V.1.1. Assessment of virulence of *B. anthracis* Sterne and *B. cereus* G9241 and mutants. In these studies, we will address the contributions of several virulence factors to the pathogenesis of *B. anthracis* Sterne and/or *B. cereus* G9241 disease. The 50% lethal doses (LD_{50}) for *B. anthracis* Sterne administered i.n. and s.c. to A/J mice are 6.3×10^4 spores and 1.6×10^3 spores, respectively and the LD_{50}s for *B. cereus* G9241 administered to A/J mice via i.n. and s.c. routes are 3.2×10^5 spores and 1.3×10^3 spores, respectively (10). We and others have previously demonstrated that the *B. cereus* G9241 megaplasmids that encode the capsule operons and the toxin genes are required for virulence (10). We propose to investigate the virulence of *B. anthracis* Sterne or *B. cereus* G9241 mutants that do not produce certain capsules, toxins, spore proteins, or virulence regulators. We will test the virulence of these strains via s.c., i.n., and/or i.g. routes.

V.1.1.1. Identification of LD_{50} of *B. anthracis* Sterne or *B. cereus* G9241 mutants delivered via s.c. or i.n. routes. We will assess the contribution of several virulence factors to the pathogenesis of *B. anthracis* Sterne or *B. cereus* G9241 disease. These experiments will be done twice with each bacterial strain in immunocompromised A/J mice, with a wide range of doses used in the first experiment and a narrow range of doses used in the second experiment to more accurately pinpoint the LD_{50}. In addition, a positive control group of mice infected with $10 \times LD_{50}$ of the parent strain (*B. anthracis* Sterne or *B. cereus* G9241) will be included for comparison purposes. If we find that a mutant is as virulent as or more virulent that the parent strain, we will repeat the LD_{50} analysis in C57BL/6 mice, which are more resistant to infection with both parent strains (higher LD_{50}s) because the mice are fully immunocompetent. In some experiments, we will challenge mice with a complemented mutant strain in which the gene of interest is expressed episomally on a plasmid; for these studies, we will add to the drinking water 5-10 g/L spectinomycin to maintain the plasmid and 25 mM isopropyl β-D-thiogalactoside to induce expression of the gene. Inasmuch as possible, more than one mutant strain will be tested in a given experiment so that negative (H_2O) and positive

(10xLD_{50} of the parent strain) control groups can be shared. The LD_{50} for each mutant strain will be determined with two experiments.

V.1.1.1.1. Subcutaneous experiment 1 for Bacillus mutants
Group 1: 5 mice: 10^1 *Bacillus* mutant spores in H_2O
Group 2: 5 mice: 10^2 *Bacillus* mutant spores in H_2O
Group 3: 5 mice: 10^3 *Bacillus* mutant spores in H_2O
Group 4: 5 mice: 10^4 *Bacillus* mutant spores in H_2O
Group 5: 5 mice: 10^5 *Bacillus* mutant spores in H_2O
Group 6: 5 mice: 10^6 *Bacillus* mutant spores in H_2O
Group 7: 5 mice: 10xLD_{50} *Bacillus* parent strain spores in H_2O
Group 8: 3 mice: H_2O
38 A/J mice and 38 C57BL/6 mice

V.1.1.1.2. Subcutaneous experiment 2
Remove two doses farthest from LD_{50} and increase to 10 mice/group for mutant strains only = **48 A/J mice and 48 C57BL/6 mice**

Total for subcutaneous experiments
(38 A/J mice + 48 A/J mice) x 10 mutant strains = **860 A/J mice**
(38 C57BL/6mice + 48 C57BL/6 mice) x 10 mutant strains = **860 C57BL/6 mice** (if needed)

V.1.1.1.3. Intranasal experiment 1 for Bacillus mutants
Group 1: 5 mice: 10^2 *Bacillus* mutant spores in H_2O
Group 2: 5 mice: 10^3 *Bacillus* mutant spores in H_2O
Group 3: 5 mice: 10^4 *Bacillus* mutant spores in H_2O
Group 4: 5 mice: 10^5 *Bacillus* mutant spores in H_2O
Group 5: 5 mice: 10^6 *Bacillus* mutant spores in H_2O
Group 6: 5 mice: 10^7 *Bacillus* mutant spores in H_2O
Group 7: 5 mice: 10xLD_{50} *Bacillus* parent strain spores in H_2O
Group 8: 3 mice: H_2O
38 A/J mice and 38 C57BL/6 mice

V.1.1.1.4. Intranasal experiment 2
Remove two doses farthest from LD_{50} and increase to 10 mice/group for mutant strains only = **48 A/J mice and 48 C57BL/6 mice**

Total for intranasal experiments:
(38 A/J mice + 48 A/J mice) x 10 mutant strains = **860 A/J mice**
(38 C57BL/6mice + 48 C57BL/6 mice) x 10 mutant strains = **860 C57BL/6 mice** (if needed)

Total for V.1.1.1:
860 A/J mice + 860 A/J mice = 1720 A/J mice
860 C57BL/6 mice + 860 C57BL/6 mice mice = 1720 C57BL/6 mice

V.1.1.2. Determination of LD_{50}s of *B. cereus* G9241 and isogenic mutants delivered via i.g. inoculation. Because we have not used the i.g. animal model previously for *Bacillus spp.*, a pilot study is needed to determine whether $NaHCO_3$-mediated stomach acid neutralization is required to promote colonization of the GI tract and whether spores or vegetative cells colonize the GI tract more efficiently. We have many years of experience with oral inoculation studies with Shiga toxin-producing *E. coli*, Shiga toxins and ricin (b)(6) and previous versions thereof), so we are confident that we will identify the optimal inoculation conditions quickly and with as few mice as possible. In their studies of *Bacillus* GI infection, Rolny *et al.* inoculated C57BL/6 mice with 10^8-10^9 *B. cereus* vegetative cells (food isolate) suspended in PBS (11), while Glomski *et al.* inoculated BALB/c mice with 10^6 spores of a non-toxigenic but capsulated and luminescent *B. anthracis* strain suspended in PBS (12). In contrast, Xie *et al.* first administered $NaHCO_3$ by gavage, then immediately delivered $2.3x10^6$-$2.3x10^9$ *B. anthracis* Sterne vegetative cells suspended in culture medium; the LD_{50} was determined to be $2.3x10^7$ Sterne cells (13). For these studies, *B. cereus* G9241 spores or vegetative cells will be administered to female A/J mice via i.g. gavage as described in V.1.B.3 above. In the pilot study, fecal samples will be collected every day for 4-7 days to enumerate the bacterial load, which will allow us to determine the efficiency of intestinal colonization. In subsequent studies, fecal collection and bacterial enumeration will be done as needed to assess colonization. In addition, intestines, stomach, spleen, liver, and lungs will be collected postmortem to assess histology and bacterial loads in those organs. Mice will be monitored for morbidity and mortality several times each day, and extremely moribund mice will be euthanized by inhalational isoflurane overdose followed by cervical dislocation.

V.1.1.2.1. Pilot study to determine the appropriate inoculum (spores vs. vegetative cells) and the appropriate medium (PBS ± $NaHCO_3$) for inoculum delivery. Some form of the pilot study will likely need to be conducted 2-3 times until we determine that the conditions are optimized.

Group 1: 10 mice: 10^9 G9241 spores in 0.1 ml PBS
Group 2: 10 mice: 10^9 G9241 vegetative cells in 0.1 ml PBS
Group 3: 10 mice: 10^9 G9241 spores in 0.1 ml PBS, pretreated with 0.05 ml 8.5% (w/v) $NaHCO_3$
Group 4: 10 mice: 10^9 G9241 vegetative cells in 0.1 ml PBS, pretreated with 0.05 ml 8.5% (w/v) $NaHCO_3$
Group 5: 5 mice: PBS only
Group 6: 5 mice: PBS only, pretreated with 0.05 ml 8.5% (w/v) $NaHCO_3$
50 A/J mice x 3 iterations = 150 A/J mice

V.1.1.2.2. Determination of LD_{50} for G9241 delivered by i.g. gavage. *B. cereus* G9241 spores or vegetative cells suspended in PBS ± $NaHCO_3$ (as determined in V.1.1.2.1) will be administered via i.g. gavage as described in V.1.B.3 above. The i.g. LD_{50} experiment will be done twice with G9241, with a wide range of doses used in the first experiment and a narrow range of doses used in the second experiment to more accurately pinpoint the LD_{50}.

V.1.1.2.2.1 Intragastric experiment 1

Group 1: 5 mice: 10^3 G9241
Group 2: 5 mice: 10^4 G9241
Group 3: 5 mice: 10^5 G9241
Group 4: 5 mice: 10^6 G9241
Group 5: 5 mice: 10^7 G9241
Group 6: 5 mice: 10^8 G9241
Group 7: 5 mice: 10^9 G9241
Group 8: 3 mice: H_2O
38 A/J mice

V.1.1.2.2.2 Intragastric experiment 2

Remove three doses farthest from LD_{50} and increase to 10 mice/group = **43 A/J mice**

V.1.1.2.3. Determination of LD_{50}s for G9241 mutants delivered by i.g. gavage.

These studies will be conducted exactly as in V.1.1.2.2 above, except that one additional group of 5 mice inoculated with 10xLD_{50} G9241 will be added to each study as a positive control group.

V.1.1.2.3.1 Intragastric G9241 mutant LD_{50} experiment 1

Group 1: 5 mice: 10^3 G9241 mutant
Group 2: 5 mice: 10^4 G9241 mutant
Group 3: 5 mice: 10^5 G9241 mutant
Group 4: 5 mice: 10^6 G9241 mutant
Group 5: 5 mice: 10^7 G9241 mutant
Group 6: 5 mice: 10^8 G9241 mutant
Group 7: 5 mice: 10^9 G9241 mutant
Group 8: 5 mice: 10xLD_{50} G9241
Group 9: 3 mice: H_2O
43 A/J mice x 6 mutant strains = 258 A/J mice

V.1.1.2.3.2 Intragastric G9241 mutant LD_{50} experiment 2

Remove three doses of the mutant farthest from LD_{50} and increase to 10 mice/group = **48 A/J mice x 6 mutant strains = 288 A/J mice**

Total for V.1.1.2: 777 A/J mice

Total for V.1.1:
1720 A/J mice + 777 A/J mice = **2497 A/J mice**
1720 C57BL/6 mice (if needed)

V.1.2. Experiment 2: Determination of toxicity of putative *B. cereus* G9241 lethal toxin (LT), edema toxin (ET), and Certhrax. The purpose of these studies is to investigate the potential for each of these toxins to contribute to *B. cereus* G9241 disease. As mentioned in the Background, LT is composed of PA + LF and ET is composed of PA + EF. The activity of these toxins in *B. anthracis* has been characterized; in these studies, we propose to confirm that the *B. cereus* G9241 toxins exhibit the same *in vivo* activities as their *B. anthracis* homologs. Additionally, Certhrax

is a *B. cereus* G9241-specific toxin that contains a PA binding domain and a functional ADP-ribosyltransferase domain; however, we do not yet know if PA is required for Certhrax activity *in vitro* or *in vivo*. Prior to initiation of LD_{50} studies in mice, we will confirm that each toxin is functional in *in vitro* systems.

The LD_{50} studies will be conducted in C57BL/6J mice according to established models of LT and ET toxicity. Female C57BL/6J mice will be injected i.p. with PA + LF (1:1 ratio) or with PA + EF (1:1 ratio) in sterile saline as described in V.1, section B4 above. Previous studies by other groups have shown that C57BL/6 mice inoculated i.p. with 100 µg PA +100 µg LF from *B. anthracis* typically die within 3 days after injection (14) and those inoculated i.v. with 25 µg PA + 25 µg EF from *B. anthracis* also die within 3 days after injection (15). Mice will be weighed daily to determine if a correlation between weight loss and eventual death exists. Mice will be carefully monitored as described in V.4.5 and euthanized as in V.4.6 if they are extremely moribund.

The published lethal doses for the *B. anthracis* toxins and the relative *in vitro* toxicities of the *B. cereus* G9241 toxins compared to the *B. anthracis* toxins will guide the dosing strategy for the first LD_{50} study for each *B. cereus* G9241 toxin.

V.1.2.1 Lethal Toxin Experiment 1: Groups 1-7 will be intoxicated with doses of the *B. cereus* G9241 toxin components that correspond with the published LD_{50}s for each *B. anthracis* toxin (i.e. for Group 1, mice will be intoxicated with doses of the *B. cereus* G9241 PA and LF that correspond to 20 LD_{50}s of the *B. anthracis* toxin components). Group 8 will be intoxicated with *B. anthracis* Sterne toxin components (control).

Group 1: 5 mice: 20xLD_{50} *B. anthracis* PA + 20xLD_{50} *B. anthracis* LF
Group 2: 5 mice: 10xLD_{50} *B. anthracis* PA + 10xLD_{50} *B. anthracis* LF
Group 3: 5 mice: 5xLD_{50} *B. anthracis* PA + 5xLD_{50} *B. anthracis* LF
Group 4: 5 mice: 1xLD_{50} *B. anthracis* PA + 1xLD_{50} *B. anthracis* LF
Group 5: 5 mice: 0.5xLD_{50} *B. anthracis* PA + 0.5xLD_{50} *B. anthracis* LF
Group 6: 5 mice: 10xLD_{50} *B. anthracis* PA
Group 7: 5 mice: 10xLD_{50} *B. anthracis* LF
Group 8: 5 mice: 10xLD_{50} *B. anthracis* PA + 10xLD_{50} *B. anthracis* LF
40 C57BL/6J mice

V.1.2.2. Lethal Toxin Experiment 2: Groups 1-5 will be intoxicated with *B. cereus* G9241 toxin components. Group 6 will be intoxicated with *B. anthracis* Sterne toxin components (control).

Group 1: 5 mice: 20xLD_{50} *B. cereus* PA + 20xLD_{50} *B. cereus* LF
Group 2: 5 mice: 10xLD_{50} *B. cereus* PA + 10xLD_{50} *B. cereus* LF
Group 3: 5 mice: 5xLD_{50} *B. cereus* PA + 5xLD_{50} *B. cereus* LF
Group 4: 5 mice: 1xLD_{50} *B. cereus* PA + 1xLD_{50} *B. cereus* LF
Group 5: 5 mice: 0.5xLD_{50} *B. cereus* PA + 0.5xLD_{50} *B. cereus* LF
Group 6: 5 mice: 10xLD_{50} *B. anthracis* PA + 10xLD_{50} *B. anthracis* LF
30 C57BL/6J mice

Total for V.1.2.1 and V.1.2.2: 40 mice + 30 mice = 70 C57BL/6J mice

V.1.2.3. Edema Toxin Experiment 1: Groups 1-7 will be intoxicated with doses of the *B. cereus G9241* toxin components that correspond with the published LD_{50}s for each B. anthracis toxin (i.e. for Group 1, mice will be intoxicated with doses of the *B. cereus* G9241 PA and EF that correspond to 20 LD_{50}s of the *B. anthracis* toxin components). Group 8 will be intoxicated with *B. anthracis* Sterne toxin components (control).

Group 1: 5 mice: 20xLD_{50} *B. anthracis* PA + 20xLD_{50} *B. anthracis* EF
Group 2: 5 mice: 10xLD_{50} *B. anthracis* PA + 10xLD_{50} *B. anthracis* EF
Group 3: 5 mice: 5xLD_{50} *B. anthracis* PA + 5xLD_{50} *B. anthracis* EF
Group 4: 5 mice: 1xLD_{50} *B. anthracis* PA + 1xLD_{50} *B. anthracis* EF
Group 5: 5 mice: 0.5xLD_{50} *B. anthracis* PA + 0.5xLD_{50} *B. anthracis* EF
Group 6: 5 mice: 10xLD_{50} *B. anthracis* PA
Group 7: 5 mice: 10xLD_{50} *B. anthracis* EF
Group 8: 5 mice: 10xLD_{50} *B. anthracis* PA + 10xLD_{50} *B. anthracis* EF
40 C57BL/6J mice

V.1.2.4. Edema Toxin Experiment 2: Groups 1-5 will be intoxicated with *B. cereus* G9241 toxin components. Group 6 will be intoxicated with *B. anthracis* Sterne toxin components (control).

Group 1: 5 mice: 20xLD_{50} *B. cereus* PA + 20xLD_{50} *B. cereus* EF
Group 2: 5 mice: 10xLD_{50} *B. cereus* PA + 10xLD_{50} *B. cereus* EF
Group 3: 5 mice: 5xLD_{50} *B. cereus* PA + 5xLD_{50} *B. cereus* EF
Group 4: 5 mice: 1xLD_{50} *B. cereus* PA + 1xLD_{50} *B. cereus* EF
Group 5: 5 mice: 0.5xLD_{50} *B. cereus* PA + 0.5xLD_{50} *B. cereus* EF
Group 6: 5 mice: 10xLD_{50} *B. anthracis* PA + 10xLD_{50} *B. anthracis* EF
30 C57BL/6J mice

Total for V.1.2.3 and V.1.2.4: 40 mice + 30 mice = 70 C57BL/6J mice

V.1.2.5. Certhrax Experiment 1: Groups 1-5 will be intoxicated with *B. cereus* G9241 toxin component combinations. Groups 6 and 7 will be intoxicated with the individual *B. cereus* G9241 toxin components.

Group 1: 5 mice: 500 µg PA + 500 µg Certhrax
Group 2: 5 mice: 100 µg PA + 100 µg Certhrax
Group 3: 5 mice: 50 µg PA + 50 µg Certhrax
Group 4: 5 mice: 5 µg PA + 5 µg Certhrax
Group 5: 5 mice: 1 µg PA + 1 µg Certhrax
Group 6: 5 mice: 100 µg PA
Group 7: 5 mice: 100 µg Certhrax
35 C57BL/6J mice x 2 forms of PA = 70 C57BL/6 mice

V.1.2.6. Certhrax Experiment 2: Groups 1-5 will be intoxicated with *B. cereus* G9241 toxin component combinations. Groups 6 and 7 will be intoxicated with the individual *B. cereus* G9241 toxin components.

Group 1: 5 mice: 20xLD_{50} *B. cereus* PA + 20xLD_{50} Certhrax
Group 2: 5 mice: 10xLD_{50} *B. cereus* PA + 10xLD_{50} Certhrax
Group 3: 5 mice: 5xLD_{50} *B. cereus* PA + 5xLD_{50} Certhrax
Group 4: 5 mice: 1xLD_{50} *B. cereus* PA + 1xLD_{50} Certhrax

Group 5: 5 mice: 0.5xLD_{50} *B. cereus* PA + 0.5xLD_{50} Certhrax
Group 6: 5 mice: 10xLD_{50} PA
Group 7: 5 mice: 10xLD_{50} Certhrax
35 C57BL/6J mice x 2 forms of PA = 70 C57BL/6 mice

Total for V.1.2.5 and V.1.2.6: 70 mice + 70 mice = 140 C57BL/6J mice

V.1.2.7: Certhrax and Lethal Toxin Synergy: If we determine that Certhrax and LF act synergistically to elicit increased cytopathicity or cytotoxicity *in vitro*, we will test the synergy hypothesis *in vivo*. For these studies, we will first identify an appropriate sublethal dose of PA1 + LF and, if PA2 acts as a binding partner for LF *in vitro* and/or for Certhrax *in vitro* and *in vivo*, of PA2 + LF. The published LD_{50} for PA1 + LF administered i.v. is ~50 µg of each component (16), so we will conduct a dose response experiment with 4 doses of PA1 + LF and of PA2 and LF. The 4 doses for the PA2 and LF dose response will be determined based on the relative toxicity of PA1 + Certhrax and PA2 + Certhrax (i.e. if the LD_{50} for PA2 + Certhrax is 4-fold lower than the LD_{50} for PA1 + Certhrax, we will use doses of PA2 + LF that are 4-fold lower than the doses for PA1 + LF).

V.1.2.7.1: LD_{50} determination for PA1 + LF to identify a sublethal dose.
5 mice: 10 µg PA1 + 10 µg LF
5 mice: 25 µg PA1 + 25 µg LF
5 mice: 50 µg PA1 + 50 µg LF
5 mice: 500 µg PA1 + 500 µg LF
20 C57BL/6 mice

V.1.2.7.2: LD_{50} determination for PA2 + LF to identify a sublethal dose. For PA2 + LF dose response, doses will be adjusted based on the relative potency of PA2-Certhrax (from V.1.2.5 and V.1.2.6 above)
5 mice: 10 µg PA2 + 10 µg LF
5 mice: 25 µg PA2 + 25 µg LF
5 mice: 50 µg PA2 + 50 µg LF
5 mice: 500 µg PA2 + 500 µg LF
20 C57BL/6 mice

V.1.2.7.3: Assessment of synergy between Certhrax and LF. The doses to be used in these studies will be extrapolated from a comparison of the *in vitro* 50% cytotoxic doses (CD_{50}) and the *in vivo* LD_{50}s. That is, if we find *in vitro* that PA + 0.25 CD_{50} LF + 0.25 CD_{50} Certhrax causes cytotoxicity to 100% of the cells, we will begin our *in vivo* studies with an estimated LD_{50} of PA + 0.25 LD_{50} LF + 0.25 LD_{50} Certhrax.
5 mice: 10 LD_{50} PA1 + 10 LD_{50} LF (positive control for LT-mediated lethality)
5 mice: 10 LD_{50} PA1/PA2 + Certhrax (positive control for Certhrax-mediated lethality)
5 mice: *PA1 + 5.0 LD_{50} LF + 5.0 LD_{50} Certhrax
5 mice: *PA1 + 1.0 LD_{50} LF + 1.0 LD_{50} Certhrax
5 mice: *PA1 + 0.5 LD_{50} LF + 0.5 LD_{50} Certhrax
5 mice: *PA1 + 0.25 LD_{50} LF + 0.25 LD_{50} Certhrax

5 mice: *PA1 + 0.1 LD_{50} LF + 0.1 LD_{50} Certhrax
5 mice: *PA1 + 0.025 LD_{50} LF + 0.025 LD_{50} Certhrax
40 C57BL/6 mice x 4 iterations = 160 C57BL/6 mice

*PA2 will be included in these experiments if we find that PA2 is the preferred *in vivo* binding partner for Certhrax in V.1.2.5 and V.1.2.6 above.

Total for V.1.2.5, V.1.2.6, and V.1.2.7: 70 mice + 70 mice + 200 mice = 340 C57BL/6J mice

Total mice for V.1.2 = 70 + 70 + 340 mice = 480 C57BL/6J mice

V.1.3. Experiment 3: *in vivo* imaging of *B. anthracis* Sterne germination, outgrowth, and dissemination. Our previous *in vivo* imaging studies used the IVIS 100 *in vivo* imaging system to visualize *B. anthracis* Sterne derivatives that produced a luminescent signal when spores germinated or grew vegetatively in response to host signals (17). The luminescent signal was sufficient to provide information about the general location *in vivo* of a large bolus of spores or vegetative bacilli, but we were unable to visualize the less intense signal *in vivo*; instead, we used *ex vivo* imaging of organs post-necropsy at specific time points post-inoculation. To more accurately study the stages of *Bacillus* growth and the locations within the host in which these events occur, we will use our Carestream Multispectral FX Pro (MS FX Pro). The MS FX Pro has a larger dynamic range and a higher signal:noise ratio for fluorescence; in addition, it has x-ray capability that permits more accurate signal localization. Construction of fluorescent *B. anthracis* Sterne reporter strains that contain one of the Red Fluorescent Proteins (RFPs) mKate2, E2-Crimson, and FP650 is underway. These reporters will be controlled by germination, vegetative growth, or sporulation promoters and will be expressed episomally. In addition, we plan to label *B. anthracis* Sterne-RFP spores with an AlexaFluor label, which will allow us to monitor deposition and uptake of spores in the airway in a manner that does not require bacterial transcription, which is required for expression of RFP. The choice of Alexa-Fluor label and RFPs allow for simultaneous measurement of multiple fluorophores at once with the MS FX Pro unmixing functionality of our *in vivo* imaging system.

V.1.3.1. Virulence assessment of *B. anthracis* Sterne-RFP strains. Our earlier studies showed that the LD_{50} for *B. anthracis* Sterne-*sspB::lux* spores administered s.c. to A/J mice is higher than that of the wild-type *B. anthracis* Sterne spores ($1.5x10^4$ CFU vs. $2.3x10^3$ CFU, respectively). Similarly, the LD_{50} for the *B. anthracis* Sterne-*sspB::lux* administered i.n. to A/J mice is $1.4x10^6$ CFU, while the LD_{50} for wild-type *B. anthracis* Sterne is $6.7x10^4$ CFU. In order to use the *B. anthracis* Sterne-RFP constructs to monitor the different stages of infection, we first need to establish the LD_{50} for these strains when delivered s.c. or i.n. As mentioned above, we will test the s.c. and i.n. virulence of three different *B. anthracis* Sterne-RFP constructs (mKate2, E2-Crimson, FP650) that are expressed by promoters that are active during germination, vegetative outgrowth, or sporulation.

V.1.3.1.1. Subcutaneous Inoculation Experiment 1
Group 1: 5 mice: H_2O or sterile saline
Group 2: 10 mice: 10^3 *B. anthracis* Sterne-RFP spores
Group 3: 10 mice: 10^4 *B. anthracis* Sterne-RFP spores
Group 4: 10 mice: 10^5 *B. anthracis* Sterne-RFP spores
Group 5: 10 mice: 10^6 *B. anthracis* Sterne-RFP spores
Group 6: 10 mice: 10^7 *B. anthracis* Sterne-RFP spores
Group 7: 10 mice: 10^8 *B. anthracis* Sterne-RFP spores
Group 8: 10 mice: 10xLD_{50} *B. anthracis* Sterne spores
75 A/J mice x 3 RFP strains = 225 A/J mice

V.1.3.1.2. Subcutaneous experiment 2
Remove two doses farthest from LD_{50} = **55 A/J mice x 3 RFP strains = 165 mice**

Total for s.c. experiments = (75 + 55) x 3 RFP strains = 390 A/J mice

V.1.3.1.3. Intranasal Inoculation Experiment 1
Group 1: 5 mice: H_2O or sterile saline
Group 2: 10 mice: 10^4 *B. anthracis* Sterne-RFP spores
Group 3: 10 mice: 10^5 *B. anthracis* Sterne-RFP spores
Group 4: 10 mice: 10^6 *B. anthracis* Sterne-RFP spores
Group 5: 10 mice: 10^7 *B. anthracis* Sterne-RFP spores
Group 6: 10 mice: 10^8 *B. anthracis* Sterne-RFP spores
Group 7: 10 mice: 10xLD_{50} *B. anthracis* Sterne spores
65 A/J mice x 3 RFP strains = 195 A/J mice

V.1.3.1.4. Intranasal experiment 2
Remove two doses farthest from LD_{50} = **45 A/J mice x 3 RFP strains = 135 A/J mice**

Total for i.n. experiments = (65 + 45) x 3 RFP strains = 330 A/J mice

Total mice for V.1.3.1 = 390 + 330 = 720 A/J mice

V1.3.2. Assessment of deposition, uptake and dissemination using Alexa Fluor-labeled live or dead spores. We will label *B. anthracis* Sterne-RFP spores with an Alexa-Fluor (AF) conjugate, a fluorescent molecule that emits fluorescence when the spore is intact (before germination occurs), so that we can monitor deposition and uptake with the *in vivo* imaging system. We will monitor germination, outgrowth, dissemination, and sporulation through detection of the RFP signal (different excitation and emission wavelengths than the AF). Thus, we will be able to observe each step of inhalational *B. anthracis* disease. In addition, mice will be inoculated with non-viable spores to observe deposition and uptake of spores by host cells in the absence of germination and to determine the length of time that spores can persist in the airway. Epidemiological data from the human anthrax outbreak in Sverdlovsk, USSR in 1979 suggest that viable spores can persist in the airway for up to 45 days after exposure (18).

Female A/J mice will be inoculated i.n. or s.c. (described in V.1, sections B1 and B2) with 10xLD_{50} AF-labeled *B. anthracis* Sterne-RFP spores (determined in V.1.3.1) in

H_2O. At 0.5, 1, 6, 12, 24, 48, 72 hrs, and 2 weeks post-inoculation, 5 mice will be anesthetized with isoflurane and placed on a heated platform within the imaging box of the MS FX Pro for imaging(~ 5 min). After whole animal imaging, each mouse will be euthanized by inhalational isoflurane overdose and cervical dislocation, the body cavity will be opened and the organs exposed for *ex vivo* imaging, then the organs will be harvested and homogenized for enumeration of spores and vegetative bacilli. This experiment will be done twice with each of the three AF-*B. anthracis* Sterne-RFP strains.

V.1.3.2.1: Dissemination of Alexa Fluor-labeled B. anthracis Sterne-RFP spores after i.n. inoculation

Group 1: 5 mice euthanized at 0.5 hr: 10xLD_{50} AF-*B. anthracis* Sterne-RFP spores
Group 2: 5 mice euthanized at 1 hr: 10xLD_{50} AF-*B. anthracis* Sterne-RFP spores
Group 3: 5 mice euthanized at 6 hrs: 10xLD_{50} AF-*B. anthracis* Sterne-RFP spores
Group 4: 5 mice euthanized at 12 hrs: 10xLD_{50} AF-*B. anthracis* Sterne-RFP spores
Group 5: 5 mice euthanized at 24 hrs: 10xLD_{50} AF-*B. anthracis* Sterne-RFP spores
Group 6: 5 mice euthanized at 48 hrs: 10xLD_{50} AF-*B. anthracis* Sterne-RFP spores
Group 7: 5 mice euthanized at 72 hrs: 10xLD_{50} AF-*B. anthracis* Sterne-RFP spores
Group 8: 5 mice euthanized at 14 days: 10xLD_{50} AF-*B. anthracis* Sterne-RFP spores
40 mice x 3 *B. anthracis* strains x 2 iterations = 240 A/J mice

V.1.3.2.2: Dissemination of Alexa Fluor-labeled B. anthracis Sterne-RFP spores after s.c. inoculation

Group 1: 5 mice euthanized at 0.5 hr: 10xLD_{50} AF-*B. anthracis* Sterne-RFP spores
Group 2: 5 mice euthanized at 1 hr: 10xLD_{50} AF-*B. anthracis* Sterne-RFP spores
Group 3: 5 mice euthanized at 6 hrs: 10xLD_{50} AF-*B. anthracis* Sterne-RFP spores
Group 4: 5 mice euthanized at 12 hrs: 10xLD_{50} AF-*B. anthracis* Sterne-RFP spores
Group 5: 5 mice euthanized at 24 hrs: 10xLD_{50} AF-*B. anthracis* Sterne-RFP spores
Group 6: 5 mice euthanized at 48 hrs: 10xLD_{50} AF-*B. anthracis* Sterne-RFP spores
Group 7: 5 mice euthanized at 72 hrs: 10xLD_{50} AF-*B. anthracis* Sterne-RFP spores
Group 8: 5 mice euthanized at 14 days: 10xLD_{50} AF-*B. anthracis* Sterne-RFP spores
40 mice x 3 *B. anthracis* strains x 2 iterations = 240 A/J mice

V.1.3.2.3. Persistence of AF-B. anthracis spores in the airway. We will investigate the number of days that non-viable AF-*B. anthracis* Sterne spores persist in the airways by daily imaging of mice inoculated i.n. with these spores. We predict that the spores will remain fluorescent until they are cleared by the mouse. The AF-*B. anthracis* Sterne spores will be inactivated by ultraviolet irradiation or fixation in 10% formalin for one week. Loss of viability will be confirmed by bacterial enumeration on agar plates and in liquid growth media. A/J mice will be inoculated i.n. with non-viable AF-*B. anthracis* Sterne spores and monitored by whole body *in vivo* and organ *ex vivo* imaging as described in V.1.3.2.1.

Group 1: 5 mice euthanized at 0.5 hr: 10^7 AF-*B. anthracis* Sterne spores
Group 2: 5 mice euthanized at 2 days: 10^7 AF-*B. anthracis* Sterne spores
Group 3: 5 mice euthanized at 4 days: 10^7 AF-*B. anthracis* Sterne spores
Group 4: 5 mice euthanized at 7 days: 10^7 AF-*B. anthracis* Sterne spores

Group 5: 5 mice euthanized at 14 days: 10^7 AF-*B. anthracis* Sterne spores
Group 6: 5 mice euthanized at 21 days: 10^7 AF-*B. anthracis* Sterne spores
Group 7: 5 mice euthanized at 28 days: 10^7 AF-*B. anthracis* Sterne spores
Group 8: 5 mice euthanized at 35 days: 10^7 AF-*B. anthracis* Sterne spores
Group 9: 5 mice euthanized at 42 days: 10^7 AF-*B. anthracis* Sterne spores
Group 10: 5 mice euthanized at 49 days: 10^7 AF-*B. anthracis* Sterne spores
Group 11 5 mice euthanized at 56 days: 10^7 AF-*B. anthracis* Sterne spores
55 mice x 2 iterations = 110 A/J mice

Total mice for V.1.3.2 = 240 + 240 + 110 = 590 A/J mice

Total mice for V.1.3 = 720 + 590 = 1310 C57BL/6J mice

V.1.4. Experiment 4. Characterization of efficacy of therapeutics to treat *B. anthracis* Sterne and/or *B. cereus* G9241 infections.

V.1.4.1. Characterization of efficacy of small molecule inhibitors of germination. Small molecule compounds (SMC) that prevent both *B. anthracis* spore germination and macrophage killing will be tested in A/J mice for the capacity to prevent disease progression and death of animals challenged i.n. or s.c. with otherwise lethal doses of *B. anthracis* Sterne spores. The SMC 6-Thioguanine (6-TG) has been shown to inhibit spore germination *in vitro* (9). In preliminary *in vivo* studies under (b)(6) we found that two doses of 6-TG administered s.c. 4 hrs and 1 hr prior to s.c. inoculation with 10xLD_{50} *B. anthracis* Sterne spores at the same site protected 10/25 mice from mortality and extended the median time-to-death for those mice that succumbed. We also found that i.v. administration of 6-TG 4 hrs and 1 hr prior to s.c. inoculation with 10xLD_{50} *B. anthracis* Sterne spores protected 4/15 mice from death; however, the median time-to-death was not altered in this group. When we administered 6-TG by i.v. injection 30 min after s.c. spore challenge, we rescued 2/15 mice.

In the current studies, we propose to further assess the therapeutic capacity of 6-TG and to determine the efficacy of two SMC that we identified in an *in vitro* screen as germination inhibitors. The two SMC are (b)(4) and (b)(4) and their use in these studies was approved in a minor modification to (b)(4) see Table 1.4.1.1 for the relevant properties of each SMC. In preliminary toxicity studies, we found that all mice injected s.c. with (b)(4) or with (b)(4) at doses up to 25 mg/kg survived. The solubility of these SMC at 25 mg/kg is poor, so

Table V.1.4.1.1 Small molecule inhibitors of *B. anthracis* Sterne spore germination

Name	**6-thioguanine (6-TG)**	(b)(4)	
Inhibitory Activity	sporistatic	sporicidal	sporicidal
Macrophage IC_{50}	450 µM	28 µM	1.6 µM
Macrophage Toxicity	>450 µM	>100 µM	10-50 µM
Mouse Toxicity	i.p. injection LD_{50} = 50 mg/kg	i.p. injection, day 5 survival 50 mg/kg, 200 mg/kg: 5/6 100 mg/kg: 4/6	i.p. injection, day 5 survival 79-266 mg/kg: 6/6 400 mg/kg: 17/18 600 mg/kg: 2/6

we will use the SMC at 0.5 mg/kg (doses up to 25 mg/kg may be used if we identify a more effective diluent that is safe to administer to mice).

Mice will be treated s.c., i.v. or i.n. with 6-TG, (b)(4) diluted in sterile saline containing ≤5% DMSO (and 0.1% Tween-80 for (b)(4) at various time points prior to or after inoculation with 10x LD_{50} *B. anthracis* Sterne spores. Table 1.4.1.2 shows the SMC dosing and timing strategy for s.c. or i.n. spore inoculation and s.c., i.v., i.n., or i.v. SMC inoculation. Two sets of experiments will be conducted for each timing and dosing strategy (Table V.1.4.1.3); in the first experiment, we will use 10 mice/treatment group, and, in the second experiment, we will use 15 mice/treatment group. Further, each experiment will have 10 control mice: 5 will be inoculated with spores only and 5 will be inoculated with SMC only.

V.1.4.1.1. Assessment of efficacy of 6-TG (b)(4) in prevention of spore germination and/or anthrax disease. As stated above, we have very preliminary data that show that pretreatment with two doses of 6-TG at the site of spore injection protected 40% of the mice and extended the median time-to-death for the rest of the treated mice. Herein, we propose to extend these studies to evaluate different doses as well as different administration times and sites for the small molecule therapeutics. In addition, we propose to determine whether two or three of the compounds have synergistic therapeutic potential when co-administered.

