are visibly moribund. The photos will be stored only on password-protected DoD computers at USUHS. Photos will be disposed of 5 years after the end of the project.

V.4.4.8. Tissue Sharing: As many of our experiments involve infected/spore-treated animals or tissues, we do not participate in any shared tissue and/or control group studies with other investigators.

V.4.5. Study Endpoint: Table V.4.5.1 below summarizes the endpoint for each proposed experiment. The study endpoint for virulence and challenge studies with infected mice will be death or euthanasia approximately 14 days post-inoculation with spores. The study endpoint for mice immunized with various exosporium protein preparations or capsule preparations and inoculated with *B. anthracis* or *B. cereus* spores will occur 43-70 days post immunization (14 days post-inoculation). The study endpoint for mice monitored for fluorescence will be 72 h or 2 weeks post-infection. For all studies, mice will be weighed daily to determine if a correlation between weight loss and eventual death exists. Investigator and staff will carefully monitor *Bacillus*-infected animals and euthanize those that appear moribund because it is our experience that these animals will ultimately succumb to *Bacillus* infection after inoculation. We define extremely moribund as when a mouse exhibits 2 or more of the following symptoms: ruffled fur, lethargy, hunched posture, impaired ambulation that prevents the animals from reaching food and water, excessive weight loss/emaciation,

difficult or labored breathing, and the inability to remain upright. Death due to infection after i.n., i.t., s.c., or i.p. inoculation with *B. anthracis* and *B. cereus* typically occurs 3-5 days post-inoculation. During this time period, mice will be inspected every 4 h during normal working hours and every 10-12 h during non-business hours. All inspections will be noted on cage cards so that LAM personnel are aware that the mice are being monitored.

Table V4.5.1. Endpoint and time to endpoint for each study in proposal			
Experiment	*Number of mice*	*Endpoint*	*Time to endpoint*
V.1.1.1	256	Death or sacrifice when moribund	14 days
V.1.1.2	3440	Death or sacrifice when moribund	14 days
V.1.2	210	Death or sacrifice when moribund	14 days
V.1.3.1	720	Death or sacrifice when moribund	14 days
V.1.3.2.1	240	Euthanasia	0.5, 1, 6, 12, 24, 48, 72 hrs, 14 days
V.1.3.2.2	240	Euthanasia	0.5, 1, 6, 12, 24, 48, 72 hrs, 14 days
V.1.3.2.3	110	Euthanasia	0.5 hr, 2, 4, 7, 14, 21, 28, 35, 42, 49, 56 days
V.1.4.1.1	25	Euthanasia	7 days
V.1.4.1.2	360	Death or sacrifice when moribund	14 days
V.1.4.2.1	250	Euthanasia	7 days
V.1.4.2.2	840	Death or sacrifice when moribund	14 days
V.1.5.1	80	Euthanasia	29 days
V.1.5.2	108	Euthanasia	0.5, 2, 6, 12, 24, 48, 72, 96 hrs, 7 days
V.1.5.3	750	Death or sacrifice when moribund	14 days

V.4.6. Euthanasia: Mice will be euthanized by either isoflurane overdose (4-5% concentration) within the isoflurane induction chamber located inside a fume hood, followed by cervical dislocation, or by CO_2 overdose. CO_2 will be delivered from a compressed gas cylinder via a regulated rate of flow in accordance with the 2007 AVMA Committee on Euthanasia. For euthanasia using CO_2, all procedures will be performed by LAM personnel in LAM facilities. Investigative staff will perform isoflurane and cervical dislocation euthanasia procedures; death will be confirmed by performing bilateral thoracotomy (as listed in the 2007 AVMA Guidelines on Euthanasia).

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol.

V.5.1.1. Study Room:

Building(s) (b)(6) Room Number(s) (b)(6) (b)(6)

V.5.1.2. Special Husbandry Provisions: Care must be taken to avoid spread of the *Bacillus* among mice in other cages. Mice infected with *Bacillus* will be left in filter-top cages in (b)(6) To minimize spore dissemination, our laboratory staff will be responsible for changing cages and feeding/watering our mice once they have been inoculated. With respect to infected animals, all bedding, animal carcasses and wastes should be treated as infectious and autoclaved. Mouse carcasses will be treated as biohazard waste and will be double bagged and labeled with a burn tag. Gloves, lab coats and masks should be worn by all personnel when handling potentially infectious material.

Food Restriction: Yes _____ No X

Fluid Restriction: Yes _____ No X

V.5.1.3. Exceptions: N/A

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care: Animals will be observed and cared for by the Center for LAM personnel according to USUHS Center for LAM SOPs. In addition, infected mice will be cared for and checked twice daily or more frequently as needed by members of Dr. (b)(6) laboratory staff working on this project.

V.5.2.2. Emergency Veterinary Medical Care: All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: Except as indicated below, all animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents; balls, toys and food enrichment treats for large animal species.

V.5.3.2. Enrichment Restrictions: N/A

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING: Dr. (b)(6) who will not do these "hands on" experiments herself, has 35 years experience working with mice in microbicidal assays and has been involved with the mouse anthrax model since 2002. Dr. (b)(6) is a senior scientist who has worked on the anthrax project since 2009 and has taken the Investigator Training Course. Dr. (b)(6) has 2 years experience working with rodents. Dr. (b)(6) is a postdoctoral fellow with 7 years of experience working with rodents and has taken the Investigator Training Course. Dr. (b)(6) has 15 years experience using animal models of infection with various organisms; she has taken the USUHS Investigator Training Course and a rodent handling course at another institution. LTC (b)(6) VMD, is a veterinary pathologist in the United States Army. He has been a veterinarian for 16 years and has 2.5 years of experience with mouse

models of infection. Mr. (b)(6) is a senior technician who has worked for 20years with EHEC/EPEC infection in mice and 7 years with anthrax models. Mr. (b)(6) has 6 years of experience working in our laboratory with mouse models of anthrax disease. Finally, Mr. (b)(6) has no experience working with rodents but has taken the Investigator Training Course. He will be trained by Mr. (b)(6) and Mr. (b)(6) Please see the table below for a specific breakdown of the procedures that each individual will perform and each person's training and experience.

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
Intranasal inoculation	(b)(6)	Senior Scientist, 15 yr experience	1 (2008), 3 (1997), 5 (UAB, 1997; UW 2004; NIH 2007)
Intranasal inoculation		Senior Scientist, 2 yr experience	1 (2009), 4 (2009-2011, Mr. (b)(6)
Intranasal inoculation		Postdoctoral Fellow, 6.5 yr experience	1 (2011), 3 (UVA, 2005), 4 (2011, Mr. (b)(6) 5 (UVA, 2005)
Intranasal inoculation		Graduate Student, 2 yrs experience	1 (2009), 3 & 5 (University of Pennsylvania School of Veterinary Medicine, 1995)
Intranasal inoculation		Senior Research Technician, 20 yrs experience	1, 4 (FDA (b)(6) 2004)
Intranasal inoculation		Research Technician, 7 yr experience	1, 4 (Drs. (b)(6) (b)(6) 2004)
Intranasal inoculation		Research Technician, 1 yr experience	1 (2010), 4 (2011, Mr. (b)(6)
Subcutaneous injection		Senior Scientist, 15 yr experience	1 (2008), 3 (1997), 5 (UAB, 1997; UW 2004; NIH 2007)
Subcutaneous injection		Senior Scientist, 2 yr experience	1 (2009), 4 (2009-2011, Mr (b)(6)
Subcutaneous injection		Postdoctoral Fellow, 6.5 yr experience	1 (2011), 3 (UVA, 2005), 4 (2011, Mr. (b)(6) 5 (UVA, 2005)
Subcutaneous injection		Graduate Student, 2 yrs experience	1 (2009), 3 & 5 (University of Pennsylvania School of Veterinary Medicine, 1995)
Subcutaneous injection		Senior Research Technician, 20 yrs experience	1 (1992), 4 (Dr (b)(6) (b)(6) 1995)
Subcutaneous injection		Research Technician, 7 yr experience	1, 4 (Drs. (b)(6) (b)(6) 2004)
Subcutaneous injection		Research Technician, 1 yr experience	1 (2010), 4 (2011, Mr. (b)(6)
Intratracheal inoculation		Senior Scientist, 15 yr experience	1 (2008), 3 (1997), 5 (UW, 2004)
Intratracheal inoculation		Senior Scientist, 2 yr experience	1 (2009), 4 (2011, Mr. (b)(6)

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)

2 USUHS Rodent Handling Course
3 Other Rodent Handling Course
4 Site Specific Training
5 External Course Training

VII. **BIOHAZARDS/SAFETY:** With respect to mice used in the anthrax model, bedding may be contaminated with *Bacillus* spores. The bedding and animal carcasses should be treated as infectious and autoclaved. Infected animals will be maintained under ABSL-2 conditions in filter-top cages. All procedures that involve the use of isoflurane will be conducted in either a chemical fume hood (euthanasia) or in an anesthesia system with waste-scavenging charcoal filters (both located in Dr. (b)(6) laboratory). In addition, all personnel who will use isoflurane will be made aware of its associated safety hazards and will be properly trained in its use.

All personnel will wear a disposable gown, gloves, and mask at all times when handling mice. A N95 respirator mask will be worn during inoculation procedures and inoculation procedures will be conducted in a Type II Biosafety Cabinet (in (b)(6) when possible. Sharps will be disposed of in approved Sharps containers located in (b)(6) and Sharps containers will be disposed of as Regulated Medical Waste through the EHS office. All cage changes will be done in a Type II Biosafety Cabinet (in (b)(6)

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

(b)(6) _____ 12/15/11

Principal Investigator Signature Date

G. Training: The following personnel will attend the next USUHS Investigator/Animal User Training Course:

_____ _____

_____ _____

H. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely, "Responsibility" for implementing animal use alternatives where feasible and conducting humane and lawful research.

(b)(6) _____ 12/15/11

Principal Investigator Signature Date

I. **Painful Procedure(s):**

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL or WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

Principal Investigator Signature Date

X. PROTOCOL ABSTRACT:

A. Animal Protocol Number: [redacted]

B. Animal Protocol Title: New Therapies and Vaccines against *Bacillus anthracis* (mice)

C. Principal Investigator: [redacted] Ph.D.

D. Performing Organization: USUHS

E. Funding: Biological Defense Research Directorate, Naval Medical Research Center

F. Objective and Approach: *Bacillus anthracis*, a Gram-positive spore-forming rod, is the causative agent of human anthrax, which can manifest as cutaneous, gastrointestinal or inhalational disease depending on the route of inoculation. Although it has long been recognized that the spores of *B. anthracis* could be used as a weapon of biowarfare and/or bioterrorism, no successful nefarious application of the microbe in the United States was reported until October 4th, 2001. From then until December 2001, 22 cases of confirmed or suspected bioterrorism-related anthrax occurred, 11 of which were inhalational. A prevailing health concern is that the people who receive antibiotic prophylaxis, as was the case for hundreds of people who were exposed in 2001, may present with inhalational anthrax after the conclusion of their therapy as dormant viable spores germinate. One way to increase the likelihood of patient survival as well as enhance the probability of protection for those exposed to *B. anthracis* spores is to prevent the germination of the infectious dormant spores into active vegetative cells. In the proposed studies, we will characterize the protective efficacy of immunizing mice with *B. anthracis* spores or spore surface (called the exosporium) proteins prior to inoculation with *B. anthracis* Sterne spores (avirulent for humans but virulent for mice) via intratracheal or subcutaneous routes. In addition, we will assess the efficacy of small molecule inhibitors of spore germination that we have identified and characterized *in vitro*. The proposed immunization and small molecule inhibitor studies will be enhanced by our ability to monitor germination, outgrowth and dissemination in the mouse through the application of an *in vivo* imaging system using spores that are fluorescent. Further, we will broaden the scope of our studies to investigate the factors of *B. cereus* that allow it to cause human disease using approaches similar to those described above for *B. anthracis*. *B. cereus* causes gastroenteritis and eye infections in otherwise healthy individuals and can cause sepsis, meningitis, and endocarditis in immunocompromised persons. The studies proposed here utilize the minimum number of mice, which are the best small animal model for *Bacillus* studies, while maintaining sufficient power to accurately assess the stages of *B. anthracis* and *B. cereus* infection.

G. Indexing Terms (Descriptors): animals, mice, *Bacillus anthracis*, *Bacillus cereus*, small molecule inhibitors, immunization, exosporium, capsule, *in vivo* imaging, fluorescence, toxin, anthrax

MEMORANDUM FOR DR (b)(6)
(b)(6)

SUBJECT: IACUC Approval of Protocol – Triennial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on December 19, 2014:

Title of Application: "Use of Salmonella Typhimurium Enterobacterial Common Antigen Mutants as a Vaccine and Vehicle for Heterologous Antigen Delivery (Mice/Mus musculus))"

USUHS Protocol Number: (b)(6)

Expiration Date: December 18, 2017

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

TECHNICIANS(S): (b)(6)

I. NON-TECHNICAL SYNOPSIS: Most infectious diseases initiate at mucus membrane surfaces and 15-20 million adults and children acquire or die of these types of infections annually. *Salmonella* spp. are a group of bacteria that causes diverse mucosal infections. Among this group, *Salmonella enterica* serovar Typhimurium (*S.* Typhimurium) is one of the most prominent strains to cause infection. As we assumed that this knowledge could help with the design of effective vaccines to prevent *Salmonella* infections, our previous studies sought to identify genes of the bacterium that were important for surviving in the host and causing disease. We identified a glycolipid known as ECA, which is ubiquitously found on the surface of *S.* Typhimurium as well as other closely related bacteria. We showed that ECA negative mutant strains did not cause disease in mice; however rather than being cleared from the animals, these mutant strains set up a persistent infection that lasts for long periods of time. Excitingly, immunization of mice with ECA negative mutant strains provided protection against a subsequent lethal challenge with wild type *S.* Typhimurium. Thus, ECA negative strains of *Salmonella* may be useful as live-attenuated vaccine strains, or as vehicles for delivery of vaccine candidates from other bacteria. The goal of the current proposal is to further analyze the potential usefulness of these strains. Specifically, we anticipate that our studies will: 1) provide insights into the efficacy of these vaccines to induce protection to other closely related bacterial species, and 2) provide functional data that support our hypothesis that these ECA mutants will be effective carriers for antigens from other bacteria.

II. BACKGROUND:

II.1. Background: Given that the human gastrointestinal mucosa is very large and that the acquisition of most infectious diseases occurs at mucosal surfaces, it is not surprising that 15-20 million adults and children acquire or die of mucosal infections annually. *Salmonella* is one bacterial genus that causes diverse mucosal infections. In

the United States, non-typhoidal *Salmonella spp.* cause an estimated 1.4 million cases of salmonellosis annually and account for greater than 500 deaths per year. *Salmonella enterica* serovar Typhimurium (*S.* Typhimurium) is one of the most prominent strains. Economically, it has been estimated that Salmonellosis costs up to $50 million per year in the U.S. as a result of medical expenses and work absences. This issue is particularly relevant to the military because of the necessity to safely feed our troops; many of our troops are stationed in countries with underdeveloped health and hygiene practices so that food preparation is a particular health issue, as is a source of clean water.

To understand the dynamic and complex interactions between the human host and *Salmonella* so that treatment modalities and therapeutic strategies can be developed, both virulence determinants of the pathogen and the relevant host factors must be identified and analyzed. One experimental approach to resolving and combating *Salmonella* infections is to develop efficacious vaccines. Effective vaccines can be generated by identification of virulence factors on the bacterium and constructing mutants that do not express these molecules.

We have identified mutants of a *Salmonella* cell surface virulence factor that appear to be efficacious live vaccine candidates. Specifically, *S.* Typhimurium, a Gram-negative enteric bacterium and a member of the Enterobacteriacae family, expresses the cell surface glycolipid that is ubiquitous among all family members: the phophoglyceride-linked Enterobacterial common antigen (ECA_{PG}). We have shown that ECA negative mutant strains were severely attenuated for virulence when inoculated into mice. However, rather than being cleared from the animal, these mutant strains set up a persistent infection that is maintained for up to 70 days post infection, which was the latest day we monitored colonization. Excitingly, immunization of mice with ECA negative mutant strains provided protection against a subsequent lethal oral or intraperitoneal challenge with wild type *S.* Typhimurium. Thus, our goal is to investigate usefulness of ECA negative strains of *Salmonella* as live-attenuated vaccine strains, or as vehicles for heterologous antigen expression.

II.2. Literature Search for Duplication:

II.2.1. Literature Source(s) Searched: The DoD Biomedical Research Database (BRD), NIH Research Portfolio Online Reporting Tools (RePORTER), and PubMed (includes Medline) were searched.

II.2.2. Date of Search: 2 September 2014

II.2.3. Period of Search: DoD BRD – 1998-2009; NIH RePORTER – 1986-2014; Pubmed 1950-2014

II.2.4. Key Words and Search Strategy: Included *Salmonella*, *S.* Typhimurium, mice, vaccine, ECA

II.2.5. Results of Search: From the BRD database, the search terms "*Salmonella* and vaccine", "*S.* Typhimurium and vaccine", and "*S.* Typhimurium and mice" retrieved 28,

13, and 11 studies, respectively. Several of the retrieved studies were performed at USUHS and provided the foundational research for the work proposed herein. The remaining studies did not duplicate this research protocol.

A search of the NIH RePORTER database using the terms "*Salmonella* and vaccine", "*S.* Typhimurium and vaccine", and "*Salmonella* and mice" returned 77, 20, and 137 studies, respectively. Several of these studies investigate the varying vaccine capabilities of *Salmonella*; however, none of the studies employ ECA mutants nor do they overlap the experiments proposed herein.

A PubMed (Medline) search using the search terms "*Salmonella* and vaccine", "*S.* Typhimurium and vaccine", and "*Salmonella* and mice" returned thousands of articles. However, none appear to be investigating the potential of ECA negative *S.* Typhimurium strains as vaccine candidates. Adding the term "ECA" to the "Salmonella and vaccine" search narrowed the results to 5 articles. One of these was a study published by our lab about our ECA negative strain as a vaccine candidate. The other 4 articles did not use ECA negative strains as potential vaccines.

III. OBJECTIVE\HYPOTHESIS: The goal of this protocol is to analyze the potential usefulness of ECA negative *S.* Typhimurium strains as vaccine candidates. Specifically, we anticipate that our studies will: 1) provide insights into the efficacy of these vaccines to induce protection to other Enterobacteriaceae family members, and 2)

IV. MILITARY RELEVANCE: *S.* Typhimurium, as well as other enteric bacterial infections, are and have been responsible for morbidity and mortality of troops stationed in countries with underdeveloped health and hygiene practices. Thus, the development of efficacious vaccines is vital to resolving and combating *Salmonella* infections, thereby reducing the morbidity and mortality associated with these infections.

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures:

V.1.1. Experiment 1: Determination of cross-protection conferred by vaccination with ECA negative strains of *S.* Typhimurium.

Rationale: To date, our studies show that ECA negative *S.* Typhimurium strains provide protection against lethal challenge with the wildtype strain from which the mutants were derived. However, it is currently unclear if this protection extends across strains or species. Therefore, groups of C57BL/6 mice will be vaccinated with ECA negative derivatives of TML or SL1344, each of which are well-characterized clinical isolates. Vaccinated animals will subsequently be challenged with a typically lethal dose of wildtype derivatives of the strain not used for vaccination. Additionally, we will test the ability of the ECA negative strains to protect against challenge with *S.* Enteritidis, which is able to infect mice but expresses a different O-antigen.

Procedure: Single strain vaccination assays of female C57BL/6 mice will be performed according to published procedures using orogastric and intraperitoneal (IP) administration of ECA negative *S.* Typhimurium strains (Michetti, P *et al. Infect. Immun.* 60(5): 1786, 1992; Schmitt, CK *et al. J. Bacteriol.* 176(2): 368, 1994; Schmitt, CK *et al. J. Bacteriol.* 178(10): 2911, 1996; Lawley, TD *et al. PLoS Pathog.* 2(2): e11, 2006; Lawley, TD *et al. Infect. Immun.* 76(1):403, 2008). Vaccinated animals will subsequently be challenged with a lethal dose of wildtype derivatives of the *S.* Typhimurium strain not used for vaccination or a wildtype *S.* Enteritidis strain. The animals will be grouped into three immunization and challenge combinations: oral immunization with oral challenge, IP immunization with oral challenge, and IP immunization with IP challenge. Animals will be immunized with either the ECA$^-$ TML strain, the ECA$^-$ SL1344 strain, or PBS, and then subsequently challenged with either wildtype TML, wildtype SL1344, or wildtype *S.* Enteritidis.

Prior to orogastric administration of bacteria, animals will be fasted (food withheld but not water) for 2 hours prior to infection and then infected orogastrically with either PBS or a dose of one of the ECA mutant strains that was previously shown to provide protection against lethal challenge. Orogastric infection will be accomplished by passing a straight or curved stainless steel atraumatic ball-tipped gavage needle (20 gauge x 1-1/2) into the terminal esophagus or the stomach. This can be done quickly and safely under manual restraint by trained individuals. Because the entire path from the open mouth of the rodent to the nonglandular portion of the stomach is covered by a thick and resistant keratinized epithelium, injury is very rare. Gavage guarantees that the fluid suspension of bacteria is delivered to the stomach rather than being spit out or being inhaled (which could cause aspiration pneumonia). This is an important point since aspiration could lead to pulmonary infection. Dosing volumes of 0.1-0.2 ml (based on animal weight not to exceed 10mL/kg) will be used in the mice as this is well-tolerated. Animals will be observed immediately after dosing and then periodically over the next few minutes to ascertain that there is no sign of aspiration or trauma before they are returned to their cages. Dosed animals will be maintained without food or water for a period of at least 1 hour but not more than 2 hours to permit gastric processing of the PBS or bacterial suspension, but then will be returned to a normal diet thereafter.

A separate group of animals will be vaccinated via intraperitoneal injection with either PBS or a dose of one of the ECA mutant strains that was previously shown to provide protection against lethal challenge. The animals will receive 50-200 µL of PBS or bacterial suspension using 23-25 gauge needles following alcohol preparation of the site for injection. Animals will be monitored for at least 1 hour but not more than 2 hours after dosing for any signs of distress.

Fecal pellets will be collected on a weekly basis for PBS and ECA- vaccinated animals. Briefly, mice will be placed individually in a clean, empty cage until a fecal pellet is passed. The fecal pellet will be collected into a clean microcentrifuge tube for processing. The mouse will be returned to its cage, minimizing its disruption and discomfort.

Blood samples will be collected via standard tail vein bleeds from each group of vaccinated animals 1 day prior to challenge without the use of anesthesia. For these bleeds, a 26 gauge needle will be used. Mice will be weighed prior to the bleed to calculate the total circulating volume based on the approximation of 58.5mL total blood volume per kg, and the blood volume collected will not exceed 10% of the calculated total blood volume of the animal. Serum will then be collected from these samples and

used to monitor antibody titers using ELISA assays.

The orogastrically and intraperitoneally vaccinated animals will be challenged 30 days post-immunization using the oral gavage and IP injection methods as described above. The animals will be challenged with either wild-type *S.* Typhimurium TML or SL1344 strains or wildtype *S.* Enteritidis. The challenged animals will be initially monitored every 8 hours during the first week for mortality and onset of end-stage disease symptoms, including hunched poster, ruffled fur, weight loss, and poor mobility. The monitoring will continue once per day for an additional 23 days until the 30-day post-challenge time point is reached.Animals surviving at the 30-day timepoint will undergo terminal cardiac bleeding to assess antibody titers. For this, the animals will be placed in a compressed gas CO_2 inhalation chamber and observed. The chamber will not be overcrowded. Cylinderized carbon dioxide with a pressure gauge and flowmeter will be used as the source of carbon dioxide. With animals in the chamber, the flow rate of CO_2 will displace at least 20% of the cage volume per minute as indicated on the flowmeter. Animals will be watched to ensure that they are lying down and that their purposeful movements have stopped. The anesthesia cage will be opened and the animal will be checked for response to toe pinch. If animal responds to toe pinch, the lid of the chamber will be closed and carbon dioxide flow will continue until the animal is adequately anesthetized as indicated by lack of response to toe pinch. If there is no response to toe pinch then the carbon dioxide flow will be stopped. Animals will then be quickly removed from the chamber and a 22 or 23 gauge needle on a syringe will be used to pierce the thoracic wall and the chamber of the heart. At this point, the animal is narcotized (anesthetized) by CO_2. After sufficient blood is obtained, the needle will be removed and the animal will immediately be euthanized by cervical dislocation. In most cases, death will already have occurred by exsanguination.