Table V.1.4.1.2 SMC Dosing and Timing Strategy

Spore/ SMC Delivery	SMC Time (hrs)	SMC Dose	Control Mice	
S.C./S.C. *or* S.C./I.V. *or* I.N./I.N. *or* I.N./I.V.	-24, -4	1	5 spores 5 SMC	Expt A

a pipet tip attached to a pipette. Mice will be monitored for morbidity and mortality multiple times daily for 2 weeks. Moribund mice will be euthanized by inhalational isoflurane overdose followed by cervical dislocation.

Total number of mice for V.1.4.1.1 = 3960 A/J mice

V.1.4.1.2. Assessment of efficacy of 6-TG, (b)(4) in combination for the prevention of spore germination and/or anthrax disease. Preliminary *in vitro* studies indicate that (b)(4) can act synergistically with 6-TG to prevent spore germination. To assess whether 6-TG and (b)(4) or 6-TG and (b)(4) can act synergistically *in vivo*, we will conduct studies similar to those described in V.1.4.1.1 above, except that two compounds will be administered simultaneously. These studies will be conducted once the best dose, timing, and route of SMC administration are determined in V.1.4.1.1. However, additional dosing studies may be done to determine whether a lower dose of one or both compounds is sufficient to prevent germination and/or anthrax disease.

Table V.1.4.2.1. Synergy Study Strategy

Spore Delivery	SMC Time (hrs)	6-TG Dose	SMC Dose	Control Mice	Number of Mice Expt A	Number of Mice Expt B	Total Mice

V.1.4.2. Assessment of therapeutic potential of antibodies against *B. cereus* G9241 virulence factors to rescue from G9241-mediated disease. In these studies, we will determine the capacity of antibodies against Certhrax or against the tetrasaccharide (TS) capsule to rescue mice from s.c. and i.n. challenge with *B. cereus* G9241 spores. We obtained from (b)(4) rabbit polyclonal antisera raised by immunization with the ADP-ribosylation domain (ADP-r) of Certhrax or with the G9241 TS capsule (in process). The antibodies in the antisera will be purified by affinity chromatography. Once we confirm *in vitro* that these antibodies can bind to and, in case the case of Certhrax, neutralize their antigen, we will administer them to mice infected with *B. cereus* G9241 spores. These studies will be completed according to the procedures described above in V.1.1, except that we will administer the antibodies at specific times after spore inoculation. Antibodies will be diluted in sterile saline and administered by i.v. or i.p. injection with a 26 gauge, 0.5 inch sterile needle attached to a tuberculin syringe.

Total number of mice for V.1.4.2 = 960 A/J mice

V.1.5. Experiment 5. Generation of Mouse Antiserum against *B. cereus* G9241. In this experiment, we propose to elicit antibodies that are reactive with *in vivo*-expressed antigens in an effort to define critical virulence factors. To do so, we will challenge A/J mice s.c. with a sublethal dose of G9241 spores, then boost at 2-3 week intervals with 1-2 x LD_{50} G9241 spores. Blood will be collected 2-5 days prior to each boost to measure the antibody response. Once a sufficient antibody titer is reached, mice will be exsanguinated by cardiac puncture under deep anesthesia, then euthanized by cervical dislocation. Mice will be monitored for morbidity and mortality (none expected), and extremely moribund mice will be euthanized by inhalational isoflurane overdose followed by cervical dislocation.

5 mice/iteration x 4 iterations = 20 A/J mice

V.2. Data Analysis: A sample size of 5-10 animals per condition will have 80% power to detect a difference of 1.3 - 1.8 standard deviations based on a *t* test for independent samples with a 5%, two-sided significance level. These are the smallest differences that would be considered clinically meaningful for this type of study. Because mice have not been extensively used for work with *Bacillus* species, we need to establish the baseline virulence of the strains and the derivatives of those strains with

which we are working. Furthermore, we are testing several compounds for therapeutic efficacy.

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered: At this time, there are no non-animal alternatives for animal use that would achieve the objectives outlined in these studies. Our justification for the use of the mouse model to study *Bacillus* virulence is that tissue culture systems challenged with *Bacillus* spores cannot always discriminate between animal-virulent and animal-attenuated strains. *In silico* simulations and *in vitro* cell culture studies were considered but rejected because they cannot address the objectives of these studies.

V.3.2. Animal Model and Species Justification: Animal use will help us to develop prophylactic and therapeutic measures to counter *B. anthracis* spore exposure in humans. The major goals of this project are to characterize small molecule compounds that inhibit germination of *B. anthracis* spores and to identify key virulence determinants in *B. cereus*. The use of murine animal models is essential to the evaluation of therapeutic and preventative strategies against disease caused by *Bacillus* spp. since no *in vitro* systems or models are currently available to predict the efficacy of such reagents. The mouse is one of three small animal models (rabbit and guinea pigs are others) available for studying *B. anthracis* and *B. cereus* virulence and the efficacy of agents that may mitigate the effects of that disease. Mice are the lowest animal on the evolutionary scale with which to perform virulence studies for *B. anthracis* and *B. cereus*.

Studies of pathogenesis and virulence of *Bacillus* spp. have historically been performed in female mice (2-4, 10, 19-22). Our laboratory has always used female mice for these studies, as have other laboratories who study *Bacillus* virulence. In addition, female mice are used to reduce the impact of fighting among the mice. Further, all of the mice in an experimental group can be housed in the same cage when female mice are used.

V.3.3. Laboratory Animals

		Species #1	Species #2
V.3.3.1.	Genus & Species:	*Mus musculus*	*Mus musculus*
V.3.3.2.	Strain/Stock:	A/J	C57BL/6
V.3.3.3.	Source/Vendor:	(b)(4)	
V.3.3.4.	Age:	5-8 weeks	5-8 weeks
V.3.3.5.	Weight:	15-25 grams	15-25 grams
V.3.3.6.	Sex:	*Female	*Female
V.3.3.7.	Special Considerations:	N/A	N/A
V.3.4.	Number of Animals Required (by Species):	**8987**	**2200**

*V.3.3.6: Studies of pathogenesis and virulence of *Bacillus* spp. have historically been performed in female mice (2-4, 10, 19-22). Our laboratory has always used female mice for these studies, as have other laboratories who study *Bacillus* virulence. In addition, female mice are used to reduce the impact of fighting among the mice. Further, all of the mice in an experimental group can be housed in the same cage when female mice are used.

V.3.5. Refinement, Reduction, Replacement (3 Rs):

V.3.5.1. Refinement: We will use small pilot studies to rapidly narrow the number of bacteria, dose of toxin, or dose of therapeutic to be administered in subsequent LD_{50} studies. These pilot studies will be done with the smallest number of mice that will provide the necessary information in a statistically significant manner. We further minimize distress during the studies by careful cage-side monitoring of the animals to determine if an animal should be euthanized as described in V.4.1.4 and V.4.5. Signs indicating that euthanasia should be implemented would include an inability to reach food and water, labored breathing, excessive weight loss, and inability to remain upright.

V.3.5.2. Reduction: The *in vivo* imaging studies described in Experiment V.1.3 represent a significant reduction in the number of animals that would be used to assess germination, dissemination, and vegetative outgrowth in traditional experiments. Traditionally, one group of 5 mice would be euthanized at each time point (up to 8 time points) to harvest organs and enumerate the spores/bacteria in those organs in order to characterize the kinetics and stages of anthrax infection. In our *in vivo* imaging studies, we can instead inoculate a single group of 5-10 mice with spores that express different fluorescently labeled proteins that are markers of germination and vegetative growth. These mice are then imaged under light isoflurane anesthesia at multiple time points throughout the study; we capture fluorescent light images to detect the general location

and density (based on relative fluorescence) of the spores/bacteria and we focus the location with x-ray imaging. Thus, an experiment that would traditionally require up to 40 mice can be completed with just 5-10 mice in these *in vivo* imaging studies.

As many of our experiments involve infected/spore-treated animals or tissues, we do not participate in any shared tissue and/or control group studies with other investigators. We have taken into consideration all information we have gleaned from 12 years of experience working with these anthrax models when proposing subsequent experiments as well as in the refinement of the total number of animals required for the proposed experiments. With respect to the number of animals required for each experiment, we have used the minimal number of animals required for biological and statistical significance (generally 5 to 10 animals per group). Most experiments will be performed in duplicate to confirm the data. In these experiments, the two spore doses that are farthest from the LD_{50} of the strain in question will be eliminated in the second experiment in order to reduce the number of mice used.

V.3.5.3. Replacement: At this time, there are no replacements for animal use that would achieve the objectives outlined in these studies. Our justification for the use of the mouse model to study *Bacillus* virulence is that tissue culture systems challenged with *Bacillus* spores cannot always discriminate between animal-virulent and animal-attenuated strains. *In silico* simulations and *in vitro* cell culture studies were considered but rejected because they cannot address the objectives of these studies.

V.4. Technical Methods:

V.4.1. Pain / Distress Assessment:

V.4.1.1. APHIS Form 7023 Information:

V.4.1.1.1. Number of Animals: Animals are assigned to pain category E because we use death/moribund status as an endpoint for the majority of our experiments. The symptoms of *Bacillus* infection, which will not be relieved using analgesics or antibiotics, are as follows: ruffled fur, lethargy, hunched posture, decreased alertness, weight loss, difficulty breathing, unresponsiveness to external stimuli, and trembling. Animals that are used as controls in each experiment (no spore inoculation) and animals that will be injected with small molecules during the studies outlined in V.1.4.1 are assigned to pain category C because we do not expect them to suffer in any way from the control treatments. See Table V.4.1.1.1 on the next page for a breakdown of pain category by experiment.

Total		**11187**	**872**	**10315**

V.4.1.2. Pain Relief / Prevention:

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization: We will use inhalation of isoflurane gas (1.5-3.0% in O_2) or i.p. injection with ketamine (100 mg/kg) and xylazine (10 mg/kg) to anesthetize animals for *in vivo* imaging studies, for i.n. inoculation, and for exsanguination. Animals used in s.c and i.p. challenge are not expected to endure anything more than momentary pain, so no analgesics will be necessary. In all anesthesia procedures, depth of anesthesia will be assessed by the onset and

maintenance of slow, shallow breathing as well as the loss of toe pinch response in the animals.

For imaging studies, isoflurane has the advantage of maintaining the mice under anesthesia during the imaging procedure while permitting the animals a quick recovery time. The anesthetized mice will be placed on a warm platform and monitored for fluorescence for 5 min at 0.5, 1, 3, 6, 12, 24, 48, and/or 72 h post infection. To anesthetize the mice and secure their immobility during imaging with the Multispectral *in vivo* imaging system, we will use the following procedures. Administration of isoflurane gas will be done via a Gas Anesthesia System that delivers isoflurane gas to a 5-port anesthesia manifold housed in the imaging chamber of the *in vivo* imaging system. Animals will be initially placed into an induction chamber and anesthetized with isoflurane (3-4%) with oxygen as the carrier gas. Once the animals are properly sedated, they will be swiftly moved to nose cones on the 5-port anesthesia manifold housed in the imaging chamber and maintained at 1.5-3.0% isoflurane. Any unused manifold ports will be closed off. Sufficient time will be given to allow the anesthetic gas to reach the manifold nose cones prior to removing the animals from the induction chamber. Both the induction chamber and manifold will be set to deliver isoflurane at a constant rate. The manifold also provides waste gas scavenging ports to help prevent gas from entering the surrounding work environment. A built-in vacuum system helps ventilate waste gas away from researchers and into disposable isoflurane-absorbing filters.

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions: Only mice that appear to be in good health will undergo anesthesia. We define good health as clean unruffled fur, alert demeanor and no obvious signs of sickness. Mice recovering from anesthesia will be placed into a clean cage with external heat applied (a heating pad placed under the recovery cage) to prevent mice from undergoing a rapid loss in body temperature. Once the mice have roused from anesthesia and appear to be moving in an alert manner, they will be placed back into a clean cage with their cage mates. All mice will be monitored in the laboratory for at least one hour prior to their return to [(b)(6)]

V.4.1.2.3. Paralytics: N/A

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures:

V.4.1.3.1. Sources Searched: AGRICOLA and PUBMED databases

V.4.1.3.2. Date of Search: 24 November 2014

V.4.1.3.3. Period of Search: AGRICOLA (1970 – November 2014), PUBMED (1966 – November 2014, English only)

V.4.1.3.4. Key Words of Search: *Bacillus* AND pain AND (alleviation OR alleviate OR alternative OR reduction) AND (mouse OR mice)

V.4.1.3.5. Results of Search: The search yielded no documents in the AGRICOLA database and two documents in PUBMED. The two manuscripts did not provide any methods for alleviation of pain or distress in the mouse models that we use.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification: No analgesics will be given to *Bacillus*-infected animals for the following reasons. Inflammation and/or the inflammatory response are key components of *Bacillus*-mediated disease (macrophages play a key role in the dissemination of *Bacillus* spp). Because we will be using the mouse as a model to study both the pathogenesis of disease and possible treatment therapies, we believe that the use of non-steroidal anti-inflammatory drugs and opioids could confound or possibly mask the extent of *Bacillus*-mediated damage that we will evaluate by histological examination or toxicity (23).

Investigator and staff will carefully monitor *Bacillus*-infected animals and euthanize those that appear moribund because it is our experience that these animals will ultimately succumb to *Bacillus* infection after inoculation. We define extremely moribund as when a mouse exhibits 2 or more of the following symptoms: ruffled fur, lethargy, hunched posture, impaired ambulation that prevents the animals from reaching food and water, excessive weight loss/emaciation, difficult or labored breathing, and the inability to remain upright. Death due to infection after i.n., s.c., or i.p. inoculation with *B. anthracis* and *B. cereus* spores typically occurs 3-5 days post-inoculation. During this time period, mice will be inspected every 4 h during normal working hours and every 8 h during non-business hours. All inspections will be noted on cage cards so that LAM personnel are aware that the mice are being monitored.

V.4.2. Prolonged Restraint: N/A

V.4.3. Surgery:

V.4.3.1. Pre-surgical Provisions: N/A

V.4.3.2. Procedure: N/A

V.4.3.3. Post-surgical Provisions: N/A

V.4.3.4. Location: N/A

V.4.3.5. Surgeon: N/A

V.4.3.6. Multiple Major Survival Operative Procedures: N/A

V.4.3.6.1. Procedures: N/A

V.4.3.6.2. Scientific Justification: N/A

V.4.4. Animal Manipulations:

V.4.4.1. Injections: We will be giving i.p., i.v. and s.c. injections. All mouse injections are given with a 26 gauge 0.5 inch needle attached to a tuberculin syringe. All doses are given in a total volume of 0.1-0.2 ml.

For Small Molecule Compound and Passive Antibody Treatment – each mouse will be injected s.c. between the scapulae, at the base of the tail, or behind the right foreleg or i.v. with 0.1 ml of the small molecule in 5% DMSO in water using a 0.5 inch, 26 gauge needle.
For Spore Challenge or Toxin Administration – for each mouse in this set of experiments, heat-activated *Bacillus* spores will be administered via s.c. injection between the scapulae, at the base of the tail, or behind the right foreleg using a tuberculin syringe attached to a 26 gauge 0.5 inch needle. Spores will be in a volume of 100-200 µl/animal. Toxin components will be injected i.p. through the ventral abdominal wall using a tuberculin syringe attached to a 26 gauge 0.5 inch needle.

V.4.4.2. Biosamples:
Blood samples will be obtained from the tail vein or the venous sinus of mice using either a 26 gauge ½" needle or by nicking the tail with a sterile razor blade and collecting about 0.1 ml of whole blood into a sterile 1 ml tube. Blood collections will occur 10-14 days apart. Exsanguination by terminal cardiac puncture will be conducted under deep isoflurane anesthesia. Once anesthetized, as confirmed by lack of toe-pinch response, each mouse will be placed on its back and a sterile 23 gauge ½" needle will be introduced directly into the heart through the chest cavity. The syringe plunger will be gently pulled to remove as much blood as possible from the mouse.
Lungs and other organs will be removed from the mice post-euthanasia as needed.

V.4.4.3. Adjuvants: N/A

V.4.4.4. Monoclonal Antibody (MAbs) Production: N/A

V.4.4.5. Animal Identification: Mice will be identified by cage cards and/or ear punch. Ear punches will be administered by (b)(6) staff (e.g. models EP-901 or EP-900, Braintree Scientific Inc., Braintree, MA 02185). (also see Section VI for staff qualifications).

V.4.4.6. Behavioral Studies: N/A

V.4.4.7. Other Procedures:
Inoculation or immunization by the i.n. route will take place under isoflurane anesthesia by the droplet method. Approximately 50 µl will be administered onto the nose of each mouse using a previously sterile pipet tip attached to a manual pipetman. The mouse will be allowed to inhale the droplet at will and then be returned to its cage. Mice will remain in the laboratory for one hour after i.n. inoculation.

Antibiotics will be administered orally in the drinking water at a dose of 5-10 g/L for experiments in which a plasmid needs to be maintained in the infecting strain (V.1.1 and V.1.3). We will use chloramphenicol, ampicillin, spectinomycin, or kanamycin. In addition, we will add 25mM isopropyl β-D-thiogalactoside (IPTG) to the water for experiments in which gene expression needs to be induced. The antibiotics will be

administered 0-16 hrs prior to inoculation and will be maintained throughout the duration of the experiment. Antibiotic/IPTG-containing water will be changed every 1-2 days.

Oral gavage of 0.1-0.2 ml spores or vegetative cells suspended in sterile saline will be performed using a 18-20 gauge feeding needle. Anesthesia is not required for this procedure.

Low fluorescence food and bedding will be provided to mice that will undergo *in vivo* imaging to reduce the background fluorescence caused by standard high-chlorophyll food and bedding. Food and bedding will be purchased from (b)(4) by the laboratory.

Imaging of mice: Anesthetized mice will be placed on a warm platform within the Carestream Multispectral *in vivo* FX Pro imaging system and monitored for fluorescence for 5 min at a time at 0.5, 1, 3, 6, 12, 24, 48, and/or 72 h post-inoculation.

Photography: Mice may be photographed during inoculation procedures, during *in vivo* imaging, and post-mortem. Photos of inoculation procedures will only be used for teaching rodent handling techniques to new members of the laboratory. Photos from *in vivo* imaging will be used in seminars presented by approved users on this protocol and may be published in research articles. No photos will be taken of mice that are visibly moribund. The photos will be stored only on password-protected DoD computers at USUHS. Photos will be disposed of 5 years after the end of the project. All photography procedures will adhere to IACUC Policy #25.

V.4.4.8. Tissue Sharing: As many of our experiments involve infected/spore-treated animals or tissues, we do not participate in any shared tissue and/or control group studies with other investigators.

V.4.5. Study Endpoint: Table V.4.5.1 below summarizes the endpoint for each proposed experiment. The study endpoint for virulence and challenge studies with infected or intoxicated mice will be death or euthanasia when extremely moribund or euthanasia approximately 14 days post-inoculation with spores. The study endpoint for mice monitored for fluorescence will be 72 h or 2 weeks post-infection. For all studies, mice will be weighed daily to determine if a correlation between weight loss and eventual death exists. Investigator and staff will carefully monitor *Bacillus*-infected animals and euthanize those that appear moribund because it is our experience that these animals will ultimately succumb to *Bacillus* infection after inoculation. We define extremely moribund as when a mouse exhibits 2 or more of the following symptoms: ruffled fur, lethargy, hunched posture, impaired ambulation that prevents the animals from reaching food and water, excessive weight loss/emaciation, difficult or labored breathing, and the inability to remain upright. Our definition of extreme moribund status is consistent with USUHS IACUC Policy #20. Death due to infection after i.n., s.c., or i.p. inoculation with *B. anthracis* and *B. cereus* typically occurs 3-5 days post-inoculation. During this time period, mice will be inspected every 4 h during normal

working hours and every 8 h during non-business hours. All inspections will be noted on cage cards so that LAM personnel are aware that the mice are being monitored.

Table V4.5.1. Endpoint and time to endpoint for each study in proposal

Experiment	*Number of mice*	*Endpoint*	*Time to endpoint*
V.1.1.1.1	760	Death or euthanasia when moribund	14 days
V.1.1.1.2	960	Death or euthanasia when moribund	14 days
V.1.1.1.3	760	Death or euthanasia when moribund	14 days
V.1.1.1.4	960	Death or euthanasia when moribund	14 days
V.1.1.2.1	150	Death or euthanasia when moribund	28 days
V.1.1.2.2.1	38	Death or euthanasia when moribund	28 days
V.1.1.2.2.2	43	Death or euthanasia when moribund	28 days
V.1.1.2.3.1	258	Death or euthanasia when moribund	28 days
V.1.1.2.3.2	288	Death or euthanasia when moribund	28 days
V.1.2.1	40	Death or euthanasia when moribund	14 days
V.1.2.2	30	Death or euthanasia when moribund	14 days
V.1.2.3	40	Death or euthanasia when moribund	14 days
V.1.2.4	30	Death or euthanasia when moribund	14 days
V.1.2.5	70	Death or euthanasia when moribund	14 days
V.1.2.6	70	Death or euthanasia when moribund	14 days
V.1.2.7.1	20	Death or euthanasia when moribund	14 days
V.1.2.7.2	20	Death or euthanasia when moribund	14 days
V.1.2.7.3	160	Death or euthanasia when moribund	14 days
V.1.3.1.1	225	Death or euthanasia when moribund	14 days
V.1.3.1.2	165	Death or euthanasia when moribund	14 days
V.1.3.1.3	195	Death or euthanasia when moribund	14 days
V.1.3.1.4	135	Death or euthanasia when moribund	14 days
V.1.3.2.1	240	Euthanasia	0.5, 1, 6, 12, 24, 48, 72 hrs, 14 days
V.1.3.2.2	240	Euthanasia	0.5, 1, 6, 12, 24, 48, 72 hrs, 14 days
V.1.3.2.3	110	Euthanasia	0.5 hr, 2, 4, 7, 14, 21, 28, 35, 42, 49, 56 days
V.1.4.1.1	3960	Death or euthanasia when moribund	14 days
V.1.4.1.2	240	Death or euthanasia when moribund	14 days
V.1.4.2	960	Death or euthanasia when moribund	14 days
V.1.5	20	Euthanasia	Up to 16 weeks

V.4.6. <u>Euthanasia</u>: Mice will be euthanized by either isoflurane overdose (4-5% concentration) within the isoflurane induction chamber located inside a fume hood, followed by cervical dislocation, or by CO_2 overdose. CO_2 will be delivered from a compressed gas cylinder via a regulated rate of flow in accordance with the 2013 AVMA Committee on Euthanasia. For euthanasia using CO_2, all procedures will be performed by LAM personnel in LAM facilities. Investigative staff will perform inhalational isoflurane overdose and cervical dislocation euthanasia procedures; death will be

confirmed by physical examination (as listed in the 2013 AVMA Guidelines on Euthanasia).

V.5. Veterinary Care: Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol.

V.5.1. Husbandry Considerations: Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol.

V.5.1.1. Study Room:

Building(s) (b)(6) Room Number(s) (b)(6) (b)(6)

V.5.1.2.

Special Husbandry Provisions:

Food Restriction:	Yes _____	No X
Fluid Restriction:	Yes	No X

V.5.1.3. Exceptions: Mice that undergo oral gavage in Experiments V.1.1.2 will have food removed the night before inoculation and water removed 2-4 hrs before inoculation. Mice that undergo *in vivo* imaging will be provided low-fluorescence food and bedding.

All mice infected with *B. cereus* or *B. anthracis* Sterne or intoxicated with Certhrax or the anthrax toxins will be housed in cages marked with "DO NOT TOUCH" cards. (b)(6) lab personnel will perform all cage changes and routine care of these animals. For safety reasons, LAM personnel should not handle these mice unless a sick call request is made.

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care: Animals will be observed and cared for by the Center for LAM personnel according to USUHS Center for LAM SOPs. In addition, infected mice will be cared for and checked twice daily or more frequently as needed by members of Dr (b)(6) laboratory staff working on this project.

V.5.2.2. Emergency Veterinary Medical Care: All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: Except as indicated below, all animals on this protocol will be provided with routine environmental enrichment in accordance with LAM

SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents; balls, toys and food enrichment treats for large animal species.

V.5.3.2. Enrichment Restrictions: N/A

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING: Dr. (b)(6) who will not do these "hands on" experiments herself, has 38 years of experience working with mice in microbicidal assays and has been involved with the mouse anthrax model since 2002. Dr. (b)(6) is a postdoctoral fellow with 10 years of experience working with rodents and has taken the Investigator Training Course. Dr (b)(6) has 18 years of experience using animal models of infection with various organisms; she has taken the USUHS Investigator Training Course and a rodent handling course at another institution. Ms (b)(6) is a graduate student with 3 years of experience working with rodents. Mr (b)(6) s a senior technician who has worked for 23 years with EHEC/EPEC infection in mice and 10 years with anthrax models. Ms (b)(6) is a senior technician who has worked with rodents for 5 years. All personnel listed here completed the CITI Investigators, Staff and Students – Lab Animal Research Training in 2014. Please see the table below for a specific breakdown of the procedures that each individual will perform and each person's training and experience.

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
Intranasal inoculation	(b)(6)	Senior Scientist, 18 yr experience	1 (2008), 3 (1997), 5 (UAB, 1997; UW 2004; NIH 2007), 6 (2014)
Intranasal inoculation		Postdoctoral Fellow, 10 yr experience	1 (2011), 3 (UVA, 2005), 4 (2011, Mr (b)(6) 5 (UVA, 2005), 6 (2014)
Intranasal inoculation		Graduate Student, 3 yrs experience	1 (2011), 4 & 5 (2011-2014, USU), 6 (2014)
Intranasal inoculation		Senior Research Technician, 23 yrs experience	1, 4 (FDA (b)(6) 2004), 6 (2014)
Intranasal inoculation		Senior Research Technician, 5 yrs experience	1 (2014), 4 (Johns Hopkins, 2009; (b)(6) lab, 2014), 5 (JHU, 2009), 6 (2014)
Subcutaneous injection		Senior Scientist, 18 yr experience	1 (2008), 3 (1997), 5 (UAB, 1997; UW 2004; NIH 2007), 6 (2014)
Subcutaneous injection		Postdoctoral Fellow, 10 yr experience	1 (2011), 3 (UVA, 2005), 4 (2011, Mr (b)(6) 5 (UVA, 2005), 6 (2014)
Subcutaneous injection		Graduate Student, 3 yrs experience	1 (2011), 4 & 5 (2011-2014, USU), 6 (2014)
Subcutaneous injection		Senior Research Technician, 23 yrs experience	1, 4 (FDA (b)(6) 2004), 6 (2014)
Subcutaneous injection		Senior Research Technician, 5 yrs experience	1 (2014), 4 (Johns Hopkins, 2009; (b)(6) lab, 2014), 5 (JHU, 2009), 6 (2014)
Intraperitoneal injection		Senior Scientist, 18 yr experience	1 (2008), 3 (1997), 5 (UAB, 1997; UW 2004; NIH 2007), 6 (2014)
Intraperitoneal injection		Postdoctoral Fellow, 10 yr experience	1 (2011), 3 (UVA, 2005), 4 (2011, Mr (b)(6) 5 (UVA, 2005), 6 (2014)
Intraperitoneal injection		Graduate Student, 3 yrs experience	1 (2011), 4 & 5 (2011-2014, USU), 6 (2014)

Intraperitoneal injection	(b)(6)	Senior Research Technician, 23 yrs experience	1, 4 (FDA (b)(6) 2004), 6 (2014)
Intraperitoneal injection		Senior Research Technician, 5 yrs experience	1 (2014), 4 (Johns Hopkins, 2009; (b)(6) lab, 2014), 5 (JHU, 2009), 6 (2014)
Isoflurane anesthesia		Senior Scientist, 18 yr experience	1 (2008), 3 (1997), 5 (UAB, 1997; UW 2004; NIH 2007), 6 (2014)
Isoflurane anesthesia		Postdoctoral Fellow, 10 yr experience	1 (2011), 3 (UVA, 2005), 4 (2011, Mr (b)(6) , 5 (UVA, 2005), 6 (2014)
Isoflurane anesthesia		Graduate Student, 3 yrs experience	1 (2011), 4 & 5 (2011-2014, USU), 6 (2014)
Isoflurane anesthesia		Senior Research Technician, 23 yrs experience	1, 4 (FDA (b)(6) 2004), 6 (2014)
Protocol activity or procedure (e.g., tail vein injections, euthanasia)	**Name of person performing activity**	**Qualifications of person performing activity (e.g., research technician, 2 yrs experience)**	**Specific training in this activity or procedure (e.g., rodent handling class, 1999)**
Isoflurane anesthesia	(b)(6)	Senior Research Technician, 5 yrs experience	1 (2014), 4 (Johns Hopkins, 2009; (b)(6) lab, 2014), 5 (JHU, 2009), 6 (2014)
Oral gavage		Postdoctoral Fellow, 10 yr experience	1 (2011), 3 (UVA, 2005), 4 (2011, Mr (b)(6) 5 (UVA, 2005), 6 (2014)
Oral gavage		Graduate Student, 3 yrs experience	1 (2011), 4 & 5 (2011-2014, USU), 6 (2014)
Oral gavage		Senior Research Technician, 23 yrs experience	1, 4 (FDA (b)(6) 2004), 6 (2014)
Oral gavage		Senior Research Technician, 5 yrs experience	1 (2014), 4 (Johns Hopkins, 2009; (b)(6) lab, 2014), 5 (JHU, 2009), 6 (2014)
In vivo imaging		Postdoctoral Fellow, 10 yr experience	1 (2011), 3 (UVA, 2005), 4 (2011, Mr (b)(6) 5 (UVA, 2005), 6 (2014)
In vivo imaging		Graduate Student, 3 yrs experience	1 (2011), 4 & 5 (2011-2014, USU), 6 (2014)
In vivo imaging		Senior Research Technician, 23 yrs experience	1, 4 (FDA (b)(6) 2004), 6 (2014)

VII. **BIOHAZARDS/SAFETY**: With respect to mice used in the anthrax model, bedding may be contaminated with *Bacillus* spores. The bedding and animal carcasses should be treated as infectious and autoclaved. Infected animals will be maintained under ABSL-2 conditions in filter-top cages. All procedures that involve the use of isoflurane will be conducted in either a chemical fume hood (euthanasia) or in an anesthesia system with waste-scavenging charcoal filters (both located in Dr. (b)(6) laboratory). In addition, all personnel who will use isoflurane will be made aware of its associated safety hazards and will be properly trained in its use.

All personnel will wear a disposable gown, gloves, and mask at all times when handling mice. A N95 respirator mask will be worn during spore inoculation procedures and spore inoculation procedures will be conducted in a Type II Biosafety Cabinet (in (b)(6) (b)(6) when possible. Sharps will be disposed of in approved Sharps containers located in (b)(6) and Sharps containers will be disposed of as Regulated Medical Waste through the EHS office. All cage changes will be done in a Type II Biosafety Cabinet (in (b)(6)

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

(b)(6) _____ 11/24/14

Principal Investigator Signature — Date

G. Training: The following personnel will attend the next USUHS Investigator/Animal User Training Course:

_____ _____

_____ _____

H. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely, "Responsibility" for implementing animal use alternatives where feasible and conducting humane and lawful research.

(b)(6) _____ 11/24/14

Principal Investigator Signature — Date

I. Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL or WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

X. **PROTOCOL ABSTRACT:**

A. **Animal Protocol Number:** (b)(6)

B. **Animal Protocol Title:** Pathogenesis of *Bacillus anthracis* Sterne and *Bacillus cereus* G9241 in mice

C. **Principal Investigator:** (b)(6) PhD

D. **Performing Organization:** Uniformed Services University of the Health Sciences

E. **Funding:** Biological Defense Research Directorate, National Institute of Allergy and Infectious Diseases

F. **Objective and Approach:** Our hypotheses for the studies proposed herein are as follows: 1) deletion of putative or known virulence genes will alter the pathogenesis of *B. anthracis* Sterne and *B. cereus* G9241; 2) Certhrax plays a significant role in gastrointestinal disease caused by *B. cereus* G9241 and antibodies against the toxin will protect against disease progression; and 3) small molecules that inhibit spore germination will reduce mortality caused by *B. anthracis* Sterne. Our goals are to characterize the progression of *B. anthracis* Sterne disease, to characterize the roles of toxins and capsules in *B. cereus* G9241 virulence, and to identify candidate therapeutics to prevent or treat anthrax disease. The specific aims are as follows: **1)** assess the virulence of *B. anthracis* Sterne or *B. cereus* G9241 strains in which a particular virulence trait has been deleted; **2)** administer *B. cereus* G9241 toxin components to assess their activity *in vivo*; **3)** monitor the location and kinetics of germination, vegetative outgrowth, and dissemination of fluorescent derivatives of *B. anthracis* Sterne and *B. cereus* G9241 in the mouse with an *in vivo* imaging system; 4) characterize the *in vivo* efficacy of small molecules that inhibit germination of *B. anthracis* Sterne spores *in vitro*; and **5)** assess the capacity of antibodies against *B. cereus* G9241 toxins or capsule to protect from disease.

G. **Indexing Terms (Descriptors):** *Bacillus anthracis* Sterne, *Bacillus cereus*, toxin, capsule, virulence, pathogenesis, small molecule compound, germination, therapeutic

MEMORANDUM FOR DR (b)(6) DEPARTMENT OF MICROBIOLOGY AND IMMUNOLOGY

SUBJECT: IACUC Approval of Protocol – Initial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) by Designated Member Review on September 17, 2015:

Animal Protocol Title: "Axenic Caenorhabditis Elegans Antigen as Treatment for Experimental Autoimmine Encephalomyelitis in Mice (Mus Musculus)"

USUHS Protocol Number: (b)(6)

Expiration Date: September 16, 2018

Supporting Grant(s) Number: TBD

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. NON-TECHNICAL SYNOPSIS:

Autoimmune diseases are characterized by hyper-reactive immune responses to self- antigens expressed on cells. The immune system mistakes a self-antigen in the body as a pathogen and mounts an attack against the cell or tissue expressing the self-antigen. These attacks are typically chronic, and lead to long-term tissue damage. Several autoimmune diseases appear to be due, in large part, to Th1-driven inflammation based on observed cytokine profiles and predominantly high levels of IFN-γ. Examples of autoimmune diseases include, but are not limited to, type-1 insulin-dependent diabetes mellitus, multiple sclerosis, Crohn's disease, inflammatory bowel disease, rheumatoid arthritis, and posterior uveitis.

Multiple sclerosis (MS) is an inflammatory disease of the nervous system in which the insulating myelin sheaths of brain and spinal cord nerve cells are targeted by an autoimmune T cell response. Chronic inflammation leads to scarring of these nerve cells and disrupted communication between the brain and body. With time, irreversible deterioration of the nerves often occurs. MS is thought to affect more than 2.3 million people worldwide. There is no known cure and treatment regimes vary with the severity of clinical symptoms. The major focus of treatment includes recovery from ongoing attacks (anti-inflammatory corticosteroids), symptoms management (physical therapy and muscle relaxants), and inhibition of remittent disease progression (immuno-modulatory drugs).

The prevalence of autoimmune diseases has increased sharply over the past few decades. While genetic factors play a role in susceptibility to these diseases, the dramatic worldwide increase in their prevalence is probably due to changes in environmental factors. One environmental change that may play a part in the recent increase in autoimmune disease is the loss of chronic parasitic worm infections in developed countries. Multiple studies have found that individuals infected with chronic parasitic worm infections have lower rates of autoimmune diseases than others living in the same environment. Experimentally, parasitic worms have been shown to protect against a variety of autoimmune diseases in several animal models. And in human trials, oral administration of porcine whipworm eggs has been shown to protect against inflammatory bowel disease.

A major limitation of working with parasitic worms is the difficulty in producing large

quantities due to their complex lifecycles. For example, *Litomosoides sigmodontis*, the parasitic worm we work with in our laboratory, requires both mite and rodent hosts to complete its lifecycle. Consequently, we tested whether molecules from crushed up *Caenorhabditis elegans*, a free-living non-parasitic worm that is easily maintained in a laboratory setting, can protect against Type 1 diabetes. Data from our lab demonstrates that repeated injections of the soluble fraction of crushed *C. elegans* protects against Type 1 diabetes in NOD mice, and appears to do so utilizing similar immuno-modulatory mechanisms seen in our studies with *L. sigmodontis*. Thus, treatment with *C. elegans* antigen (aCeAg) suggests a plausible new avenue of therapy for Th1-associated autoimmune diseases.

The goal of this project is to analyze the potential for protective and/or suppressive effects of aCeAg treatments in the relapsing/remitting Multiple Sclerosis model of SJL/j mice. Thus, we will determine the potential therapeutic reach of this non-parasitic nematode-derived treatment, and gain a better understanding of the immuno-modulatory responses to such treatments.

II. BACKGROUND:

II.1. Background:

The prevalence of allergies and autoimmune diseases has increased sharply over the past few decades. While genetic factors play a role in susceptibility, the dramatic worldwide increase of these hyperinflammatory diseases is probably due to changes in environmental factors. One environmental change that may play a part in the recent increase in autoimmune disease is the loss of chronic parasitic worm infections in developed countries. Multiple studies have found that individuals infected with chronic parasitic worm infections have lower rates of autoimmune disease than others living in the same environment. Experimentally, parasitic worms have been shown to protect against a variety of autoimmune diseases, including Multiple sclerosis, in several animal models. In humans, oral administration of porcine whipworm eggs has been shown to protect against inflammatory bowel disease.

Until recently, most people had lifelong infections with parasitic worms. As helminths have been identified in Neolithic and pre-Columbian mummies, it is likely that the human immune system evolved in the setting of chronic infection with these parasites. Consequently, it has been posited that the loss of parasitic worm infections is partially responsible for the increased prevalence of autoimmune and allergic diseases in developed countries – the notion being that now, in the absence of the immuno-modulatory responses triggered by helminths, our immune systems have become hyper-responsive.

Unlike most bacterial or viral pathogens, helminth infections induce the production of specific IgE. This IgE binds to basophils and mast cells through the Fc epsilon receptor I (FcεRI), the high affinity IgE receptor. Helminth specific antigens thus activate basophils and mast cells by cross-linking IgE molecules and aggregating FcεRIs. As helminths are large organisms that release substantial amounts of antigen, and as these infections last for years, helminth infections likely induce a state of chronic basophil and mast cell activation. Indeed, recent time course studies in our lab demonstrate that both chronic basophil activation and chronic mast cell activation occur during infection of mice with the filarial nematode *Litomosoides sigmodontis*.

Helminth infections also induce production of the cytokine IL-10. IL-10 is an anti-inflammatory cytokine that was initially described as a Th2-type or Treg-type cytokine

but it is now known that IL-10 is more broadly expressed. IL-10 acts as a crucial feedback regulator of diverse immune responses, including Th1-mediated and Th2-mediated immune responses.

There are at least two likely mechanistic rationales for postulating that chronic activation of basophils and mast cells may protect against Th1-driven autoimmune disease. First, factors released by basophils and mast cells may have direct immuno-modulatory properties that are protective against Th1-mediated autoimmune diseases. Basophils, for example, release large quantities of IL-4 when activated and have been shown to do so in response to parasite antigen in filaria-infected patients as well as in animal models of helminth infection. IL-4 counter regulates Th1 responses and has been shown to improve Th1-driven autoimmune diseases. Similarly, histamine, which is released from both basophils and mast cells, has been shown *in vitro* to suppress Th1 responses by signaling through the H2 receptor on lymphocytes. Second, chronic activation of basophils and mast cells could induce negative feedback pathways that tamp down ongoing autoimmune responses. Interestingly, there is substantial evidence that chronic immunotherapy, in which patients with IgE-mediated allergies are given weekly injections of allergen, augments immune regulatory networks such as the suppressive cytokine IL-10 and natural T-regulatory cells.

To determine whether recapitulation of the IgE-mediated immune responses induced by helminths can afford protection against autoimmunity in the absence of actual infection, non-obese diabetic (NOD) mice were repeatedly administered intraperitoneal injections of axenic *C. elegans* homogenate. Like parasitic helminthes, *C. elegans* is in the phylum Nematoda. NOD mice spontaneously develop Type 1 diabetes (also known as insulin dependent diabetes mellitus), a form of diabetes that develops from the autoimmune destruction of the insulin-producing beta islet cells of the pancreas, and are a recognized animal model for Type 1 diabetes. To mimic chronic helminth infections *in vivo* without using live parasitic worms, NOD mice were treated with twice weekly injections of axenic *C. elegans* homogenate. Treated mice exhibited increases in circulating basophils, eosinophils, total IgE, and *C. elegans*-specific IgE. These immunologic changes are consistent with those observed in chronic helminth infections. Additionally, splenocytes of *C. elegans*-treated mice released substantial quantities of the down-regulatory cytokine IL-10, whereas those from control-treated mice did not. Consistent with our hypothesis, mice given axenic *C. elegans* antigen injections were significantly protected from developing autoimmune diabetes (10% disease rate vs. 80% in controls) and exhibited less inflammation in the pancreatic islets.

These results demonstrate that axenic *C. elegans* homogenate therapy can protect against the onset of Type I diabetes in NOD mice and suggests that repeated administration of axenic *C. elegans* homogenate represents a new avenue of therapy for Th1-associated autoimmune diseases.

The goal of our current project is to analyze protective and/or suppressive effects of aCeAg treatments in the relapsing/remitting Multiple Sclerosis model of SJL/j mice. Additionally, we will investigate possible immuno-modulatory changes to better understand the therapeutic mechanisms of this treatment. In doing so, we will determine the potential reach of this non-parasitic nematode-derived treatment of autoimmune disease.

III. OBJECTIVE\HYPOTHESIS: The objective of this proposal is to discover potential new treatments for Multiple sclerosis and to better understand the immuno-modulatory mechanisms of helminth/nematode therapy.

IV. MILITARY RELEVANCE:

Multiple sclerosis and other type 1-driven autoimmune processes are common diseases that cause a high degree of morbidity worldwide. Since it is an exclusion criterion for enlistment in the U.S. military (with typical diagnoses of the disease occurring between the ages of 20 and 50), and as it is estimated that 400,000 Americans have been diagnosed, this disease significantly limits the number of Americans able to volunteer for active military duty. Additionally, the research described in this proposal has the potential to lead to new modalities of treatment for other autoimmune diseases that are common in military personnel, including Type 1 diabetes, rheumatoid arthritis, and systemic lupus erythematosis.

V. MATERIALS AND METHODS:

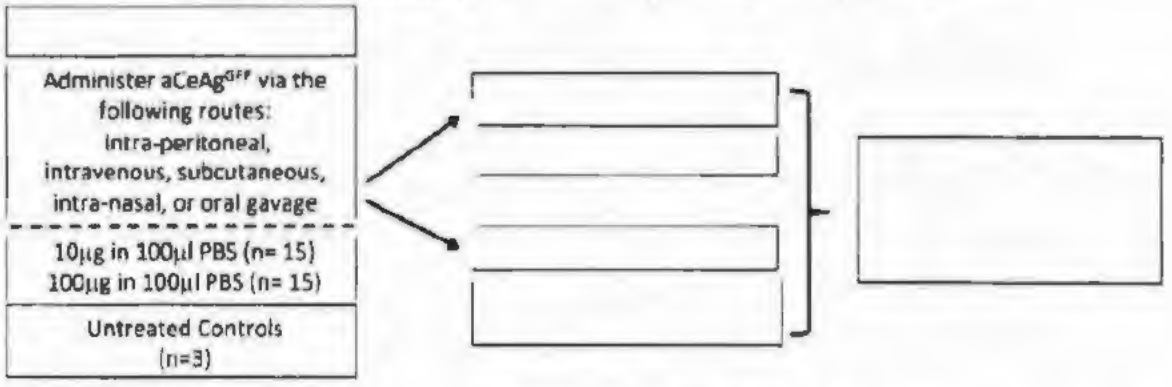
V.1. Experimental Design and General Procedures:

V.1.1. Experiment 1: The purpose of this procedure is to establish a snapshot of the pharmacokinetics (pK) of axenically derived *C. elegans* antigen ($aCeAg^{-/+GFP}$) in SJL/j mice. Pain Category C -- 33 mice

Experimental design: aCeAgG$^{-/+GFP}$ will be processed in the laboratory via methods previously described by C.P. Morris, *et al.* (Experimental Parasitology 135, 2013). Briefly, soluble proteins will be isolated from a homogenate of axenically grown *C. elegans*. This fraction will be sterile filtered and analyzed for endotoxins levels via Limulus Amebocyte Lysate (LAL) assay (Pierce Cat# 88282). Samples measuring at or below 0.2EU/ml will be used for injection.

Mice will be treated with 10 and 100 μg doses of aCeAg$^{-/+GFP}$, in 100μl Phosphate Buffered Saline (PBS) by one of the following routes: intra-peritoneal, intravenous, subcutaneous, intra-nasal, or oral gavage. Blood will be drawn 1 hour post-treatment by tail bleed (~75μl), and 6 hours post -treatment (and following euthanasia) by cardiac puncture (~500 μl). Serum will be processed and analyzed for the amount of aCeAg proteins they contain. Comparisons will be made among the various routes of aCeAg$^{-/+GFP}$ administration.

	Expt 1 - Animal # (33 mice total)			
	Admin. Route	aCeAg (0μg)	aCeAg (10μg)	aCeAg (100μg)
Group 1	N/A	3	---	---
Group 2	IP injection	---	3	3
Group 3	IV. injection	---	3	3
Group 4	SC injection	---	3	3
Group 5	Intra-nasal	---	3	3
Group 6	Oral gavage	---	3	3



V.1.2. Experiment 2: Immunomodulation induced by helminth infections typically takes several weeks to develop. As such, we envision aCeAg (or other worm-derived products) as immuno-modulatory drugs for chronic inflammatory diseases rather than therapeutics for acute exacerbations of autoimmune disease. To test this, we plan to use a remitting/relapsing mouse model of multiple sclerosis.

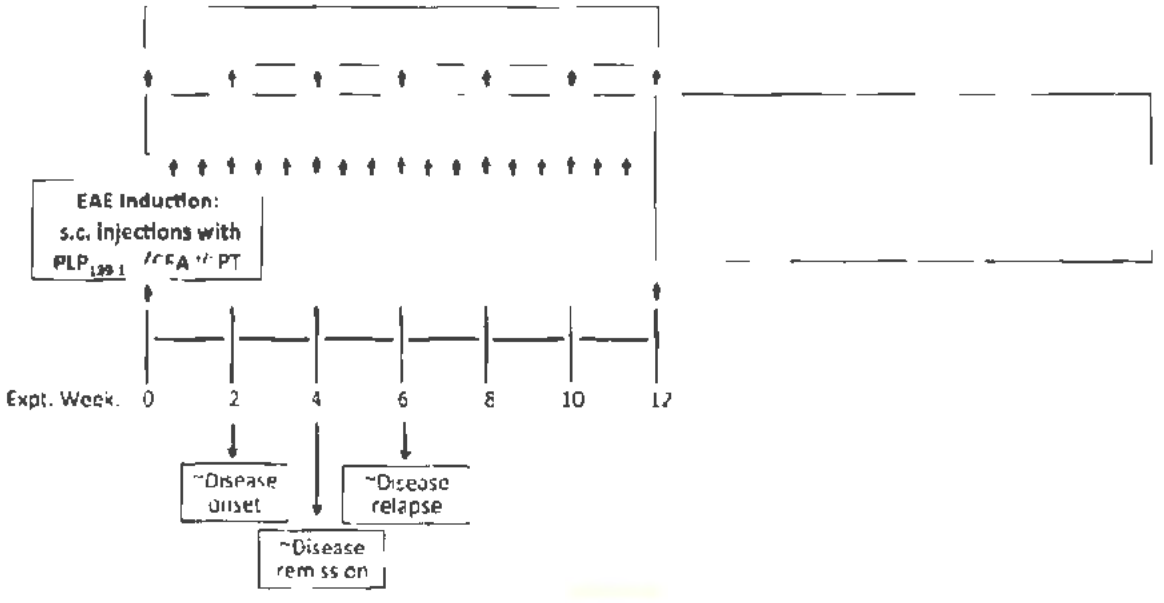
Experiment 2A – The purpose of this experiment is to establish the relapsing EAE model in our laboratory. Pain Category C -- 5-10 mice, Pain Category E -- 10-20 mice

Experimental design: EAE will be induced in SJL/j female mice by immunization with the antigenic Myelin Proteolipid Protein ($PLP_{139-151}$) peptide in complete Freund's adjuvant (CFA), with and without an added Pertussis Toxin (PTX) challenge. Reagents will be obtained from Hooke Laboratories ($PLP_{139-151}$/CFA Emulsion - cat. no. EK-0120), and $PLP_{139-151}$/CFA Emulsion PTX - cat. no. EK-2120). These mice will develop relapsing-remitting paralysis, with typical EAE onset between 9 and 13 days after

immunization (with PTX) and 11 to 15 days after immunization (without PTX), and peak of disease 1 to 2 days after disease onset for each mouse. The peak of disease lasts 1 to 3 days, with mice completely or partially recovering within 7-10 days. Approximately 50 to 80% of mice will show an increase in EAE severity (relapse) after initial partial or complete recovery. This usually occurs 20 to 40 days after immunization. Mice are typically observed for 40 to 45 days after immunization. This is sufficient for at least 50% of mice to relapse.

To determine which regimen best results in a recurrent EAE phenotype, at 6-10 weeks of age mice will be given a total of four subcutaneous injections (in the upper trunk ~2cm from the base of each fore- and hind-limb, consisting of one of the following regimens: 50µl of Phosphate Buffered Saline (PBS) alone, 50µg of $PLP_{139-151}$/CFA emulsion in 50µl PBS, 50µg $PLP_{139-151}$/CFA emulsion in 50µl PBS plus 500ng pertussis toxin in 100µ PBS given by i.p. injection. Mice will be observed daily from experiment Day 7 through study duration for the development of clinical symptoms, which manifest as a peripheral neuropathy ranging from limp tail or weak hind limb to complete hind limb paralysis (detailed description below in section V.4.1.2.1.). We expect disease onset 9 to 15 days after induction, remission of disease within 2 to 3 days after onset, and relapse of disease occurring for 50% to 80% of induced animals. If we do not observe disease onset within 15 days of induction, the experiment will be repeated, in a new set of animals, using 100 µ of $PLP_{139-151}$ in groups 2(a) and 3(a).

	Expt 2A - Animal # (15 - 30 mice total)	
	Treament	# SJL/j
Group 1	PBS treated mice	5 - 10
Group 2	PLP139-151/CFA challenged mice	5 - 10
Group 3	PLP139-151/CFA + Pertussin Toxin challenged mice	5 - 10

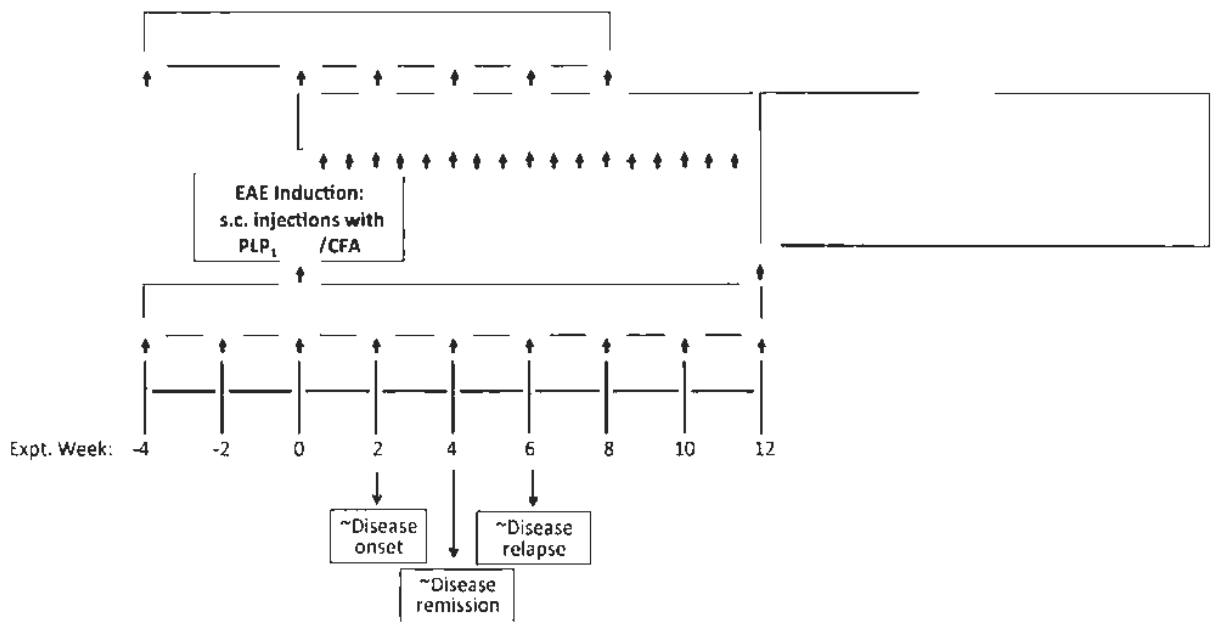


Experiment 2B – The purpose of this procedure is to test whether repeated administration of aCeAg, started before induction of EAE, prevents clinical disease. Pain Category C – 20 mice Pain Category E -- 20 mice

Experimental design: aCeAg$^{-/+GFP}$ immunotherapy, consisting of IP injections of 100μg/mouse in 100μl PBS, will be started 4 weeks prior to induction of EAE, and will continue twice weekly for the duration of the study. EAE will be induced when mice are 8 weeks of age. Specifically, we will use the proteolipid protein (PLP) induction model for experimental autoimmune encephalomyelitis (EAE) in SJL/j mice. SJL/j female mice will receive a total of four subcutaneous injections of a $PLP_{139-151}$/CFA emulsion (50μg in 50μl PBS) in the upper trunk, ~2cm from the base of each fore- and hind-limb) on experiment Day 0. Mice may also receive an intra-peritoneal injection of Pertussis toxin (500ng in 100μl PBS), depending on the results of experiment 2A. Mice will be observed daily from experiment Day 7 through study duration for the development of clinical symptoms, which manifest as a peripheral neuropathy ranging from limp tail or weak hind limb to complete hind limb paralysis (detailed description below in section V.4.1.2.1.). Additionally, ~75 μ of blood will be drawn every 2 to 4 weeks, by tail bleed, and plasma will be frozen, until study's end, for assessment of antibody responses to aCeAg$^{-/+GFP}$ and $PLP_{139-151}$.

At week 12 animals will be euthanized. A final 500μl of blood will be collected for plasma analysis of IgG and IgE levels, the brain and spinal cord will be extracted for histological analysis of inflammation, and the spleen and draining lymph nodes will be collected for analysis of lymphocyte proliferation and cytokine secretion profiles.

	Expt 2B - Animal # (40 mice total)	
	Treament	**# SJL/j**
Group 1	**PBS treated mice**	**10**
Group 2	**PBS treated mice with $PLP_{139-151}$/CFA challenge**	**10**
Group 3	**aCeAg treated mice**	**10**
Group 4	**aCeAg treated mice with $PLP_{139-151}$/CFA challenge**	**10**



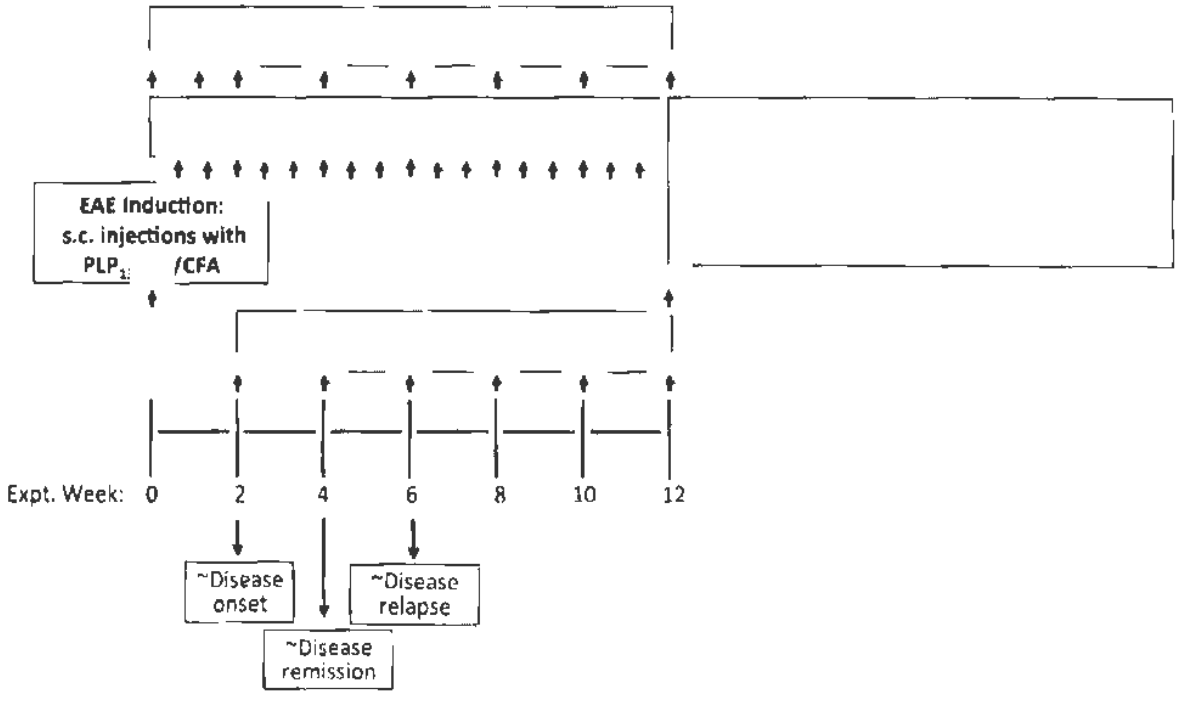
Experiment 2C - In this experiment we will test whether aCeAg injections can ameliorate relapse in animals that have already been sensitized to develop EAE.

Pain Category C -- 40 mice, Pain Category E -- 40 mice

Experimental design: The proteolipid protein (PLP) induction model for EAE (as described in Experiments 2A and 2B) will be induced in 8-week old SJL/j mice. aCeAg immunotherapy, consisting of IP injections of 100μg/mouse in 100μl PBS, will be started 1 week after the induction of EAE, and will continue twice weekly for the duration of the study. Mice will be observed daily from experiment Day 7 through study duration for the development of clinical symptoms, which manifest as a peripheral neuropathy ranging from limp tail or weak hind limb to complete hind limb paralysis (detailed description below in section V.4.1.2.1.). Additionally, ~75 μ of blood will be drawn every 2 to 4 weeks, by tail bleed, and plasma will be frozen, until study's end, for assessment of antibody responses to $aCeAg^{-/+GFP}$ and $PLP_{139-151}$.

At week 12 animals will be euthanized. A final 500μl of blood will be collected for plasma analysis of IgG and IgE levels, the brain and spinal cord will be extracted for histological analysis of inflammation, and the spleen and draining lymph nodes will be collected for analysis of lymphocyte proliferation and cytokine secretion profiles. Because the occurrence of relapsing EAE is somewhat variable, this experiment will require 20 animals per treatment group.

	Expt 2C - Animal # (80 mice total)	
	Treament	**# SJL/j**
Group 1	**PBS treated mice**	**20**
Group 2	**PBS treated mice with $PLP_{139-151}$/CFA challenge**	**20**
Group 3	**aCeAg treated mice**	**20**
Group 4	**aCeAg treated mice with $PLP_{139-151}$/CFA challenge**	**20**



V.2. Data Analysis:

Primary endpoint is clinical EAE disease activity scoring. A sample size of 10 mice in each group will have 80% power to detect a probability of 0.862 that an observation in one group is less than an observation in another group using a Mann-Whitney rank-sum test with a 0.05 two-sided significance level. For experiments 2A and 2B a total of 70 SJL/j mice are required

For analysis of EAE relapse greater variability (and standard deviation) is expected, thus it is recommended that 15-20 animals per groups be analyzed. For experiment 2C a total of 80 SJL/j mice are required.

As experiment 1 is observational, statistical analysis is not required.

Experiment 1: The purpose of this experiment is to obtain a pharmacokentic snapshot of aCeAg metabolism in SJL/j mice based of route of administration.

Five groups of 6 animals each will be used, in which 3 animals will receive10μg of aCeAg, and 3 animals will receive a 100μg dose of aCeAg. Three animals will serve as negative controls with no treatment. Each group will differ in the route of aCeAg administration – intra-peritoneal injection, intra-venous injection, subcutaneous injection, intra-nasal administration, or oral gavage. 200 μl of blood will be drawn at 1 hour by tail bleed. Mice will be euthanized at 6 hours and 500 μl of blood drawn by cardiac puncture. Blood samples will be drawn into plasma separator tubes. Plasma will then be tested for presence of known *C. elegans*$^{-/+GFP}$ antigen proteins, CAPG-1 and -/+GFP, by sandwich ELISA. This experiment requires a total of 5 groups x 6 mice/group plus 3 control animals = 33 mice.

Experiment 2A: The purpose of this experiment is to establish the relapsing model of EAE in our laboratory.

Because we simply want to determine if we can recapitulate this established model, in this experiment we will only be using 5 mice per group. If the initial study does not demonstrate substantial phenotype during relapse, the experiment will be repeated using a higher dose of PLP. The primary outcome is clinical score during relapse (approximately weeks 6-8). Given that there are 3 groups of mice in this experiment (EAE, PLP/CFA, and PLP/CFA + pertussis toxin), this experiment will require 15-30 mice.

Experiment 2B: The purpose of this experiment is to assess whether aCeAg injections are protective in a relapsing/remitting model of multiple sclerosis. Here we will test whether repeated administration of aCeAg started before induction of EAE prevents clinical disease.

Four groups of 10 SJL/j female mice each will be used. Four weeks prior to EAE induction, 100 μg of aCeAg$^{-/+GFP}$ will be given twice weekly by intra-peritoneal injection, and treatment will continue to experiment endpoint. EAE will be induced, in 8-week old mice, via subcutaneous injections of PLP/CFA into the upper trunk, ~2cm from the base of each fore- and hind-limb. We will score these animals for clinical manifestation of disease (a peripheral neuropathy ranging from limp tail or weak hind limb to complete hind limb paralysis; see details below and in section V.4.1.2.1), as well as disease remission and relapse. Additionally, we will analyze plasma levels of IgG and IgE antibodies. We will

examine brain and spinal cord sections for inflammation, and splenocytes and draining lymph node cells for proliferation and cytokine production. As this experiment requires 10 animals per group, and as there are 4 groups, this experiment requires 40 mice.

Experiment 2C: The purpose of this experiment is to assess whether aCeAg injections are suppressive in a relapsing/remitting model of multiple sclerosis. In part 2C we will test whether aCeAg injections can ameliorate relapse in animals that have already been sensitized to develop EAE.

Four groups of 20 SJL/j female mice each will be used. EAE will be induced, in 8-week mice, via subcutaneous injections of PLP and complete Freund's adjuvant behind each shoulder and on either side of the tail. One week following sensitization, we will score these animals for clinical manifestation of disease (a peripheral neuropathy ranging from limp tail or weak hind limb to complete hind limb paralysis; see details below and in section V.4.1.2.1), as well as disease remission and relapse. Additionally, we will analyze plasma levels of IgG and IgE antibodies. We will examine brain and spinal cord sections for inflammation, and splenocytes and draining lymph node cells for proliferation and cytokine production. Given the variability in occurrence of relapsing EAE, this experiment will require 20 animals per treatment group for a total of 4 groups x 20 mice/group = 80 mice.

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered: Alternative methods for studying autoimmune disease outside of *in vivo* approaches do not currently exist. The studies supported by this protocol specifically examine *in vivo* autoimmune pathogenesis, a phenomena without an *in vitro* equivalent. Further, our studies will be determining potential protective and/or suppressive immunotherapies.

V.3.2. Animal Model and Species Justification: Mice were chosen based on the similarities between the models utilized and human autoimmune disease. In addition, mice are a very well characterized model system, with a multitude of immunologically relevant mouse specific tools available. No smaller, less sentient mammalian species with appropriate genetic components and inflammatory responses are readily available for studying these aspects of autoimmunity. Examination in non-mammalian species is problematic, as the autoimmune disease model is only known to occur in higher vertebrate species. Current *in vitro* systems do not recapitulate the complex interactions between the cells and extracellular components necessary to model the interactions of T-cells with the target organs of interest. *In silico* models are insufficient for dissection of pathogenic T-cell interactions with target tissues due to the vast number of still unknown players that play a role in the examined processes.

SJL/j mice were chosen for the EAE studies due to the similarities between the disease model and autoimmune mediated CNS disease in humans. This model provides a well-described system that has been used in many published studies for examination of mechanisms involved in autoimmune mediated CNS diseases such as MS. Additionally, reagents necessary for these studies are readily available.

V.3.3. Laboratory Animals

		Species #1	Species #2
V.3.3.1.	Genus & Species:	*Mus musculus*	
V.3.3.2.	Strain/Stock:	SJL/j	
V.3.3.3.	Source/Vendor:	(b)(4)	
V.3.3.4.	Age:	4-12 weeks	
V.3.3.5.	Weight:	10-25g	
V.3.3.6.	Sex:	Female	
V.3.3.7.	Special Considerations:	None	
V.3.4.	Number of Animals Required (by Species):	183	

V.3.5. Refinement, Reduction, Replacement (3 Rs):

V.3.5.1. Refinement: All animals with EAE are observed daily for advanced disease. If advanced disease is detected food and water sources on the floor of the cage will be provided. In addition animals will be euthanized if they meet any of the alternate endpoint criteria outlined in section V4.5. Analgesics were considered but cannot be used to relieve pain due to their effects on the immune and neuronal cells being tested.

V.3.5.2. Reduction: Statistical analyses were utilized to determine the minimum number of animals required to test individual hypotheses, thus allowing us to determine with a fair degree of power the likelihood of whether our hypotheses are correct. The number of animals requested represent the minimum number we consider necessary for completion of our studies. We are using 5-20 mice per group, and every effort is made to ensure the scientific utility of data derived from each animal used in this study by monitoring, evaluating and modifying group size as needed to obtain clear and consistent data. Every effort will be made to minimize the numbers of mice used without compromising research results.

V.3.5.3. Replacement: All of our studies require animals with an intact immune system, and therefore cannot be replicated *in vitro*.

V.4. Technical Methods:

V.4.1. Pain / Distress Assessment:

V.4.1.1. APHIS Form 7023 Information:

V.4.1.1.1. Number of Animals:

	Species #1	Species #2
V.4.1.1.1.1. Column C:	103	
V.4.1.1.1.2. Column D:		
V.4.1.1.1.3. Column E:	80	

V.4.1.2. Pain Relief / Prevention:

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization:

Inhalation anesthesia for immobilization for intra-nasal administrations: We will follow IACUC policy for our procedures. Mice undergoing intranasal inoculation will first be

anesthetized with isoflurane at 1-4.5% in a chamber using a precision vaporizer. Once they are immobilized, they will be removed from the induction chamber and depth of anesthesia will be monitored to ensure both adequate anesthesia (lack of movement with toe pinch) and adequate respiration.

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions:
Monitoring of EAE: Experimental Allergic Encephalomyelitis (EAE) is an autoimmune disorder characterized by a chronic relapsing, and remitting paralysis secondary to central nervous system (CNS) demyelination caused by T cells, and mice can go into remission even after development of stage III disease. Ordinarily, animals will be monitored for clinical symptoms daily and weighed every other day to determine weight loss associated with autoimmune disease. Animals with score of 4 will be monitored twice daily until the symptoms have resolved to a lower score. If resolution does not occur within 3 days the animal will be euthanized. A standardized system has been devised for classification of disease severity in both atypical and classical EAE. (Abromson-Leeman, Bronson et al. 2004; Lees, Iwakura et al. 2008). Clinical symptoms will be graded and recorded daily using the following scales:

Classical EAE symptoms
1- Flaccid Tail
2- Delay in righting reflex, hind limb weakness
3- Flaccid paralysis in 1 hind limb
4- Flaccid paralysis in both hind limbs
5- Moribund

Atypical EAE symptoms
1- Tail Rigor
2- Wide stance, leaning, or directed locomotion to a single side, mild ataxia
3- Continual turning to a single side, rigor in a single limb, moderate ataxia
4- Rolling, rigor in multiple limbs, severe ataxia
5- Moribund

Ataxia symptoms
1- Mild ataxia (stumbling)
2- Moderate ataxia (weaving)
3- Severe ataxia (moribund)

Mice will be considered moribund if they are found to be incapable of directed mobility at will. Specifically, mice with paralysis, rigor, or weakness in three or more limbs will be considered moribund. Additionally any mouse that is found to be incapable of directed continuous (lasting longer than 1s) movement due to vertigo or ataxia will be defined as moribund. Any mice with scores higher than a 2 on any EAE disease score scale will be provided with moistened food and transport gel on the cage floor to insure access to food and water. Hydration will be monitored by physical examination. If animals show signs of injury or difficulty ambulating they will be relocated to a separate cage to protect them from potential negative interactions with cage-mates. Mice with distended bladders that do not urinate upon handling will be considered incapable of self-elimination and the bladder will be expressed twice daily until symptoms subside or the mouse is euthanized. Skin lesions and ulcers are expected in many of the mice after complete CFA administration. Lesions will be monitored for development of abscesses or draining lesions. If such a discharge occurs mice will be euthanized.

PubMed: search 6 - 1 unique studies; None relevant
PubMed: search 7 - 7 unique studies; None relevant

V.4.1.4. **Unalleviated Painful or Distressful Procedure Justification**:

(1) Some mice used under this proposal will develop EAE following treatment. The neurological symptoms associated with EAE will be experienced without relief for the remainder of the time described in individual experiment descriptions. The induction and development of EAE is vital to all major scientific questions addressed in this proposal. As analgesics work by modulation of neuronal and inflammatory processes treatment with analgesics could compromise our neuro-immunological findings. It is my belief that the utilization of the EAE system will allow us to address unique questions relating to neuro-inflammation that may in turn provide significant human benefit, thus justifying the moderate and temporary pain and distress the animals may experience.

(2) The use of Complete Freund's Adjuvant (CFA) is needed in the EAE model to generate an inflammatory response, thus breaking the animal's immunological tolerance to the antigenic Proteolipid protein peptide ($PLP_{139-151}$). This leads to the formation of multiple small, disseminated lesions of demyelination, micro-necrosis in the brain and spinal cord and the onset of clinical symptoms. Although multiple adjuvants are sufficient to induce EAE in rats, CFA is thought to be uniquely capable of reliably generating autoimmunity in mice (Stromnes and Goverman 2006). Researchers have tried muramyldipeptide, purified lipid A, and saponins in various water-in-oil emulsions without much success. One research group claims to have achieved EAE in C57BL/6 mice using Quil A, however these results have not been duplicated, and Quil A has not been proven effective with the SJL/j mouse model of MS. As such for these studies, no adequate substitute is available. In spite of using the minimally effective amount of CFA

(CFA suspended 1:1 (v/v) with the antigen preparation; subcutaneous injection of 0.05 ml per site), the adjuvant may cause skin lesions or ulcers at the site of injection. Mice will be monitored for development of abscesses or draining lesions. If discharge is observed the veterinary staff will be consulted and/or the mice will be euthanized.

V.4.2. Prolonged Restraint: N/A

V.4.3.4. Location: N/A

V.4.3.5. Surgeon: N/A

V.4.3.6. Multiple Major Survival Operative Procedures:

V.4.3.6.1. Procedures: N/A

V.4.3.6.2. Scientific Justification: N/A

V.4.4. Animal Manipulations:

V.4.4.1. Injections:

SQ injection- Subcutaneous injections of aCeAg (for pharmacokinetic analysis) will be administered between the shoulder blades using a 25-27G needle with less than or equal to 100 µl total volume. Subcutaneous injections of CFA/PBS emulsion containing $PLP_{139-151}$ peptide (for induction of EAE) will be administered into the upper trunk, ~2cm from the base of each fore- and hind-limb, using a 25-27G needle with 50 µl total volume per site.

IP injection – Intraperitoneal injections of aCeAg (for pharmacokinetic analysis), aCeAg and/or PBS (for EAE therapy/control), and/or pertussis toxin in PBS (for induction of EAE) will be done using a 23-25 gauge needle into the caudal ventral abdomen of recipient mice. All IP injections will be done with no more than 200 µl of volume.

IV injection- Intravenous injections of aCeAg (for pharmacokinetic analysis), in a volume no greater than 200µl, will be done in the lateral tail vein using a 25-30 gauge needle. Mice will first be restrained in a commercial Pexiglas chamber. The chamber will be covered with a piece of paper and a heat lamp will be placed over the tail to dilate the veins. Care will be taken not to overheat the animal. After locating the tail vein, the site will be disinfected with an alcohol swab. The needle will be placed parallel to the tail pointing toward the head. Following the injection, the needle will be removed and gentle pressure will be applied to the site until bleeding stops (~30 seconds).

V.4.4.2. Biosamples:

Ante-mortem biosampling

A. Blood draws: Up to 75µl of blood will be drawn every two weeks until time of euthanasia by tail bleed. Mice will be placed in a Broome restrainer while awake. A heat lamp is then placed over the tail of the mice for one to two minutes. Then, a shallow incision is made on the ventral surface of the tail just lateral to midline across one of the two lateral tail veins with a #10 scalpel blade. Drops of blood are then

directly collected into a small test tube. At the end of collection, mice are removed from the heat lamp and direct pressure is applied to the incision site with clean gauze.

Post-mortem biosampling

A. Terminal bleed: We only conduct terminal bleeds after animals have been euthanized by carbon dioxide as described in section V.4.6. The terminal bleed is a supplemental method to ensure death. The maximum possible amount of blood obtainable will be drawn by withdrawing blood directly from the heart post-mortem using a 20-23 gauge needle inserted into the left ventricle of the heart. Collected blood will be transferred into microtube for plasma processing.