As detailed below, we will need 216 mice to complete the experiment outlined above, and the study will be repeated once to verify obtained results. In addition, we request 10% extra animals for unforeseen problems.

Experiment totals:
[2 immunization strains X 3 immunization/challenge route combinations X 3 challenge strains X 8 animals per group = 144 animals, 1 mock-immunized group X 3 immunization/challenge route combinations X 3 challenge strains X 8 animals per group = 72 animals; 144 + 72 = 216 animals x 2 (biological repeats) = 432 animals]
Additional animals (~10%) = 43 mice
Grand total of animals requested for Experiment #1 = 475 mice

V.1.2. <u>Experiment #2:</u> Determine whether ECA negative strains of *S.* Typhimurium can be utilized as a vehicle for heterologous antigen delivery.

Rationale: Numerous lines of research suggest that the ability to utilize attenuated bacterial strains as vehicles for delivery of foreign antigens is an attractive means of developing novel vaccines. Moreover, regulated delayed antigen synthesis (RDAS) systems for use in recombinant attenuated *Salmonella* vaccine (RASV) strains have been shown to enhance downstream immune responses due to a reduction in the adverse effects of high-levels of antigen synthesis. To determine whether or not ECA negative strains can be utilized to this end, we will investigate the delivery of two potential heterologous antigens. Groups of BALB/c animals will be vaccinated with ECA negative strains bearing RDAS vectors encoding the *Streptococcus pneumoniae* PspA protein (carried on pPspA) or expressing the O antigen portion *of Pseudomonas*

aeruginosa LPS (carried on pLPS2). Importantly, these two antigens were chosen because prior studies in different RASV strains have shown that appropriate delivery of these antigens provides protection against *S. pneumoniae* and *P. aeruginosa* challenge, respectively.

Procedure:

Single strain vaccination assays of female BALB/c mice will be performed according to published procedures using orogastric and intraperitoneal (IP) administration of the ECA negative SL1344 *S.* Typhimurium strain, an ECA negative SL1344 strain carrying either pLPS2 or pPspA, or PBS. Vaccinated animals will subsequently be challenged with a lethal dose of wildtype SL1344 *S.* Typhimurium, wildtype *S. pneumoniae*, or wildtype *P. aeruginosa*.

Prior to orogastric administration of bacteria, animals will be fasted (food withheld but not water) for 2 hours prior to infection and then infected orogastrically with either the ECA negative SL1344 *S.* Typhimurium strain, an ECA negative SL1344 strain carrying either pLPS2 or pPspA, or PBS. Orogastric infection will be accomplished by passing a straight or curved stainless steel atraumatic ball-tipped gavage needle (20 gauge x 1-1/2) into the terminal esophagus or the stomach. This can be done quickly and safely under manual restraint by trained individuals. Because the entire path from the open mouth of the rodent to the nonglandular portion of the stomach is covered by a thick and resistant keratinized epithelium, injury is very rare. Gavage guarantees that the fluid suspension of bacteria is delivered to the stomach rather than being spit out or being inhaled (which could cause aspiration pneumonia). Dosing volumes of 0.1-0.2 ml (based on animal weight not to exceed 10mL/kg) will be used in the mice as this is well-tolerated. Animals will be observed immediately after dosing and then periodically over the next few minutes to ascertain that there is no sign of aspiration or trauma before they are returned to their cages. Dosed animals will be maintained without food or water for a period of at least 1 hour but not more than 2 hours to permit gastric processing of the PBS or bacterial suspension, but then will be returned to a normal diet thereafter.

In addition, a separate group of animals will be vaccinated via intraperitoneal injection with either the ECA negative SL1344 *S.* Typhimurium strain, an ECA negative SL1344 strain carrying either pLPS2 or pPspA, or PBS. The animals will receive 50-200 µL of PBS or bacterial suspension using 23-25 gauge needles following alcohol preparation of the site for injection. Animals will be monitored for at least 1 hour but not more than 2 hours after dosing for any signs of distress.

The orogastrically and intraperitoneally vaccinated animals will be challenged 30 days post-immunization. The animals will be challenged with either wildtype SL1344 *S.* Typhimurium, wildtype *S. pneumoniae*, or wildtype *P. aeruginosa*. *S.* typhimurium will be delivered via oral gavage, while *S. pneumoniae* and *P. aeruginosa* will be delivered as a bacterial suspension that is placed into the external nares of the animals. For these infections, mice will be anesthetized by intraperitoneal administration of a freshly prepared mixture of ketamine hydrochloride (65 mg/kg) and xylazine (10 mg/kg) in a 200uL volume. After anesthesia, mice will be held upright and 25uls of bacterial suspension will be placed within each nostril (50 uls total). This suspension is subsequently inhaled by the animals and results in inhalational pneumonia. Following anesthesia, the mice are placed on their backs next to each other and monitored until all have recovered from the anesthesia.

Fecal pellets will be collected on a weekly basis for PBS and ECA- vaccinated animals. Briefly, mice will be placed individually in a clean, empty cage until a fecal pellet is passed. The fecal pellet will be collected into a clean microcentrifuge tube for processing. The mouse will be returned to its cage, minimizing its disruption and discomfort.

Blood samples will be collected via standard tail vein bleeds from each group of vaccinated animals 1 day prior to challenge. For these bleeds, a 26 gauge needle will be used. Mice will be weighed prior to the bleed to calculate the total circulating volume based on the approximation of 58.5mL total blood volume per kg, and the blood volume collected will not exceed 10% of the calculated total blood volume of the animal. Serum will then be collected from these samples and used to monitor antibody titers against *S. pneumoniae* PspA and *P. aeruginosa* O antigen using ELISA assays. The challenged animals will be initially monitored every 8 hours during the first week for mortality and onset of end-stage disease symptoms, including hunched poster, ruffled fur, weight loss, and poor mobility. The monitoring will continue once per day for an additional 23 days until the 30-day post-challenge time point is reached. Animals surviving at the 30-day timepoint will undergo terminal cardiac bleeding to assess antibody titers. For this, the animals will be placed in a compressed gas CO_2 inhalation chamber and observed. The chamber will not be overcrowded. Cylinderized carbon dioxide with a pressure gauge and flowmeter will be used as the source of carbon dioxide. With animals in the chamber, the flow rate of CO_2 will displace at least 20% of the cage volume per minute as indicated on the flowmeter. Animals will be watched to ensure that they are lying down and that their purposeful movements have stopped. The anesthesia cage will be opened and the animal will be checked for response to toe pinch. If animal responds to toe pinch, the lid of the chamber will be closed and carbon dioxide flow will continue until the animal is adequately anesthetized as indicated by lack of response to toe pinch. If there is no response to toe pinch then the carbon dioxide flow will be stopped. Animals will then be quickly removed from the chamber and a 22 or 23 gauge needle on a syringe will be used to pierce the thoracic wall and the chamber of the heart. At this point, the animal is narcotized (anesthetized) by CO_2. After sufficient blood is obtained, the needle will be removed and the animal will immediately be euthanized by cervical dislocation. In most cases, death will already have occurred by exsanguination.

As detailed below, we will need 128 mice to complete the experiment outlined above, and the study will be repeated once to verify obtained results. In addition, we request 10% extra animals for unforeseen problems.

Additional animals (~10%) = 26 mice
Grand total of animals requested for Experiment #2 = 282 mice

V.1.3 Experiment #3: Test the ability of an ECA- strain of *S.* Typhimurium to protect against lethal challenge with other *S.* Typhimurium strains.

Rationale: To date, our data indicate that intraperitoneal or orogastric vaccination with an SL1344 ECA- strain is able to provide complete protection from subsequent oral challenge with the wildtype *S.* Typhimurium TML strain. The dose of TML used for the challenge was 5.00E+04, which represents the approximate oral LD50 for this strain. Therefore, we need to validate our preliminary findings and determine the limits of protection. Therefore, groups of C57BL/6 mice will be inoculated with PBS or vaccinated with an ECA negative derivative of *S.* Typhimurium strain SL1344. The vaccinated animals will subsequently be challenged intaperitoneally with a dose equivalent to 1, 10, 100 or 1000 times the LD50 of the wildtype SL1344, TML or LT2 strains of *S.* Typhimurium. Extending our studies to higher doses of SL1344 and TML and including another well-studied virulent *S.* Typhimurium strain will allow us to make broader statements about the protection that we observe.

Procedure: Single strain vaccination assays of female C57BL/6 mice will be performed according to published procedures using orogastric and intraperitoneal

(IP) administration of ECA negative *S.* Typhimurium strains (Michetti, P *et al. Infect. Immun.* 60(5): 1786, 1992; Schmitt, CK *et al. J. Bacteriol.* 176(2): 368, 1994; Schmitt, CK *et al. J. Bacteriol.* 178(10): 2911, 1996; Lawley, TD *et al. PLoS Pathog.* 2(2): e11, 2006; Lawley, TD *et al. Infect. Immun.* 76(1):403, 2008). Vaccinated animals will subsequently be challenged with varying doses of wildtype derivatives of *S.* Typhimurium SL1344, TML or LT2. The animals will be grouped into two immunization and challenge combinations: oral immunization with IP challenge and IP immunization with IP challenge. Animals will be immunized with either the ECA$^-$ SL1344 strain or PBS, and then subsequently challenged with either wildtype SL1344, TML or LT2.

Prior to orogastric administration of bacteria, animals will be fasted (food withheld but not water) for 2 hours prior to infection and then infected orogastrically with either PBS or a dose of the ECA- SL1344 strain that was previously shown to provide protection against lethal challenge. Orogastric infection will be accomplished by passing a straight or curved stainless steel atraumatic ball-tipped 20 gauge gavage needle into the terminal esophagus or the stomach. This can be done quickly and safely under manual restraint by trained individuals without the use of anesthesia. Because the entire path from the open mouth of the rodent to the nonglandular portion of the stomach is covered by a thick and resistant keratinized epithelium, injury is very rare. Gavage guarantees that the fluid suspension of bacteria is delivered to the stomach rather than being spit out or being inhaled (which could cause aspiration pneumonia). This is an important point since aspiration could lead to pulmonary infection. Dosing volumes of 0.1-0.2 ml (based on animal weight not to exceed 10mL/kg) will be used in the mice as this is well-tolerated. Animals will be observed immediately after dosing and then periodically over the next few minutes to ascertain that there is no sign of aspiration or trauma before they are returned to their cages. Dosed animals will be maintained without food or water for a period of at least 1 hour but not more than 2 hours to permit gastric processing of the PBS or bacterial suspension, but then will be returned to a normal diet thereafter.

A separate group of animals will be vaccinated via intraperitoneal injection with either PBS or a dose of one of the ECA mutant strains that was previously shown to provide protection against lethal challenge. The animals will receive 50-200 μL of PBS or bacterial suspension using 23-25 gauge needles following alcohol preparation of the site for injection. Animals will be monitored for at least 1 hour but not more than 2 hours after dosing for any signs of distress.

Fecal pellets will be collected on a weekly basis for PBS and ECA- vaccinated animals. Briefly, mice will be placed individually in a clean, empty cage until a fecal pellet is passed. The fecal pellet will be collected into a clean microcentrifuge tube for processing. The mouse will be returned to its cage, minimizing its disruption and discomfort. Blood samples will be collected via standard tail vein bleeds from each group of vaccinated animals 1 day prior to challenge without the use of anesthesia. For these bleeds, a 26 gauge needle will be used. Mice will be weighed prior to the bleed to calculate the total circulating volume based on the approximation of 58.5mL total blood volume per kg, and the blood volume collected will not exceed 10% of the calculated total blood volume of the animal. Serum will then be collected from these samples and used to monitor antibody titers using ELISA assays.