B. Recovery of lymph nodes and organs of interest: Once euthanasia and terminal bleed is complete, brachial lymph nodes, pancreatic lymph nodes thoracic cavity lymph nodes (parathymic, post-mediastinal, and paravertebral lymph nodes), spleen, etc. will be removed for further study using aseptic techniques via lymph node dissection, midline thoracotcomy, and midline laparotomy. Histology may be performed on the tissues obtained.

V.4.4.3. Adjuvants: Complete Freund's adjuvant has been commonly used for decades in immunologic studies in mice and while multiple adjuvants are sufficient to induce EAE in rats, CFA is thought to be uniquely capable of reliably generating autoimmunity in mice (Stromnes and Goverman 2006). Researchers have tried muramyldipeptide, purified lipid A, and saponins in various water-in-oil emulsions without much success. One research group claims to have achieved EAE in C57BL/6 mice using Quil A, however these results have not been duplicated, and Quil A has not been proven effective with the SJL/j mouse model of MS. As such for these studies, no adequate substitute is available. Mice will be treated with a CFA emulsion containing the PLP immuno-dominant peptide or PBS. Four subcutaneous injections will be administered into the upper trunk, ~2cm from the base of each fore- and hind-limb, using a 25-27G needle with 50 µl total volume per site. Mice will be watched for development of adverse reactions and subsequent euthanasia as described in section V.4.5.

V.4.4.4. Monoclonal Antibody (MAbs) Production: N/A

V.4.4.5. Animal Identification: Cage cards will be used. Animals may be identified by 2mm ear punch.

V.4.4.6. Behavioral Studies: N/A

V.4.4.7. Other Procedures:

Oral gavage inoculation – Oral inoculation of aCeAg (for pharmacokinetic analysis), in a volume no greater than 200µl will be performed. Mice will be manually restrained at the neck and back scruff, with the neck vertically extended. A 22 gauge ball tip needle will be gently passed through the mouth and pharynx into the esophagus. Contents of the syringe will be slowly administered.

Intranasal inoculation – Intranasal inoculation of aCeAg (for pharmacokinetic analysis), in a volume no greater than 30µl will be performed on anesthetized mice. Animals will be anesthetized with isoflurane at 1-4.5% in a chamber using a precision vaporizer. Once they are immobilized, they will be removed from the induction chamber and depth

of anesthesia will be monitored to ensure both adequate anesthesia (lack of movement) and adequate respiration. The mice will be manually restrained with the tail anchored between the small finger and the palm (Simmons and Brick, 1970). While held in a supine position with the head elevated. The end of a micropipette will be placed at or in the external nares, and the solution will be slowly injected.

V.4.4.8. Tissue Sharing: Unused tissues will be available after termination of experimental procedures with the understanding that mice have been manipulated and may have disease-associated tissue inflammation.

V.4.5. Study Endpoint: Euthanasia at pre-determined time. Alternatively mice will be euthanized if they are judged to be moribund or display any of the following criteria associated with EAE development:

i. Total weight loss exceeding 20% of body weight at start of experiment.
ii. Inability to rest.
iii. Hunched posture, head tucked into abdomen, lethargy lasting for >24 hours.
iv. Any condition that interferes with fecal or urinary elimination.

or development of other issues sometimes found in the mouse population:

v. Formation of multiple sores on tail.
vi. Diarrhea, if debilitating or prolonged over 3 days.
vii. Spreading alopecia that covers ~25% or more body surface area.
viii. Excessive scratching with associated scabbing
ix. Persistent coughing, labored breathing, or nasal discharge.
x. Jaundice.
xi. Bleeding from any orifice and/or prolapse.
xii. Pus-like discharge from sores.

While we do not anticipate any complications as a result of aCeAg inoculations, any animal that shows signs of distress, pain, illness, or anaphylactic shock (respiratory distress, edema, wheezing) will be evaluated by the veterinary staff and the P.I. and then euthanized.

V.4.6. Euthanasia: Carbon dioxide. Animals will be euthanized by Center for LAM or research personnel using cylinderized CO_2 in compliance with the most current version of the AVMA Guidelines. Euthanasia will be performed in (b)(6) or in room (b)(6) If possible, animals will be euthanized in their home cage. If not, a clean rodent cage will be used. Animals will be placed in a chamber that is not overcrowded (each animal can place all four feet on the bottom of the cage). With animals in the chamber, the flow rate will displace 10-30% of the chamber volume per minute. Gas flow will be maintained for at least one minute after apparent clinical death. Animals will be verified as dead (lack of heart beat and lack of respirations, blanched retinas, cyanotic mucous membranes) before removal of the chamber.

Note: For all euthanized animals, a supplemental method to ensure death (cervical dislocation or bilateral thoracotomy or terminal bleed) will be used in addition to carbon dioxide.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol.

V.5.1.1. Study Room:

Building(s) (b)(6) Room Number(s) as assigned by LAM. (b)(6)

V.5.1.2. Special Husbandry Provisions:

Food Restriction: Yes _____ No __X__

Fluid Restriction: Yes _____ No __X__

V.5.1.3. Exceptions: None

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care: Animals will be cared for by LAM personnel according to LAM SOPs.

We will also monitor daily and weigh every other day following development of EAE clinical symptoms. Arrangements will be made with the Laboratory of Animal Management (LAM) staff for placement of food and water sources on the floor of cages as needed for animals that may have difficulty accessing the normal feed and water sources.

V.5.2.2. Emergency Veterinary Medical Care: All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. LAM personnel, once daily, conduct essential husbandry procedures and health rounds during weekend and holidays.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: Except as indicated below, all animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents; balls, toys and food enrichment treats for large animal species.

V.5.3.2. Enrichment Restrictions: None

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
Injections	(b)(6)	9 years experience	IACUC investigator training course April 2006
Tail bleeds		9 years experience	
Euthanasia (C02, cardiac puncture)		9 years experience	

Injections	(b)(6)	4 years experience	IACUC investigator training course March 2011
Euthanasia (C02, cardiac puncture)		4 years experience	
Oral gavage		To be learned; training provided by (b)(6)	
Tail bleed		To be learned; training provided by (b)(6)	
Intranasal administration		To be learned; training provided by (b)(6)

VII. BIOHAZARDS/SAFETY: Lab personnel will wear personal protective equipment (gloves, masks, lab coats or scrubs) when handling animals. Lab personnel will be briefed on safety measures to prevent accidental needle sticks with CFA (e.g. do not recap needles, proper disposal of needles) and the potential consequences of accidental injection of CFA into human tissues (e.g. localized inflammation, possible conversion to a positive TB test). If used for tissue fixation, paraformaldehyde will be used in a hood and personnel will wear personal protective equipment.

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. **Training:** I verify that I have attended the USUHS Investigator/Animal User Training [redacted]

Principal Investigator Signature — Date: 7/30/2015

G. **Training:** The following personnel will attend the next USUHS Investigator/Animal User Training Course:

_____ _____

_____ _____

H. **Responsibility:** I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely, "Respons[redacted] use alternatives where feasible and conducting humane a[redacted]

X. PROTOCOL ABSTRACT:

A. **Animal Protocol Number:**

B. **Animal Protocol Title:** Efficacy of *Caenorhabditis elegans* antigen as a protective treatment of experimental autoimmune encephalomyelitis (an animal model of multiple sclerosis) in mice

C. **Principal Investigators:** [redacted] M.D.

D. **Performing Organization:** USUHS

Over the last decade, studies have shown an inverse relationship between endemic helminth infections and the incidence of allergy and/or autoimmune disease in developing regions. Further, the potential use of helminth-derived immuno-regulatory therapy as a protective measure against inflammatory disease has been validated in both animal and clinical studies [1,2]. However, several obstacles impede the overall usefulness of helminic treatments including difficulties in obtaining large quantities (due to complex lifecycles), variability in purification and inter-batch efficacy, and the disease causing potential of live infections [3]. Here we propose a strategy for utilizing the beneficial effects of helminth immuno-suppression while avoiding the complicating issues associated with helminth isolation/treatment.

We have shown in a proof-of-concept study that treatment of Non-obese Diabetic (NOD) mice with soluble antigens from axenically grown *C. elegans* (aCeAg) nematodes is protective for the onset of Type I Diabetes. Mechanistically, we have shown that these antigen treatments increase the levels of basophils, eosinophils, and polyclonal and antigen-specific IgE immunoglobulins, in a similar manner to that seen with *L. sigmodontis* treatments [4]. Further, we observe increased production of the suppressive cytokine IL-10, but not of the pro-inflammatory cytokine IFNγ, from splenocytes of aCeAg-treated animals [4].

Our current study aims to analyze the potential for protective and/or suppressive effects of aCeAg treatments in the relapsing/remitting Multiple Sclerosis model of SJL/j mice. Thus, we will determine the potential therapeutic reach of this non-parasitic nematode-derived treatment, and gain a better understanding of the immuno-modulatory responses to such treatments.

MEMORANDUM FOR DR. (b)(6) DEPARTMENT OF MICROBIOLOGY

SUBJECT: IACUC Approval of Protocol –Initial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on January 5, 2016:

Animal Protocol Title: (b)(4)

USUHS Protocol Number: (b)(6)

Expiration Date: January 4, 2019

Supporting Grant(s) Number: (b)(6),(b)(4)

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. NON-TECHNICAL SYNOPSIS:

Malaria is a tropical parasitological disease that remains a global health problem, causing more than half a million deaths and 250 million cases annually. Expanded control and treatment programs in the past decade have reduced the incidence of the disease and led to the call for efforts to eliminate, possibly even eradicate, malaria. To do this new strategies are needed that target the sexual stages of the parasites, called gametocytes that are responsible for disease transmission. The current recommended chemotherapy for malaria does not effectively kill mature gametocytes, allowing malaria to be transmitted for more than a week after the clearance of asexual parasites. Previous drug screens used assays that only detected asexual replication and therefore did not monitor activity against gametocytes. (b)(4) (b)(4) (b)(4) The goal of this research is three fold 1) to use a rodent malaria model to analyze the *in vivo* safety of selected compounds with *in vitro* gametocytocidal activity 2) to use a rodent malaria model to analyze the *in vivo* malaria transmission blocking efficacy of selected compounds with *in vitro* gametocytocidal activity at doses found safe in mice 3) define the stage specificity and timing of compound inhibition from intraerythrocytic development to oocyst formation. Together these approaches should identify classes of compounds that can be targeted for further drug development, as well as advance our understanding of gametocyte metabolism and facilitate the design of effective control strategies. The mouse studies described in this work will be performed in full accordance with the Institutional Animal Care and Use Committee at USUHS

II. BACKGROUND:

II.1. Background:

Malaria transmission requires the production of male and female gametocytes in the human host. These gametocytes are then taken up in a blood meal by a mosquito and begin a multistep developmental process that leads to the formation of human-infectious sporozoites. In contrast to the 48 hr asexual replication cycle of *Plasmodium falciparum*, the development of mature gametocytes takes 10-12 days [8]. Mature gametocytes then circulate in the peripheral blood for several days and are resistant to almost all known antimalarial drugs. Consequently, transmission can continue for over a week or longer after the clearance of asexual stages [9]. Primaquine, an 8-aminoquinoline, effectively eliminates late stage gametocytes and has recently been included in mass drug administration efforts to reduce malaria transmission [10-

12], but it has a short half-life and does not affect early stage gametocytes, allowing continued production of infectious mature gametocytes. Primaquine can also have serious side effects in individuals with genetic deficiencies in glucose-6-phosphate dehydrogenase (G6PD) or NADPH-methemoglobin reductase [13]. Unfortunately, people living in malaria endemic areas have a high prevalence of these genetic mutations, and this fact has raised concerns about the widespread use of primaquine to block transmission [13]. The active metabolite of artemisinin, dihydroartemisinin, also has gametocytocidal activity, but its gametocyte IC50 is ~100 times higher than that required to kill asexual stages. Mosquito feeding assays have demonstrated that malaria patients remain infectious to mosquitoes for over a week after treatment [9]. This time course is consistent with artemisinin's preferential effect on immature gametocytes. Even this partial effect on transmission has been implicated in the decreased transmission observed over the past several years [14]. Unfortunately, the mechanism of action of neither of these compounds is known, so their efficacy does not provide clues to gametocyte vulnerabilities.

New, safe, potent gametocytocidal compounds are needed to effectively block malaria transmission and prevent the spread of malaria [3]. The biology of gametocytes and asexual parasites differ significantly, resulting in differential sensitivity to common antimalarials. One of the primary differences is the lack of DNA replication during gametocyte development, and consequently gametocytes are resistant to drugs that target de novo pyrimidine synthesis, such as sulfadoxine–pyrimethamine, atovaquone and dihydroorotate dehydrogenase inhibitors [15]. After developing into a stage II gametocyte, *P. falciparum* is no longer affected by compounds that block hemoglobin digestion or erythrocyte invasion, such as the 4-aminoquinolines and protease inhibitors [15]. Gametocytes also are not lysed by sorbitol, suggesting a reduction in permeability pathways such as the plasmodial surface anion channel (PSAC) [16-18]. Likewise, gametocytes are not cleared by antibacterial agents such as clindamycin and tetracycline analogs that target the apicoplast, a relict plastid carried by Plasmodium [19]. Additional apicoplast-specific enzyme systems have not yet been evaluated in gametocytes.

There are several reasons for the lack of drug studies on gametocytes and mosquito infectivity. First, although gametocytes can be detected in 95% of malaria patients by analyzing RNA samples, they are difficult to detect by Giemsa-stained thick smear and consequently they are often not analyzed in field studies [20, 21]. Additionally, few laboratories have experience growing gametocytes in culture and many lab-adapted lines have lost the ability to produce gametocytes. Even in lines that do make gametocytes, maturation takes 12 days and the yield is generally very low in comparison to asexual stages, because only a small subpopulation of asexual parasites differentiates into gametocytes. Consequently, ~50 fold fewer gametocytes than asexual parasites are produced from the same amount of stock culture over the same time period. The lack of DNA replication during gametocytogenesis also rules out the possibility of measuring increases in DNA content to estimate gametocyte viability, which is frequently used to estimate the growth of asexual stages. Consequently, (b)(4) (b)(4) (b)(4) does not require genetically engineered parasites that often produce few gametocytes and allows screening of field isolates to study resistance patterns. However, the production of late stage gametocytes is inherently time and resource intensive, therefore (b)(4) (b)(4) (b)(4) In contrast (b)(4) tested are inactive against mature

gametocytes. Consistent with the ineffectiveness of most approved anti-malarials against gametocytes, (b)(4)
(b)(4)
These data demonstrate the distinct biology of the transmission stages and emphasize the importance of screening additional compounds for gametocytocidal activity. The additional screening of (b)(4) provided an efficient overview of pathways that are essential for gametocyte viability and allowed comparison with previous data obtained using asexual parasites. (b)(4) and 3 had not previously been reported to have anti-malaria activity and will continue to be developed as drug candidates in (b)(4)
(b)(4) will produce and screen new derivatives *in vitro* gametocytocidal activity. Compound with potent *in vitro* gametocytocidal activity will be selected and advanced for *in vivo* testing in mice.

II.2. Literature Search for Duplication:

II.2.1. Literature Source(s) Searched: Pubmed, NIH RePORTER, DTIC

II.2.2. Date of Search: Nov 10, 2015

II.2.3. Period of Search: Pubmed (English filter, 1948-present); NIH RePORTER (active awards only, 2000-2015)

II.2.4. Key Words and Search Strategy:
NIH RePORTER: (malaria transmission-blocking drug) NOT vaccine, only identified our current R01. The more general term "malaria" was used because this includes studies done in all species, including mice.

Pubmed: "(malaria transmission-blocking drug) NOT Vaccine"

DTIC: "malaria transmission blocking drug".

II.2.5. Results of Search:
Pubmed: "(malaria transmission-blocking drug) NOT Vaccine" = 97 hits, The number of articles on transmission-blocking drug discovery has increased in the last five years with 70 of these article being published from 2012-present. This increase reflects the realization that none of the current anti-malarials used for first line treatment block transmission. Consequently patients remain infectious for at least a week after symptoms resolve allowing the parasite to continue to move through the population. Three hits were from our group, including a recent Science Reports article (2014) describing a large screen of > 7000 bioactive compounds that has led to this proposal. The compounds being screened in this proposal are not being developed by other groups, many will be novel derivatives synthesized by our collaborators.

NIH RePORTER: "(malaria transmission-blocking drug) NOT vaccine", only identified our current R01 that supports this project.

DTIC: "malaria transmission blocking drug". There were 3 hits, but only one involved malaria drug development, the other two were screening for malaria immunity or vector control. The one drug development project is focused on optimizing a different chemical compound, ELQ-300, for oral administration. We will not be testing this compound unless it is in collaboration with the DOD PI. We are collaborators with that DOD PI on another grant to test some of his other compounds for transmission-blocking activity.

III. OBJECTIVE\HYPOTHESIS: The objectives of these proposed studies are:

1) Determine the *in vivo* safety of selected gametocytocidal compounds using the rodent malaria model, *Plasmodium berghei* in mice.
2) Determine the *in vivo* malaria transmission blocking efficacy of selected gametocytocidal compounds using the rodent malaria model *Plasmodium berghei* in mice at doses found to be safe.
3) Define the stage specificity and timing of compound inhibition from intraerythrocytic development to oocyst formation

IV. MILITARY RELEVANCE:

40% of the world's population lives in malaria endemic areas and, therefore, it continues to be a threat to military personnel deployed to these areas. The potential for infection was most recently demonstrated when 5 US soldiers working in Liberia to control the Ebola epidemic were diagnosed with the disease. Since 2005, 800 U.S Troops have been infected with malaria (Air Forces Health Surveillance Center). Of most concern is that resistance has been reported for all the current anti-malarials. This finding has increased the push for the identification of novel drugs that target clinical symptoms and can effectively block transmission to reduce the spread of malaria through the population.

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures:

Compounds that are found to be 10 times more potent against *P. falciparum* gametocytes than mammalian cells *in vitro* will be selected for further *in vivo* testing using the rodent malaria *P. berghei*/mouse model. Both commercially available and newly synthesized compounds may be used during the course of this work. In accord with IACUC Policy 27, if available pharmaceutical grade compounds will be purchased. If pharmaceutical grade is not available, compounds approved for cell culture use will be obtained. For the remaining compounds the purest preparation available will be used and each lot will be tested in vitro for cytotoxicity against mammalian cells prior to use in animals. A dose escalation model will be used to evaluate *in vivo* safety (Experiment 1, V.1.1) and compound concentrations found to be safe will be tested for the ability to block parasite transmission via a mosquito (Experiment 2, V1.2). To better define the transmission-blocking kinetics and stage specificity of the selected compounds, RBCs infected with mature gametocytes will be harvested and stimulated *in vitro* to fertilize and differentiate over the next 24 hours into ookinetes as they do in the mosquito midgut. Selected compounds will be added at specific times during this process and tested for an effect on ookinete production. The results will be used to determine stage sensitivity and the time needed to block development. The goal of this work is to identify safe compounds with potent, multi-stage, transmission-blocking activity for further preclinical development as a novel

anti-malarial.

V.1.1. Experiment 1:

V.1.1.1) Safety testing: Compounds found to have potent gametocytocidal activity *in vitro*, will first be screened for cytotoxicity in the mammalian cell line, such as HepG2 cells. The compound concentrations needed to reduce viability of HepG2 cells and gametocytes will be compared. Those compounds with 10 times more activity against gametocytes will be candidates for *in vivo* studies in mice. If the compound has not been previously tested in mice, the initial safety studies described here will be completed prior to (Exp 2) transmission-blocking efficacy testing using the rodent malaria, *P. berghei* in mice (CD-1 outbred mice, (b)(4)

For the safety studies a dose escalation model will be followed starting with a dose of 1 mg/kg administered by intravenous (IV) or intraperitoneal (IP) injection (50-200 µl) to two outbred CD1 mice (b)(4) (16). For the next 4 days the mice will be monitored daily for signs of distress, including, decreased/impaired motility, hunched posture, ruffled fur, difficulty breathing, diarrhea, and skin lesions and will be euthanized if they appear unhealthy. The compound formulations will vary depending on the solubility of the compounds and could include a range of carriers. Carrier selection will be based on the properties of the compound and previous literature and could include, up to 2% methyl cellulose, 50% Polyethylene glycol (PEG), 25% n-Methylpyrrolidone, 5% Dimethyl sulfoxide (DMSO), 7.5% ethanol or 18% PEG-40 Hydrogenated Castor Oil (cremophor RH40 or kolliphor RH40). All these carriers have been used previously in animals (http://www.pharma-ingredients.basf.com/Solubilizer /Kolliphor_range/Kolliphor_RH40.aspx), http://www.bu.edu/orccommittees/iacuc/policies-and-guidelines/administration-of-drugs-and-experimental-compounds-in-mice-and-rats/).

If there are no adverse reactions two days after the injection another two mice will be treated with 2 mg/kg. In the absence of adverse reactions from the higher dose, the experiment will be repeated using doses of 4 mg/kg and then 8 mg/kg. If there continues to be no adverse effects, the compound will then be tested for transmission-blocking efficacy at 4 and 8 mg/kg as described below in Exp 2. If the compound completely blocks transmission, higher doses will not be tested. If the compound does not block transmission at these doses additional safety testing will be done at 16 mg/kg. If there continues to be no adverse effects, the dose will be increased in 2 fold increments until a maximum dose of 128 mg/kg. This upper level was selected, because this is a drug development project and it is unlikely that a compound that requires a 128 mg/kg dose for activity will be advanced without additional modification.

Compounds that are found to be safe and effective by IV/IP administration will then be tested for safety and efficacy when administered by gastric gavage first at 50 mg/kg then if safe the dose will be increased 2 fold to a maximum of 400 mg/kg.

V.1.1.2) Over the course of the 3 year project we anticipate testing up to 100 compounds for safety. At a maximum the carrier control and 8 different doses of compound will be tested by IV or IP injection and 4 doses by gavage in two mice. 100 x (1+8+4) x 2 =2,600

V.1.2. Experiment 2:

V.1.2.1) Transmission-blocking Efficacy Testing: To extend the study to the evaluation of efficacy against gametocytes, 2 mice will be restrained by hand and inoculated IP with *P. berghei* and then returned to the cage. They will be monitored for parasitemia by Giemsa-stained smear of a drop of blood from a tail nick every other day until parasites are observed. To obtain blood for the smear, the mice will be restrained briefly for a tail nick to collect a drop of blood on a microscope slide. Once parasites are observed the mice will be observed daily to monitor well-being and assess parasitemia. When the parasitemia is >5%, the mouse will be

anesthetized with inhaled isoflurane and the blood will be collected by cardiac puncture and transferred to 2 mice that will be restrained by hand and the parasites will be transferred by IP injection. The donor mouse will be euthanized after the cardiac puncture by an overdose of isoflurane and exsanguination. The gametocytemia of the newly infected mice will be followed daily by Giemsa-stained smear until it is >1% and then some of the blood from the tail nick will be diluted into sterile phosphate buffered saline (PBS) with heparin to test the ability of male gametocytes to exflagellate when cooled to room temperature (rt). Exflagellation, the production and release of motile flagella that can fertilize female gametes can be observed under the microscope at 400x magnification and is used as a marker of gametocyte sexual maturity. Once exflagellation is observed in the blood sample the highest well-tolerated dose of compound from Exp. 1 or carrier alone will be administered by IV,IP or gavage to the mice. One to two hours after drug administration the mice will be anesthetized with an IP injection of 3 mg/kg acepromazine maleate and 60 mg/kg ketamine and laid on the top of a sealed container containing *Anopheles stephensi* mosquitoes provided by the Entomology Section of Preventative Medicine and Biostatistics Department. After the blood meal the mouse will be returned to the cage to recuperate so that the course of parasitemia can continue to be followed to monitor parasitemia after drug treatment or the mouse will euthanized while still anesthetized by cervical dislocation. The blood fed mosquitoes will be maintained to assess parasite transmission. Transmission can be evaluated by harvesting mosquitoes on days 7-12 post blood meal to count the number of *Plasmodium* oocysts that have developed in the midgut. Alternatively, to determine if the mosquito can transmit malaria to a naive mouse, 21±2 days after the initial blood feed, a naive mouse will be anesthetized and placed on top of the sealed cage containing the *P. berghei*-infected blood fed mosquitoes. After the *P. berghei*-exposed mosquitoes have taken a blood meal the mouse will be allowed to recuperate and after 5 days the parasitemia will be followed by a tail bleed as described above to evaluate whether they were infected.

V.1.2.2) If all hundred compounds are found to be safe they will be tested for transmission blocking activity in triplicate in up to 6 drug concentrations by IV or IP and 4 drug concentrations by oral gavage. The concentrations will be selected based on the safety profile of the compound. Initially, a single mouse will be tested for each treatment, 1) a selected safe high dose, 2) half the high dose and a carrier control. One donor mouse will be needed to provide parasites 2 experimental mouse. 100 compounds x 15 [3 mice (2 concentrations and carrier*) x 5 (for a total of 6 IV/IP concentrations and 4 oral gavage concentrations)] x 3 (triplicates)] = 4500 experimental and 4500/2 =2250 donor mice = 6750 mice total.

*Only 4 or fewer mice can be tested at once due the time needed for setting up the mosquito feed. Since this is an initial "dose finding" screen only 2 concentrations and a carrier control will be tested at a time to inform the selection of additional doses for further experiments. This strategy will be explained in more detail in the Refine and Reduce Section.

V.1.3. Experiment 3:

V.1.3.1) Define the stage specificity and timing of compound inhibition from intraerythrocytic development to oocyst formation. *P. berghei* gametocytes can be harvested from the mouse, stimulated to fertilize and over the next 24 hours develop into motile ookinetes *in vitro* (Rodriguez et al. *Exp Parasitol. 2002 May;101(1):73-6. In vitro* development allows direct evaluation of the effects of the compound throughout this period. Understanding the kinetics of compound activity and determining the parasites stages that are susceptible will facilitate in the design of effective dosing strategies. For these experiments, the production of sexual stage parasite will be augmented by pre-treating the mouse with one IP injection of phenylhydrazine

(1.2 mg in PBS) 3 days before the inoculation of 10^8 *P. berghei*-infected RBCs from a donor mouse as described above. Three days after the IP injection of parasitized RBC the mice will be treated with pyrimethamine to eliminate any remaining asexual parasites. One to two days after the pyrimethamine treatment the mouse will be anesthetized with isoflurane and the sexual stage parasites will be harvested by heart puncture. After the cardiac puncture the donor mouse will be euthanized by an overdose of isoflurane and exsanguination. The harvested blood will be centrifuged and the cell pellet will be incubated at 18°C in ookinete medium (RPMI media (KD Biomedical) + 10% Fetal bovine serum (FBS) pH 8.0) for 15 minutes and exflagellation centers will be quantified at 400x magnification. After 1 hour, parasites can be further analyzed for fertilization and zygote formation by measuring DNA content [37] using DNA dye SYTO 59 (Life technologies) and flow cytometry. Ookinetes can be observed up to 24 hours post culture and quantified by Giemsa stained smear. To evaluate the time course and the drug sensitivity of parasites after exflagellation, compound will be administered to the mice by gavage if that is effective or by IV or IP 0-2 h prior to the cardiac puncture or the compound will be added directly to the *in vitro* culture at 20 min, 2 hr, 6 hr and 12 hr after fertilization. If there are differences between stages, additional time points and exposure times could be investigated. The *in vitro* results will be compared to the effect of 1.5 hr *in vivo* compound treatment. Together, the data from this aim will allow us to determine the timing and stage specificity of the selected compounds gametocytocidal activity in *P. berghei*, *in vivo* and *in vitro*. Having a more refined time line for the selected compound's activity in the midgut will identify which stages are susceptible and facilitate the modeling of the effects of compound administration and characterization of the target molecule.

V.1.3.2) It is anticipated that the stage specificity and kinetics of 30 compounds will be analyzed at a maximum of 5 different time points in replicate over the course of the 3 year project. For each compound a carrier control will be needed and for each phenylhydrazine treated mouse a donor mouse is need to provide the initial parasite inoculum. (30 compounds + 30 carrier controls)=60 x 5 time points x 3 (triplicate) = 900 experimental and 900 donor mice= 1,800 mice total

V.2. Data Analysis:

Exp 1: Safety will be assessed qualitatively by screening daily for signs of distress, including , decreased/impaired motility, hunched posture, ruffled fur, difficulty breathing, diarrhea, and skin lesions. If any 2 or these are observed the mouse will be euthanized immediately and no higher doses of compound will be administered. This is a conservative endpoint. It is designed to minimize the exposure of mice to untested compound, not for a statistical analysis

Exp 2: Transmission-blocking activity will be defined as a significant difference in oocyst numbers per mosquito midguts using a Mann-Whitney U Test. The mosquito feed is an established assay for transmission-blocking activity and it has been found that the numbers of oocysts in at least 20 mosquitoes need to be counted to have high confidence about the infectivity of a single mouse. We will then repeat the assay 3 more times to confirm that the effect is due to the treatment. If there is no significant difference between the treated and untreated groups in three mice at the maximum safe dose we will conclude that the compound was not effective.

Exp 3: The production of ookinetes will be counted and used to assess the kinetics and stage specificity using an ANOVA and Bonferroni posttest. The experiment will be repeated 3 times to confirm the results. Enough gametocytes are needed to generate > 30 ookinetes in the control group to have a statistical significance.

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered: All the compounds will first be tested in *in vitro* against parasites and the mammalian cell line, HepG2 and found to have a 10 fold higher potency against parasites than mammalian cells. These initial tests will screen out cytotoxic compounds, however *in vivo* testing is still required to evaluate compound safety and efficacy in a complex living system that contains many cell types that interact with each other and the compound. This complexity cannot yet be reproduced *in vitro* and requires testing in an intact animal.

V.3.2. Animal Model and Species Justification:
The *Plasmodium berghei*/mouse model is well established for testing malaria transmission. It has been used for successfully for years to evaluate anti-malaria drugs and vaccine strategies and found to predict compounds that will also work against human malarias (Ramkaran AE. (1969) Trans R Soc Trop Med Hyg 63(1):8.The sensitivity of *P. berghei* in *A. stephensi* to chemotherapy) and is still the gold standard used today (Baragaña et al. (2015) Nature. 522:315-20).

V.3.3. Laboratory Animals

		Species #1	Species #2
V.3.3.1.	Genus & Species:	*Mus musculus*	
V.3.3.2.	Strain/Stock:	CD-1	
V.3.3.3.	Source/Vendor:	(b)(4)	
V.3.3.4.	Age:	5-10 weeks	
V.3.3.5.	Weight:	20-35 gm	
V.3.3.6.	Sex:	Female so that they can be housed together	
V.3.3.7.	Special Considerations:	NA	

V.3.4. Number of Animals Required (by Species):

Mice 8450 over 3 years

V.3.5. Refinement, Reduction, Replacement (3 Rs):

V.3.5.1. Refinement: The mice will be group housed with environmental enrichment and anesthesia will be used prior to potentially painful or distressful procedures, including the IV

injection, cardiac puncture and Mice will also be monitored closely once they are inoculated with compound or parasites and euthanized if found to exhibit at least 2 of the following signs of distress, decreased/impaired motility, hunched posture, ruffled fur, difficulty breathing, diarrhea, and skin lesions.

V.3.5.2. Reduction:

To minimize the number of compounds that will be tested, initially the compounds pre-screened *in vitro* for a 10 fold great effect on parasites than mammalian cells. Any compounds that have already been tested for safety in mice will be tested for transmission activity at safe concentrations. Only if the compound does not block transmission and there is no published data indicating that higher doses are toxic, will additional higher doses be tested for safety. Additionally, to further reduce the number of mice used only a maximum of 4 compound doses (1, 2, 4, & 8 mg/kg) will be tested for safety before efficacy is tested. These are drug levels that have been found to effectively block transmission with other compounds and it is likely that the safety of higher doses will not have to be tested. Only if the compound is not effective, will higher IV/IP doses up to 128 mg/kg will be tested for safety. 128 mg/kg chosen as the maximal level, since if the compound is not effective at that IV/IP dose it is unlikely to be advanced as an antimalarial.

V.3.5.3. Replacement: All the compounds will be tested for safety and efficacy *in vitro* first and only compounds that are 10 times more effective against parasites than mammalian cells will be advanced for *in vivo* safety testing.

V.4. Technical Methods:

V.4.1. Pain / Distress Assessment:

V.4.1.1. APHIS Form 7023 Information:

V.4.1.1.1. Number of Animals:

	Species #1 CD-1	Species #2
V.4.1.1.1.1. Column C:	2200*	
V.4.1.1.1.2. Column D:		
V.4.1.1.1.3. Column E:	8950*	

V.4.1.2. Pain Relief / Prevention:

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization:

	Substance/Agent	DEA	Amount Given	Delivery Route
1	isoflurane	No	3-5%	inhalation
2	Acepromazine maleate	No	3 mg/kg	IP

3	ketamine	Yes	60 mg/kg	IP

Description and Adverse Effects

Ketamine and Acepromazine maleate are used together as a pharmacological restraint during the 20 min mosquito feed. They are mixed prior to administration by a single IP injection. The correct dose per animal size is needed to avoid an overdose. The loss of eye blink or reflex movement just as a pinch between the toes will be used to confirm anesthesia. For isoflurane breathing rate will also be used to determine anesthesia level

Isoflurane is used as a short acting pharmacological restraint during the IV injection and the cardiac puncture. It is administered by inhalation in a fume hood for the safety of the experimenter. A small piece of gauze soaked in isoflurane is placed at the base of a 50 ml conical tube and then a piece of filter paper or sintered glass filter will be inserted to prevent the mouse from coming into contact with liquid isoflurane. The tube will be held over the mouse's nose. The loss of eye blink or reflex movement just as a pinch between the toes will be used to confirm anesthesia and breathing rate will be used to determine anesthesia level. After cardiac puncture the mouse will be euthanized, while after the IV injection the mouse will be isolated from other mice until it regains consciousness.

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions: N/A

V.4.1.2.3. Paralytics: None

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures:

V.4.1.3.1. Sources Searched: Altweb, PubMed

V.4.1.3.2. Date of Search: Nov 10, 2015

V.4.1.3.3. Period of Search: 1947-present

V.4.1.3.4. Key Words of Search:
Altweb: Berghei, Transmission-blocking, drug development
Pubmed: "Berghei AND Transmission-blocking"

V.4.1.3.5. Results of Search:
Altweb: 0 results were found for berghei as well as transmission-blocking. An article was found for drug development that concluded that following *in vitro* cytotoxicity assays, animal testing was still needed assess the effect of potential drug candidates in intact organisms Rovida, et al. Altex 32(3), 2015

Pubmed: "Berghei AND Transmission-blocking" had 99 articles, including 11 in the past year that used the *in vivo P. bergheil*mouse model to assess malaria transmission.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification

The long term goal of this work is to identify a compound that can be developed as an anti-malaria drug that could be used in humans to eliminate malaria, which currently is responsible for >200 million clinical cases and > half a million deaths/ annually. We are using the well-established rodent malaria, P. berghei/mouse model to evaluate both safety and efficacy as a first step to determine which compounds should be advanced for further development of a drug that could be used in humans. No alternative in vitro models have yet been developed that predict the complex interactions of chemical compounds in the context of an intact organism.

Selected compounds that in vitro are 10 time more active against malaria parasites will be tested for safety in healthy mice using the dose escalation protocol described in Exp 1. The mice cannot be anesthesized during this test, because we need to know the maximum safe dose for the efficacy experiments (Exp 2) and the presence or absence of physical signs of distress are how we are determining safety. Once 2 signs of distress are observed the animal will be euthanized and no higher doses will be tested.

All the mice that are infected with P. berghei including the donors will also be in category E. The parasites required for the experiments proposed in Exp 2 and 3 need to be generated in the mice because Exp 2 is evaluating in vivo efficacy and for Exp 3 there is no other in vitro assay to produce ookinetes. After the initial parasite inoculation it can take a week or longer for the parasitema to reach a high enough level (>10 % parasitemia) for in vivo testing or gametocyte isolation. Generally physical symptoms are not observed until the parastema is >30%, but the course of the infection cannot be precisely predicted. It is not possible to keep the mouse anesthetized during the entire infection therefore, although we monitor the mice daily, we cannot guarantee that the mice will not experience distress and they have been included in category E.

V.4.2. Prolonged Restraint: NA

V.4.3. Surgery: NA

V.4.3.1. Pre-surgical Provisions: NA

V.4.3.2. Procedure: NA

V.4.3.3. Post-surgical Provisions: NA

V.4.3.4. Location: NA

V.4.3.5. Surgeon: NA

V.4.3.6. Multiple Major Survival Operative Procedures: NA

V.4.3.6.1. Procedures: NA

V.4.3.6.2. Scientific Justification: NA

V.4.4. Animal Manipulations:

V.4.4.1. Injections:

-IV injection:the mouse will be pharmacologically restrained using isoflurane, and no more than 200 ul fluid will be injected into the retro orbital venous sinus using a ≤27.5 gauge needle or tail vein using a ≤25 gauge needle.

-IP injection: the mouse will be restrained by hand and less than 410 ul of liquid will be introduced into the peritoneum via a 23 gauge syringe needle. A 23 gauge needle is used to decrease shear stress to the *P. berghei* infected RBCs. Enough shear stress can be generated during rapid flow through a 25 gauge needle to lyse infected and uninfected RBCs.

V.4.4.2. Biosamples:

Samples that will be collected from the mice

Species	Fluid	Amount	Frequency	Site/method	Postmortem
Mus musculus	blood	20 microliters	daily	tail bleed	No
Mus musculus	blood	200 microliters	once	mosquito bite	No
Mus musculus	blood	1 milliliter	once	heart puncture	No

The mice will also be infected with *P. berghei* parasites, which can be lethal if untreated, therefore after infection the mice will be monitored daily for signs of lethargy or distress and will be euthanized if they appear unhealthy.

V.4.4.3. Adjuvants:

In addition to the test compounds the following substances may administered to the mice during the course of the study.

	Substance/Agent	DEA	Amount Given	Delivery Route
1	phenylhydrazine	No	200 ul of 6 mg/ml PBS	IP
2	pyrimethamine	No	200 ul 1 mg/ml PBS-2%Tween20	IP IV or PO
3	RPMI	No	400 ul	IP IV or PO
4	methylcellulose	No	200 ul of a 2% solution	IP IV or PO
5	Polyethylene glycol (PEG)	No	200 ul of a 40% solution	IP IV or PO
6	n-Methylpyrrolidone	No	200 ul of a 25% solution	IP IV or PO
7	DMSO Dimethyl sulfoxide	No	200 ul of a 5% solution	IP IV or PO
8	kolliphor RH40 /cremophor RH40	No	200 ul of a 18% solution	IP IV or PO
9	Ethanol	No	200ul of a 7.5% solution	IP IV or PO

1) Phenylhydrazine induces the parasites to undergo sexual differentiation. The phenylhydrazine protocol is routinely used to enhance the production of sexual-stage *P. berghei* parasites (Rodriquez et al (2002) Exp Parasitol 101:73-76.

2) Pyrimethamine kills asexual parasites and the Tween20 is a nontoxic detergent that helps dissolve the pyrimethamine. Pyrimethamine is actually used therapeutically in human to treat human malaria.
3) RPMI is a type of tissue culture media that can be used in place of PBS to resuspend the parasites to provide more nutrient rich environment which enhances viability. RPMI is used to grow eukaryotic cells *in vitro* and will have no adverse efect on the mice.
4) Methylcellulose is a nontoxic compounds that is used as a thickener and emulsifier in food. It decreases clearance of the compound. Methyl cellulose is not toxic and even approved for use in food.
5) Polyethylene glycol (PEG) is used to enhance the solubility of hydrophobic compounds in aqueous solutions.
6) n-Methylpyrrolidone, like DMSO, it contains both polar and nonpolar regions allowing it to dissolve in water and oil and therefore is used to enhance the solubility of hydrophobic compounds in aqueous solutions.
7) DMSO Dimethyl sulfoxide, Contains both polar and nonpolar regions allowing it to dissolve in water and oil and therefore is used to enhance the solubility of hydrophobic compounds in aqueous solutions.
8) kolliphor RH40 or cremophor RH40 (PEG-40 Hydrogenated Castor Oil) is used to enhance the solubility of hydrophobic compounds in aqueous solutions. It is approved for use in human drug formulations.
9) Ethanol is used to enhance the solubility of hydrophobic compounds in aqueous solutions.

V.4.4.4. **Monoclonal Antibody (MAbs) Production**: NA

V.4.4.5. **Animal Identification**:

-Ear tag: the mouse will be restrained by hand and a small hole will be made in its ear with an ear punch to identify the mouse. There is usually little or no bleeding.

V.4.4.6. **Behavioral Studies**: NA

V.4.4.7. **Other Procedures**:

- PO administration by oral gavage: the mouse will be restrained by hand and a bulb tipped 18 and 20 gauge gastric gavage needle will be used to deliver defined amounts of compound directly into the stomach of mice $\geq$ 25 gms and 20-25 gms. respectively.

-Tail bleed: the mouse will be restrained by hand and a small nick will be made at the tip of the tail. A drop of blood will be collected on a microscope slide, then the nick will be allowed to clot.

-Monitoring for Distress. Following the administration of a compound or the appearance of circulating *P. berghei* parasites, mice will be evaluated daily for distress. Since the compounds we are using have not been administered to mice before the possible symptoms are not known and will require a general screen for decreased or impaired motility, hunched posture, ruffled fur, difficulty breathing, diarrhea, and skin lesions. If any 2 of these are observed the mouse will be euthanized. In the case of *P. berghei*, the parasitemia usually increases to ~10% over the first 5-7 days with few associated symptoms. Depending on the age and genetic background of mouse the parasitemia can plateau at ~30% with few symptoms for another week before the parasites are cleared or the mouse can become anemic. Alternatively, some mice at ~30% parasitemia develop symptoms of cerebral malaria and can die if not treated. The physical

manifestations of cerebral malaria are quite obvious and include difficulty moving (ataxia or paralysis), hunched posture, hyperventilation and convulsions. If a mouse exhibits any two of these after *P. berghei* infection or just one of these signs in combination with a parasitemia of >15% the mouse will be euthanized.
-Mosquito feed: The mouse will be anesthetized with ketamine and acepromazine and laid on the top of a sealed cage containing no more than 90 mosquitoes for 20 min. After the blood meal the mouse will be euthanized by exsanguination under anesthesia or in some cases returned to the cage to recuperate and the mosquitoes will be maintained for 21 days. At that time a naïve mouse will be anesthetized and placed on top of a sealed cage containing the mosquitoes that had previously taken a blood meal from a *P. berghei* infected mouse. After the Plasmodium-exposed mosquitoes have taken a blood meal the mouse is allowed to recuperate and after 5 days the parasitemia will be followed by tail bleed as described above to evaluate whether they were infected.

-Exsanguination by cardiac puncture. The mouse will be anesthetized with isoflurane and a 25 gauge needle will be used to withdraw blood from the heart.

V.4.4.8. Tissue Sharing: A portion of the tissue obtained in the course of the study may be provided to collaborators to assess compound levels for pharmacokinetic evaluation to determine drug absorption, bioavailability, distribution and metabolism.

V.4.5. Study Endpoint:

Exp 1: Mice will be monitored daily for signs of distress for 4 days after compound administration. If no distress is observed they could be transferred to another protocol or euthanized by CO_2 narcosis or anesthetized and exsanguinated by cardiac puncture. If 2 signs of distress are observed including, decreased/impaired motility, hunched posture, ruffled fur, difficulty breathing, diarrhea, and skin lesions and will be euthanized by CO_2 narcosis or anesthetized and exsanguinated by cardiac puncture.

Exp 2: *P. berghei* donor mice will be anesthetized and exsanguinated by cardiac puncture to harvest *P. beghei* infected RBCs for transfer to another mouse.
After exposure of *P. beghei* infected experimental mice to mosquitoes for 20 minutes they will either be euthanized by exsanguination under anesthesia immediately or allowed to revive and continue to be monitored for a week. At this time they could be transferred to another protocol or euthanized by exsanguination under anesthesia or CO_2 narcosis.

Exp 3: *P. berghei* donor and experimental mice will be anesthetized and exsanguinated by cardiac puncture to harvest *P. beghei* infected RBCs for transfer to another mouse or to test in vitro ookinetes development.

If any time a mouse is observed to have 2 signs of distress including, decreased/impaired motility, hunched posture, ruffled fur, difficulty breathing, diarrhea, and skin lesions and will be euthanized by CO_2 narcosis or anesthetized and exsanguinated by cardiac puncture.

V.4.6. Euthanasia:

The mice will be euthanized after being anesthetized and exsanguinated by cardiac puncture to harvest blood. This procedure will be done in a fume hood to protect personnel from inhaling

the anesthetic. Once the mouse has lost consciousness and reflex movement, a 25 gauge syringe needle will be inserted into the heart and the blood will be withdrawn into a 1 ml syringe.

Following the procedure the lack vital signs (breathing and heartbeat) will be observed for 5 minutes to confirm death will be done. The mouse carcasses will be disposed of by incineration.

If a blood sample is not needed a mouse could also be euthanized by CO_2 narcosis followed by cervical dislocation or bilateral thoracotomy.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol.

V.5.1.1. Study Room:
Building(s) (b)(6) Room Number(s) TBD

V.5.1.2. Special Husbandry Provisions: N/A

Food Restriction:	Yes	_____	No	X
Fluid Restriction:	Yes		No	X

V.5.1.3. Exceptions: N/A _____ _____

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care: Animals will be observed and cared for by the Center for LAM personnel according to LAM SOPs.

V.5.2.2. Emergency Veterinary Medical Care: All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: Except as indicated below, all animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents.

V.5.3.2. Enrichment Restrictions: N/A

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein	Name of person performing activity	Qualifications of person performing activity (e.g.,	Specific training in this activity or procedure

injections, euthanasia)		research technician, 2 yrs experience)	(e.g., rodent handling class, 1999)
(handling or care of animals, euthanizing animals, or non-surgical procedures (e.g., administration of drugs or other experimental procedures).	(b)(6)	PI, >20 years of experience work with mice and Plasmodium parasites	Citi and USUHS training courses
(handling or care of animals, euthanizing animals, or non-surgical procedures (e.g., administration of drugs or other experimental procedures).)		Post-doc, > 4 years experience working with the P. berghei/mouse model of malaria	Citi and USUHS training courses
(handling or care of animals, euthanizing animals, or non-surgical procedures (e.g., administration of drugs or other experimental procedures).)		Post-doc, > 4 years' experience working with parasite infected mice.	Citi and USUHS training courses

VII. BIOHAZARDS/SAFETY:

P. berghei is not infectious to humans and there is no mouse to mouse transmission.

Good laboratory practices will be followed. A lab coat and gloves will be worn when working with the compounds, the mice and in the LAM facility. Face mask are not required but will be provided if requested by a staff member.

Isoflurane will be used in a fume hood and all needles will be disposed of in sharps containers.

VIII. ENCLOSURES:

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

(b)(6) 12/8/15

Principal Investigator Signature Date

have attended

G. Training: The following personnel ~~will attend~~ the next USUHS Investigator/Animal User Training Course:

(b)(6) (b)(6)

H. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely, "Responsibility" for implementing animal use alternatives where feasible and conducting humane and lawful research.

(b)(6) 12/8/15

Principal Investigator Signature Date

I. Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

D. Performing Organization: Uniformed Services University of the Health Sciences

E. Funding: (b)(4)

F. Objective and Approach: Malaria is a tropical parasitological disease that remains a global health problem, causing more than half a million deaths and 250 million cases annually. Expanded control and treatment programs in the past decade have reduced the incidence of the disease and led to the call for efforts to eliminate, possibly even eradicate, malaria. To do this new strategies are needed that target the sexual stages of the parasites, called gametocytes that are responsible for disease transmission. The current recommended chemotherapy for malaria does not effectively kill mature gametocytes, allowing malaria to be transmitted for more than a week after the clearance of asexual parasites. Previous drug screens used assays that only detected asexual replication and therefore did not monitor activity against gametocytes. (b)(4) (b)(4) (b)(4) The goal of this research is three fold 1) to use a rodent malaria model to analyze the *in vivo* safety of selected compounds with *in vitro* gametocytocidal activity 2) to use a rodent malaria model to analyze the *in vivo* malaria transmission blocking efficacy of selected compounds with *in vitro* gametocytocidal activity at doses found safe in mice 3) define the stage specificity and timing of compound inhibition from intraerythrocytic development to oocyst formation. Together these approaches should identify classes of compounds that can be targeted for further drug development, as well as advance our understanding of gametocyte metabolism and facilitate the design of effective control strategies. The mouse studies described in this work will be performed in full accordance with the Institutional Animal Care and Use Committee at USUHS. The sequential dose escalation and low dose efficacy testing are designed to minimize the animal usage.

MEMORANDUM FOR DR (b)(6) DEPARTMENT OF MEDICAL AND CLINICAL PSYCHOLOGY

SUBJECT: IACUC Approval of Protocol – Initial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on April 2, 2014:

Title of Application: "Behavioral Investigations of Nicotine and Caffeine in rats (Rattus Norvegicus)"

USUHS Protocol Number: (b)(6)

Expiration Date: April 1, 2017

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

TECHNICIANS(S): (b)(6)

I. NON-TECHNICAL SYNOPSIS:

Stress is a pervasive experience that affects behaviors, cognitions, and biological responses. Insufficient sleep is a particularly disruptive stressor that is experienced by civilians and Warriors. Threat of attack also is a stressor that is commonly experienced by Warriors. Nicotine and caffeine are legal drugs that are used by many civilians and service members. These drugs are often consumed during stressful situations. Each of these variables (i.e., insufficient sleep, threat of attack, nicotine, and caffeine) alone can have psychological effects (on behavior and cognition). It is important to examine if nicotine or caffeine use alters psychological effects of stress – either potentiating or attenuating effects of stressors. The experiments described in this application use a rodent model of Warrior Stress and sleep disruption to determine how psychological responses to stress are altered by nicotine or caffeine administration in male and female rats. The behaviors assessed include motor responses (to index anxiety, depression, . and learning), sensorimotor (including reflexes and nociception), and cognitive responses (including attention, memory, learning). Blood samples will be assessed for stress hormones (corticosterone). It is hypothesized that: the stressors will deleteriously affect the measured behaviors; nicotine will attenuate these effects; caffeine will potentiate these effects; and females will be more sensitive than males to the effects of stress, nicotine, and caffeine.

II. BACKGROUND:

II.1. Background:

Stress is a psychobiological process that can involve physical, psychological (i.e., behavioral, cognitive, motivational/emotional), social demands, or stressors (negative [distress] and positive [eustress]). Responses to acute stressors usually are adaptive, whereas responses to chronic stress often are disruptive to health (McEwen, 2007). Stress is experienced by everyone (civilians and service members) and can affect behaviors and cognitions (Baum, Gatchel, & Krantz, 1997). Nicotine (in tobacco products and in other delivery systems) and caffeine (in beverages and food stuffs) are licit substances that are consumed by many people and are commonly consumed while under stress (Grunberg, Berger, & Hamilton, 2011). Research has examined effects of

stress on drug self-administration (including nicotine and caffeine), but there has been little study of whether consumption of each of these drugs potentiates or attenuates effects of stress. Because these drugs are legal and use is so prevalent, actions of these drugs can be mistakenly underestimated. Whether use of these drugs potentiates or attenuates effects of stress is important to determine whether consumption of nicotine and caffeine while stressed, makes performance and mental health better or worse. This information is needed to advise individuals and decision-makers responsible for the health and performance of individuals who consume these substances while under stress.

The proposed experiments will use an animal model to investigate psychological effects of stressors (sleep disruption, a rat model of "Warrior Stress," or both stressors together). This experiment also will examine whether nicotine and caffeine alter psychological effects of stress. Additionally, we will examine if males and females respond differently to the combination of stress and these licit drugs. Animals (rats) will be used as subjects to allow for true experiments that: manipulate all relevant independent variables; maintain controlled environments and housing conditions; measure all behaviors in comparable ways; and include genetically similar subjects. This type of preclinical investigation has proved to be valuable to gather information about stress, stress effects, and effects of drugs (including nicotine and caffeine; Faraday, 2005; Grunberg, 1992; Grunberg, Berger, et al., 2011; Jacob, Wilson, & Benowitz, 1981). Findings from this investigation will provide information that could later be tested in humans. The following sections provide relevant information about effects of stress and the drugs nicotine and caffeine on behavior and provide the rationale for conducting the proposed experiments.

Stress is pervasive and has short and long term mental and physical health effects (Baum et al., 1997; McEwen, 1998). Additionally, stress affects health behaviors, cognition, and performance. Stressed individuals increase health-harming behaviors (e.g., cigarette smoking; Grunberg, Berger, et al., 2011) and decrease health-promoting behaviors (e.g., exercise; American Psychological Association, 2012). The experience of stress has been associated with decreased attention (Liston et al., 2006) and impairments in learning and memory (Diamond, Fleshner, Ingersoll, & Rose, 1996). Chronic stress and extreme stress have been linked to psychiatric problems such as anxiety, depression, and PTSD (Ford & Kidd, 1998; Goenjian et al., 2000). Stress also negatively affects performance (Beilock, 2008; Motowidlo, Packard, & Manning, 1986; Westman, 1990).

A particularly powerful stressor is **insufficient sleep**. Disrupted and insufficient sleep is a commonly reported condition among civilians and service members (see Military Relevance section below). According to the Center for Disease Control (2011), 37% of Americans report that they sleep less than the recommended 7-8 hours per night. Disturbed and insufficient sleep has been associated with increased use of tobacco and alcohol (McKnight-Eily et al., 2011), poor cardiovascular health (Franzen et al., 2011), and increased suicide attempts (Fitzgerald, Messias, & Buysse, 2011). Poor sleep adversely affects cognitive functioning, including deficits in alertness, attention, and psychomotor vigilance (Wesensten, Killgore, & Balkin, 2005b) as well as results in slow, unstable mental processes filled with errors (Doran, Van Dongen, & Dinges, 2001). Sleep disruption also has serious negative effects on executive (cognitive) function (Killgore, Kahn-Greene, Grugle, Killgore, & Balkin, 2009). This proposal seeks

to incorporate sleep interruption as a stressor of interest to examine effects of insufficient sleep on behavior and potential interactions with nicotine and caffeine.

It is noteworthy that stress is directly associated with drug use, including nicotine and caffeine (Grunberg & Baum, 1985; Grunberg, Berger, & Starosciak, 2010; Kassel, Stroud, & Paronis, 2003; Ratliff-Crain, 1991; Shaham, Klein, Alvares, & Grunberg, 1993; Shiffman, 1993). Several explanations have been offered to explain this association: drug use decreases stress ("self-medication hypotheses"); drugs are used to relieve withdrawal-like symptoms that resemble or are caused by or exacerbated by stress ("withdrawal hypotheses"); stress alters drug actions ("pharmacodynamic hypotheses"); and drug use increases stress which then increases drug use ("positive feedback loop hypotheses"; Grunberg et al., 2010). Despite these speculative mechanisms (b)(6) (b)(6) there has been little direct, empirical examination of psychological effects of stress and nicotine or stress and caffeine, even though these drugs are commonly self-administered. The proposed work is designed to begin to fill this gap.

Nicotine and caffeine are two drugs that can be used legally and are easily accessible. In the U.S. 19% of adults smoke cigarettes (Center for Disease Control and Prevention, 2012) that contain nicotine and 90% of individuals consume caffeine (Iversen, Iversen, Bloom, & Roth, 2009). These numbers rise when other nicotine-containing substances (e.g., chew, dip, cigars, nicotine replacement products) are included. These numbers rise even more for military personnel for nicotine (see below).

Nicotine. Nicotine, the primary pharmacologically-active drug in tobacco, has many effects that reinforce its self-administration. Nicotine's reinforcing effects include: physical dependence, decreased appetite, improved attention, perceived stress relief, and pain reduction. Our laboratory has contributed to these findings using rat paradigms to conduct true experiments which have produced results that have been later confirmed in human samples (Acri, Morse, Popke, & Grunberg, 1994; Faraday & Grunberg, 1999; Grunberg, 1982, 1989, 1991, 1997; Grunberg & Phillips, 2004; Winders & Grunberg, 1989). The question remains, however, whether using nicotine while under stress makes stress responses better or worse – a question that has not yet been examined.

Nicotine is reported to improve cognitive functioning (Amitai & Markou, 2009; Potter & Newhouse, 2008). Nicotine also is associated with improved cognitive and motor performance (Rose, Ross, Kurup, & Stein, 2010). This drug is unusual in that it has been classified as a sympathomimetic drug (*Goodman & Filman's The Pharmacological Basis of Therapeutics*, 2006) but it also has a paradoxical dual action to either increase or decrease sympathetic nervous system activity depending on the physiological and psychological state of the individual (Grunberg & Starosciak, 2010; USDHHS, 1988). As mentioned above, cigarette smoking increases during stress. Some investigators have suggested that this increase results because nicotine (acting via *positive reinforcement*) reduces stress and that smokers are self-medicating to relieve the symptoms of stress (e.g., irritability; Grunberg, Berger, et al., 2011). However, this suggestion has not been the focus of careful empirical investigations in animals or in human subjects. Because nicotine in tobacco products are addictive (USDHHS, 1988), studies of nicotine over the past 20 years have focused on mechanisms underlying the addiction process and development of tobacco cessation products, including new nicotine delivery systems and medications that mimic effects of nicotine. Investigators have not examined effects of nicotine to potentially reduce stress.

Considering that stress often disrupts cognitive processing and other behaviors along with reported effects of nicotine, we hypothesize that nicotine will attenuate disruptive effects of stress on cognitive function and other behaviors.

Caffeine. Caffeine is another licit substance that is associated with improved cognitive functioning and performance (Seidl, Peyrl, Nicham, & Hauser, 2000). Many studies have reported that caffeine can be used safely and effectively to improve performance and stave off fatigue (Baranski et al., 2001; IOM-CMNR Institute of Medicine Committee on Military Nutrition Research, 2001). Yet, few studies have examined effects of caffeine under stressful situations (Sunram-Lea, Owen-Lynch, Robinson, Jones, & Hu, 2012). The research that is available reports that caffeine is associated with increases in glucocorticoids (e.g., cortisol, ACTH; Dhingra et al., 2007; Gavrieli et al., 2011; Hino et al., 2007; Lin, Uhde, Slate, & McCann, 1997) – these previous studies have not focused on behavioral or cognitive effects of caffeine and stress. Because caffeine indirectly activates some of the same pathways that stress activates (e.g., sympathetic nervous system), the combination of caffeine and stress may affect behavior and health in undesirable ways (James, 2004, 2011). In addition, caffeine may interfere with sleep and, thereby, increase stress. Sleep hygiene guidelines, for example, suggest avoiding caffeine consumption 6 hours before going to sleep (Alabama Sleep Clinic, 2012). Most of the reported research studying caffeine and sleep has investigated how caffeine can be used to offset deleterious effects of sleep disruption and to delay sleep onset. These investigations, however, have not considered caffeine's effects when other stressors (e.g., threat of attack – see below under Independent Variables "Warrior Stress Paradigm") are present.

The relationship between caffeine, stress, and poor sleep has not been examined. It is important to understand how these variables interact to affect behavior because caffeine is used by most civilians and almost all service members and these individuals experience stress. It also is important to examine how these variables interact because the use of these drugs increases during times of stress and potentially (especially in the case of caffeine) during times of limited sleep. We hypothesize that caffeine will potentiate effects of stress.

Males and females. The male psychological and biological stress responses have been extensively studied in animals and humans and can be summarized as the "fight-or-flight response" (Cannon, 1935; Faraday, 2005; Mason, 1975; Selye, 1946, 1973). In response to stress, males generally become aggressive (fight) or escape the threatening situation (flight). The female stress response involves similar biological systems (i.e., the sympathetic branch of the autonomic nervous system and the hypothalamic-pituitary-adrenal axis) but seems to involve different behavioral responses that have been called the "tend-and-befriend" response (Taylor et al., 2000). When a female experiences stress, the fight-or-flight response still occurs but she also increases care for her young and/or seeks social interaction. There has been relatively little experimental examination of sex differences in stress responses; animal subjects allow for true experiments to be conducted ethically and logistically. For example, we recently discovered that female rats display more anxiety-related behavior and more depression-related behavior after exposure to a "Warrior Stress" (see below) than do male rats (Yarnell, 2012a). In addition, we have found that female rats are more sensitive to stress than male rats with regard to peripheral stress hormones (i.e., corticosterone).

The proposed experiments include male and female rats as subjects to investigate sex differences in effects of nicotine and caffeine during stress. We

hypothesize that females will be particularly sensitive to effects of stress and to effects of these drugs on stress.

II.2. Literature Search for Duplication:

II.2.1. Literature Source(s) Searched:

Medline (PubMed), PsycInfo, F1000Biology (and electronic journal review service), BRD, and RePORT

II.2.2. Date of Search:

February, 2014

II.2.3. Period of Search:

All years available on each database (ranging from past year to past 30 years)

II.2.4. Key Words and Search Strategy:

Nicotine, chronic nicotine administration, acute nicotine administration, caffeine, stress, rats, sex differences, age differences, locomotion, activity, neurobehavioral functioning, hot plate, nociception, acoustic startle reflex, pre-pulse inhibition, passive avoidance, memory, anxiety, depression, cognition (words are entered separately and in combination; rat is entered with each term [i.e., rat+nicotine+stress+locomotion/activity, rats+nicotine+stress+neurobehavioral functioning, rat+nicotine+stress+hotplace/nociception, rat nicotine+stress+acoustic startle response/prepulse inhibition, rats+nicotine+stress+passive avoidance/learning, rats+nicotine+stress+anxiety/depression, rats+nicotine+stress+cognition, etc)) have been searched in data base searches. We also read electronic and paper journals regularly and search for phrases, titles, and abstracts relevant to our work.

II.2.5. Results of Search:

There has been extensive work on stress, nicotine, and the various behavioral measures included in our work (i.e., nicotine + various behavioral measures, stress + behavioral measures). There has been some work on effects of caffeine in rats and the various behavioral measures. However, there has been little work combining these variables in the ways that we do (e.g., effects stress and nicotine on behavioral responses). The Warrior Stress Paradigm (b)(6) methods/results have not been published. Sleep disruption has been studied in rats (>60,000 hits), but not looking as extensively at the different behavioral measures or in combination with nicotine, caffeine, or the Warrior Stress Paradigm. Also, research has focused more on male rats. Overall, literature searches on the topics to be covered in our experiments indicate the value of our approaches and have not revealed existing literature or data that would supercede our experiments.

III. OBJECTIVE\HYPOTHESIS:

The current proposal focuses on psychological (especially behavioral and cognitive) effects of stress, nicotine, and caffeine using animal models (male and female rats) to allow for carefully controlled experimental examination of behavioral measures related to anxiety, depression, sensorimotor reflexes, attention, learning, and memory. The overarching aim of this project is to enhance the health of Warriors under stressful conditions by investigating whether nicotine (which Warriors self-administer via smokeless and smoked tobacco products) and caffeine (which Warriors self-administer via caffeinated beverages and caffeine pills) alter behavioral responses to stress. We hypothesize that nicotine will attenuate effects of stress, whereas caffeine will potentiate

effects of stress, and that effects of stress and of these drugs will be greater in females than in males.

Specific Aim 1: To determine effects of military-relevant stressors (threat of attack; sleep disruption) on behaviors (motor, sensorimotor, cognition) in male and female rats.

Hypothesis 1: Stress will deleteriously affect the measured behaviors, including: motor (increased indices of anxiety and depression based on particular locomotor activity parameters); sensorimotor (impaired neurobehavioral functioning); and cognition (impaired attention, learning, and memory).

Specific Aim 2: To determine whether nicotine alters the effects of stress.

Hypothesis 2: Nicotine will attenuate deleterious effects of stress on motor (i.e., decrease behavioral measures related to anxiety and depression), sensorimotor (i.e., improve sensorimotor responses), and cognitive measures (i.e., attenuate deleterious effects of stress on attention, learning, and memory).

Specific Aim 3: To determine whether caffeine alters the effects of stress.

Hypothesis 3: Caffeine will potentiate deleterious effects of stress on motor (i.e., increase behavioral measures related to anxiety and depression), sensorimotor (i.e., worsen sensorimotor responses), and cognitive measures (i.e., worsen deleterious effects of stress on attention, learning, and memory).

Specific Aim 4: To determine if males and females are affected differently by the combination of stress and licit drugs (nicotine or caffeine).

Hypothesis 4: Females will be particularly sensitive to effects of stress and to effects of these drugs on stress (i.e., nicotine will be more beneficial for female than for male rats under stress; caffeine will be more deleterious for female than for male rats under stress).

IV. MILITARY RELEVANCE:

Warriors experience unique **stressors** associated with deployment and combat exposure, and recent reports indicate a dramatic increase in combat exposure and greater rates of anxiety, depression, and acute stress disorder (Joint Mental Health Advisory Team, 2011). In addition, psychological stress is highly correlated with drug use and abuse (Grunberg, Berger, et al., 2011). Deployment stressors place Warriors at significant risk of physical and mental health consequences that disrupt day-to-day life as well as performance under pressure (Vasterling et al., 2006). These consequences include neurological compromise, anxiety, depression, and posttraumatic stress disorder (PTSD). Hoge and colleagues (Hoge et al., 2004) reported that a significant percentage of service members met criteria for major depression, PTSD, and drug use after deployment. In another sample, 35% of Veterans who served in Iraq sought mental health services in the year following their return and 12% were diagnosed with a mental health problem (Hoge, Auchterlonie, & Milliken, 2006). Additionally, multiple deployments have been associated with more psychological problems, decreased morale, and increased use of psychopharmaceuticals (Joint Mental Health Advisory Team, 2011).

Many of the stressors experienced by service members are comparable to stressors experienced by civilians (e.g., work demands, family pressures, and insufficient sleep). Even the threat of death (that is experienced by service members in combat) may be experienced by police officers, firefighters, and civilians who are in dangerous situations (e.g., domestic violence, living or traveling in high crime rate

areas). What is unique about the Warriors experience is that the stressors are often extreme versions of stressors and are often experienced simultaneously and for extended periods of time. For example, it is typical for a Warrior to have interrupted sleep, go on a life threatening mission, and be required to perform (behaviorally and cognitively) under environmentally unpleasant conditions (e.g., loud noises) day after day. A majority (70-91%) of Warriors returning from combat report sleep-related disturbances (Ulmer, Edinger, & Calhoun, 2011). Service members who have disturbed and insufficient sleep are at risk for poor cardiovascular health (Franzen et al., 2011) and increased suicide attempts (Fitzgerald et al., 2011). Additionally, they may increase the use of licit drugs (e.g., nicotine and alcohol) because of poor sleep (McKnight-Eily et al., 2011).

The proposed experiments will evaluate behavioral and cognitive effects of **military-relevant stressors using rat paradigms** developed in our laboratory to model sleep disruption, threat of attack, and exposure to environmental mild stressors (Grunberg, 2011; Kwon et al.; Perry, 2009; Yarnell, 2012a; Yarnell, Chwa, Hamilton, & Grunberg, 2011; Yarnell & Grunberg, 2012). These experiments also will examine whether nicotine and caffeine (legal drugs that are consumed by many service members while in stressful situations) alter behavioral, cognitive, and biological effects of stress.

Although about 1/5 American civilians smoke cigarettes, almost 1/3 military personnel currently smoke cigarettes and even more use smokeless **nicotine**-containing tobacco products (Bray & Hourani, 2007). Many young never-smokers and occasional smokers become regular smokers after military basic training (Haddock, Klesges, Talcott, Lando, & Stein, 1998), suggesting that the military environment (e.g., high stress) may be a factor in smoking initiation. Perhaps, intake of nicotine is a way to help attenuate the stress of military life.

Caffeine consumption is not monitored in the military and there are no statistics available for the use or abuse of caffeine in this organization. Nonetheless, any member of the military will report that Warriors consume vast quantities of caffeine (James, 2011; Moosey, 2012; Yarnell, 2012b). Popular energy drinks are sold in the exchange and others are free in the dining hall. Coffee is also a staple for most Troops. Standard rations include caffeine supplements in the form of caffeinated gums and powdered drinks (Armed with Science, 2011). The use of caffeine is encouraged as a way to enhance performance and counter effects of sleep disruption (IOM-CMNR Institute of Medicine Committee on Military Nutrition Research, 2001). This recommendation was made based on extensive scientific investigation (IOM-CMNR Institute of Medicine Committee on Military Nutrition Research, 2001). However, effects of caffeine while under stress (e.g., in combat situations where service members may be exposed to stressful and traumatic events) have not been examined. We hypothesize that caffeine intake while under stress may exacerbate effects of stressors.

The experiments that we propose focus on behavioral, cognitive, and biological effects of nicotine, caffeine, and stress in rat paradigms to better understand how these variables are interacting. This work is intended and designed to be relevant to the health and well-being of military personnel living and working in various environments.

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures:

(b)(6) research program has produced a robust characterization of effects of **nicotine**, including effects on: reward and addictive processes, food consumption and body weight, attention, anxiety-like behavior, nociception, and heart morphology (Elliott, Faraday, & Grunberg, 2003; Grunberg & Phillips, 2004; Winders & Grunberg, 1989). (b)(6) discovered that there are sex and age differences in responses to nicotine in adolescent and adult rats (Faraday, Elliott, & Grunberg, 2001; Grunberg, Winders, & Wewers, 1991). (b)(6) reported effects of **caffeine** to alter cognitive processes in rats (Faraday & Grunberg, 1999) and humans (Stine, O'Connor, Yatko, Grunberg, & Klein, 2002).

(b)(6) have examined how **stress** changes the actions of nicotine and related self-administration and withdrawal behaviors. (b)(6) discovered that stress alters pharmacokinetic and pharmacodynamic effects of nicotine consistent with increased nicotine self-administration during stress (Grunberg, Morse, & Barrett, 1983; Winders, Grunberg, Benowitz, & Alvares, 1998). (b)(6) discovered that: stress exacerbates behavioral sensitization to nicotine (an index of the development of drug dependence; Hamilton, Starosciak, Chwa, & Grunberg, 2012); nicotine withdrawal occurs in male and female rats and is affected by environment relevant to stress (Hamilton, Berger, Perry, & Grunberg, 2009); and withdrawal effects of nicotine differ based on rat strains relevant to stress-sensitivity (Perry, 2009). We have yet to examine how nicotine or caffeine alter psychological effects of stress. In other words, does nicotine or caffeine change responses to stress?

(b)(6)

For example, one military-relevant project (b)(6) focused on effects of **predator stress** and **sleep disruption** (SD) on the behavior of rats. (b)(6) developed an effective sleep disruption paradigm for rats. Results indicated that rats in the sleep disruption condition displayed greater anxiety-like behavior, increased alcohol consumption, and higher corticosterone blood levels (a biomarker of stress; Perry, 2009). Moreover, sleep disrupted female rats were more anxious than males.

(b)(6) "Warrior Stress Paradigm" (WSP) that uses rats to model impending threat of attack in novel environments (Kwon et al.; Yarnell, 2012a; Yarnell et al., 2011; Yarnell & Grunberg, 2012) based on previous studies (Berger, 2009; Hamilton, 2010; Hayley, Borowski, Merali, & Anisman, 2001; Long, 2010; Meyerhoff, 2006; Perry, 2009; Starosciak, 2010; Willner, Towell, Sampson, Sophokleous, & Muscat, 1987) . The WSP attempts to model the anticipatory stress that a Warrior experiences prior to conducting a life threatening mission and the disruptive stimuli that are found in a deployed setting. Rats are exposed to a combination of the threat of death (predator scent) and specific, disruptive environmental stimuli (e.g., flashing lights, loud noise) for 20 minutes per day for 7 days. This combination produces a mild stress response in the rat.

The proposed experiments build on this work by investigating effects of two powerful, military-relevant stressors (sleep disruption and the Warrior Stress Paradigm) individually and in combination. Additionally, these experiments will examine whether nicotine and caffeine alter the behavioral effects of stress.

(b)(6) (b)(6) The Revised Neurobehavioral Severity Scale (NSS-R) is a series of 10 sensory and motor tests (Grunberg, Yarnell, Chwa, Hutchison, & Barry, 2011; Yarnell, 2012a; Yarnell, Barry, & Grunberg, in preparation; Yarnell & Grunberg, 2012). This test battery is based on similar versions found in the literature (Hamm, 2001; Mahmood et al., 2001; Shohami, Novikov, & Bass, 1995), but offers a more reliable and sensitive way to conduct the assessment for changes in neurobehavioral functioning (b)(6) (b)(6) to investigate five different forms of brain injury in rats and mice (Cole et al., 2011; A. Sharma et al., in preparation; P. Sharma, Su, Barry, Grunberg, & Lei, 2012). (b)(6) found changes in response to stress using this test battery (Yarnell, 2012a; Yarnell & Grunberg, 2012). In the proposed experiment the NSS-R will be used to test how sleep disruption and "Warrior stress" affect **sensory and motor function**. Rats' performance as a result of these stressors and under the influence of nicotine and caffeine will be tested.

The experiments that are included in this research application are designed to build upon our recent findings. We have the relevant conceptual knowledge and technical experience to perform the proposed experiments. We have developed all of the procedures to manipulate non-painful stress and to measure behavioral indices of sensory and motor performance, memory, attention, anxiety, and depression. These measures will be used in the proposed project to determine if nicotine or caffeine alters effects of stress on behavior.

V.1.1. Experiment 1: Biobehavioral effects of nicotine and stress in a rat model

This experiment is designed to determine the behavioral and biological effects of stress and nicotine in rats. It is hypothesized that: (a) stress will deleteriously affect the measured behaviors, including motor (increased indices of anxiety and depression based on particular locomotor activity parameters); sensorimotor (impaired neurobehavioral functioning; and cognition (impaired attention, learning, and memory); (b) nicotine will attenuate deleterious effects of stress on motor (i.e., decrease behavioral measures related to anxiety and depression), sensorimotor (i.e., improve sensorimotor responses), and cognitive measures (i.e., attenuate deleterious effects of stress on attention, learning, and memory); (c) effects of stress, nicotine, and the combination will be more pronounced in female than in male rats (i.e., nicotine will be more beneficial for female than for male rats under stress).