The orogastrically and intraperitoneally vaccinated animals will be challenged 30 days post-immunization using the IP injection methods as described above. The animals will be challenged with wild-type *S.* Typhimurium SL1344, TML or

LT2. The challenged animals will be initially monitored every 8 hours during the first week for mortality and onset of end-stage disease symptoms, including hunched poster, ruffled fur, weight loss, and poor mobility. The monitoring will continue once per day for an additional 23 days until the 30-day post-challenge time point is reached. Animals surviving at the 30-day timepoint will undergo terminal cardiac bleeding to assess antibody titers. For this, the animals will be placed in a compressed gas CO_2 inhalation chamber and observed. The chamber will not be overcrowded. Cylinderized carbon dioxide with a pressure gauge and flowmeter will be used as the source of carbon dioxide. With animals in the chamber, the flow rate of CO_2 will displace at least 20% of the cage volume per minute as indicated on the flowmeter. Animals will be watched to ensure that they are lying down and that their purposeful movements have stopped. The anesthesia cage will be opened and the animal will be checked for response to toe pinch. If animal responds to toe pinch, the lid of the chamber will be closed and carbon dioxide flow will continue until the animal is adequately anesthetized as indicated by lack of response to toe pinch. If there is no response to toe pinch then the carbon dioxide flow will be stopped. Animals will then be quickly removed from the chamber and a 22 or 23 gauge needle on a syringe will be used to pierce the thoracic wall and the chamber of the heart. At this point, the animal is narcotized (anesthetized) by CO_2. After sufficient blood is obtained, the needle will be removed and the animal will immediately be euthanized by cervical dislocation. In most cases, death will already have occurred by exsanguination.

As detailed below, we will need 480 mice to complete the experiment outlined above, and the study will be repeated once to verify obtained results. In addition, we request 10% extra animals for unforeseen problems.

Immunization		Challenge		
Strain	Route	S. Typhimurium	Dose x LD_{50}	Mice
PBS	Oral	SL1344 WT	1, 10, 100, 1000	10/dose
ECA-SL1344	Oral	SL1344 WT	1, 10, 100, 1000	10/dose
PBS	Oral	TML	1, 10, 100, 1000	10/dose

PBS	[illegible]	LT2	1, 10, 100, 1000	10/dose
ECA-SL1344	[illegible]	LT2	1, 10, 100, 1000	10/dose

Experiment totals:
[1 immunization strain X 2 immunization/challenge route combinations X 3 challenge strains X 4 doses X 10 animals per group = 240 animals, 1 mock-vaccinated group X 2 immunization/challenge route combinations X 3 challenge strains X 4 doses X 10 animals per group = 240 animals; 240 + 240 = 480 animals X 2 (biological repeats) = 960 animals]
Additional animals (~10%) = 96 mice
Grand total of animals requested for Experiment #3 = 1,056 mice

V.1.4. Experiment #4: Test the ability of a ECA- strain of *S.* Typhimurium to protect against lethal challenge with other *Salmonella* serovars.

Rationale: To date, our data indicate that intraperitoneal vaccination with the ECA- strain SL1344 is able to provide partial protection against challenge with greater than 10,000 LD50 of the *S.* Enteriditis R11 strain. While no protection was seen from animals that were vaccinated orally, we did observe a slight but insignificant increase in the MTD (mean time to death) of the vaccinated animals. To validate our preliminary IP findings and determine whether higher levels of protection can be obtained using decreased doses of the R11 challenge strain, we will repeat these studies. Additionally we will explore cross protection against two other common *Salmonella* serovars. Therefore, groups of C57BL/6 mice will be inoculated with PBS or vaccinated with an ECA negative derivative of SL1344 and subsequently challenged intaperitoneally with a dose equivalent to 1, 10, 100 or 1000 times the LD50 of wildtype R11 *S.* Enteriditis, *S.* Stanleyville strain J65 or the *S.* Dublin strain R17. This expansion of our studies will allow us to make broader statements about the protection that we observe.

Procedure: Single strain vaccination assays of female C57BL/6 mice will be performed according to published procedures using orogastric and intraperitoneal (IP) administration of PBS and ECA negative *S.* Typhimurium strains (Michetti, P *et al. Infect. Immun.* 60(5): 1786, 1992; Schmitt, CK *et al. J. Bacteriol.* 176(2): 368, 1994; Schmitt, CK *et al. J. Bacteriol.* 178(10): 2911, 1996; Lawley, TD *et al. PLoS Pathog.* 2(2): e11, 2006; Lawley, TD *et al. Infect. Immun.* 76(1):403, 2008). Vaccinated animals will subsequently be challenged with varying doses of wildtype derivatives of R11 *S.* Enteriditis, J65 *S.* Stanleyville or R17 *S.* Dublin. The animals will be grouped into two immunization and challenge combinations: oral immunization with IP challenge and IP immunization with IP challenge. Animals will be immunized with either the ECA- SL1344 strain or PBS, and then subsequently challenged with either R11 *S.* Enteriditis, J65 *S.* Stanleyville or R17 *S.* Dublin.

Prior to orogastric administration of bacteria, animals will be fasted (food withheld but not water) for 2 hours prior to infection and then infected orogastrically with either PBS or a dose of the ECA- SL1344 strain that was previously shown to provide protection against lethal challenge. Orogastric infection will be accomplished by passing a straight or curved stainless steel atraumatic ball-tipped 20 gauge gavage needle into the terminal esophagus or the stomach. This can be done quickly and safely under manual restraint by trained individuals without the use of anesthesia. Because the entire path from the open mouth of the rodent to the nonglandular portion of the stomach is covered by a thick and resistant keratinized epithelium, injury is very rare. Gavage guarantees that the fluid suspension of bacteria is delivered to the stomach rather than being spit out or being inhaled (which could cause aspiration pneumonia). This is an important point since aspiration could lead to pulmonary infection. Dosing volumes of 0.1-0.2 ml (based on animal weight not to exceed 10mL/kg) will be used in the mice as this is well-tolerated. Animals will be observed immediately after dosing and then periodically over the next few minutes to ascertain that there is no sign of aspiration or trauma before they are retumed to their cages. Dosed animals will be maintained without food or water for a period of at least 1 hour but not more than 2 hours to permit gastric processing of the PBS or bacterial suspension, but then will be returned to a normal diet thereafter.

A separate group of animals will be vaccinated via intraperitoneal injection with either PBS or a dose of one of the ECA- SL1344 strain that was previously shown to provide protection against lethal challenge. The animals will receive 50-200 μL of PBS

or bacterial suspension using 23-25 gauge needles following alcohol preparation of the site for injection. Animals will be monitored for at least 1 hour but not more than 2 hours after dosing for any signs of distress.

Fecal pellets will be collected on a weekly basis for PBS and ECA- vaccinated animals. Briefly, mice will be placed individually in a clean, empty cage until a fecal pellet is passed. The fecal pellet will be collected into a clean microcentrifuge tube for processing. The mouse will be returned to its cage, minimizing its disruption and discomfort. Blood samples will be collected via standard tail vein bleeds from each group of vaccinated animals 1 day prior to challenge without the use of anesthesia. For these bleeds, a 26 gauge needle will be used.Mice will be weighed prior to the bleed to calculate the total circulating volume based on the approximation of 58.5mL total blood volume per kg, and the blood volume collected will not exceed 10% of the calculated total blood volume of the animal. Serum will then be collected from these samples and used to monitor antibody titers using ELISA assays.

The orogastrically and intraperitoneally vaccinated animals will be challenged 30 days post-immunization using the IP injection methods as described above. The animals will be challenged with wild-type R11 *S.* Enteriditis, J65 *S.* Stanleyville or R17 *S.* Dublin. The challenged animals will be initially monitored every 8 hours during the first week for mortality and onset of end-stage disease symptoms, including hunched poster, ruffled fur, weight loss, and poor mobility. The monitoring will continue once per day for an additional 23 days until the 30-day post-challenge time point is reached. Animals surviving at the 30-day timepoint will undergo terminal cardiac bleeding to assess antibody titers. For this, the animals will be placed in a compressed gas CO_2 inhalation chamber and observed. The chamber will not be overcrowded. Cylinderized carbon dioxide with a pressure gauge and flowmeter will be used as the source of carbon dioxide. With animals in the chamber, the flow rate of CO_2 will displace at least 20% of the cage volume per minute as indicated on the flowmeter. Animals will be watched to ensure that they are lying down and that their purposeful movements have stopped. The anesthesia cage will be opened and the animal will be checked for response to toe pinch. If animal responds to toe pinch, the lid of the chamber will be closed and carbon dioxide flow will continue until the animal is adequately anesthetized as indicated by lack of response to toe pinch. If there is no response to toe pinch then the carbon dioxide flow will be stopped. Animals will then be quickly removed from the chamber and a 22 or 23 gauge needle on a syringe will be used to pierce the thoracic wall and the chamber of the heart. At this point, the animal is narcotized (anesthetized) by CO_2. After sufficient blood is obtained, the needle will be removed and the animal will immediately be euthanized by cervical dislocation. In most cases, death will already have occurred by exsanguination.

As detailed below, we will need 480 mice to complete the experiment outlined above, and the study will be repeated once to verify obtained results. In addition, we request 10% extra animals for unforeseen problems.

Immunization		Challenge		
Strain	Route	Salmonella Serovar	Dose x LD_{50}	Mice
PBS	Oral	S. Enteritidis	1, 10, 100, 1000	10/dose
ECA-SL1344	Oral	S. Enteritidis	1, 10, 100, 1000	10/dose
PBS	Oral	S. Stanleyville	1, 10, 100, 1000	10/dose
ECA-SL1344	Oral	S. Stanleyville	1, 10, 100, 1000	10/dose
PBS	Oral	S. Dublin	1, 10, 100, 1000	10/dose
ECA-SL1344	Oral	S. Dublin	1, 10, 100, 1000	10/dose
Strain	Route	Salmonella Serovar	Dose x LD_{50}	Mice
PBS	IP	S. Enteritidis	1, 10, 100, 1000	10/dose
ECA-SL1344	IP	S. Enteritidis	1, 10, 100, 1000	10/dose
PBS	IP	S. Stanleyville	1, 10, 100, 1000	10/dose
ECA-SL1344	IP	S. Stanleyville	1, 10, 100, 1000	10/dose
PBS	IP	S. Dublin	1, 10, 100, 1000	10/dose
ECA-SL1344	IP	S. Dublin	1, 10, 100, 1000	10/dose
			*total:	480

Experiment totals:
[1 immunization strain X 2 immunization/challenge route combinations X 3 challenge strains X 4 doses X 10 animals per group = 240 animals, 1 mock-vaccinated group X 2 immunization/challenge route combinations X 3 challenge strains X 4 doses X 10 animals per group = 240 animals; 240 + 240 = 480 animals X 2 (biological repeats) = 960 animals]
Additional animals (~10%) = 96 mice
Grand total of animals requested for Experiment #4 = 1,056 mice

V.1.5. Experiment #5: Determine if protection is induced in immunodeficient animals

Rationale: The data generated through Experiments #1, #2, #3, and #4 investigate the contribution of *Salmonella* specific antibodies to protection. Given that *Salmonella* is an intracellular pathogen, there is a good chance that both humoral and cell mediated responses may be involved in protection. Thus, we will also utilize animals deficient in various immunological components to determine whether both humoral and cell-mediated immunity is involved in protection. To this end, we will vaccinate animals that are deficient for these components with the ECA- SL1344 strain and then determine whether protection is lost in the absence of the respective component. For animals that are deficient in T-cells we will utilize B6.129P2-*Tcrb*^{tm1Mom} *Tcrd*^{tm1Mom}/J mice, which carry double mutations in T-cell receptor (TCR) beta and delta. For B-cell deficient animals we will utilize B6.129S2-*Ighm*^{tm1Cgn}/J mice, which do not develop mature B-cells. Finally, since no macrophage deficient animals currently are available, B6.FVB-Tg(ITGAM-DTR/EGFP)34Lan/J mice, which carry a transgenic diphtheria toxin receptor from a "macrophage-specific" promoter will be used to deplete macrophages via administration of diphtheria toxin via established protocols. Groups of 4 animals from each immunodeficient group will be vaccinated orally with PBS or the ECA-SL1344 strain and followed as described above. 30 days post-vaccination, animals will challenged intraperitoneally with a dose equivalent to 10 LD50 of wildtype SL1344. Mortality and morbidity will be monitored for 30 days.

Procedure: Single strain vaccination assays of the immunodeficient mice will be

performed according to published procedures using orogastric administration of our ECA negative SL1344 *S.* Typhimurium strain or PBS (Michetti, P *et al. Infect. Immun.* 60(5): 1786, 1992; Schmitt, CK *et al. J. Bacteriol.* 176(2): 368, 1994; Schmitt, CK *et al. J. Bacteriol.* 178(10): 2911, 1996; Lawley, TD *et al. PLoS Pathog.* 2(2): e11, 2006; Lawley, TD *et al. Infect. Immun.* 76(1):403, 2008). Vaccinated animals will subsequently be challenged with a dose equivalent to 10 LD50 of wildtype SL1344.