Design: This experiment is a 3 (control, 3 mg/kg, 6 mg/kg) x 4 (no stress, WSP, SD, WSP+SD) x 2 (male, female) full factorial mixed design = 24 treatment groups. Each animal will be evaluated before and after injury. There will be 10 animals per each of the 24 treatment groups for a total of 240 animals (plus 20 animals for pilot work). **Grand total of 260 rats are requested.** This experiment will be run in cohorts of 24 – 48 animals per cohort. The "pilot" animals are needed to train personnel in the techniques used in this experiment.

Subjects: Subjects will be young adult male and female Sprague-Dawley rats (2 - 3 months old). This strain and age is comparable to subjects used in many of our previous experiments with rats.

Induction of "Stress": For animals in the WSP group, non-painful stress will be manipulated by exposure for 20 min per day for 7 days to fox urine and lights or sounds as developed and used in our laboratory (Acri et al., 1994; Berger, 2009; Faraday,

2000; Hamilton, 2010; Kant, Leu, Anderson, & Mougey, 1987; Kant, Mougey, & Meyerhoff, 1986; Long, 2010; Perry, 2009; Raygada, Shaham, Nespor, Kant, & Grunberg, 1992; Shaham, Klein, Alvares, & Grunberg, 1993; Starosciak, 2010; Yarnell et al., 2011). Environmental stimuli to manipulate stress include lights, noises (e.g., whistle, laboratory timer), and tilting the cage based on Willner et al. (1987). A combination of these stimuli avoids habituation of the stress response. Details are provided below (See section V.4.4.7). For animals in the SD group, their sleep will be disrupted for 9 out of 12 of the animals' 12 hour sleep period for 7 days as developed and used in out laboratory (Perry, 2009). Details are provided below (See section V.4.4.7).

Drug administration. Nicotine will be administered chronically via subcutaneous minipump implanted in a brief surgical procedure followed procedures develop by Grunberg (1982) to model exposure to nicotine comparable to levels achieved by human cigarette smoking and to be comparable to dosages that can be achieved by medicinal nicotine patches (Winders et al., 1998). Details are provided below (See section V.4.3.2).

Dependent measures. Measures include body weight, food and liquid consumption, activity, attention, memory, anxiety, depression, sensory responses, and blood chemistry (corticosterone [to index stress], nicotine, cotinine [primary metabolite of nicotine]). Details are provided below (See section V.4.4.6).

Procedure. Animals will acclimate to the facility for 2 days. Each animal then will be handled 3 - 5 min/day for 3 days to minimize handling stress. Animals will be assigned to treatment groups such that same-sex groups have similar body weights. Minipumps will be implanted to deliver nicotine or saline. Stress will be started after minipump implantation and will continue for 7 days, then behavior will be measured, then continued for another 7 days with behavior measured at the end before the end of the study. See Timeline below for details (See section V.4.5). Animals will be euthanized by exposure to carbon dioxide followed by decapitation following LAM procedures. Blood will be collected, prepared, and stored for later analyses. Brains will be removed and stored for later tissue sharing analyses.

V.1.2. <u>Experiment 2: Biobehavioral effects of of caffeine and stress in a rat model</u>

This experiment is designed to determine the behavioral and biological effects of stress and caffeine in rats. It is hypothesized that: (a) stress will deleteriously affect the measured behaviors, including motor (increased indices of anxiety and depression based on particular locomotor activity parameters); sensorimotor (impaired neurobehavioral functioning; and cognition (impaired attention, learning, and memory); (b) caffeine will potentiate deleterious effects of stress on motor (i.e., increase behavioral measures related to anxiety and depression), sensorimotor (i.e., worsen sensorimotor responses), and cognitive measures (i.e., worsen deleterious effects of stress on attention, learning, and memory); (c) effects of stress, caffeine, and the combination will be more pronounced in female than in male rats (i.e., caffeine will be more deleterious for female than for male rats under stress).

Design: This experiment is a 3 (control, 1.5 mg/ml, 3 mg/ml) x 4 (no stress, WSP, SD, WSP+SD) x 2 (male, female) full factorial mixed design = 24 treatment groups. Each animal will be evaluated before and after injury. There will be 10 animals per each of the 24 treatment groups for a total of 240 animals (plus 20 animals for pilot work). **Grand total of 260 rats are requested.** This experiment will be run in cohorts of 24 – 48

animals per cohort. The "pilot" animals are needed to train personnel in the techniques used in this experiment.
Subjects: identical to Experiment 1
Induction of stress: identical to Experiment 1
Exposure to caffeine: Caffeine will be administered through the drinking water based on the procedures of Holtzman (1983) and Goldberg and colleagues (Gasior, Shoaib, Yasar, Jaszyna, & Goldberg, 1999; Jaszyna, Gasior, Shoaib, Yasar, & Goldberg, 1998; Shoaib, Swanner, Yasar, & Goldberg, 1999) to model exposure to caffeine comparable to levels achieved by human consumption. In order to reduce the amount of additional stress (since stress is an independent variable), we decided not to use a gavage to administer caffeine. This oral self-administration method has been reported to be reliable. Water bottles are weighed daily to measure consumption. In addition, biological samples are taken at the end of the study to validate caffeine exposure. Details are provided below (See section V.4.1.2.2).
Dependent variables: Identical to Experiment 1
Procedure: Identical to Experiment 1 except that caffeine will be manipulated instead of nicotine.

V.2. Data Analysis:

Samples sizes (n=10 per experimental "cell") for each experiment were based on previous experiments in our laboratory and in the published literature that have yielded statistically significant findings with behavioral and biological dependent variables comparable to those to be used in the proposed experiments. Specifically, moderate to large effect sizes (η^2= 0.06-0.14) are expected for behavioral measures in response to stress and drug manipulations. Power analyses (G*Power) are based on previous experiments in our laboratory which yielded these effect sizes in samples of ten per "cell." The data will be analyzed by ANOVA or MANOVA (with and without covariates) with repeated measures as appropriate. Tukey HSD *post hoc* tests or Dunnett's t will be used to compare differences between conditions. All analyses will be two-tailed with alpha = 0.05.

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered:

This research project relies on behavioral responses in living organisms. Rats are subjects because their responses are similar to and predictive of human responses. Non-animal alternatives such as computer modeling and cell cultures were considered but are not suitable to assess behaviors in organisms because there currently are no non-animal alternatives that provide information about effects of stress, nicotine, and caffeine in living organisms.

V.3.2. Animal Model and Species Justification:

Rats are the subjects because they allow for true experiments to be conducted and because biobehavioral findings with rats have been excellent predictors of information relevant to the human condition. There is an abundance of research literature using rats in animal models of a variety of human conditions including drug abuse, stress, and mental and physical health disorders. With regard to the present research, for example, rat models have been used extensively to investigate stress, nicotine, and caffeine (e.g., Acri et al., 1994; al'Absi, 2012; Balfour et al., 1986; Barron et al., 2005; Benwell & Balfour, 1985; Collins et al., 1986; Corrigall & Coen, 1989, 1991;

Gasior et al., 1999; Glick et al., 1970; Goldberg, 2012; Goldberg et al., 1981; Grunberg, 1982, 1992; Hansen, 1979; Holtzman, 1983; Jaszyma et al., 1998; Larson et al., 1961; Marks et al., 1986; Shoaib et al., 1999; Slotkin et al., 1986). Our laboratory has used rats, mice, other rodents, and primates in our research. Our findings with rats have been reliable (in our laboratory and in other laboratories) and have proven to be valid in predicting effects in human subjects and human populations with regard to the topics that we study.

Subjects. Subjects are male and female Sprague-Dawley rats, the most commonly used lab rats in various studies, including investigations of stress and licit drugs. Sprague-Dawley albino rats are considered to be the standard test rat for nicotine and stress experiments. Adult animals are approximately 55 days old upon arrival (Spear, 2000) and in consultation with the breeder.

V.3.3. Laboratory Animals		**Species #1**	**Species #2**
V.3.3.1.	**Genus & Species:**	Rattus norvegicus (Rat)	
V.3.3.2.	**Strain/Stock:**	Sprague-Dawley	
V.3.3.3.	**Source/Vendor:**	(b)(4)	
V.3.3.4.	**Age:**	Adult (about 55 days)	
V.3.3.5.	**Weight:**	Adult males (about 200 grams); adult females (about 150 grams)	
V.3.3.6.	**Sex:**	Males and females	
V.3.3.7.	**Special Considerations:**	N/A	

V.3.4. Number of Animals Required (by Species): 520 rats

Please note: Each experiment will be run as a series of smaller sub-experiments for logistical reasons:
Experiment 1 = 240 rats (plus 20 additional pilot rats) = 260 rats
Experiment 2 = 240 rats (plus 20 additional pilot rats) = 260 rats

V.3.5. Refinement, Reduction, Replacement (3 Rs):

V.3.5.1. Refinement: Animals are carefully monitored to limit or avoid pain and distress. Animals are observed daily for any behavioral signs of distress, including vocalizations, weight loss, changes in food consumption, changes in reactivity, and any signs of injury. If there are any indications of pain or distress, then the LAM staff is consulted. With regard to logistical and technical refinements, many of the behavioral assessments use automated equipment interfaced with computers to allow for the collection of dozens of parameters simultaneously. The use of sophisticated software and computerized technologies allows us to collect fine-grained and complete data sets for

every animal included in the experiment, eliminating the need for additional studies that might otherwise have been necessary. Our many years of behavioral investigations regarding stress and various drugs also have allowed us to minimize the sample sizes as we have refined testing to be sensitive and reliable.

V.3.5.2. Reduction: The sample sizes for the proposed work were derived from power analyses of pilot data and past work in our laboratory and in other laboratories. These samples sizes, therefore, constitute the minimum number of animals necessary to obtain meaningful results and represent a useful application of knowledge of statistical effect size and the concept of power. In addition, in each experiment multiple dependent variables are measured. Measurement of many variables in the same animals markedly reduces the total number of experiments conducted.

V.3.5.3. Replacement: There are no appropriate replacement methods (in-vitro, computer models) for the proposed work.

V.4. Technical Methods:

V.4.1. Pain / Distress Assessment:

Animals will be anesthetized during implantation of minipumps (in Experiment 1). Animals will be observed daily by investigators and by LAM staff to check health and well-being and to insure that there is no undue pain or distress based on behaviors and vocalizations. Any indications of pain or distress will be dealt with by alleviating the cause of the problem and/or by contacting LAM personnel for assistance and guidance

V.4.1.1. APHIS Form 7023 Information:

V.4.1.1.1. Number of Animals:

	Species #1	Species #2
V.4.1.1.1.1. Column C:	80	
V.4.1.1.1.2. Column D:	40	
V.4.1.1.1.3. Column E:	400	

V.4.1.2. Pain Relief / Prevention:

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization:

In Experiment 1 (to implant minipumps), subjects are first anesthetized by inhalation anesthetic to prevent pain. Isoflurane is mixed with oxygen (i.e., 2 – 4% Isoflurane; with an oxygen flow rate of 0.5 - 1.0 liters/minute). Subjects are placed inside an induction chamber saturated with Isoflurane vapor. Subjects are removed from the chamber when tail pinch produces no reflex movement and anesthesia is maintained using a mask/nose cone attached to the anesthetic vaporizer (with Isoflurane concentration ranging from 0.25 – 3% to maintain appropriate depth of anesthesia)

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions:

The non-surgical procedure that may induce momentary discomfort (e.g., hot plate test of nociceptive responses) is included for scientific purposes and is short in duration (< 60 sec). Animals are observed daily by investigators and by LAM staff to check on their health and well-being and to assure that there is no undue pain or distress. Animals also are carefully monitored during behavioral testing procedures. In addition, animals are closely monitored during all procedures that involve any pain or potential distress (e.g., during and after minor surgery; during and after injections). Pain/distress is assessed based on behaviors and vocalizations. Any indications of

pain or distress are dealt with by alleviating the cause of the problem or by contacting LAM personnel for assistance and guidance.

Caffeine (obtained from Sigma) will be administered based on the procedures of Holtzman (1983) and Goldberg and colleagues (Gasior, Shoaib, Yasar, Jaszyna, & Goldberg, 1999; 1981; Jaszyna, Gasior, Shoaib, Yasar, & Goldberg, 1998; Shoaib, Swanner, Yasar, & Goldberg, 1999). This paradigm is considered to be the optimal strategy to model caffeine consumption in humans (al'Absi, 2012; Gasior et al., 1999; Goldberg, 2012; Jaszyna et al., 1998; Shoaib et al., 1999). Rats in the lower caffeine condition will receive drinking water with caffeine increased from 0.25 mg/ml to 1.5 mg/ml over the course of 10 days. After the initial 10 days, rats in this condition will receive drinking water with 1.5 mg/ml for the remaining 10 days of the experiment. Rats in the higher caffeine condition will receive drinking water with caffeine base increased from 0.25 mg/ml to 3 mg/ml over the course of 15 days. After the initial 15 days, rats in the higher caffeine condition will receive drinking water with 3 mg/ml caffeine for the remaining 5 days of the experiment. It is noteworthy that the route of administration (oral ingestion) at the particular concentrations that will be used produced behavioral effects in rats and are considered to be (based on the published literature and communication with the investigators cited) the optimal approach to parallel human consumption of caffeine of servicemen. Currently in the military, consumption of approximately 200-300 mg of caffeine is encouraged to enhance performance and delay sleep onset during continuous operations (IOM-CMNR, 2001). This recommendation is based on extensive research (Killgore et al., 2009; Lieberman, Tharion, Shukitt-Hale, Speckman, & Tulley, 2002; McLellan, Bell, & Kamimori, 2004; McLellan et al., 2005; McLellan, Kamimori, Voss, Tate, & Smith, 2007; Wesensten et al., 2002; Wesensten, Killgore, & Balkin, 2005a) that examined effects of caffeine on performance in rested and sleep-deprived service members. Warriors report consuming greater than 300 mg per day (Lieberman, 2012) and those who use energy drinks may be consuming 80 mg - 500 mg per serving ("Caffeine content of drinks," 2012). Therefore, it is likely that service members are consuming more than moderate doses of 200-300 mg.

We also will use two mild stress paradigms ("Warrior Stress Paradigm" and "Sleep Disruption" described in Section V.4.4.7. below). WSP involves 10 – 20 min exposure to fox urine on a cotton ball and some environmental mild stressors detailed below (e.g., overhead lights turned on and off). This procedure is repeated once/day for 14 days (with a 3 day break for behavior after the first 7 days) for animals in the WSP and WSP+SD groups. Animals are free to move around a cage and are not restrained in any way. For animals in the SD and WSP+SD groups, it will involve their natural sleep being disrupted by noises (e.g., loud banging, bells, voices) during 9 total hours of the animals' 12 hour sleep period for 14 days (with a 3 day break for behavior after the first 7 days). Sounds will vary from 65 - 80 dB. Total duration of the sounds range from 6 seconds to approximately 1 minute. Total hourly sound exposure will not exceed 6 minutes at any time during this study. Animals are free to move around a cage and are not restrained in any way.

V.4.1.2.3. Paralytics: N/A

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures:

V.4.1.3.1. Sources Searched:

Medline (PubMed), PsycInfo, F1000Biology, AGRICOLA

V.4.1.3.2. Date of Search:
February, 2014
V.4.1.3.3. Period of Search:
All years available on each database are searched (from recent work up to 30 years in the past).
V.4.1.3.4. Key Words of Search:
osmotic minipumps, minipump implantation, chronic administration paradigms, pain, alternatives, analgesia, anesthesia, surgery, acute drug administration, stress, rat (these words are searched in various combinations[i.e., rat+osmotic minipump+pain, rat+osmotic minipump+alternatives, rat+osmotic minipump+analgesia, rat+osmotic minipump+anesthesia, rat+osmotic minipump+surgery, etc)
V.4.1.3.5. Results of Search:
Searches looking at literature from the last 30 years, focusing more on the past 5 years, did not discuss the rats being in pain from the minipump implantations (>9500 hits). Besides daily injections, which cause discomfort each time, no other alternatives to the minipump implantation procedure have been found (>9000 hits). No alternatives to the nociception procedures have been found (>19,000 hits). There are many stressors used in rodent literature (immobilization, tail shock, feline exposure), but no milder alternative for the stress manipulations have been found (>80,000 hits). No alternatives are available to avoid using live animals for the assessment of effects of stress, caffeine, and nicotine in intact rats and the procedures that are followed.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification: Animals receiving the Warrior Stress Paradigm receive the stress paradigm in a cage separate from their home cage and are returned to their home cages once the paradigm is complete (for details, see section V.4.4.7). On the days that the animals receive stress, they receive no behavioral measures (i.e., during this time, they only receive the stress paradigm and are left to rest after). This paradigm's stressors are mild and brief (exposure to fox urine, lights, and sound). It is used to model the impending threat of attack in a novel environment that Warriors face while in deployed settings.

Animals receiving the Sleep disruption paradigm receive the stress paradigm in their home cage. The animals are exposed to sounds periodically during their sleep cycle. This paradigm is used to model interrupted sleep that many Warriors face.

V.4.2. Prolonged Restraint: No prolonged restraint will be used.

V.4.3. Surgery:
V.4.3.1. Pre-surgical Provisions:

All minipump implantation surgeries will be performed in the LAM facility by the Grunberg research team and in consultation with LAM staff to insure proper preparation and safeguards. Implantation of osmotic minipumps uses aseptic technique. Subjects will be anesthetized by inhalation anesthetic LAM equipment (vaporizer) and Isoflurane mixed with oxygen. Subjects will be placed inside an induction chamber saturated (at 4-5%) with Isoflurane vapor. Subjects will be removed from the chamber when tail pinch produces no reflex movement and anesthesia will be maintained (at 1-1.5%) using a mask/nose cone attached to the anesthetic vaporizer.

V.4.3.2. **Procedure:**

Subjects are anesthetized by inhalation anesthetic using LAM anesthetic equipment (vaporizer) and Isoflurane and oxygen. Subjects are placed inside an induction chamber saturated with Isoflurane vapor. Subjects are removed from the chamber when tail pinch produces no reflex movement and anesthesia is maintained using a mask/nose cone attached to the anesthetic vaporizer. A 3 x 5 cm area between the withers is shaved and cleaned with the antiseptic Betadine. A 2 cm transverse incision within the shaved region approximately 1 cm below the scapulae is made with blunt-nosed, curved-tipped Mayo surgical scissors, a pocket is created by gently spreading the subcutaneous tissues with the scissor tips, and the minipump is inserted. Incisions are closed with two-three 9 mm stainless steel wound clips. This procedure takes approx. 4 min per subject. The surgical area is thoroughly cleaned before and after procedures. Investigators wear surgical masks, gloves, and laboratory coats or surgical scrubs. The procedures are performed under aseptic conditions. All surgical material will be sterilized between animals using the glass bead sterilizers.

Minipump anchoring. The minipump is not anchored. For the majority of animals, it remains in the subcutaneous pocket created between the withers (shoulder blades) and can be palpated easily. On rare occasions, it migrates under the skin to other subcutaneous locations. When migration occurs, animals are monitored daily for minipump position to be sure that it does not interfere with normal behaviors (i.e., eating, drinking, grooming) or animal comfort.

Instruments. Surgical instruments are cleaned and sterilized by the (b)(6) lab before each procedure and in between animals.

V.4.3.3. **Post-surgical Provisions:**

One dose of buprenorphine (0.05-0.1mg/kg) given subcutaneously after surgery will be given for pain relief. Subjects will be returned to their cage and observed post-surgery until they are able to demonstrate recovery such as return of righting reflex, or coordinated voluntary movement. They also will be monitored three times a day until they have completely recovered from the minor surgical procedures.

Surgical incision monitoring. The incision site is closely examined daily for signs of infection or lack of healing. If signs of infection or lack of healing are observed, then veterinary consult will be requested for antibiotic administration or other appropriate care. Over 30 years of our experience and the implantation of several thousand rats with these devices, the incidence of infection has been less than 0.1%. In addition, we have never observed any problems with the surgical incisions in animals exposed to water (as in behavioral tests described below).

Post-op antibiotics. Post-operative antibiotics are not administered unless there are signs of infection (i.e., reddening or swelling of the incision site). A veterinarian will be consulted for appropriate course of action, antibiotic choice and route of administration in cases of infections.

Surgery-Experimental procedure time lag. Animals are allowed 16 hours to recover from surgery before the commencement of any behavioral testing. In our experience, by 15 minutes post-surgery animals are moving and by 2 hrs post-surgery animals are eating, drinking, and grooming normally. By 16 hrs post-surgery, the incision site exhibits signs of healing.

Animal disposition if surgical complications occur. In our experience, the only surgical complication that might occur is infection of the incision site, and this complication is rare. Should this complication develop, treatment with antibiotics will be

requested from the veterinary staff. If the infection is mild and resolves quickly with treatment, then the animal will remain in the experiment. If the infection is debilitating (i.e., the animal's behaviors indicate that it is in pain), or any other surgical complications occur, then a request will be placed for the animal to be euthanized by LAM personnel (carbon dioxide inhalation followed by decapitation).

V.4.3.4. Location:

Surgeries to implant the minipumps will be conducted in the LAM facility. Behavioral measures will be conducted in the laboratories assigned to Dr. (b)(6) in LAM at USUHS.

V.4.3.5. Surgeon: PI and all co-investigators and technicians

V.4.3.6. Multiple Major Survival Operative Procedures: N/A

V.4.3.6.1. Procedures: N/A

V.4.3.6.2. Scientific Justification: N/A

V.4.4. Animal Manipulations:

V.4.4.1. Injections: N/A

V.4.4.2. Biosamples:

At the end of each experiment, animals will be euthanized as described below. Blood samples and some tissue samples will be collected and stored for later analysis.

Biological and Physiological Measures

1) Corticosterone assessment. Trunk blood samples are obtained during sacrifice in some experiments. Total serum corticosterone is measured by ELISA/EIA. All samples and standards are run in duplicate.

2) Nicotine and cotinine levels. Blood samples are assayed for nicotine and cotinine by HPLC in some experiments (Jacob et al., 1981). Structural analogs of both nicotine and cotinine are used as internal standards. Calibration curves are linear from 1-100 ng/ml for nicotine and 10-1000 ng/ml for cotinine. The limit of quantification is 1 ng/ml for nicotine and 10 ng/ml for cotinine. The detection limits are 0.5 ng/ml for nicotine and 5 ng/ml for cotinine. Inter-day and intra-day variability have been determined from the repeated analysis of spiked plasma and brain tissue samples. The mean coefficient of variation ranges from 1.1 to 7.8% for nicotine concentrations ranging from 1 to 100 ng/ml. The mean coefficient of variation ranges from 0.8 to 9.5% for cotinine concentrations ranging from 10-1000 ng/ml. No interference is found from various nicotine metabolites. Assay specificity is verified by comparing concentrations of nicotine and cotinine in pooled plasma and in pooled brain samples.

3) Brain assays. Brains are harvested following decapitation and rapidly frozen with dry ice or liquid nitrogen. Brains will be stored for possible, later analysis (please see Tissue Sharing section V.4.4.8).

V.4.4.3. Adjuvants: N/A

V.4.4.4. Monoclonal Antibody (MAbs) Production: N/A

V.4.4.5. Animal Identification:

Animals cages will be identified with a cage card generated by LAM according to SOP upon arrival to USU. In addition, cages are numbered corresponding to the animals in that cage and rat tails are coded with a marker using a stripe system that corresponds to units of ten or ones, depending on the location of the mark on the tail.

V.4.4.6. Behavioral Studies:

This project focuses on behavioral evaluations in rats. Each measure is described below. The duration of behavioral testing on each day depends on the

specific measure used and is listed below. The specific behavioral measures used in each experiment is listed under the dependent variables section of each experiment. No more than three types of behavioral measure are made of each animal on a given day and will take less than 1½ hours per day.

1) Body weight, and food and liquid consumption (minimal handling of animals)
2) Open field activity: 1 hr
3) Neurobehavioral Severity Scale-Revised: 5 min
4) Hot Plate: < 60 sec
5) Acoustic startle and pre-pulse inhibition: 20 min
6) Passive Avoidance: 5 min

Open field locomotion. Locomotor activity is a collection of sensitive unconditioned behaviors that occur when an animal moves in its environment. Various parameters of open field locomotion provide information about gross motor movement, general health, anxiety, depressive-like behavior, and learning (i.e., habituation). These measures have been used in rat studies (b)(6) for many years and have provided reliable and valuable data (e.g., Bowen, Eury, & Grunberg, 1986; Elliott, Faraday, Phillips, & Grunberg, 2004; Elliott & Grunberg, 2005; Faraday, Elliott, Phillips, & Grunberg, 2003; Faraday, O'Donoghue, & Grunberg, 2003; Faraday, Scheufele, Rahman, & Grunberg, 1999; Grunberg & Bowen, 1985; Morse et al., 1997). Horizontal activity provides information about gross motor performance and general health; center time provides an index of anxiety (with an inverse relationship between center time and anxiety); vertical activity provides an index of depression (with escape behaviors inversely related to depression) (Berger, 2009; Faraday, 2005; Grippo, Beltz, & Johnson, 2003; Hamilton, 2010; Long, 2010; Perry, 2009; Sarkisova, Kulikov, Midzyanovskaya, & Folomkina, 2008; Shafer, 2006; Starosciak, 2010; Zhuang, Xu, & Chun-Zhi, 2007). Locomotor activity is measured using an Accuscan Electronics infrared photocell system (Accuscan Electronics, Columbus, OH), located in a dedicated room within the animal facility. This room is constructed of cinderblock walls, acoustic tile ceiling and steel doors so that sound is kept to a minimum. One hour activity measurements will be obtained during animals' active or dark cycle. Dark cycle measurement is done because animals' baseline level of activity during this part of the circadian cycle is sufficiently high to allow measurement of activity decrements and also low enough that activity increases can be reliably measured. Animals will be placed singly in a 40 x 40 x 30 cm clear Plexiglas arena and a Plexiglas lid with multiple holes to allow air flow. The lid ensures that subjects have adequate ventilation but cannot escape during data collection. A photocell array measures horizontal locomotor activity and vertical activity. Data will be automatically gathered and transmitted to a computer equipped with "Fusion" software (from Accuscan Electronics). Once subjects are placed in the test areas, the experimenter turns off the lights and leaves the room. Chambers are cleaned between subjects with a clidox-s solution. The duration of locomotor activity testing is a maximum of 60 min per day.

Neurobehavioral observation. Observations will be made and recorded using the Neurobehavioral Severity Scale-Revised (NSS-R) (b)(6) (b)(6) (Grunberg, Yarnell, Chwa, Hutchison, & Barry, 2011) and based on neurological severity scales in the literature (Hamm, 2001; Shohami, Novikov, & Bass, 1995) using a Likert-format scoring system. These measures include observation of a righting response, leg flexion, balance, and sensory responses to mild stimuli (e.g.,

touching ear with cotton-tipped stick, response to light). The measures are similar to those described in CNRM SOP #2 (on USUHS LAM web page).

Hot plate nociception. Hot plate response measures supraspinal nociceptive responses (Berry et al., 2007; Ding, Shum, Ko, & Zhuo, 2005). The hot plate task will be performed with an Omnitech/Accuscan Electronics Analgesia Monitor (Model HPrx). Subjects are placed on a 26 x 26 cm square hot plate platform, enclosed on all sides by Plexiglas walls and covered with a removable Plexiglas top. The metal plate heated to 51°C (a temperature that will elicit a nociceptive response without tissue damage). Hotplate latencies are measured as the time from placement on the heated surface until the animal raised and licked a rear paw. To prevent tissue damage, a maximum latency of 60 sec is allowed. Animals that do not lick their paws at all during the 60-sec period are removed from the heated surface. The platform is cleaned between subjects.

Acoustic startle response with and without pre-pulse inhibition. Acoustic startle reflex (ASR) amplitudes and pre-pulse inhibition (PPI) are measured in a Med Associates Acoustic Response Test System based on procedures of Davis and Sollberger (1971) and Faraday and Grunberg (2000). ASR and PPI provide information about information processing and attention. ASR and PPI are measured in a Med Associates Acoustic Response Test System consisting of weight-sensitive platforms inside individual sound-attenuated chambers. Subjects' movements in response to stimuli are measured as a voltage change by a strain gauge inside each platform. Each rat is placed individually in a ventilated holding cage. Startle stimuli range from 110 to 120 dB and are white noise bursts of 20 ms duration sometimes preceded 100 ms by 68 or 82 dB 1kHz pure tones (pre-pulses). Each stimulus combination is presented 8 times. Total testing period is about 20 min.

Passive Avoidance. Passive avoidance is an index of learning and general cognition. An animal is placed into an apparatus with two chambers separated by a sliding door. After being placed in one of the chambers, a light turns on and the door opens. The other chamber is dark, which rodents prefer. During the training period, crossing over into the dark chamber causes the animal to receive an electrical shock. The animal is tested the next day with no electrical shock. Remaining in the lit chamber, against the animal's natural instincts, indicates that learning has occurred. The Gemini model (San Diego Instruments, San Diego, CA) consists of two chambers (21 cm x 25 cm x 17 cm). A 50 watt light bulb is present in both compartments. The shocks (0.8 mA) are delivered through a grid floor. The training and testing operations are controlled by computer software ("PA", San Diego Instruments, San Diego, CA). During the training period, rats will be placed in a chamber. After 60s, the light will turn on and the door to the second, ark chamber will open. Upon crossing into the dark chamber, a 0.8 mA shock will be delivered for a period of one second. The latency to cross will be recorded by the computer. Rats will be removed after 300 seconds. The testing period occurs 24 hours after the training period. The procedure is identical, except that the rats will not be shocked upon crossing into the darkened chamber.

V.4.4.7. Other Procedures:

Nicotine chronic administration and surgical procedure. Nicotine or physiologic saline (also used as vehicle for the nicotine solution) is administered via Alzet osmotic mini-pumps for one to three weeks. Nicotine solution is made from nicotine dihydrochloride or nicotine bitartrate (obtained from Sigma); concentrations are expressed as nicotine base. Dosages are calculated based on body weight.

Stress manipulation. [(b)(6)] a non-painful "**Warrior Stress Paradigm**" to model impending threat of attack in novel environments (Yarnell et al., 2011) based on previous studies, [(b)(6)] e.g., Berger, 2009; Hamilton, 2010; Long, 2010; Perry, 2009; Starosciak, 2010 [(b)(6)] [(b)(6)] Hayley, Borowski, Merali, & Anisman, 2001; Meyerhoff, 2006; Willner et al., 1987). Predator stress is manipulated by introducing a cotton ball with commercially purchased synthetic fox urine into a test cage with the rat. Unpredictable, non-painful stressors include noise, flashing light, and cage shaking. The animal is transferred from its home cage to the stress cage with lid. The fox urine (15mL) is absorbed by a large cotton ball and placed in varying spots in the stress cage. The procedure is conducted in a room separate from the housing room and the behavioral rooms. A bright florescent overhead light remains on during the procedure. This procedure lasts 20 minutes. The stimuli are presented for 14 days (7 consecutive days, the 3 days of behavioral measurements, then 7 additional consecutive days; see table below) in a manner designed to minimize habituation of the response. Each manipulation occurs no more than once per day. A combination of these stimuli avoids habituation of the response.

Timeline of Stress Days		
Stress Day	**Predator Stress**	**Unpredictable Event**
1	Fox Urine (20 min)	None
2	Fox Urine (10 min)	Whistle at 12, 15 & 19 min
3	Fox Urine (10 min)	Coin Shake at 11, 14, & 17 min
4	Fox Urine (10 min)	Flashing Lights at 13, 16, & 19 min
5	Fox Urine (10 min)	Cage Shake at 12, 15, & 18 min
6	Fox Urine (10 min)	Flashing Lights at 12, 16, & 19 min
7	Fox Urine (10 min)	Whistle at 11, 13, 16 & 18 min
8	Fox Urine (10 min)	Coin Shake at 12, 16, & 19 min
9	Fox Urine (10 min)	Flashing Lights at 11, 15, 19 min
10	Fox Urine (10 min)	Cage Shake at 11, 14, & 17 min
11	Fox Urine (10 min)	Coin Shake at 13, 16, & 19 min
12	Fox Urine (10 min)	Whistle at 12, 14, 17 min
13	Fox Urine (10 min)	Flashing Lights at 11, 14, 18 min
14	Fox Urine (10 min)	Cage Shake at 12, 15, & 18 min

Sleep Disruption. Sleep disruption will be manipulated based on methods previously used [(b)(6)] (Perry, 2009). The natural sleep of the rats will be intermittently disrupted by varying high and low frequency environmental sounds (to prevent habituation) for a period of 14 days. These noises (loud banging, bells, voices, shattering glass, vehicular traffic, etc.) are pre-recorded onto a CD and will be programmed to play on an hourly loop for 9 total hours of the animals' 12 hour sleep period. Sounds will vary from 65 - 80 dB. Total duration of the sounds range from 6 seconds to approximately 1 minute. Total hourly sound exposure will not exceed 6 minutes at any time during this study.

Body weight, food and liquid consumption. Body weight is measured using electronic balances programmed to take multiple weighings within a short period of time to account for movement artifacts. Food and liquid consumption are calculated by weighing food and water on subsequent days. Foods includes standard rodent laboratory chow (available in LAM) and sugar-containing foods and solutions to assess taste preferences in response to the independent variables.

V.4.4.8. Tissue Sharing:

Some brain samples may be shared with other investigators to perform additional assays.

V.4.5. Study Endpoint:

The study endpoint is euthanasia in each experiment. Each experiment will be run in five separate counter-balanced cohorts. The timeline below summarizes daily activities for each cohort within each experiment. Considering pilot work, time between cohorts, and time to run each cohort, each experiment will require about 6 months to collect behavioral data and blood samples. Biochemical assays and data analyses will require several additional months per experiment.

Timeline for Experiment 1

	Mon	Tues	Wed	Thurs	Fri	Sat	Sun
Week 1		Arrive	Gentle	Gentle ASR acclimation 1	Gentle OFA Acclimation ASR Acclimation 2		
Week 2	BL OFA BL NSS-R BL HP	PA Training	BL PA BL ASR	Minipump	Nic/Sal Stress/NS	Nic/Sal Stress/NS	Nic/Sal Stress/NS
Week 3	Nic/Sal Stress/NS	Nic/Sal Stress/NS	Nic/Sal Stress/NS	Nic/Sal Stress/NS	Nic/Sal T1 OFA T1 NSS-R T1 HP	Nic/Sal T1 PA	Nic/Sal T1 ASR
Week 4	Nic/Sal Stress/NS	Nic/Sal Stress/NS	Nic/Sal Stress/NS	Nic/Sal Stress/NS	Nic/Sal Stress/NS	Nic/Sal Stress/NS	Nic/Sal Stress/NS
Week 5	Nic/Sal T2 OFA T2 NSS-R T2 HP	Nic/Sal T2 PA	Nic/Sal T2 ASR	Euthanasia			

Timeline for Experiment 2

	Mon	Tues	Wed	Thurs	Fri	Sat	Sun
Week 1		Arrive	Gentle	Gentle	Gentle		
				ASR acclimation 1	OFA Acclimation		
					ASR Acclimation 2		
Week 2	BL OFA BL NSS-R BL HP	PA Training	BL PA		Caf/Sal	Caf/Sal	Caf/Sal
			BL ASR		Stress/NS	Stress/NS	Stress/NS
Week 3	Caf/Sal	Caf/Sal	Caf/Sal	Caf/Sal	Caf/Sal	Caf/Sal	Caf/Sal
	Stress/NS	Stress/NS	Stress/NS	Stress/NS	T1 OFA T1 NSS-R T1 HP	T1 PA	T1 ASR
Week 4	Caf/Sal	Caf/Sal	Caf/Sal	Caf/Sal	Caf/Sal	Caf/Sal	Caf/Sal
	Stress/NS	Stress/NS	Stress/NS	Stress/NS	Stress/NS	Stress/NS	Stress/NS
Week 5	Caf/Sal	Caf/Sal	Caf/Sal	Euthanasia			
	T2 OFA T2 NSS-R T2 HP	T2 PA	T2 ASR				

Gentling involves 2 - 3 minutes of gentle handling
ASR/PPI = acoustic startle reflex with and without pre-pulse inhibition
ASR acclimation entails putting rat in ASR chamber for 15 min without taking measurements.
OFA acclimation entails putting rat in open field activity (OFA) chamber for 60 min without taking measurements.
BL = baseline (i.e., pre-nicotine/caffeine) measurements
NSS-R = Neurobehavioral Severity Scale-Revised
HP = hot plate nociception measure
PA Training entails putting rat in the passive avoidance (PA) box for up to 5 minutes or until they cross to the other side of the chamber
Nicotine admin = minipump implantation to deliver nicotine or saline continuously throughout Exp. 1
Nic = Nicotine
Sal = Saline
Caf = Caffeine
Stress = either 20 min/day of Warrior Stress Paradigm to half of the subjects in each experiment and/or sounds playing for 9 out of 12 of animals' sleep period to half of the subjects in each experiment

V.4.6. Euthanasia:

Rats will be euthanized using carbon dioxide inhalation from a compressed gas cylinder. Euthanasia will be done in a LAM designated procedure room followed by

rapid decapitation by guillotine. This euthanasia procedure is in compliance with the 2013 AVMA Guidelines on Euthanasia.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations:

Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol.

V.5.1.1. Study Room:

Building(s) (b)(6) Room Number(s) (b)(6) (b)(6)

V.5.1.2. Special Husbandry Provisions: Animals will be single housed

Food Restriction: Yes _____ No __X__

Fluid Restriction: Yes _____ No __X__

V.5.1.3. Exceptions: N/A

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care:

Animals will be observed and cared for by the Center for LAM veterinary technicians and veterinarians according to USUHS Center for LAM SOPs. Animals will be monitored for health, human treatment and husbandry considerations twice daily by LAM personnel during routine weekday rounds and at least once daily on weekends/holidays. This is in addition to, and not in place of, the monitoring that is done by the principal investigator and their staff. In the event of a debilitating illness or adverse reaction, the decision to treat or euthanize an animal will be made by either the veterinarian and/or the principal investigator.

V.5.2.2. Emergency Veterinary Medical Care:

All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays. In the case of an emergency health problem, if the responsible person (e.g. investigator) is not available or if the investigator and veterinary staff cannot reach consensus on treatment, the veterinarian has the authority to treat the animal, remove it from the experiment, institute appropriate measures to relieve severe pain or distress, or perform euthanasia as necessary.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy:

Animals will be single housed without toys because these experiments are designed to determine effects of several interventions. Enrichment itself attenuates effects of injury as reported by (b)(6) (Elliott & Grunberg, 2005).

V.5.3.2. Enrichment Restrictions:

Animals will be single housed without toys to assess effects of stress, nicotine, and caffeine. Enrichment would interfere with the specific aims of this research project.

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Personnel	Procedure	Qualifications/Training
(b)(6)	Animal Handling	USUHS Investigator Training and Animal Handling courses (several sessions, including sessions in 1980 and in early 1990s); NIH/NIMH training courses (several in mid 1980s); > 30 years experience with rats and other rodents
	Drug Administration	USUHS Investigator Training and Animal Handling courses; NIH/NIMH training courses; > 30 years experience with rats and other rodents
	Surgical Implant of Osmotic Mini-pumps	NIH/NIMH training courses; > 30 years experience with rats and other rodents; 1200+ surgeries performed
	Behavioral Measures	NIH/NIMH training courses; > 30 years experience with rats and other rodents
	Biological sample collection	NIH/NIMH training courses; > 30 years experience with rats and other rodents
	Anesthetized Decapitation	NIH/NIMH training courses; 25+ years experience with rats; 1000+ decapitations performed
(b)(6)	Animal Handling	USUHS Investigator Training (Summer, 2009) and Animal Handling course (July, 2009); 5 years experience with rats; training by Dr (b)(6) and lab personnel
	Drug Administration	USUHS Investigator Training and Animal Handling courses; training by Dr (b)(6) and lab personnel
	Surgical Implant of Osmotic Mini-pumps	Training by Dr (b)(6) and lab personnel; 2 years experience with rats
	Behavioral Measures	Training by Dr (b)(6) and lab personnel; 5 years experience with rats
	Biological sample collection	Training by Dr (b)(6) and lab personnel; 5 years experience with rats
	Anesthetized Decapitation	Training by Dr (b)(6) and lab personnel
(b)(6)	Animal Handling	USUHS Investigator Training and Animal Handling courses (Fall, 2010); 4 years experience with rats; training by Dr (b)(6) and lab personnel
	Drug Administration	USUHS Investigator Training and Animal Handling courses; training by Dr (b)(6) and lab personnel
	Surgical Implant of Osmotic Mini-pumps	Training by Dr (b)(6) and lab personnel; 1 year experience with rats
	Behavioral Measures	Training by Dr (b)(6) and lab personnel; 4 years experience with rats
	Biological sample collection	Training by Dr (b)(6) and lab personnel; 4 years experience with rats
	Anesthetized Decapitation	Training by Dr (b)(6) and lab personnel
(b)(6)	Animal Handling	USUHS Investigator Training (Fall, 2010) and Animal Handling course (Fall, 2010); 4 years experience with rats; training by Dr (b)(6) and lab personnel
	Drug Administration	USUHS Investigator Training and Animal Handling courses; training by Dr (b)(6) and lab personnel
	Surgical Implant of Osmotic Mini-pumps	Training by Dr (b)(6) and lab personnel; 1 year experience with rats
	Behavioral Measures	Training by Dr (b)(6) and lab personnel; 4 years experience with rats

	Biological sample collection	Training by Dr. (b)(6) and lab personnel; 4 years experience with rats
	Anesthetized Decapitation	Training by Dr (b)(6) and lab personnel
(b)(6)	Animal Handling	USUHS Investigator Training (Fall, 2011) and Animal Handling course (Fall, 2011); 3 years experience with rats; training by Dr (b)(6) and lab personnel
	Drug Administration	USUHS Investigator Training and Animal Handling courses; training by Dr. (b)(6) and lab personnel
	Surgical Implant of Osmotic Mini-pumps	Training by Dr (b)(6) and lab personnel; 1 year experience with rats
	Behavioral Measures	Training by Dr (b)(6) and lab personnel; 3 years experience with rats
	Biological sample collection	Training by Dr. (b)(6) and lab personnel; 3 years experience with rats
	Anesthetized Decapitation	Training by Dr. (b)(6) and lab personnel
(b)(6)	Animal Handling	USUHS Investigator Training (Fall, 2012) and Animal Handling course (Fall, 2012); 2 years experience with rats; training by Dr (b)(6) and lab personnel
	Drug Administration	USUHS Investigator Training and Animal Handling courses; training by Dr (b)(6) and lab personnel
	Surgical Implant of Osmotic Mini-pumps	Training by Dr (b)(6) and lab personnel; 1 year experience with rats
	Behavioral Measures	Training by Dr (b)(6) and lab personnel; 2 years experience with rats
	Biological sample collection	Training by Dr (b)(6) and lab personnel; 2 years experience with rats
	Anesthetized Decapitation	Training by Dr (b)(6) and lab personnel
(b)(6)	Animal Handling	USUHS Investigator Training (Fall, 2013) and Animal Handling course (Fall, 2013); ½ year experience with rats; training by Dr (b)(6) and lab personnel
	Drug Administration	USUHS Investigator Training and Animal Handling courses; training by Dr. (b)(6) and lab personnel
	Surgical Implant of Osmotic Mini-pumps	Training by Dr (b)(6) and lab personnel
	Behavioral Measures	Training by Dr. (b)(6) and lab personnel; ½ year experience with rats
	Biological sample collection	Training by Dr. (b)(6) and lab personnel; ½ year experience with rats
	Anesthetized Decapitation	Training by Dr (b)(6) and lab personnel
(b)(6)	Animal Handling	USUHS Investigator Training (Fall, 2013) and Animal Handling course (Fall, 2013); ½ year experience with rats; training by Dr. (b)(6) and lab personnel
	Drug Administration	USUHS Investigator Training and Animal Handling courses; training by Dr (b)(6) and lab personnel
	Surgical Implant of Osmotic Mini-pumps	Training by Dr (b)(6) and lab personnel
	Behavioral Measures	Training by Dr (b)(6) and lab personnel; ½ year experience with rats
	Biological sample collection	Training by Dr (b)(6) and lab personnel; ½ year experience with rats
	Anesthetized Decapitation	Training by Dr (b)(6) and lab personnel

(b)(6)	Animal Handling	USUHS Investigator Training (Fall, 2013) and Animal Handling course (Fall, 2013); ½ year experience with rats; training by Dr. (b)(6) and lab personnel
	Drug Administration	USUHS Investigator Training and Animal Handling courses; training by Dr. (b)(6) and lab personnel
	Surgical Implant of Osmotic Mini-pumps	Training by Dr. (b)(6) and lab personnel
	Behavioral Measures	Training by Dr. (b)(6) and lab personnel; ½ year experience with rats
	Biological sample collection	Training by Dr. (b)(6) and lab personnel; ½ year experience with rats
	Anesthetized Decapitation	Training by Dr. (b)(6) and lab personnel
(b)(6)	Animal Handling	USUHS Investigator Training (Spring, 2010) and Animal Handling (Spring, 2010) courses; 4 years experience with rats; training by Dr. (b)(6) and lab personnel
	Drug Administration	USUHS Investigator Training and Animal Handling courses; training by Dr. (b)(6) and lab personnel
	Surgical Implant of Osmotic Mini-pumps	Training by Dr. Grunberg and lab personnel
	Behavioral Measures	Training by Dr. (b)(6) and lab personnel; 4 years experience with rats
	Biological sample collection	Training by Dr. (b)(6) and lab personnel; 4 years experience with rats
	Anesthetized Decapitation	Training by Dr. (b)(6) and lab personnel
(b)(6)	Animal Handling	USUHS Investigator Training (Spring, 2011) and Animal Handling (Spring, 2011) courses; training by Dr. (b)(6) and lab personnel
	Drug Administration	USUHS Investigator Training and Animal Handling courses; training by Dr. (b)(6) and lab personnel
	Surgical Implant of Osmotic Mini-pumps	Training by Dr. Grunberg and lab personnel
	Behavioral Measures	Training by Dr. (b)(6) and lab personnel; 3 years experience with rats
	Biological sample collection	Training by Dr. (b)(6) and lab personnel; 3 years experience with rats
	Anesthetized Decapitation	Training by Dr. (b)(6) and lab personnel

VII. BIOHAZARDS/SAFETY:

When lab personnel work with nicotine, personnel wear lab coats, two layers of gloves, a mask, and protective eye wear. When personnel work with anesthetic vapors, personnel wear protective masks. All laboratory personnel wear laboratory coats, gloves, and masks when working with animals.

VIII. ENCLOSURES: N/A

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

(b)(6) [redacted] 2/27/14
Date

G. Training: The following personnel will attend the next USUHS Investigator/Animal User Training Course:

N/A

H. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely, "Responsibility" for implementing animal use alternatives where feasible and conducting humane and lawful research.

(b)(6) [redacted] 2/27/14

Principal Investigator Signature Date

I. Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL or WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

(b)(6)

2/27/14
Date

X. PROTOCOL ABSTRACT:

A. **Animal Protocol Number:** (b)(6)

B. **Animal Protocol Title:** Behavioral investigations of nicotine and caffeine in rats (Rattus norvegicus)

C. **Principal Investigator:** (b)(6) Ph.D.

D. **Performing Organization:** Uniformed Services University of the Health Sciences

E. **Funding:** USUHS

F. **Objective and Approach:**

Stress is a pervasive experience that affects behaviors, cognitions, and biological responses. Insufficient sleep is a particularly disruptive stressor that is experienced by civilians and Warriors. Threat of attack also is a stressor that is commonly experienced by Warriors. Nicotine and caffeine are legal drugs that are used by many civilians and service members. These drugs are often consumed during stressful situations. Each of these variables (i.e., insufficient sleep, threat of attack, nicotine, and caffeine) alone can have psychological effects (on behavior and cognition). It is important to examine if nicotine or caffeine use alters psychological effects of stress – either potentiating or attenuating effects of stressors. The experiments described in this application use a rodent model of Warrior Stress and sleep disruption to determine how psychological responses to stress are altered by nicotine or caffeine administration in male and female rats. The behaviors assessed include motor responses (to index anxiety, depression, and learning), sensorimotor (including reflexes and nociception), and cognitive responses (including attention, memory, learning). Blood samples will be assessed for stress hormones (corticosterone). It is hypothesized that: the stressors will deleteriously affect the measured behaviors; nicotine will attenuate these effects; caffeine will potentiate these effects; and females will be more sensitive than males to the effects of stress, nicotine, and caffeine.

G. **Indexing Terms (Descriptors):**

Stress, nicotine, caffeine, behavioral responses of rats to stress, nicotine, caffeine, behavioral responses in rats, tobacco,

March 14, 2013

MEMORANDUM FOR DR. (b)(6) DEPARTMENT OF NEUROLOGY

SUBJECT: IACUC Approval of Protocol – Triennial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on March 14, 2013:

Animal Protocol Title: "Phenserine, an Acetylcholinesterase Inhibitor with Possible Neuroprotective Efficacy Against soman-Induced Neuropathology in Male Sprague-Dawley Rats"

USUHS Protocol Number: (b)(6)

Expiration Date: March 13, 2016

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

TECHNICIANS(S): N/A

I. **NON-TECHNICAL SYNOPSIS:** Nerve agents cause mass casualties and are a threat to military and civilian populations. Nerve agents inactivate acetylcholinesterase, an enzyme that breaks down acetylcholine. Inactivation of acetylcholinesterase leads to the accumulation of acetylcholine in synapses and results in the overactivation of muscarinic and nicotinic acetylcholine receptors in the brain and periphery. Acetylcholine is an excitatory neurotransmitter in the brain. Accumulation of acetylcholine in synapses causes status epilepticus via the overactivation of muscarinic type acetylcholine receptors. Status epilepticus is a dangerous complication of nerve agent exposure that can lead to brain damage. The muscarinic antagonist, atropine, is effective in controlling the seizures but only if given within several minutes after onset of status epilepticus. Diazepam, an anti-convulsant, is efficacious if given within minutes after onset of status epilepticus. Exposure to nerve agents produces rapid inactivation and "aging" of acetylcholinesterase. Aging results in an irreversible bond between agent and the enzyme and results in irreversible inhibition of acetylcholinesterase. Because of the rapid onset and nature of the nerve agent-enzyme reaction, neuroprotective agents are needed to reduce brain damage and improve outcome.

II. BACKGROUND:

II.1. Background:

The organophosphorus nerve agents, sarin, soman, VX, and tabun are among the most lethal chemical weapons ever developed by man. Some of these agents were used in wars and more recently in terrorist attacks in Japan in the early 1990s. The possibility that the warfighter will be exposed to nerve agents and the possibility of another terrorist attack underscore the required need to develop effective and safe countermeasures against nerve agents.

The major mechanism of acute nerve agent toxicity is the irreversible inhibition of acetylcholinesterase (AChE). This enzyme degrades the neurotransmitter

acetylcholine. When AchE is inhibited, excessive levels of acetylcholine (Ach) accumulate in the synaptic cleft leading to progression of toxic signs including a muscarinic receptor activation syndrome consisting of hypersecretions, miosis, profuse sweating, diarrhea, bradycardia, hypotension and bronchoconstriction. Central nervous system-related effects include: anxiety, confusion, ataxia, seizures, cardiorespiratory paralysis, and coma.

The current therapeutic strategies to reduce nerve agent toxicity include atropine, an anti-cholinergic drug that reduces the muscarinic receptor activation syndrome, an oxime, compounds that reactivate nerve agent inhibited AChE and a benzodiazepine, drugs that effectively control nerve agent-induced convulsions when given soon after seizure initiation. Because of the limitations of these treatments, alternative therapies that combine with current therapies have been sought to provide greater survival, protection of the brain against nerve agents and improved functional outcome.

Phenserine is a reversible AChE inhibitor that was synthesized on the physostigmine backbone. By virtue of its phenyl group, phenserine is more lipophilic compared to physostigmine. Phenserine readily and preferentially enters the brain following its systemic administration and achieves levels that are 10-fold higher than concomitant levels in plasma. Phenserine selectively inhibits AChE in plasma and brain and has a minimal effect on butyrylcholinesterase (BChE). Phenserine is dramatically less acutely toxic than is physostigmine and is safe. An additional feature of phenserine, that is not available for huperzine A, galantamine or similar anticholinesterases, is that phenserine has a chiral center and naturally exists in the active form as (-)-phenserine. Phenserine entered Phase III trials for the treatment of Alzheimer's Disease and is well tolerated (1-5). Recently, phenserine has been formulated for transdermal application and has been tested in animals (6).

Phenserine has been used in over 1,000 Alzheimer patients and the drug is well-tolerated. Memory testing showed significant improvement in a test for short-term memory. A four week trial of phenserine in Alzheimer patient showed improvement on Alzheimer's Disease Assessment Scale-cognitive Subscale and on Clinically Interview-based Impression of Change but the results never did reach statistical significance. The reasons for pointing out these studies is to demonstrate that this compound is ready for translational neuroscience in that it can be readily and rapidly brought to the warfighter if neuroprotective efficacy is established.

Huperzine A, a reversible AChE inhibitor that crosses the blood brain barrier, protects against soman-induced convulsions and the neuropathological changes in the hippocampus. The efficacy of huperzine A appears to be primarily related to the selectivity of huperzine A for peripheral AChE which preserves scavenger capacity of plasma butyrylcholinesterases (BChE) for nerve agents and to the protection conferred by huperzine A on cerebral AChE. Thus, efficacy of huperzine A seems to be related to a protection of both peripheral and central stores of AChE. In a similar fashion, phenserine has a 10:1 brain to plasma ratio and selectively binds to acetylcholinesterase. By selectively inhibiting acetylcholinesterase, phenserine protects acetylcholinesterase and butyrylcholinesterase (BChE) is free to bind nerve agent. In so doing, BChE acts as a chemical sponge (scavenger) to reduce the amount of

nerve agent available for binding to AChE. Thus, efficacy by phenserine may relate to protection of both peripheral and central stores of AChE.

II.2. Literature Search for Duplication:

II.2.2. Date of Search: November 27, 2012

II.2.3. Period of Search: 1980-2012

II.2.4. Key Words and Search Strategy: phenserine, soman, rat, hippocampus, nerve agent,

II.2.5. Results of Search:

November 27, 2012

Toxline: 500 references on soman and effects in vivo. No references on the possible neuroprotective effect of phenserine against soman.
Crisp: 17 grants but none deal with phenserine and soman.
BRD: no hits
PubMed: No hits
No duplication of this proposal.

III. OBJECTIVE\HYPOTHESIS: The long-term objective is to develop an effective combinatorial drug regimen to maximize neuronal survival and functional outcome against soman-induced neuropathology. We believe there is a high likelihood of achieving a higher level of neuroprotection and improved functional outcome by targeting different pathways that are involved in soman-induced brain damage.

(-)-Phenserine has properties similar to huperzine A and these properties make it an attractive candidate drug to protect against soman-induced seizures and brain damage. An additional feature of phenserine, that is not available for Hyperzine A, galantamine and similar anticholinesterases, is that phenserine has a chiral center and naturally exists as the (-)-enantiomeric form as (-)-phenserine. This is the chirally pure form that has anticholinesterase activity that moved into phase III clinical assessment in Alzheimer's disease and is the basis for the proposed work.

Only one study exists in the literature which shows neuroprotective efficacy by Huperzine A in the hippocampus of guinea pigs following soman injection. Whether Huperzine A protects against soman-induced damage in other vulnerable brain regions is unknown. In this proposal, we will test the neuroprotective efficacy of (-)-phenserine and compare the results to (+)-phenserine which lacks anticholinesterase activity and is utilized as a pharmacological tool to determine whether actions by (-)-phenserine to protect the brain against soman are due to anticholinesterase inhibition or some other

mechanism.

IV. MILITARY RELEVANCE: The neurological effects of chemical weapons on the performance and operations of our military would be devastating. This is, in fact, a major goal of the terrorists. They want to cripple the military at a sufficient level and long enough so that when the levels of the chemical weapons are no longer toxic the terrorists can penetrate into and destroy military facilities, equipment and soldiers.

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures:

V.1.1. Experiment 1: To test a dose and time course of neuroprotective efficacy of (-)-phenserine as a pretreatment strategy (-)-Phenserine selectively inhibits AChE and has a minimal effect on BChE in plasma and brain. (-)-Phenserine achieves a 10-fold higher level in brain compared to plasma, and (-)-phenserine is safe and has fewer side effects than physostigmine.

We have data suggesting that pretreatment of (-)-phenserine at a dose of 1 mg/kg iv is neuroprotective against soman-induced brain damage. Percent neuroprotection for each of the four vulnerable brain regions are: amygdala (50), piriform cortex (48), hippocampus (85) and prefrontal cortex (45). The results are significant but we don't know where the 1 mg/kg dose is on the neuroprotection curve. It is possible that a lower dose may achieve similar levels of neuroprotection. Since dose selection is of utmost importance to maximize brain protection and minimize side effects in humans exposed to nerve agents, the proposed experiments set out to determine levels of neuroprotection using two additional pretreatment doses of (-)-phenserine (0.3 and 3 mg/kg iv) using the same two time points (30 min and 4 hours) proposed in the grant proposal (30 min and 4 hours). All three doses (0.3, 1, 3 mg/kg, iv) will be considered as part of the original protocol.

Phenserine-preconditioned rats (male, Sprague-Dawley 250-300 gm) will be intravenously injected with the active stereoisomer of phenserine [(-)-phenserine] or the inactive isomer of phenserine [(+)-phenserine] (0.3 and 3 mg/kg) **4 hours or 30 min** before nerve agent. Rats receiving nerve agent will be injected with the oxime HI-6 (125 mg/kg, ip) and 30 min later will receive soman (180 ug/kg, sc) and post-exposure treatment with atropine (2 mg/kg, im, 1 min after soman im). These treatments, HI-6 (125 mg/kg, ip) and 30 min later soman (180 ug/kg, sc) and post-exposure treatment with atropine (2 mg/kg, im) 1 min after soman, have been shown to reliably produce electrographic seizure activity within approximately10 min. Rats are allowed to seize for 40 min and then treated with 10 mg/kg, im, diazepam to stop/attenuate the seizures. There will be 10 rats/group in an attempt to get at least 6 survivors/soman-exposure group (Table 1-2)

Table 1: Phenserine Pretreatment Groups and Group Sizes for Experiment 1

Treatment Groups	HI-6 30 min Soman 9 min Atropine 1 min Diazepam 40 min	Treatment (Time before seizure onset)	Group Size	Pain Category
Group 1 Adult Male Rats	HI-6→Soman→atropine→seizure →diazepam	(-)-phenserine (30 min)	20 Male Rats (10 for each dose)	E

Table 2: Control groups - No Soman Exposure and Group Sizes for Experiment 1

Treatment Group	HI-6 30 min Saline 0 min, Atropine 1 min Diazepam 40 min	Treatment (Time before Saline injection)	Group Size	Pain Category
Group 5 Adult Male Rats	HI-6→Saline→atropine →Diazepam	(-)-phenserine (30 min)	12 Male Rats (6 for each dose)	C
Group 6 Adult Male Rats	HI-6→Saline →atropine →diazepam	(+)-phenserine (30 min)	12 Male Rats (6for each dose)	C
Group 7 Adult Male Rats	HI-6→Saline →atropine →diazepam	(-)-phenserine (4 h)	12 Male Rats (6 for each dose)	C
Group 8 Adult Male Rats	HI-6→Saline →atropine →diazepam	(+)-phenserine (4 h)	12 Male Rats (6 for each dose)	C
TOTAL			**48 Male Rats**	**48 C**

Table 3: Control groups - Soman Exposure No Treatment and Group Sizes for Experiment 1

Treatment Group	HI-6 30 min Soman 0 min, Atropine 1 min Diazepam 40 min	Saline (Time before seizure onset)	Group Size	Pain Category
Group 9 Adult Male Rats	HI-6→Soman→atropine→ seizure→diazepam	Saline (30 min)	20 Male Rats (10 for each dose)	E
Group 10 Adult Male Rats	HI-6→Soman→atropine→ seizure→diazepam	Saline (4 h)	20 Male Rats (10 for each dose)	E
TOTAL			**40 Male Rats**	**40 E**

We will weigh all animals and determine the survival rate of all animals just before perfusion.

Rats will be perfused 24 hours after soman injection, perfused and brains fixed. Brain sections will be made on a cryostat and placed on slides. Alternate slides will be stained with cresyl violet and fluoroJade C. Animal survival in all groups will be recorded just prior to the animals being perfused.

V.1.2. Experiment 2: To test the neuroprotective efficacy of (-)-phenserine as a treatment strategy. (-)-Phenserine-treatment rats (male, Sprague-Dawley 250-300 gm) will be intravenously injected with the active stereoisomer of phenserine [(-)-phenserine] or the inactive stereoisomer of phenserine [(+)-phenserine] (0.3 or 3 mg/kg) either 5 min or 30 min after soman injection. Rats receiving nerve agent will be injected with the oxime HI-6 (125 mg/kg, ip) and 30 min later will receive soman (180 ug/kg, sc) and post-exposure treatment with atropine (AMN, 2 mg/kg, im) 1 min after soman. Rats are allowed to seize for 40 min and then treated with diazepam (10 mg/kg, im) to stop/ attenuate the seizures.

Treatment Group	HI-6 30 min Soman 0 min, Atropine 1 min Diazepam 40 min	Treatment (Time after seizure onset)	Group Size	Pain Category
Group 11 Adult Male Rats	HI-6→Soman→atropine→seizure →diazepam	(-)-phenserine (5 min)	20 Male Rats (10 for each dose)	E

Table 4. Phenserine Treatment Groups and Group Sizes for Experiment 2.

Table 5. Control Groups No Soman Exposure and Group Sizes for Experiment 2

Treatment Group	HI-6 30 min Saline 0 min, Atropine 1 min Diazepam 40 min	Treatment (Time after Saline injection)	Group Size	Pain Category
Group 15 Adult Male Rats	HI-6→Saline→atropine →Diazepam	(-)-phenserine (5 min)	12 Male Rats (6 for each dose)	C

METHODS

Chemicals. (-)-Phenserine and (+)-phenserine are provided by Dr. (b)(6) All other reagents except soman will be purchased from commercial sources or as indicated. Soman, atropine, HI-6, and diazepam will be supplied by Dr. (b)(6) (b)(6) at the Institute of Chemical Defense.

Drug treatments. (-)-Phenserine and (+)-phenserine will be freshly prepared on the day of experimentation. Phenserine readily dissolves in physiological saline and an appropriate working stock concentration will be used for injection purposes for a final doses of 0.3 and 3 mg/kg IV.

Treatment and pretreatment procedure (Experiments 1-2). Phenserine-treated rats will be intravenously injected into the jugular vein by an indwelling catheter as a bolus with (-)-phenserine or (+)-phenserine prior to (Specific Aim 1) or after (Specific Aim 2) soman challenge. Saline-injected animals will be treated in an identical manner and will

be used as controls for the treatment and pretreatment group.

Interval from catheterization to soman injection. The interval from catherization to injection of soman is standardized.

Rats will be euthanized at 24 hours after injection of soman (Specific Aims 1, 2).

V.2. Data Analysis: Values from experimental and control groups are averaged and compared using analysis of variance ($p<0.05$ to reject the null hypothesis that the group means were equal). Post hoc analyses will use the Tukey test for multiple group comparison. A sample size of ten animals per group will have 80% power to detect differences between groups of 1.8 standard deviations, based on one-way ANOVA with Tukey's post-hoc multiple comparisons among 10 group means with a 5%, two-sided significance level. Even with death of four animals per group, a sample size of six animals per group will have 80% power to detect differences between groups of 2.4 standard deviations, based on one-way ANOVA with Tukey's post-hoc multiple comparisons among 10 group means with a 5%, two-sided significance level. For the categorical outcome of mortality, the Fisher exact test has 80% power to detect a significant difference between groups when the mortality is at least 85% in one group compared with no more than 15% in the second group, based on a 5% two-sided significance level with ten animals per group.

V.3. Laboratory Animals Required and Justification: Chemical warfare agents or nerve agents are some of the most lethal compounds known to mankind. Nerve agents induce severe seizures, brain damage and death. Anticholinergic drugs are only effective if given within 5 minutes after the initiation of seizures. Thus, these agents have limited value in protecting the brain against nerve agent-induced seizures. Therefore, efficacious drugs are needed to reduce brain damage and improve outcome. Phenserine is a reversible acetylcholinesterase inhibitor that has a high brain to periphery penetration. Our goal is to determine whether phenserine protects vulnerable neurons against soman-induced brain damage. Because we are studying cellular mechanisms and responses, there are currently no non-animal alternatives that can meet our needs for these studies.

V.3.1. Non-animal Alternatives Considered: N/A

V.3.2. Animal Model and Species Justification: The male Sprague-Dawley rats for the in vivo studies were selected because this is the common gender and species of rat used in the literature. This allows us to compare our results directly with the many published results from other laboratories using chemical warfare agents or other acetylcholinesterase inhibitors such as paraoxon.

V.3.3. Laboratory Animals

	Species #1	Species #2
V.3.3.1. Genus & Species:	Rattus Norvegicus	

V.3.3.2. **Strain/Stock**: Sprague-Dawley

V.3.3.3. **Source/Vendor**: (b)(4)

V.3.3.4. **Age**: adult

V.3.3.5. **Weight**: 250-275 grm

V.3.3.6. **Sex**: male

V.3.3.7. **Special Considerations**: N/A

V.3.4. **Number of Animals Required (by Species)**: 336 (240 Category E and 96 Category C)

V.3.5. **Refinement, Reduction, Replacement (3 Rs)**:

V.3.5.1. **Refinement**: All surgeries will be performed under appropriate anesthesia. Any rat exhibiting signs of pain or impairment beyond that from this model will be euthanized at an early endpoint. No other refinement alternatives were considered.

V.3.5.2. **Reduction**: We are using 10 rats/group in the treated group which provides a sufficient number to determine statistical significance even if 4 rats/group die (see V.2). We will use 6 rats/group in the control groups (no soman) as no deaths are expected in this group of animals. We will minimize the number of animals used in this study as much as possible but without affecting statistical significance. Using rats will allow us to study whether phenserine protects against soman-induced neuropathology without using higher species.

V.3.5.3. **Replacement**: This type of study requires a whole biological system because there is no currently available in-vitro or computer modeling systems that can be used to study the physiologic effects of treatments and exposures proposed in this protocol. No other replacements were considered.

The requirement for seizures (40 min). The protocol involving the use of soman was developed by Dr. (b)(6) my collaborator at (b)(6) Dr. (b)(6) is a senior scientist at (b)(6) and an established investigator in the nerve agent field. According to Dr (b)(6) the dose of soman used to inject the animals is the dose that elicits seizures in 100% of the animals. Animals must seize for 40 min in order for the brain to be damaged. If the animals don't seize, they have to be euthanized and cannot be used for further study. The dose of soman used in this study is 1.6 x LD_{50}. The LD_{50} is the dose that kills 50% of the animals so 1.6xLD_{50} will result in more than 50% death in soman-treated animals alone. You can see from Dr (b)(6) publications that he uses 2xLD_{50} often to determine efficacy (21-26). We are working on another project where we have convincing data indicating that alpha-linolenic acid protects against soman-induced brain damage. Our work was recently published using

the method listed in this animal protocol (27).

V.4. Technical Methods:

V.4.1. Pain / Distress Assessment:

V.4.1.1. APHIS Form 7023 Information:

V.4.1.1.1. Number of Animals:

	Species #1	Species #2
V.4.1.1.1.1. Column C:	96	
V.4.1.1.1.2. Column D:		
V.4.1.1.1.3. Column E:	240	

V.4.1.2. Pain Relief / Prevention: There is momentary discomfort upon injection of HI-6, atropine (AMN), and soman. Because the animals are in status epilepticus which involves hyperexcitability of both hemispheres, it is unlikely that the animals feel any discomfort when they are injected with diazepam.

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization:
When the rats are delivered from the supplier (b)(4) they will be allowed to acclimate to LAM for 1 week. The animals will then be subjected to anesthesia for placement of the external jugular catheters. Animals will be allowed to recover for 1 week and will then be injected via external jugular catheter (see V.4.4.1.). When the animals have stabilized at (b)(6) following soman exposure, they will be brought back to USUHS where they will be placed in quarantine, observed by laboratory personnel and injected with 5 ml lactate ringers solution sc every 6 hours. All animals will be euthanized 24 hours after soman exposure.

Anesthesia for placement of external jugular catheter:
Rats will be placed in an induction chamber then anesthesia will be induced with 3-4% isoflurane from a precision vaporizer delivered in 1-2 Liters per minute of oxygen. Once the rats are in lateral recumbancy, they will be moved to a mask and prepared for surgery. Maintenance anesthesia will be delivered at 1-3% isoflurane in 0.5 to 1 Liter per minute of oxygen. Anesthesia will be adjusted based on response to toe pinch and depth of respirations. Once animal is adequately anesthetized (no response to toe pinch) then surgical procedures will begin. At the completion of the procedure, the rats will be removed from anesthetic and allowed to awaken in a home cage. All rats except for naïve will have external jugular catheters placed for injection of either vehicle or a stereoisomer of phenserine. The procedure itself takes 15-20 min. Animals are not kept under anesthesia any longer than necessary.

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions: Animals will have three days to acclimate to their surroundings once delivered to USUHS and before being used for any in vivo experiments. Rats will be observed by the PI or technician to ensure they appear healthy prior to undergoing surgery.

Animal monitoring post-soman. The animals will be watched throughout the 24 hour period. Monitoring will be performed in the rats' home cage, and will continue through the night until they are perfused. Any animals that show unexpected neurologic signs following soman injection or hunched posture, lethargy, anorexia, or other clinical signs potentially indicative of infection may be euthanized at an early endpoint or treated at the discretion of the veterinarian and/or PI. Research personnel will weight rats just prior to being perfused (24 hours after soman). Supplemental feeding in the form of wet mash will be provided by LAM personnel as directed by the veterinarian or requested by the PI and 5 ml Lactated Ringer's sc every 6 hours will be administered for rats over the 24 hour period. Gel squares will be placed in each cage as a fluid supplement for the animals. The survival rate will also be determined just prior to the animals being perfused (24 hours after soman injection).

Supplemental (alternative approach) feeding. LAM personnel may place wet mash/ chow on the cage floor for rats that may not be able to gnaw pellets to get food – as requested by the PI, PI staff or LAM veterinarian.

Soman-induced seizures: The animals will not receive anesthesia or analgesia during the time the animals seize following injection of soman. Rats receiving soman will be injected with the oxime HI-6 (125 mg/kg, ip) and 30 min later will receive soman (180 ug/kg, sc) and post-exposure treatment with atropine methyl nitrate (2 mg/kg, im, 1 min after soman. All soman-treated animals will receive diazepam (10 mg/kg im) 40 min after onset of status epilepticus.

V.4.1.2.3. Paralytics: N/A

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures: There is no alternative for inducing brain damage in rats that mimics the damage caused by soman to determine whether the proposed research plan using phenserine protects against soman-induced brain damage or improves functional outcome. The only way to carry out the research plan is to allow the animals to seize for 40 min. This is the protocol established by Dr. (b)(6) at (b)(6) to induce brain damage followed by injection of diazepam to stop/attenuate the seizures.

V.4.1.3.1. Sources Searched: BRD, DTIC Private STINET, CRISP

V.4.1.3.2. Date of Search: November 27, 2012

V.4.1.3.3. Period of Search: 1980-2012

V.4.1.3.4. Key Words of Search: rat, pain, kainic acid, seizure, hippocampus, piriform cortex, amygdala, neuronal damage, brain damage, gluatamate receptor, glutamate receptor, animal welfare, BHLHB2, alternative, reduce, refine, prevent, control, manage,

eliminate, alleviate, decrease, diminish

V.4.1.3.5. Results of Search:

DTIC Private STINET: 520 hits. One study discussed seizures as it relates to chemical warfare agents and measuring seizures on the battlefield. These studies offered no advantage over the proposed methods.

BRD: no hits

CRISP: 17 hits. Several discussed reduce or refine but were not relevant to the proposed study.
Soman-induced convulsions: The treatment plan for inducing status epilepticus by soman in rats is a standard procedure that is routinely performed by many laboratories including our laboratory and outlined in the scientific literature. Sprague-Dawley rats have been used in the literature.

Interpretation: There presently is no alternative to employment of rat as an *in vivo* animal model to study the role of phenserine to protect against soman-induced neuropathology.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification: 240 male rats will receive soman at a dose that will induce seizures, an effect that is seen in humans exposed to nerve agents. The rats will experience some level of physical stress and discomfort for some period of time during the experiments. Analgesic, sedatives and/or anesthetic agents cannot be used because they will modify the pain but also seizure threshold preventing us from fully evaluating the effect of soman and as such we will not be able to draw any conclusions on the proposed effect of phenserine on neuronal survival or functional outcome. The objective of this study is to determine the effect of a single injection of phenserine on neuronal survival 24 hours after soman treatment. The purpose of the study is to find additional therapies to protect the brain so emergency room physicians will have more than one drug to use on patients exposed to these deadly weapons. Without exposing the animals to soman, it is not possible for us to conduct these studies. These studies are justified because the use of soman is a model for nerve agent-induced seizures, an expected effect of nerve agent exposure of military personnel in international conflicts and civilian populations. Identification of new neuroprotective agents is highly relevant to enhance treatment response capabilities. Thus, the knowledge obtained from the proposed investigations may benefit many active duty personnel as well as civilians.