Prior to orogastric administration of bacteria, animals will be fasted (food withheld but not water) for 2 hours prior to infection and then infected orogastrically with either PBS or a dose of the ECA- SL1344 strain that was previously shown to provide protection against lethal challenge. Orogastric infection will be accomplished by passing a straight or curved stainless steel atraumatic ball-tipped 20 gauge gavage needle into the terminal esophagus or the stomach. This can be done quickly and safely under manual restraint by trained individuals without the use of anesthesia. Because the entire path from the open mouth of the rodent to the nonglandular portion of the stomach is covered by a thick and resistant keratinized epithelium, injury is very rare. Gavage guarantees that the fluid suspension of bacteria is delivered to the stomach rather than being spit out or being inhaled (which could cause aspiration pneumonia). This is an important point since aspiration could lead to pulmonary infection. Dosing volumes of 0.1-0.2 ml (based on animal weight not to exceed 10mL/kg) will be used in the mice as this is well-tolerated. Animals will be observed immediately after dosing and then periodically over the next few minutes to ascertain that there is no sign of aspiration or trauma before they are returned to their cages. Dosed animals will be maintained without food or water for a period of at least 1 hour but not more than 2 hours to permit gastric processing of the PBS or bacterial suspension, but then will be returned to a normal diet thereafter. To deplete the macrophages, B6.FVB-Tg(ITGAM-DTR/EGFP)34Lan/J mice will be given diphtheria toxin via IP injection according to published procedures (Cailheir, JF *et al. J. Immunol.* 174(4):2336, 2005). Briefly, twenty-four hours prior to vaccination, the animals will receive *a* dose of diphtheria toxin at 25ng/g using 23-25 gauge needles following alcohol preparation of the site for injection. The diphtheria toxin will be diluted in PBS at a concentration of 2.5ng/ul such that the mice will be dosed with approximately 100-200ul. Animals will be monitored for at least 1 hour but not more than 2 hours after dosing for any signs of distress.

Fecal pellets will be collected on a weekly basis for PBS and ECA- vaccinated animals. Briefly, mice will be placed individually in a clean, empty cage until a fecal pellet is passed. The fecal pellet will be collected into a clean microcentrifuge tube for processing. The mouse will be returned to its cage, minimizing its disruption and discomfort. Blood samples will be collected via standard tail vein bleeds from each group of vaccinated animals 1 day prior to challenge without the use of anesthesia. For these bleeds, a 26 gauge needle will be used. Mice will be weighed prior to the bleed to calculate the total circulating volume based on the approximation of 58.5mL total blood volume per kg, and the blood volume collected will not exceed 10% of the calculated total blood volume of the animal. Serum will then be collected from these samples and used to monitor antibody titers using ELISA assays.

The orogastrically vaccinated animals will be challenged 30 days post-immunization via IP injection. Briefly, the animals will receive 50-200 µL of the bacterial suspension using 23-25 gauge needles following alcohol preparation of the site for injection. Animals will be monitored for at least 1 hour but not more than 2 hours after dosing for any signs of distress. The animals will be challenged with a dose equivalent

to 10 times the LD50 of wildtype *S.* Typhimurium SL1344. The challenged animals will be initially monitored every 8 hours during the first week for mortality and onset of end-stage disease symptoms, including hunched poster, ruffled fur, weight loss, and poor mobility. The monitoring will continue once per day for an additional 23 days until the 30-day post-challenge time point is reached. Animals surviving at the 30-day timepoint will undergo terminal cardiac bleeding to assess antibody titers. For this, the animals will be placed in a compressed gas CO_2 inhalation chamber and observed. The chamber will not be overcrowded. Cylinderized carbon dioxide with a pressure gauge and flowmeter will be used as the source of carbon dioxide. With animals in the chamber, the flow rate of CO_2 will displace at least 20% of the cage volume per minute as indicated on the flowmeter. Animals will be watched to ensure that they are lying down and that their purposeful movements have stopped. The anesthesia cage will be opened and the animal will be checked for response to toe pinch. If animal responds to toe pinch, the lid of the chamber will be closed and carbon dioxide flow will continue until the animal is adequately anesthetized as indicated by lack of response to toe pinch. If there is no response to toe pinch then the carbon dioxide flow will be stopped. Animals will then be quickly removed from the chamber and a 22 or 23 gauge needle on a syringe will be used to pierce the thoracic wall and the chamber of the heart. At this point, the animal is narcotized (anesthetized) by CO_2. After sufficient blood is obtained, the needle will be removed and the animal will immediately be euthanized by cervical dislocation. In most cases, death will already have occurred by exsanguination.

As detailed below, we will need 24 mice to complete the experiment outlined above, and the study will be repeated once to verify obtained results. In addition, we request 10% extra animals for unforeseen problems.

Experiment totals:
[1 immunization strain X 3 types of immunodeficient mice X 4 animals per group = 12 animals, 1 mock-vaccinated group X 3 types of immunodeficient mice X 4 animals per group = 12 animals; 12 + 12 = 24 animals X 2 (biological repeats) = 48 animals]
Additional animals (~10%) = 5 mice
Grand total of animals requested for Experiment #5 = 53 mice

V.2. Data Analysis: The percent protection will be calculated as well as meantime to death (MTD): MTD = the sum of all X values divided by the total number of mice dead, where X is the days post-infection multiplied by the number of mice that died that day.

The biological replicates will be pooled for data analysis such that n=16/group. Pooling the survival data allows us to detect a difference of 80% vs. 25% survival when employing a log-rank test with a 5%, two-sided significance level and 80% power. (Power calculations were performed using STATA version 12 software (stpower procedure) and were based on a method described in: Freedman, L. S. 1982. Tables of the number of patients required in clinical trials using the logrank test. *Statistics in Medicine* 1: 121–129.)

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered: Whenever possible, we test our *Salmonella* strains on tissue culture cells. Unfortunately, *in vitro* tissue culture models are not appropriate for investigating the effectiveness of potential vaccine candidates. Additionally, computer modeling programs are not suitable for predicting the immunization ability of bacterial strains.

V.3.2. Animal Model and Species Justification:
Mice were chosen for these studies for a variety of reasons: 1) genetically inbred animals are required to effectively study immune responses and vaccine efficacy; 2) many animals are necessary to control the studies in a satisfactory manner; 3) mice are the least sentient species we can use to evaluate potential therapies. It is necessary, in this case to use *in vivo* models in order to effectively determine the usefulness of our strains in vaccination strategies.

V.3.3. Laboratory Animals

	Species #1	Species #2
V.3.3.1. Genus & Species:	*Mus musculus*	
V.3.3.2. Strain/Stock:	C57BL/6; BALB/c; B6.129P2-*Tcrb*^{tm1Mom} *Tcrd*^{tm1Mom}/J; B6.129S2-*Ighm*^{tm1Cgn}/J; B6.FVB-Tg(ITGAM-DTR/EGFP)34Lan/J	
V.3.3.3. Source/Vendor:	(b)(4)	
V.3.3.4. Age:	6-8 weeks	
V.3.3.5. Weight:	18-20 grams	
V.3.3.6. Sex:	Female	
V.3.3.7. Special Considerations:		

V.3.4. Number of Animals Required (by Species): Mice = 2,922

V.3.5. Refinement, Reduction, Replacement (3 Rs):

V.3.5.1. Refinement: Animals are sedated and anesthetized by CO_2 inhalation to alleviate pain and distress prior to cervical dislocation. Additionally, we use the gavage procedure to infect the animals to minimize the possibility of aspiration pneumonia.

Whenever possible, visibly moribund mice will be euthanized rather than being monitored until the end of the observation period.

V.3.5.2. Reduction: As many of our experiments involve infected animals or tissues, we do not participate in any shared tissue and/or control groups with other investigators. To reduce the number of animals necessary for the study proposed here, we have used the minimal number of animals required for biological and statistical significance.

V.3.5.3. Replacement: Whenever possible, we will test our strains on tissue culture cells. Unfortunately, *in vitro* tissue culture models are not appropriate for revealing vaccine efficacy and are limited in the amount of information that they provide concerning host response to infection.

V.4. Technical Methods:

V.4.1. Pain / Distress Assessment:

V.4.1.1. APHIS Form 7023 Information:

V.4.1.1.1. Number of Animals:

	Species #1	Species #2
V.4.1.1.1.1. Column C:		
V.4.1.1.1.2. Column D:		
V.4.1.1.1.3. Column E:	2,922	

Malaise is often observed in mice injected with wildtype *S.* Typhimurium, while acute fatal pneumonia may occur in mice infected with *S. pneumoniae* or *P. aeruginosa*. The administration of our potential vaccine strains may prevent such response in animals challenged with wildtype strains. However, it is not possible to know how many animals will respond to the variables in the studies designed in this proposal, and thus, it is not possible to know how many mice will experience pain or distress. Thus, it is formally possible that all 2,922 mice could experience pain or distress. When animals become moribund indicated by severe changes in body weight (>20% weight loss (assessed daily) compared to controls or to the baseline), behavior, appetite, excretion, hair coat, etc., they will be euthanized. No analgesics will be given to mice post-challenge in these studies, since administration of analgesics confounds the results of virulence assessment assays. First, studies have shown that analgesics directly affect the immune response in various ways, including the inhibition of antibody production and the enhancement of bacterial killing (Bancos, S. *et al. Cell Immunol.* 258(1):18–28, 2009; Stables, M.J. *et al. Blood.* 116(16):2950-2959, 2010). Second, NSAID analgesics, including ibuprofen and diclofenac, have displayed anti-microbial activity against *Salmonella* (Al-Janabi, A.A. *J Glob Infect Dis.* 2(2):105–108, 2010; Dastidar, S.G. *et al. Int J Antimicrob Agents.* 14(3):249-51, 2000). In fact, the administration of diclofenac provided protection in mice against *Salmonella* challenge (Dastidar, S.G. *et al. Int J*

Antimicrob Agents. 14(3):249-51, 2000). Third, morphine administration increases the bacterial load in *Salmonella*-infected mice (MacFarlane, A.S. *et al. J Infect Dis*. 181(4):1350-8, 2000; Breslow, J.M. *et al. Microb Pathog*. 49(6):330-5, 2010). Finally, opioids have the ability to alter the virulence of pathogenic microbes (Babrowski,T. *et al. Ann Surg*. 255:386–393, 2012; reviewed in Moss, J. *Mayo Clin Proc*. 83(10):1116-30, 2008). Thus, analgesics will not be administered in an effort to eliminate any factors that would alter the normal course of our challenge infection and impede the interpretation of data relating to the efficacy of our vaccine candidate.

V.4.1.2. Pain Relief / Prevention:

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization: For challenge studies described in experiment 2, animals that will be intranasal infected with *S. pneumoniae* or *P. aeuriginosa* will be anesthetized by intraperitoneal administration of a freshly prepared mixture of ketamine hydrochloride (65 mg/kg) and xylazine (10 mg/kg) in a 200uL volume. Following infection, the mice are placed on their backs next to each other and monitored until all have recovered from the anesthesia.

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions: We have not observed any overt complications from any of the procedures described other than occasional oral bleeding from the gavage. In our hands, this is rare and has occurred only when training a new person in this technique. There are extremely rare instances in which mice are severely injured during gavage. Laboratory personnel will monitor the behavior and general health of the animals following infection before returning them to LAM. Animals showing signs of injury due to gavage (as evidenced by shaking, sometimes accompanied by circling and other signs of distress) will be humanely euthanized as described in the euthanasia section (V.4.6). We will also frequently check all animals that are infected and/or dosed until it is time for the study to end; if evidence of signs of distress is noted, they will be humanely euthanized immediately.

V.4.1.2.3. Paralytics: N/A

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures:

V.4.1.3.1. Sources Searched: Toxline and PubMed

V.4.1.3.2. Date of Search: 2 September 2014

V.4.1.3.3. Period of Search: Pubmed (1950-Current) Toxline (1950's-Current)

V.4.1.3.4. Key Words of Search: *S.* Typhimurium, alleviate, mice, vaccine, survival, alternative

V.4.1.3.5. Results of Search: The search terms "*S.* Typhimurium and alleviate" and "*S.* Typhimurium and alleviate and mice" returned 6 and 1 articles, respectively, on Toxline. Unfortunately, none of these articles describes methods of pain alleviation during *S.* Typhimurium infection. The additional search terms "*S.* Typhimurium and

vaccine and survival and alternative" returned 1 article, which did not present alternative models for the proposed studies.

Searches on PubMed with "*S.* Typhimurium and alleviate" returned 22 articles, while "*S.* Typhimurium and alleviate and mice" returned 4 articles; however, none of these discusses a method of alleviating the potential pain in mice infected with *S.* Typhimurium. Additionally, searching with the terms "*S.* Typhimurium and vaccine and survival and alternative" returned 8 articles, none of which provided an alternative to survival studies of vaccine candidates.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification:

We believe that these experiments are justified because animals serve as surrogates for volunteer studies, and our long-range goal is to develop vaccines to specifically prevent salmenollosis. Since in the US alone, 1.4 million cases of salmonellosis occur annually causing greater than 500 deaths per year, it is important to develop efficacious vaccines to help prevent recurrence of this disease. Additionally, the development of a live-attenuated vaccine capable of heterologous delivery of foreign antigens would potentially provide a resource for the prevention of a multitude of infectious diseases. Unfortunately, to effectively determine the usefulness of a vaccine strain, it is imperative to perform survival studies in mice such as those we have proposed herein.

No analgesics will be given to mice post-challenge in these studies, since administration of analgesics confounds the results of virulence assessment assays. First, studies have shown that analgesics directly affect the immune response in various ways, including the inhibition of antibody production and the enhancement of bacterial killing (Bancos, S. *et al. Cell Immunol.* 258(1):18–28, 2009; Stables, M.J. *et al. Blood.* 116(16):2950-2959, 2010). Second, NSAID analgesics, including ibuprofen and diclofenac, have displayed anti-microbial activity against *Salmonella* (Al-Janabi, A.A. *J Glob Infect Dis.* 2(2):105–108, 2010; Dastidar, S.G. *et al. Int J Antimicrob Agents.* 14(3):249-51, 2000). In fact, the administration of diclofenac provided protection in mice against *Salmonella* challenge (Dastidar, S.G. *et al. Int J Antimicrob Agents.* 14(3):249-51, 2000). Third, morphine administration increases the bacterial load in *Salmonella*-infected mice (MacFarlane, A.S. *et al. J Infect Dis.* 181(4):1350-8, 2000; Breslow, J.M. *et al. Microb Pathog.* 49(6):330-5, 2010). Finally, opioids have the ability to alter the virulence of pathogenic microbes (Babrowski,T. *et al. Ann Surg.* 255:386–393, 2012; reviewed in Moss, J. *Mayo Clin Proc.* 83(10):1116-30, 2008). Thus, analgesics will not be administered in an effort to eliminate any factors that would alter the normal course of our challenge infection and impede the interpretation of data relating to the efficacy of our vaccine candidate.

V.4.2. Prolonged Restraint: N/A

V.4.3. Surgery: N/A

V.4.3.1. Pre-surgical Provisions: N/A

V.4.3.2. **Procedure**: N/A

V.4.3.3. **Post-surgical Provisions**: N/A

V.4.3.4. **Location**: N/A

V.4.3.5. **Surgeon**: N/A

V.4.3.6. **Multiple Major Survival Operative Procedures**: N/A

V.4.3.6.1. **Procedures**: N/A

V.4.3.6.2. **Scientific Justification**: N/A

V.4.4. **Animal Manipulations**:

V.4.4.1. **Injections**: Groups of animals will receive 50-200 µL intraperitoneal (IP) injections of either PBS or a bacterial suspension for vaccination or challenge. These injections will be performed with 23-25 gauge needles following alcohol preparation of the site for injection.

For challenge studies described in experiment 2, animals that will be intranasally infected with *S. pneumoniae* or *P. aeuriginosa* will be anesthetized by intraperitoneal administration of a freshly prepared mixture of ketamine hydrochloride (65 mg/kg) and xylazine (10 mg/kg) in a 200uL volume.

V.4.4.2. **Biosamples**:

Blood:
1) Blood samples will be collected via standard tail vein bleeds from each group of vaccinated animals 1 day prior to challenge without the use of anesthesia. For these bleeds, a 26 gauge needle will be used. Mice will be weighed prior to the bleed to calculate the total circulating volume based on the approximation of 58.5mL total blood volume per kg, and the blood volume collected will not exceed 10% of the calculated total blood volume of the animal. Serum will then be collected from these samples and used to monitor antibody titers using ELISA assays.

2) Animals surviving at the 30-day timepoint will undergo terminal cardiac bleeding to assess antibody titers. For this, the animals will be placed in a compressed gas CO_2 inhalation chamber and observed. When respiratory arrest occurs, they will be quickly removed and a 22 or 23 gauge needle on a syringe will be used to pierce the thoracic wall and the chamber of the heart. At this point the animal is narcotized (anesthetized) by CO_2. After sufficient blood is obtained, the needle will be removed and the animal will immediately be euthanized by cervical dislocation. In most cases, death will already have occurred by exsanguination. Serum will then be collected from these blood samples and used to monitor antibody titers using ELISA assays.

Fecal Pellets: Mice will be placed individually in a clean, empty cage until a fecal pellet is passed. The fecal pellet will be collected into a clean microcentrifuge tube for processing. The mouse will be returned to its cage, minimizing its disruption and discomfort. We propose to perform the fecal collections on a weekly basis for challenged mice and PBS-inoculated animals as a negative control.

V.4.4.3. Adjuvants: N/A

V.4.4.4. Monoclonal Antibody (MAbs) Production: N/A

V.4.4.5. Animal Identification: cage cards will be used

V.4.4.6. Behavioral Studies: N/A

V.4.4.7. Other Procedures: Manual restraint of animals will be used during oral inoculation of mice: 0.1-0.2 ml of bacteria solution will be inoculated by **gavage** using a straight or curved stainless steel atraumatic ball-tipped gavage needle (20 gauge x 1-1/ 2) into the terminal esophagus and the stomach.

V.4.4.8. Tissue Sharing: As many of our experiments involve infected animals or tissues, we do not participate in any shared tissue and/or control groups with other investigators.

V.4.5. Study Endpoint: Maximum survival of animals will be 30 days post-challenge, after which animals will be euthanized. Since animals will be dosed with a normally lethal amount of bacteria to test the efficacy of our vaccine strains, we will be initially watching the animals every 8 hours during the first week for mortality and onset of end-stage disease symptoms. The monitoring will continue once per day for an additional 23 days until the 30-day post-challenge time point is reached. Therefore, an early endpoint for moribund animals will be considered in the event of severe changes in body weight (>20% weight loss (assessed daily) compared to controls or to the baseline), behavior, appetite, excretion, hair coat, etc. in accordance with USU IACUC Policy 020. Moribund (dying) animals will be euthanized. These animals will undergo terminal cardiac bleeding to assess antibody titers. For this, the animals will be placed in a compressed gas CO_2 inhalation chamber and observed. The chamber will not be overcrowded. Cylinderized carbon dioxide with a pressure gauge and flowmeter will be used as the source of carbon dioxide. With animals in the chamber, the flow rate of CO_2 will displace at least 20% of the cage volume per minute as indicated on the flowmeter. Animals will be watched to ensure that they are lying down and that their purposeful movements have stopped. The anesthesia cage will be opened and the animal will be checked for response to toe pinch. If animal responds to toe pinch, the lid of the chamber will be closed and carbon dioxide flow will continue until the animal is adequately anesthetized as indicated by lack of response to toe pinch. If there is no response to toe pinch then the carbon dioxide flow will be stopped. Animals will then be quickly removed from the chamber and a 22 or 23 gauge needle on a syringe will be used to pierce the thoracic wall and the chamber of the heart. At this point, the animal is narcotized (anesthetized) by CO_2. After sufficient blood is obtained, the needle will be

removed and the animal will immediately be euthanized by cervical dislocation. In most cases, death will already have occurred by exsanguination.

V.4.6. Euthanasia: The PI and other research staff as assigned to the protocol will perform these procedures. Euthanasia will be performed using terminal cardiac bleeds following CO_2 inhalation in a compressed gas CO_2 inhalation chamber according to the most recent AVMA Guidelines on Euthanasia. The chamber will not be overcrowded. Cylinderized carbon dioxide with a pressure gauge and flowmeter will be used as the source of carbon dioxide. With animals in the chamber, the flow rate of CO_2 will displace at least 20% of the cage volume per minute as indicated on the flowmeter. Animals will be watched to ensure that they are lying down and that their purposeful movements have stopped. The anesthesia cage will be opened and the animal will be checked for response to toe pinch. If animal responds to toe pinch, the lid of the chamber will be closed and carbon dioxide flow will continue until the animal is adequately anesthetized as indicated by lack of response to toe pinch. If there is no response to toe pinch then the carbon dioxide flow will be stopped. Animals will then be quickly removed from the chamber and a 22 or 23 gauge needle on a syringe will be used to pierce the thoracic wall and the chamber of the heart. At this point, the animal is narcotized (anesthetized) by CO_2. After sufficient blood is obtained, the needle will be removed and the animal will immediately be euthanized by cervical dislocation. In most cases, death will already have occurred by exsanguination.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol.

V.5.1.1. Study Room:

Building(s) (b)(6) Room Number(s) (b)(6)

V.5.1.2. Special Husbandry Provisions: As a precaution animals will be housed in cages with micro-isolater lids or in cages kept on individually vented racks (Thoren units). Animals will be placed on **floor grids** during fasting to keep them dry and to prevent coprophagia. Cages containing fasting animals will be clearly labeled to prevent inadvertent feeding by LAM personnel. Additionally, if LAM personnel identify dead animals, they will alert laboratory personnel to remove the carcass.

Food Restriction: Yes _____ No X

Fluid Restriction: Yes _____ No X

Animals will be fasted (food withheld but not water) for 2 hours prior to all gavage procedures, including the administration of bacterial suspensions. Additionally, dosed animals will be maintained without food or water for a period of at least 1 hour but not more than 2 hours to facilitate gastric processing of the PBS or bacterial suspensions.

This fasting and fluid restriction period provides limited distress to the animal and increases the likelihood of achieving successful infection, thus decreasing the total number of animals. Afterwards, the animals will be returned to a normal diet for the remainder of the study.

V.5.1.3. Exceptions: N/A

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care: LAM personnel will provide routine checks for health and general husbandry at least once/day. Infected animals will be checked daily by myself or other laboratory personnel. Any animals exhibiting signs of illness will be evaluated by a LAM veterinarian. Animals will typically be monitored for changes in body weight, behavior, appetite, excretion, hair coat, etc. After consulting with the PI (if available), moribund animals will be euthanized as described.

V.5.2.2. Emergency Veterinary Medical Care: All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: Except as indicated below, all animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents.

V.5.3.2. Enrichment Restrictions: Animals will be placed on floor grids during fasting (prior to orogastric procedures) to keep them dry and to prevent coprophagia.

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING: Dr. (b)(6) has considerable experience working with animal models of bacterial pathogenesis. His previous work includes utilization of infant mice and rabbits for the study of *V. cholerae* (training and experience since 1996 at (b)(6) He has been working with gerbil and mice models of *H. pylori* infection since 2001 (training at (b)(6) (b)(6) Any other personnel recruited to this project will be appropriately trained and added to all current protocols.

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)

VII. BIOHAZARDS/SAFETY: Since S. Typhimurium, S. Enteritidis, *S. pneumonia*, and *P. aeruginosa* are classified as BSL 2/ABSL 2 agents by the CDC, animals will be housed at the ABSL 2 level. Gloves, face-masks and lab coats will be worn by all personnel handling infected animals or infected tissues within the animal rooms and laboratory when interacting with the animals. Cages that housed infected animals will be double-bagged, sprayed with disinfectant, and autoclaved.

VIII. ENCLOSURES: N/A

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

(b)(6) _____ 10/29/14

Principal Investigator Signature Date

G. Training: The following personnel will attend the next USUHS Investigator/Animal User Training Course:

_____ _____

_____ _____

H. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely, "Responsibility" for implementing animal use alternatives where feasible and conducting humane and lawful research.

(b)(6) _____ 10/29/14

Principal Investigator Signature Date

I. Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

X. PROTOCOL ABSTRACT:

A. Animal Protocol Number: (b)(6)

B. Animal Protocol Title: Use of *Salmonella* Typhimurium Enterobacterial Common Antigen Mutants as a Vaccine and Vehicle for Heterologous Antigen Delivery (Mice/*Mus musculus*)

C. Principal Investigator: (b)(6) Ph.D.

D. Performing Organization: Uniformed Services University (USU)

E. Funding: Uniformed Services University (USU)

F. Objective and Approach: Given that the human gastrointestinal mucosa is very large and that the acquisition of most infectious diseases occurs at mucosal surfaces, it is not surprising that 15-20 million adults and children acquire or die of mucosal infections annually. *Salmonella* is one bacterial genus that causes diverse mucosal infections. In the United States, non-typhoidal *Salmonella* spp. cause an estimated 1.4 million cases of salmonellosis annually and account for greater than 500 deaths per year. *Salmonella enterica* serovar Typhimurium (*S.* Typhimurium) is one of the most prominent strains.

We have identified mutants of a *Salmonella* cell surface virulence factor that appear to be efficacious live vaccine candidates. Specifically, *S.* Typhimurium, a Gram-negative enteric bacterium and a member of the Enterobacteriacae family, expresses the cell surface glycolipid that is ubiquitous among all family members: the phophoglyceride-linked Enterobacterial common antigen (ECA_{PG}). We have shown that ECA negative mutant strains were severely attenuated for virulence when inoculated into mice. However, rather than being cleared from the animal, these mutant strains set up a persistent infection that was maintained for up to 70 days post infection. Excitingly, immunization of mice with ECA negative mutant strains provided protection against a subsequent lethal oral or intraperitoneal challenge with wild type *S.* Typhimurium. Thus, ECA negative strains of *Salmonella* may be useful as live-attenuated vaccine strains, or as vehicles for heterologous antigen expression.

To this end, we will use a mouse model of *S.* Typhimurium infection to determine whether vaccination with ECA negative strains of *S.* Typhimurium provides protection against other strains and species of *Salmonella*. Mice will be first vaccinated with ECA negative derivatives of TML or SL1344 strains and then subsequently challenged with a lethal dose of wildtype derivatives of the *S.* Typhimurium strain not used for vaccination or *S.* Enteritidis, which expresses a different O antigen. Additionally, we will determine whether ECA negative strains of *S.* Typhimurium can be utilized as a vehicle for heterologous antigen delivery. Mice will be vaccinated with ECA negative strains bearing vectors encoding the *Streptococcus pneumoniae* PspA protein or expressing the O antigen portion of *Pseudomonas aeruginosa*. These animals will then we challenged with virulent *S. pneumoniae* or *P. aeruginosa* to determine the

protective efficacy of the vaccine. Together, these studies will reveal the ability of ECA negative strains of *Salmonella* to act as live-attenuated vaccine strains or vehicles for heterologous antigen delivery.

G. Indexing Terms (Descriptors): *Salmonella*, *S.* Typhimurium, vaccine, mice, ECA, heterologous antigen delivery

January 13, 2015

MEMORANDUM FOR DR. (b)(6) DEPARTMENT OF MICROBIOLOGY

SUBJECT: IACUC Approval of Protocol – Triennial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on January 13, 2015:

Animal Protocol Title: "Pathogenesis of Bacillus Sterne and Bacillus cereus G9241 in Mice"

USUHS Protocol Number: (b)(6)

Expiration Date: January 12, 2018

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. NON-TECHNICAL SYNOPSIS: *Bacillus anthracis*, the bacterium responsible for anthrax, persists in the environment as a dormant, well-protected spore that is resistant to damage and drying. Disease occurs when the spores are inhaled, ingested, or enter wounds in the skin. Once in the body, the dormant spores germinate, or lose their protective coating, and expand into rod-shaped bacteria that multiply and produce toxins that lead to often fatal disease in the patient. Spores of *B. anthracis* have long been considered potential biological weapons. In October 2001, 22 cases of anthrax occurred as a result of deliberate exposure, including 11 patients who suffered the most lethal inhalational disease form. The aggressive use of quinolones and other antibiotics coupled with the early recognition of disease resulted in the survival of 6 of the 11 patients. Hundreds of other individuals potentially exposed to anthrax spores required an extended course of antibiotic therapy due to the concern that they still carried spores in their lungs that could germinate after the conclusion of their antibiotic treatment. Our overarching goals are to 1) determine how *Bacillus* species cause anthrax(-like) disease, and 2) develop therapies that prevent the first stage of disease, specifically germination of the spores. Our experiments will be done with *B. anthracis* Sterne, a strain that does not cause disease in humans and that is used as a vaccine in cattle, and in *Bacillus cereus* G9241, a strain that caused anthrax-like lung disease in a welder but that is attenuated like *B. anthracis* Sterne in mice. A major aim is to study how certain traits of *B. anthracis* and *B. cereus* influence disease progression. Identification of these traits, or virulence factors, will illuminate which are important targets for antimicrobials and vaccines. We will measure the outcome of infection in mice exposed to Sterne or G9241 versus that seen when mice are infected with strains mutated (deficient) in those traits. Further, we will test chemical compounds that alter germination of spores in lab cultures for their capacity to prevent disease in mice infected with spores.

II. BACKGROUND:

II.1. Background: Our studies will continue to investigate two highly related species from the genus *Bacillus*: *B. anthracis* and *B. cereus*. The infectious form of *B. anthracis* and *B. cereus* for animals and humans is the spore. To cause systemic disease, the spore must germinate and undergo outgrowth as a vegetative rod-shaped bacterium. Although the pathogenesis of inhalational, cutaneous, and gastrointestinal anthrax likely involves the same general steps, the morbidities and mortalities differ significantly. After introduction of spores into the host via inhalation, ingestion, or wound contamination, the spores are rapidly phagocytosed by resident macrophages (MΦs). We and others have shown through *in vivo* imaging studies that the spores germinate in the MΦs, either at the site of inoculation or after the MΦs have migrated to the regional lymph nodes (1-4). The spores germinate to form encapsulated vegetative rods, which replicate in the MΦs and produce toxins that kill the MΦs. The extracellular bacilli then disseminate within the host and express the full constellation of virulence factors.

The two principal toxins produced by the vegetative bacteria are Edema Toxin (ET) and Lethal Toxin (LT). Edema Factor (EF) and Lethal Factor (LF) interact with and are delivered to the cell interior by the shared binding subunit Protective Antigen (PA). PA is the principal component of the licensed anthrax vaccine (Biothrax®). ET is comprised of PA and EF and LT is comprised of PA and LF. ET is a calmodulin-dependent adenylate cyclase that converts ATP to cAMP within its target cells. Lethal toxin is a zinc-metalloprotease that cleaves mitogen-activated protein kinase kinases (MAPKK) within MΦs, which can lead to apoptosis of the MΦ and release of vegetative cells and toxins into the surrounding milieu. In addition to the toxins, all strains of *B. anthracis* and some strains of *B. cereus* that cause disease in humans produce one or more capsules. The capsules protect the vegetative bacteria from phagocytosis by macrophages and neutrophils, particularly during dissemination through the lymph and blood to distal sites.

The majority of animal models of anthrax disease mimic inhalational or subcutaneous anthrax in humans [see (5) for review of animal models of anthrax disease]. Inhalational models have been used most often, despite the relatively low frequency of inhalational anthrax (compared to the other routes of inoculation), because aerosolized spores have the potential to be used as bioweapons. Like humans, non-human primates and rabbits are particularly susceptible to the effects of LT and ET, a characteristic that makes these animal models particularly useful for studies of late stage anthrax disease as well as for vaccine and therapeutic development. Mice and guinea pigs can be used to model both the infection (early) and toxemia (late) stages of disease. Mice have been used most extensively due to their low cost, ease of handling, and genetic diversity. Mouse models of anthrax disease are used to mimic inhalational [aerosol, intranasal (i.n.), intratracheal inoculation], cutaneous [subcutaneous (s.c.) inoculation], and gastrointestinal [oral/intragastric (i.g.) inoculation] forms of human anthrax, and all of these models are useful for studies of infection and toxemia. In addition, intravenous (i.v.) or intraperitoneal (i.p.) injection of spores or purified toxins can be useful for investigations of the roles of capsules and toxins in *Bacillus* pathogenesis.

All of our *B. anthracis* animal studies are conducted with *B. anthracis* Sterne, an attenuated strain that does not produce capsule and that is used as a vaccine for cattle.

B. anthracis Sterne is fully virulent in A/J mouse models of anthrax disease; A/J mice are C5-deficient and are defective in neutrophil recruitment, so they are more susceptible to infections caused by *Bacillus* species. The genes that encode the toxin components in *B. anthracis* (*pag, lef, cya*) are located on the pXO1 megaplasmid. The pXO2 megaplasmid, which is not present in *B. anthracis* Sterne, encodes the genes required for production of a poly-D-glutamic acid capsule. Our studies of *B. cereus* virulence are conducted with *B. cereus* G9241, a strain that was isolated from the blood and sputum of a welder who had anthrax-like lung disease (6). *B. cereus* G9241 is unique among *B. cereus* strains for the following reasons: 1) *B. cereus* typically causes mild gastroenteritis rather than anthrax-like pneumonia in humans; and 2) the strain contains two megaplasmids, pBCXO1 and pBC210. The pBCXO1 megaplasmid is 99% identical to pXO1 in *B. anthracis*. One key difference between the two megaplasmids is that the *hasACB* operon on pBCXO1 is intact, which provides *B. cereus* G9241 with the tools necessary to produce a hyaluronic acid capsule (7). The *hasACB* operon on the *B. anthracis* pXO1 contains a frameshift mutation that renders the operon non-functional. In addition, pBC210 contains a second functional polysaccharide capsule operon and a homolog of the gene that encodes PA (*pagA2*). A third toxin, Certhrax, which functions as an ADP-ribosyltransferase, is encoded on pBC210 as well (8); the role of Certhrax in *B. cereus* G9241 pathogenesis will be investigated in the studies described in this protocol. Our preliminary *in vivo* experiments with G9241 and G9241 Δ*certhrax* suggest that Certhrax may reduce virulence of G9241 in subcutaneous and intranasal models. Further *in silico* analysis and literature reports of related toxins have led us to speculate that Certhrax may play a role in gastrointestinal disease.

Despite the prominent role that the toxins play in anthrax disease, we propose that if spore germination can be blocked, the vegetative cells that express these toxins will not be formed. We hypothesize that administration of a small molecule that inhibits germination as a therapeutic will protect mice from anthrax disease. The small molecule 6-thioguanine (6-TG), an analog of known *in vitro* germinants inosine and alanine, was previously shown to inhibit germination of *B. anthracis* spores *in vitro* and in MΦs (9). In preliminary mouse studies under (b)(6) we determined that two s.c. injections (-4, -1 hr) of 6-TG prior to s.c. inoculation with *B. anthracis* Sterne spores extends the median time-to-death by 1-2 days and reduces the mortality rate from 100% to ~50% (unpublished). We screened 3722 small molecules to identify compounds that have the capacity to alter germination of *B. anthracis* Sterne spores in a high-throughput *in vitro* assay. We discovered 20 potential lead compounds that inhibit the spore germination rate by at least 2/3, and we found that 2 of the lead compounds exert sporicidal activity *in vitro* and inhibit spore germination in MΦs. In very preliminary analyses, we found that both compounds have the capacity to reduce mortality in the same animal model system described above for 6-TG.

II.2. Literature Search for Duplication:

II.2.1. Literature Source(s) Searched:

II.2.2. Date of Search: 3 October 2014

II.2.3. Period of Search: BRD: 1998-2009 (most recent); RePORT: 2004-2014, Active Projects; PubMed

II.2.4. Key Words and Search Strategy: *Bacillus* AND (spores OR capsule OR germination OR dissemination OR immunization OR Certhrax) AND (mouse OR mice)

II.2.5. Results of Search:
RESULTS FROM BRD: Search of the BRD database resulted in 102 hits, of which 42 were unique and 9 were from my laboratory. Other studies utilized guinea pigs and rabbits to ascertain *B. anthracis* virulence properties. Sixteen documents were from our collaborators at (b)(6) and outlined our joint studies to investigate spore proteins as vaccine candidates and the roles of antibodies against spores in inhibition of germination and growth. An additional document was from another collaborator and resulted in a joint publication between our laboratories. The remaining studies were focused on the following topics: development of vaccines against anthrax disease that are based on PA and LF; development of multivalent vaccines against two bioterrorism threats (*B. anthracis*, *Yersinia pestis*, *Burkholderia spp*, ricin); the use of hyperbaric oxygen, antimicrobials, or antibodies against PA and/or LF as post-exposure prophylaxis; the role of the unique poly-D-glutamic acid capsule of *B. anthracis* in disease; the contribution of different spore structures on pathogenesis; and methods for detection of *B. anthracis* spores. None of the studies identified in the BRD database overlap with the studies proposed here, except those outlined in proposals from my laboratory.

RESULTS FROM NIH RePORT: The search parameters included *Bacillus* and mouse/mice and [spore (24) OR capsule (5) OR dissemination (3) OR immunization (55) OR Certhrax (0)], where the number in parentheses indicates the number of awards that were identified by the search parameters. An award to my collaborator Dr. (b)(6) is to investigate the regulation of *B. anthracis* virulence factors; we are working with the (b)(6) lab on similar studies in *B. cereus*. Of the 24 awards that matched with "spore", 6 focused on the use of spore proteins as vaccine candidates in the context of PA, 4 on treatment, 2 on toxins, 7 on pathogenesis, and 6 on irrelevant organisms (bacillus can be used to define rod-shaped bacteria). Two of the 5 capsule-oriented awards focused on multi-valent vaccine development, two on pathogenesis, and one was irrelevant. Only one of the 3 dissemination-focused awards was targeted toward *B. anthracis* vaccine development; the others were irrelevant. Finally, 55 awards involved *Bacillus* immunization in mice, but 37 of them were focused on other organisms [mostly the use of the bacillus Calmette-Guerin (BCG) vaccine against *Mycobacterium tuberculosis*]. Twelve focused on *B. anthracis* vaccine development and/or *B. anthracis* toxins, one was directed toward treatment, and four focused on pathogenesis. None of the studies described in this protocol is the focus of any of the awards identified by NIH RePORT.

RESULTS FROM PUBMED: The search parameters were as follows: *Bacillus* AND (spores OR capsule OR germination OR dissemination OR immunization OR Certhrax) AND (mouse OR mice) NOT *Mycobacterium* NOT mycobacteria filtered by "English only". The search yielded 730 results, of which 213 were deemed irrelevant because they focused on BCG as a vaccine or adjuvant, other *Bacillus spp.*, other organisms (*Listeria monocytogenes*, *Streptococcus pneumoniae*), sterilization techniques (*Bacillus* spores are used to determine sterility), immunization with *Bacillus thuringiensis* Cry

toxins, the use of *Bacillus spp.* as probiotics, or cancer. A further 71 articles described the use of spores from various *Bacillus spp.* as a platform for vaccine delivery of heterologous antigens, and three reports showed the efficacy of lethal toxin variants as vaccine adjuvants. A total of 119 articles focused on the pathogenesis of anthrax disease in mice. These studies focused on the interactions of *Bacillus anthracis* spores and/or vegetative cells with various cells in the host, including macrophages and dendritic cells. In addition, many of the papers described the progression of anthrax disease in mice, guinea pigs, rabbits, and monkeys. Of the pathogenesis studies, four focused on the development of models of gastrointestinal anthrax disease and eight described intranasal and aerosol models of anthrax lung disease.

Further, a few dozen articles described the characterization of strains that contained mutations in *B. anthracis* genes. An additional 27 studies demonstrate the activities and functions of the anthrax toxins lethal toxin and edema toxin, which are critical virulence factors for *B. anthracis*. The other major virulence factor is the poly-D-glutamic acid capsule, which is the focus of 23 articles; of the 23, 16 focused on the protective capacity of anti-capsular antibodies during *B. anthracis* infection. A total of 143 papers focused on the development of vaccines against anthrax. The vast majority (95) described many different versions of vaccines that target Protective Antigen (PA), while others focused on the use of *B. anthracis* Sterne spores (10), spore proteins (3), lethal factor (17), and other *Bacillus* antigens (20). Most of the papers that demonstrate the use of spore proteins as vaccine candidates are from my laboratory and/or the laboratory of our collaborator Dr. (b)(6) Twenty-two manuscripts described the structure and function of spores, while an additional 19 papers focused on germination. Two of those manuscripts are from the laboratory of our collaborator Dr. (b)(6) (b)(6) they describe the discovery and characterization of 6-thioguanine as a germination inhibitor. A total of 35 papers describe studies of treatments for anthrax disease, including 11 that describe monoclonal antibodies that reduce mortality, 12 that assess the efficacy of various antibiotics, and 12 that describe lesser known treatment approaches. An additional 21 articles focused on different methods to detect *Bacillus* spores in the environment and how to rapidly differentiate non-pathogenic species from *B. anthracis*. One paper provided preliminary characterization of Certhrax, the novel ADP-ribosyltransferase produced by *B. cereus* G9241 that is the focus of some of the experiments in this protocol. Three other manuscripts described *B. cereus* G9241: two studies from our competitor Dr. (b)(6) laboratory described surface structures that play a role in virulence, and the third paper is the first paper to describe the strain.

A total of nine manuscripts were published by my laboratory. The studies described herein are follow-on studies to those previously published. None of our proposed experiments overlap with published research.

III. OBJECTIVE\HYPOTHESIS: Our hypotheses for the studies proposed herein are as follows: 1) deletion of putative or known virulence genes will alter the pathogenesis of *B. anthracis* Sterne and *B. cereus* G9241; 2) Certhrax plays a significant role in gastrointestinal disease caused by *B. cereus* G9241 and antibodies against the toxin will protect against disease progression; and 3) small molecules that inhibit spore germination will reduce mortality caused by *B. anthracis* Sterne. Our **goals** are to

characterize the progression of *B. anthracis* Sterne disease, to characterize the roles of toxins and capsules in *B. cereus* G9241 virulence, and to identify candidate therapeutics to prevent or treat anthrax disease. The specific aims are as follows: **1)** assess the virulence of *B. anthracis* Sterne or *B. cereus* G9241 strains in which a particular virulence trait has been deleted; **2)** administer *B. cereus* G9241 toxin components to assess their activity *in vivo*; **3)** monitor the location and kinetics of germination, vegetative outgrowth, and dissemination of fluorescent derivatives of *B. anthracis* Sterne and *B. cereus* G9241 in the mouse with an *in vivo* imaging system; **4)** characterize the *in vivo* efficacy of small molecules that inhibit germination of *B. anthracis* Sterne spores *in vitro*; and **5)** assess the capacity of antibodies against *B. cereus* G9241 toxins or capsule to protect from disease.

IV. **MILITARY RELEVANCE**: The potential use of *B. anthracis* as a weapon of biowarfare was brought to the forefront in the aftermath of the terrorist attacks of September 11th, 2001. From October to December 2001, a total of 22 cases of confirmed or suspected bioterrorism-related anthrax occurred in the United States. Eleven of these cases were inhalational (the most lethal form of the infection) and resulted in the death of 6 individuals. In light of these events, the development of therapeutic agents against *B. anthracis* infection is paramount for the protection of both deployed military personnel and civilians who may come into contact with sabotaged contaminated materials. Further, a more complete understanding of the progression of disease caused by these two highly related *Bacillus* species will inform future development of more effective vaccine and therapeutic candidates.

V. **MATERIALS AND METHODS**:

V.1. **Experimental Design and General Procedures**:

A. Three general types of experiments will be conducted in the studies outlined in this protocol.

1. Mice will be inoculated with *B. anthracis* or *B. cereus* spores or vegetative cells, or with purified toxin components by intranasal (i.n.), subcutaneous (s.c.), intragastric (i.g.), intraperitoneal (i.p.), or intravenous (i.v.) administration and monitored for morbidity and mortality with death as an endpoint. The purpose of these studies is to determine 1) if isogenic mutant strains that lack a particular virulence factor exhibit a difference virulence profile than the parent strain, 2) if the toxins produced by *B. cereus* G9241 exhibit similar activity *in vivo* as do their *B. anthracis* counterparts, 3) if Certhrax contributes to *B. cereus* G9241 virulence, or 4) the *in vivo* location(s) of *B. anthracis* and *B. cereus* strains that fluoresce at a particular stage in growth (germination, vegetative outgrowth, dissemination). In some studies of specific virulence factors (i.e. Certhrax, pBC210 capsule), rabbit polyclonal antibodies against the virulence factor will be administered before or after spore or toxin challenge to assess the capacity of the antibodies to protect or rescue mice from disease.

2. Mice will be challenged with *B. anthracis* Sterne spores and treated with small molecules known to inhibit germination *in vitro*. The purpose of these studies is to

determine whether the small molecule(s) could be used as post-exposure prophylaxis to prevent germination and subsequent vegetative outgrowth in the host.

3. Mice will be immunized multiple times with viable *B. cereus* G9241 spores to generate convalescent sera to identify proteins and/or polysaccharides that are expressed during infection. The purpose of this study is to determine if and where specific virulence factors (i.e. Certhrax) are produced during the course of disease.

B. For all of the mouse studies outlined in this protocol, 6-8 week old female A/J or C57BL/6 mice will be challenged by one of five routes (i.n., s.c., i.g., i.p., or i.v.) with *Bacillus anthracis* Sterne spores, *B. cereus* G9241 spores or vegetative cells, or purified toxin components (i.g., i.p., or i.v. only). Moribund mice will be euthanized by inhalational isoflurane overdose followed by cervical dislocation. We define moribund as when the mouse is crouched down or lying in the bottom of the cage with little movement, even when gently prodded. Other nonspecific signs that will be used are ruffled fur, lethargy, hunched posture, decreased alertness, weight loss, and difficulty breathing.

1. For i.n. inoculation, mice will be anesthetized with inhaled isoflurane delivered via a Xenogen XGI-8 gas anesthesia system or with i.p. ketamine (100 mg/kg) and xylazine (10 mg/kg). Once anesthesia is confirmed by non-response to toe pinch, mice will be inoculated i.n. by manually pipetting 50 µl heat-activated spores in H_2O onto the nares (25 µl/per nostril). The mice will be held upright until the inoculum is inhaled (~1 min), then returned to their cages to recover from the anesthesia. Mice will remain in the laboratory for one hour after inoculation to permit careful monitoring of mice. The study endpoint will be either death (see section V.4.5) or euthanasia 14 days post-challenge. Obviously moribund animals will be euthanized by inhalational overdose of CO_2 or isoflurane followed by cervical dislocation (see section V.4.6).

2. For s.c. inoculation, 100-200 µl heat-activated *Bacillus* spores will be administered to each mouse behind the foreleg, between the scapulae, or at the base of the tail using a tuberculin syringe attached to a 26 gauge 0.5 inch needle. Mice will remain in the laboratory for one hour after inoculation to permit careful monitoring of mice. The study endpoint will be either death (see section V.4.5) or euthanasia 14 days post-challenge. Obviously moribund animals will be euthanized by inhalational overdose of CO_2 or isoflurane followed by cervical dislocation (see section V.4.6).

3. For i.g. inoculation, six- to eight-week-old mice will be fasted overnight to reduce the volume of the stomach contents so that the entire inoculum can be administered, in addition, water will be removed from the cages 2-4 hrs prior to inoculation. The next morning, groups of 10 mice will be fed 10^2 to 10^9 vegetative cells or heat-activated spores of the *Bacillus* strain to be tested in 50-100 µl PBS with or without 8.5% sodium bicarbonate ($NaHCO_3$) to neutralize the stomach acid (see V.1.1.2 below). The inoculation will be accomplished by oral gavage with a 20 gauge, 1 ½" disposable gavage needle. After inoculation the animals will then be returned to their cages and permitted food and water *ad libitum*. The endpoint for this study is

extreme morbidity or mortality, as defined in Section V.4.5, and the experiment will be continued for up to 28 days. Mice will be monitored for signs of extreme morbidity (see Section V.4.5 below for definition of extreme morbidity), and obviously moribund animals will be euthanized by inhalational overdose of CO_2 or isoflurane followed by cervical dislocation (see section V.4.6). In some experiments, mice will be euthanized by the same method at earlier time points to permit postmortem tissue harvest followed by histology and/or bacterial/spore enumeration.

4. For i.p. inoculation, 100-200 µl heat-activated *Bacillus* spores or purified toxin components will be administered into the peritoneal cavity through the ventral abdominal wall using a tuberculin syringe attached to a 26 gauge 0.5 inch needle. For i.v. inoculation, 100-200 µl heat-activated *Bacillus* spores or purified toxin components will be administered to each mouse by tail venipuncture or retro-orbital injection using a tuberculin syringe attached to a 26 gauge 0.5 inch needle. Mice will remain in the laboratory for one hour after inoculation to permit careful monitoring of mice. The study endpoint will be either death (see section V.4.5) or euthanasia 14 days post-challenge. Obviously moribund animals will be euthanized by inhalational overdose of CO_2 or isoflurane followed by cervical dislocation (see section V.4.6).