V.4.2. Prolonged Restraint: N/A

V.4.3. Surgery: N/A

V.4.3.1. Pre-surgical Provisions: Surgeons will wear sterile gloves, mask, lab coat or scrub top. A general assessment of physical and behavioral health will be carried out on each rat before surgery. LAM veterinarians will be consulted should any sign of

abnormality in appearance and/or behavior be observed.

V.4.3.2. Procedure:
Rats will be anesthetized and maintained with isoflurane in oxygen by nosecone (see **V.4.1.2.1.**). After the induction of anesthesia, the rats (with the nosecone) will be placed in lateral recumbancy and prepared for surgery. Maintenance anesthesia will be delivered at 1-3% isoflurane in 0.5 to 1 Liter per minute of oxygen. Anesthesia will be adjusted based on response to toe pinch and depth of respirations. Once animal is adequately anesthetized (no response to toe pinch) then surgical procedures will begin. Only sterile instruments will be used. A supplemental heat source, such as an electric heating pad or circulating warm water blanket, will be set at 37°C throughout the duration of anesthesia. Rats will be monitored for dermal burns.

Placement of external jugular catheter. Anesthetized rats will be placed in dorsal recumbancy. Fur will be clipped from the ventral neck and interscapular region. Skin will be prepared for aseptic surgery using either betadine or alcohol or chlorhexidine scrub. The animal will be draped using sterile towels. A 1.5 to 2 cm long incision by a scalpel will be made in the ventrolateral aspect of the neck, parallel and approximately 0.5 cm lateral to midline. The external jugular vein will be dissected free of surrounding tissue and stabilized with a proximally placed tie of 4-0 suture. A catheter introducer will be used to guide the placement of the jugular catheter. A 4-0 ligature will be placed at the distal end of the catheter to secure it in place. Tissue adhesive may also be used to help stabilize the catheter in the jugular vein. Catheter will be tested for patency by flushing with sterile saline. The catheter will then be tunneled subcutaneously to exit via an approximately 2.5 cm incision in the interscapular region. Wound clips or suture material will be used to close the interscapular area. Tissue glue or suture material (3-0-5-0 nylon) will be used to close the ventral neck incision. If placement in one side of the jugular area is problematic, the procedure will be repeated on the opposite jugular vein. The procedure takes 15-20 min from start to finish. All animals will be allowed to be awakened and they are kept on a 37 degree C warmer until awake. When animals are awake, they are placed in a home cage.

All animals are awake when they are injected with soman.

Tail vein injections. I have much experience with tail vein injections. If you master the technique successfully, this route is superior over surgical placement of indwelling catheters. However, the problem with tail vein injections is failure to deliver the entire amount of drug into the vein. If some of the drug escapes into the extravascular space, we may not be able to show neuroprotective efficacy. Determining drug blood levels are beyond the scope of this grant proposal.

V.4.3.3. Post-surgical Provisions: Immediate post-operative care will be provided by the investigators and rats will be monitored continuously until they are ambulatory. Animals are expected to ambulate. Animals will be returned to their cages post-surgery only after they have recovered sufficiently from anesthesia. Food and water will be provided *ad libitum*. Room maintenance and climate control is as per LAM SOP. Investigators will weigh the animals just prior to perfusion (24 hours after injection of soman). Following surgery, rats will be monitored continuously until they are

ambulatory. The incision site will be monitored daily for signs of infection (erythema, edema, presence of an exudate, induration etc). Because the catheter will be inserted into the external jugular vein (indwelling catheter), we will also examine the area for signs of bleeding. Catheters will remain in place for about one week. Each catheter will be flushed once daily with heparinized saline to prevent clotting of the tip.

All animals undergoing catherization will receive buprenorphine, 0.01-0 05 mg/kg, subcutaneous (SC), every 8-12 hrs for 2 days. The alternative drug is acetaminophen, 6 mg/ml in drinking water for 2 days.

In addition to Center for LAM SOP's, study personnel will monitor animals using the checklist for animals exhibiting pain/distress beyond expectations of this study. If LAM personnel notice any of the following: persistent convulsions or tremors, self mutilation, continuous circling, or persistent labored breathing, and study personnel are unavailable, the LAM veterinarian may make the decision to euthanize the animal.

V.4.3.4. Location: LAM procedure room

V.4.3.5. Surgeon: To be determined. Dr. (b)(6) will instruct new personnel on how to insert external jugular catheters. Dr. (b)(6) is currently inserting jugular vein catheters in rats successfully. Dr. (b)(6) has six years of experience in placing these catheters in rats.

V.4.3.6. Multiple Major Survival Operative Procedures: N/A

V.4.3.6.1. Procedures:

V.4.3.6.2. Scientific Justification:

V.4.4. Animal Manipulations:

V.4.4.1. Injections:

Drug	Concentration	Dose	Route	Site	Frequency
Phenserine or saline	1 mg/ml	1-3 mg/kg	Iv Needle : 22-25 gauge Vol : 250-270 µl	Into indwelling catheter between shoulders	once
Posiphen	1 mg/ml	1-3 mg/kg	Iv Needle : 22-25 gauge Vol : 250-270 µl	Into indwelling catether between shoulders	once
HI-6	250 mg/ml	125 mg/kg	Ip (150 µl), 25 gauge needle	Abdomen	once
soman	360 ug/ml	180 ug/kg	Sc (150 µl) ; 25 gauge	Above thigh posteriorly	once

			needle		
Atropine	4 mg/ml	2 mg/kg	Im (120 µl) ; 23-25 gauge needle	thigh	once
Diazepam	5 mg/ml	10 mg/kg	Im (600 µl) ; 23-25 gauge needle	thigh	once

Soman treatment (Specific Aims 1-3). Male Sprague-Dawley rats (250-300 gm) receiving nerve agent will be injected with the oxime HI-6 (125 mg/kg, ip) and 30 min later will receive soman (180 ug/kg, sc) and post-exposure treatment with AMN (2 mg/kg, im, 1 min after soman. These treatments, HI-6 (125 mg/kg, ip) and 30 min later soman (180 ug/kg, sc) and post-exposure treatment with ANM (2 mg/kg, im) 1 min after soman, have been shown to reliably produce electrographic seizure activity within approximately10 min. Rats are allowed to seize for 40 min and then treated with 10 mg/kg, im, diazepam to stop/attenuate the seizures (as per Dr. (b)(6) protocol at (b)(6)

Phenserine will be injected via catheter in either a pretreatment or post-treatment paradigm followed by nerve agent + oxime injection. We will use a needle size ranging from 22 to 25 gauge.

IP Injections: For animals requiring fluid replacement, 5 ml of sterile lactate ringers will be injected sc. The rat will be manually restrained and tilted so that the head is facing downward and its abdomen is exposed. The injection site will be disinfected and the needle (23-25 gauge) attached to the syringe containing the sterile solution inserted cranially into the abdomen at a 30-45 degree angle caudal to the umbilicus and lateral to the midline. Once the needle is inserted, we will aspirate. If nothing is aspirated, the lactated ringer solution is injected.

V.4.4.2. Biosamples:

In vivo experiments. The brains from the male Sprague-Dawley rats will be collected at the time of euthanize. Brain will be preserved for future studies. Brain tissue may be removed to determine phenserine levels to ensure proper injection.

V.4.4.3. Adjuvants: N/A

V.4.4.4. Monoclonal Antibody (MAbs) Production: N/A

V.4.4.5. Animal Identification:

A patch will be shaved on each animal's back and then marked with non-toxic permanent ink with an individual ID. Sometimes, the ink fades in which case the ID will

be re-inked on the patch. All cages have cage cards per LAM. Rats that receive nerve agent injection will be checked for their ink mark labels prior to injection of nerve agent to make sure they are clearly labeled.

V.4.4.6. Behavioral Studies: N/A

V.4.4.7. Other Procedures:

Transcardial perfusion. When rats are euthanized, they will be placed under deep pentobarbital (50-75 mg/kg) anesthesia. Once adequate anesthesia is achieved (lack of response to toe pinch, slow even respirations), a midsternal thoracotomy will be performed to expose the heart and the rats will undergo transcardial perfusion with cold PBS and 10% formalin. Generally, about 200 cc of each solution is sufficient *per animal*, but, more will be used if required. Transcardial perfusion will be performed in (b)(5)

General histological procedures. For each brain studied, we will place two sections per slide and prepare 60 slides per rat. Every other slide will be stained with cresyl violet and every other slide will be stained with FluoroJade.C. Nissl-positive undamaged neurons and fluorescent-positive degenerating neurons are counted in the four brain regions [piriform cortex, hippocampus (CA1, CA3), cerebral cortex, amygdala]. Counts will be performed without knowledge of the treatment history of the rats.

Cresyl Violet staining (Experiments 1,2). Dried slides will be stained with cresyl violet in the following manner:

Treatment	Time
95% ETOH	15 min.
70% ETOH	1 min.
50% ETOH	1 min.
DH2O	2 min.
DH2O	1 min
Cresyl Violet Stain*	2 min.
DH2O	1 min.
50% ETOH	1 min.
70% acid ETOH**	2 min.
95% ETOH	2 min
95% ETOH	a few dips
100% ETOH	1 min
Histoclear	mounting media

*Cresyl violet preparation: add 1.25g cresyl violet acetate and 0.75 ml glacial acetic acid to 250 ml warm DH20, cool and filter.
**2 ml glacial acetic acid in 200 ml 70% ETOH.
Note: Some people find histoclear vapor to be irritating and may require a mask.

Histofluorescent labeling of degenerating neurons with Fluoro-Jade B (Experiments 1 and 2). Formalin-fixed brains will be prepared as outlined above (Transcardial perfusion of rats for brain fixation) and brain sections will be cut through

the designated brain regions on a cryostat.
The sections will be collected in 0.1M neutral phosphate buffer and mounted on 2% gelatin coated slides and then air dried on a slide warmer at 50 degrees C for at least 30 min. The slides will be transferred to a solution of 0.06% potassium permanganate for 10 minutes on a shaker table to insure consistent background suppression between sections. The slides will be rinsed in distilled water for 2 minutes. From this point forward, the protocol is performed as much as possible away from the light. The staining solution will be prepared from a 0.01% stock solution for Fluoro-Jade C (10 mg of Fluoro-Jade C in 100 mL of distilled water). To make up 200 mL of staining solution, 20 mL of stock solution will be added to180 mL 0.1% acetic acid (180 µL Acetic Acid in 180 mL distilled water). This results in a final dye concentration of 0.001%. The stock solution is stable for 2 months when stored at 4 °C but the freshly made staining solution is prepared within 10 minutes of use and will not be reused. After 30 minutes in the staining solution in the dark, the slides will be rinsed for one minute in each of three distilled water washes. Excess water will be removed by briefly (about 15 seconds) draining the slides vertically on a paper towel. The slides will be rapidly placed on a slide warmer, set at approximately 50 °C, until they are fully dry (about 5-10 minutes). The dry slides will be cleared by immersion in xylene for at least one minute before coverslipping with DPX (Sigma-Aldrich, St. Louis, MO), a non-aqueous non-fluorescent plastic mounting media. Sections spaced 125 µm apart will be viewed under fluorescein (FITC) optics in an Axiovert Zeiss microscope equipped for epifluorescence and photographed (10x magnification) using Axiovision software. A grid (170 x 170 µm) will be placed over a representative field in each of the four brain regions and the number of fluorescent cells will be counted, providing an estimate of the mean number of degenerating neurons for each animal. The mean number of Fluoro-Jade B-positive neurons ± SD will be calculated and graphed as a histogram.

Quantification of viable neurons (Experiments 1,2). The neuronal density of the four brain regions will be quantified. For example, analysis of neuronal density in the hippocampus will be performed on coronal sections of the dorsal hippocampus stained with cresyl violet and corresponding to brain sections located between 3.14 and 4.16 mm posterior to bregma. Neurons will be scored as undamaged if they are Nissl-positive with a round to oval shaped cell body that exhibits no evidence of cell shrinkage. Degenerating neurons characterized by shrunken cell bodies will be excluded. Neuronal density values will be expressed as mean ± SD. Counts are performed by an investigator without knowledge of the treatment history of the rats. Slides are placed on a Zeiss standard microscope with fluorescence capability. This microscope is connected to a PC for imaging and photography. Three representative fields are photographed from each of the four brain regions (cortex, hippocampus, amygdala, piriform cortex) from cresyl violet- and FluoroJade C-stained slides. The viable (cresyl violet) and degenerating (fluoroJade C) neurons are quantified; graphed and standard statistical methods are used to determine significance.

Animal transportation: The USUHS cargo van will be used to transport animals and the anticipated drive time one-way is 80 min and the number of miles one-way is 63. The maximum time the animals will be in the cargo van is 160 min. This van will be wiped down with disinfectant prior to and after the transport. The cargo van is heated and has air conditioning; LAM personnel usually place a small device that monitors the

temperature in the van. Only laboratory personnel that work on this project will drive the van to and from [(b)(6)] All animals will be transported to [(b)(6)] on the morning of soman injection. Animals will be pre- or post-injected with phenserine or saline at USUHS or at [(b)(6)] as per the experimental design. **An animal protocol will also be submitted to [(b)(6)] for approval.**

After the rats are stabilized following the injection of diazepam (40-60 min), the rats will be brought back from [(b)(6)] by lab personnel on the day of nerve agent injection and placed in a room designated by LAM. All animals will be in their home cage (1 rat/cage). See **V.4.1.2.2 for animal monitoring.**

All soman injections will be performed by Dr. [(b)(6)] at [(b)(6)]

V.4.4.8. Tissue Sharing: The brains from Specific Aim 1-2 will be collected at the time of euthanasia and remain available for future studies. All other tissues (organs etc) will be made available to other investigator upon request.

V.4.5. Study Endpoint: The study endpoint for rats used for Specific Aim 1-2 is survival until the pre-determined post-operative time point, after which they will be euthanized.

V.4.6. Euthanasia:

Experiment 1-2: Research personnel will perform all euthanasias except in cases where a LAM veterinarian make the decision that a particular animal needs to be euthanized. At the indicated endpoint, each rat will be deeply anesthetized with Pentobarbital (50-75 mg/kg ip). Animals should be deeply anethetized within 30 minutes. A midsternal thoracotomy will be performed to expose the heart and the rats will undergo transcardial perfusion with PBS and the 10% formalin in PBS. This procedure results in euthanasia from exsanguination under deep nembutal anesthesia.

Rats that reach an early endpoint (see **V.4.5**) will be euthanized via cylinderized CO_2. The research technician or the PI will perform this early euthanasia. The apparatus for euthanasia by CO_2 is located in [(b)(6)] Alternately, if requested by the PI, animals will be euthanized by Center for LAM personnel) using cylinderized CO_2 in compliance with the 2007 AVMA guidelines on Euthanasia. Euthanasia will he performed in the LAM CAF. If possible, animals will be euthanized in their home cage. If not, a clean rodent cage will be used. Animals will be placed in the cage so that it is not overcrowded (each animal can place all four feet on the bottom of the cage.) With animals in the chamber, the flow rate of CO_2 will displace at least 20% of the chamber volume per minute. Gas flow will be maintained for at least one minute after respiration has stopped before removing animals from the cage. A supplemental method to ensure death (cervical dislocation or bilateral thoracotomy) may be used.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol.

V.5.1.1. Study Room:
Building(s) (b)(6) Room Number(s) _____

Surgery Room: External jugular catheter placement will occur in a (b)(6) (see V.4.3.2).

Soman Injection: All animals will be transported in their home cages to (b)(6) from the USUHS loading dock on the day of soman injection. Dr. (b)(6) will inject HI-6, atropine, soman and valium. Once the animals are stabilized, the animals will returned to USUHS on the same day. LAM personnel will assist in loading and off loading the animals in their home cages. The animals will be placed in a room assigned by LAM when they return to USUHS.

V.5.1.2. Special Husbandry Provisions:

Food Restriction: Yes _____ No x

Fluid Restriction: Yes No x

V.5.1.3. Exceptions: _____ _____

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care:

V.5.2.2. Emergency Veterinary Medical Care: All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: Except as indicated below, all animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents.

V.5.3.2. Enrichment Restrictions:

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
Animal handling,	(b)(6)	3 years experience	Rodent handling

External jugular vein catherization, euthanasia by transcardial perfusion	(b)(6)	insering jugular vein catheter,15 year experience in rodent handling, surgery and tissue dissection, 5 years experience in transcardial perfusion	course June 1, 2007 at USUHS.
External jugular vein catherization, animal handling, drug injections, euthanasia via transcardial perfusion		6+ yr experience rodent handling, surgery and tissue dissection; 6 month experience in euthanasia by transcardial perfusion. External jugular vein catherization – 2 years of experience	Animal investigator training course (May 2008). Rodent Handling Course (30 May 2008).
Animal handling, agent injections, drug injections		39+ years rodent handling, surgery and tissue dissection; 15 years in EEG electrode emplacement in primates; 39 years EEG electrode emplacement in rodents	Occ Health/zoonotic disease (01/05/04), Rodent Handling (02/05/04), aseptic techniques and rodent anesthesia (November 2006), Anesthesia (March 2006) and XCSM (nerve agent) custodian
Animal handling, drug injections		B.S. Environmental Scinece; 2+ yr rodent handling (MRICD), 2+ yr rodent surgery (MRICD)	Occ Health/zoonotic disease (21 June 2005), Rodent Handling (21 Jun 2005) and XCSM (nerve agent) User
Animal handling, drug injections		M.S. Biology, 3 yr experience assistant small animal veterinary practice; 7 yr experience ORISE research assistant	Occ Health/zoonotic disease (21 Jun 2005), Rodent Handling (21 Jun 2005), Anesthesia (03 Feb 2006) and XCSM (nerve agent) user
Euthanasia via transcardial perfusion		30+ yr rodent handling, surgery, tissue dissection,	30 + years experience and on-the-job training

	(b)(6)	euthanasia	in handling small laboratory animals, anesthesia, guillotine usage, perfusion. Rodent handling course and investigator training course at NIH
Animal handling, tissue dissection, drug injections, transcardial perfusion		30+ yr rodent handling, surgery and tissue dissection; 3 yr experience on transcardial perfusion	Investigator training course at USUHS (Nov 1993).
External jugular vein catherization, animal handling, drug injections, euthanasia via transcardial perfusion		3 years of rodent handling, and experience in animal behavior and transcardial perfusion	Investigator training course and rodent handling at USUHS (July 2012)
Supply of phenserine		Over 30 yr experience as medicinal chemist	

VII. BIOHAZARDS/SAFETY:

The first grant proposal in my laboratory that used soman was initiated in 2006. None of my laboratory personnel developed any side effects of acetylcholinesterase inhibition from working on this project. There is no risk to my laboratory personnel as a result of handling animals exposed to Soman and their bedding materials and excreta.

All soman injections will be performed by Dr. (b)(6) at (b)(6)

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

(b)(6) _____ 1/4/13

Principal Investigator Signature Date

G. Training: The following personnel will attend the next USUHS Investigator/Animal User Training Course:

_____ _____

_____ _____

H. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely "Responsibility" for implementing animal use alternatives where feasible and conducting humane and lawful research.

(b)(6) _____ 1/4/13

Principal Investigator Signature Date

I. Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL** or **WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

(b)(6) _____ 1/4/13

Principal Investigator Signature Date

X. PROTOCOL ABSTRACT:

A. Animal Protocol Number:

B. Animal Protocol Title: Phenserine, an acetylcholinesterase inhibitor with possible neuroprotective efficacy against soman-induced neuropathology in male Sprague-Dawley rats

C. Principal Investigator: (b)(6)

D. Performing Organization: USUHS and (b)(6)

E. Funding: DTRA

F. Objective and Approach: The objective is to find treatment modalities to reduce brain damage caused by nerve agents and improve outcome. Phenserine is a compound developed by Dr (b)(6) at the (b)(6) NIH, Baltimore, MD. This drug was tested in a phase 3 trial as a therapy for Alzheimer's Disease. The drug was very well tolerated with no reported side effects. Phenserine is more lipophilic compared to physostigmine. Phenserine readily and preferentially enters the brain following its systemic administration and achieves levels that are 10-fold higher than concomitant levels in plasma. Phenserine selectively inhibits AChE in plasma and brain and has a minimal effect on butyrylcholinesterase (BChE). Phenserine is dramatically less acutely toxic than is physostigmine and is safe. An additional feature of phenserine, that is not available for huperzine A, galantamine or similar anticholinesterases, is that phenserine has a chiral center and naturally exists in the active form as (-)-phenserine. Phenserine entered Phase III trials for the treatment of Alzheimer's Disease and is well tolerated (1-5). Recently, phenserine has been formulated for transdermal application and has been tested in animals (6). The approach is to pretreat or post-treat animals with phenserine and determine neuroprotective efficacy in soman-injected animals. Neuroprotective efficacy will be determined quantitatively by counting the number of surviving and degenerating neurons in brain sections stained with cresyl violet and FluoroJade C respectively.

G. Indexing Terms (Descriptors): phenserine, rat, soman, neuroprotection, acetylcholinesterase, neuropathology.

March 15, 2013

MEMORANDUM FOR DR. (b)(6) DEPARTMENT OF NEUROLOGY

SUBJECT: IACUC Approval of Protocol – Triennial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on March 15, 2013:

Animal Protocol Title: "Linolenic Acid: An Omega 3 Fatty Acid That Protects Against Soman-Induced Neuropathology in Sprague-Dawley Rats"

USUHS Protocol Number: (b)(6)

Expiration Date: March 14, 2016

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. NON-TECHNICAL SYNOPSIS: Nerve agents represent a key threat to the United States military and civilian populations. These agents block a crucial brain enzyme, acetylcholinesterase, which in turn leads to brain hyperactivity. Brain hyperactivity results in seizures. A severe type of seizure is one lasting more than thirty minutes and is called status epilepticus and is commonly observed following exposure to chemical warfare agents. Status epilepticus is a medical emergency because it can lead to severe brain damage and/or death. Certain drugs are effective but must be given within five minutes after onset of seizures. Thus, compounds that protect the brain against nerve agents are required to attenuate or prevent damage and improve outcome.

Linolenic acid is an omega-3 fatty acid and found in canola oil. Linolenic acid is a dietary supplement that can be purchased over the counter. Linolenic acid has been shown to reduce brain damage induced by kainic acid, a compound that is found in a particular type of seaweed and induces seizures. Therefore, we tested whether linolenic acid may protect against soman-induced brain damage. Our data suggest that injecting linolenic acid either before or after soman significantly protects vulnerable brain cells against soman-induced brain damage twenty four hours after nerve agent injection. Our next goal is to determine whether the protection by linolenic acid is long lasting. Brain networks will be examined through behavioral testing.

Catheters will be placed into a medium sized vein and patency of the catheters will be maintained by a heparin-saline solution. Drugs to improve the survival of the animals will be administered before and after injection of the nerve agent, soman and a well-established agent that stops the seizures will be injected in all animals that receive soman. The neuroprotective agent, α-linolenic acid, will be injected into the animals three times over a 7 day period via the catheters either prior to or after nerve agent.

Our recent data show that three injections of linolenic acid further improve brain cell survival and exert an anti-depressant effect. We will test the hypothesis that chronic administration of α-linolenic acid either prior to or after soman improves functional outcome

II. BACKGROUND:

II.1. Background: Nerve agents and neurodegeneration. Nerve agents irreversibly inhibit the cholinesterase enzyme. Inhibition of acetylcholinesterase (AchE) results in elevated acetylcholine (Ach) levels in synapses in the peripheral and CNS leading to the progression of toxic signs including hypersecretions, tremors, seizures, respiratory distress and ultimately death.

It is established that prolonged seizures are responsible for the neuropathology caused by nerve agents. Termination of seizures within 10 min results in no neuronal cell death whereas 20 minutes of seizure activity results in mild neuronal cell death; further delay in controlling seizures dramatically increases the neuropathology in animal models. Moreover, the longer seizures continue the higher the probability for the development of status epilepticus, a serious complication of seizure activity defined as a prolonged seizure or continuous seizures lasting more than thirty minutes without regaining consciousness. Neurodegeneration occurs most frequently in the piriform cortex, followed by the amygdala, hippocampus, thalamus, cerebral cortex and caudate/putamen. The brain region that shows the most severe damage is the piriform cortex followed by the hippocampus, cortex, thalamus, amygdala and caudate/putamen. Anticonvulsants such as benzodiazepines decrease seizure activity and improve outcome but their efficacy to attenuate or abolish nerve agent-induced seizures depends upon the administration time post-exposure of the nerve agent. For example, the mean latency for seizure termination by midazolam (the most effective anticonvulsant) given five minutes after the induction of seizure activity induced by either soman or sarin was twenty minutes. Thus, even under the most ideal conditions, it still requires twenty minutes to terminate seizure activity induced by these agents (2). In addition, benzodiazepines such as midazolam can cause respiratory depression and exacerbate nerve agent-induced respiratory depression leading to increased brain injury and/or death.

Glutamate and excitotoxicity. Neurodegeneration caused by prolonged seizure activity is an example of hypoxic-ischemic neuronal injury. The primary event in nerve agent-induced seizures is the excessive accumulation of Ach in synapses which results in the release of the excitatory amino acid glutamate. Glutamate, the endogenous neurotransmitter required for normal physiological excitation, is involved in the pathophysiology of hypoxic-ischemic neuronal injury. Although this neuropathological process can be mediated by any of the excitatory amino acid receptors, the N-methyl-D-aspartate (NMDA) glutamate receptor subtype plays a crucial role. Overactivation of postsynaptic NMDA receptors is thought to result in a massive influx of calcium leading to biochemical and metabolic events that result in neurodegeneration. This process is referred to as excitotoxicity. The NMDA glutamate receptor subtype plays a crucial role in neuronal cell death mediated by nerve agents. These results confirm the role of NMDA receptors in nerve agent-induced neurodegeneration and validate the mechanism of neuronal cell death.

The vulnerable brain regions that are involved in nerve agent-induced neuropathology would be expected to impair learning and memory (hippocampus, dorsal medial nucleus of the thalamus), emotional memory (amygdala), cognition (cortex) and movement (caudate/putamen). Because of the long latency required to terminate seizures,

soldiers are at high risk for developing the neuropathology. Thus, it is essential to develop effective neuroprotective treatments and preventative therapies.

Linolenic acid is an essential fatty acid and the only omega-3 fatty acid found in vegetable products. It is most abundant in canola oil. It is commercially available and can be purchased over the counter as a nutritional supplement. Beneficial effects of PUFAs have been shown in the cardiovascular field and in preventing fatal ventricular arrhythmias by reducing cardiac excitability. PUFA's may also have beneficial effects on brain function such as depression. Also, there is some evidence that PUFA's may reduce seizure activity by decreasing neuronal excitability perhaps by opening potassium channels.
Injection of linolenic acid (500 nmol/kg iv) thirty minutes after an epileptic insult (kainic acid 10 mg/kg ip) is neuroprotective. Linolenic acid also exhibits delayed neuroprotective properties. Thus, injection of linolenic acid (500 nmol/kg, iv) three days prior to an epileptic insult (kainic acid 7.5 mg/kg, ip) almost completely inhibited kainic acid-induced neuronal damage in the CA1 and CA3 subfields of the rat hippocampus. The severity of seizure activity was attenuated but was not thought to contribute to delayed neuroprotection. Finally, linolenic acid (10 uM, i.c.v.) thirty minutes prior to 10-30 minutes global ischemia almost completely blocked ischemic-induced neuronal cell loss in the hippocampus whereas injection of palmitic acid, a saturated fatty acid, exerted no neuroprotection. Linolenic acid is also neuroprotective when injected intravenously thirty minutes after a ten minute global ischemic insult. These results show that linolenic acid protects against an epileptic insult when given as a treatment or pretreatment paradigm. The fact that linolenic acid also protects against ischemia provides further confirmation of its neuroprotective effect since ischemic and epileptic-induced neurodegeneration are examples of hypoxic-ischemic neurodegeneration that involve NMDA receptor-mediated excitotoxicity.

Linolenic acid increases activated NF-κB in the hippocampus. Thus, NF-κB is a biomarker. We first showed and confirmed that injection of linolenic acid intravenously at a dose of either 100 nmol/kg or 500 nmol/kg increased activated NF-kappaB in hippocampal nuclear extracts. Injection of linolenic acid three days prior to soman injection protects vulnerable neurons against soman-induced neuropathology in four critical brain regions: piriform cortex, amygdala, hippocampus and cortex. Our results show that pretreatment with linolenic acid (500 nmo/kg IV) protects vulnerable neurons in the cortex [35.6%], in the hippocampus [81.02%], in the amygdala [63.34%], and in the piriform cortex [45.14%] using the FluoroJade C staining method. Moreover, linolenic acid reduces the degree of swelling in the piriform cortex in soman-treated animals. Injection of linolenic acid thirty minutes after soman injection is also neuroprotective in the four brain regions but there is no difference in the degree of swelling in the piriform cortex from linolenic acid-treated and soman-treated animals.

This is the first study to show that linolenic acid, an over the counter dietary supplement provides significant protection against the neuroprotection by a potent nerve agent. We now extend our findings by: 1) determining whether protection extends out to a 7 day time frame; 2) determining whether the observed neuroprotection by linolenic acid improves functional outcome; and 3) determine whether multiple injections of linolenic acid improve neuronal survival over and above a single injection.

II.2. **Literature Search for Duplication:**

II.2.1. **Literature Source(s) Searched**: BRD, PubMed, DTIC, ToxNet

II.2.2. **Date of Search**: December 1, 2012

II.2.3. **Period of Search**: 1980-2012

II.2.4. **Key Words and Search Strategy**: linolenic acid, soman, rat, nerve agent, nuclear factor kappaB, neuroprotection.

II.2.5. **Results of Search:**

BRD: no hits
DTIC: no hits
PubMed: 3 hit. One paper (b)(6) described the neuroprotective effect of linolenic acid against kainic acid-induced status epilepticus and the second paper described that the protective effect against ischemic stroke requires activated NF-κB. The third paper (b)(6) which was published in the journal *Neurotoxicology* in 2012 (33(5):1219-29). The current project is an extension of the first project and seeks to determine the long-term efficacy and the efficacy of three injections of α-linolenic acid on delayed neurodegeneration and behavior outcome.

TOXNET: No hits
No duplication of the proposed study.

III. **OBJECTIVE\HYPOTHESIS:** Linolenic acid protects against soman-induced neuropathology. If iv linolenic acid is neuroprotective, we will develop subcutaneous neuroprotective doses of linolenic acid for future studies.

IV. **MILITARY RELEVANCE**: The neurological effects of chemical weapons on the performance and operations of our military would be devastating. This is, in fact, a major goal of the terrorists. They want to cripple the military at a sufficient level and long enough so that when the levels of the chemical weapons are no longer toxic the terrorists can penetrate into and destroy military facilities, equipment and soldiers.

V. **MATERIALS AND METHODS:**

V.1. **Experimental Design and General Procedures:**

V.1.3. Specific Aim 3. To determine behavior measures in LIN500-treated rats prior to or after soman injection. Status epilepticus induced by soman damages the following brain regions: piriform cortex, amygdala, hippocampus, thalamus, cerebral cortex and caudate/putamen. Since linolenic acid provides significant protection against soman-induced neuropathology, we wish to determine whether the increased neuronal survival improves functional outcome by performing behavior tests designed to test

specific areas of the brain known to be damaged by soman. The behavior measures performed in this specific aim are: locomotor activity and rotarod test, open field center time, forced swim test, shuttle box performance test, and social interactions. The software also detects seizure activity including onset, duration and frequency. One group of rats will be **pretreated** (500 nmol/kg, iv; 3 doses) with linolenic acid (500 nmol/kg iv, LIN500; ≤300 µL) prior to soman injection (day 1, 3, 7 prior to injection of soman) and a second group will be **post-treated** with 3 doses of linolenic acid (500 nmol/kg, LIN500 iv) on day 1, 3, 7 after injection of soman.

For the pretreatment paradigm: groups of male Sprague-Dawley rats:

Table 1: α-Linolenic acid Pretreatment Groups and Group Sizes for Experiment 1

Treatment Group	**HI-6 30 min Soman 0 min, Atropine 1 min Diazepam 40 min**	**Treatment (Time before seizure onset)**	**Group Size**	**Pain Category**
Group 1 Adult Male Rats	HI-6→Soman→atropine→seizure →diazepam	α-linolenic acid (1 day, 3 days, 7 days)	17 Male Rats	E
TOTAL			**17 Male Rats**	**17 E**

Table 2: α-Linolenic acid Pretreatment Groups and Group Sizes for Experiment 1

Treatment Group	**HI-6 30 min Saline 0 min, Atropine 1 min Diazepam 40 min**	**Treatment (Time before Saline injection)**	**Group Size**	**Pain Category**
Group 2 Adult Male Rats	HI-6→Saline→atropine →Diazepam	α-linolenic acid (1 day, 3 days, 7 days)	9 Male Rats	C
TOTAL			**9 Male Rats**	**9 C**

Table 3: Control Groups and Group Sizes for Experiment 1

Treatment Group	**HI-6 30 min Soman 0 min, Atropine 1 min Diazepam 40 min**	**Saline (Time before seizure onset)**	**Group Size**	**Pain Category**
Group 3 Adult Male Rats	HI-6→Soman→atropine→ seizure→diazepam	Vehicle (1 day, 3 days, 7 days)	17 Male Rats	E
TOTAL			**17 Male Rats**	**17 E**

Because we are performing behavioral measures on the animals injected with α-linolenic acid, all groups of animals, including controls, need to be included in this study.

For the treatment paradigm: groups of male Sprague-Dawley rats:

Table 4: α-Linolenic acid Treatment Groups and Group Sizes for Experiment 1

Treatment Group	HI-6 30 min Soman 0 min, Atropine 1 min Diazepam 40 min	Treatment (Time after seizure onset)	Group Size	Pain Category
Group 4 Adult Male Rats	HI-6→Soman→atropine→seizure →diazepam	α-linolenic acid (1 day, 3 days, 7 days)	17 Male Rats	E
TOTAL			**17 Male Rats**	**17 E**

Table 5: Control groups - No Soman Exposure and Group Sizes for Experiment 1

Treatment Group	HI-6 30 min Saline 0 min, Atropine 1 min Diazepam 40 min	Treatment (Time after Saline injection)	Group Size	Pain Category
Group 5 Adult Male Rats	HI-6→Saline→atropine →Diazepam	α-linolenic acid (1 day, 3 days, 7 days)	9 Male Rats	C
TOTAL			**9 Male Rats**	**9 C**

Table 6: Control groups - Soman Exposure No Treatment and Group Sizes for Experiment 1

Treatment Group	HI-6 30 min Soman 0 min, Atropine 1 min Diazepam 40 min	Saline (Time after seizure onset)	Group Size	Pain Category
Group 6 Adult Male Rats	HI-6→Soman→atropine→ seizure→diazepam	Saline (5 min)	17 Male Rats (17 for each dose)	E
TOTAL			**17 Male Rats**	**17 E**

When the behavioral testing of the rats is completed, all rats will be euthanized, brains fixed, sectioned and stained to quantify neuronal survival and degenerating neurons. **All animals will be weighed daily. During the first 24 hours after soman injection, laboratory personnel will stay with animals in LAM. After the first 24 hours, laboratory personnel will check animals every 8 hours. All animals will receive Lactate Ringer's (5 ml, sc) or more if the rats are not drinking up to 25 ml/day, wet mash, apple slices and gel squares. We will determine the survival rate of all animals and quantify the results just prior to perfusion.**

Methods

Chemicals. Linolenic acid will be purchased from Nu-Chek Prep, Elysian, Minnesota. All other reagents except soman will be purchased from commercial sources or as

indicated. Soman will be supplied by Dr. (b)(6) at the (b)(6) (b)(6)

Drug treatments. Linolenic acid will be freshly prepared on the day of experimentation. Linolenic acid will be first dissolved in ethanol at a molar concentration and then diluted in NaCl 0.9% solution to reach a final concentration of 500 µM. The pH of the solution will be adjusted to 7.0 for bolus intravenous injection. Vehicle (0.05% ethanol) will be prepared in an identical fashion but in the absence of linolenic acid.

Soman injections: Soman (180 ug/kg, sc in Sprague Dawley male rats, ~300g weight) will be injected in conjunction with pretreatment with the oxime HI-6 (125 mg/kg, ip, 30 min before soman) and post-exposure treatment with methyl atropine (2mg/kg, im, 1 min after soman). Under these conditions, seizures are produced with a high probability (>95%). Animals are allowed to seize for 40 min and then treated with 10 mg/kg, im, diazepam (valium) to stop the seizures.

Linolenic acid treatment procedure (Specific Aim 1). Linolenic acid-treated rats will be intravenously injected into the jugular vein as a bolus (500 nmol/kg body weight) 30 min after soman challenge. Vehicle-injected animals will be treated in an identical manner and will be used as controls for the treatment group.

Quantification of viable neurons. The neuronal density of the six brain regions will be quantified. For example, analysis of neuronal density in the hippocampus will be performed on coronal sections of the dorsal hippocampus stained with cresyl violet and corresponding to brain sections located between 3.14 and 4.16 mm posterior to bregma. Neurons will be scored as undamaged if they are Nissl-positive with a round to oval shaped cell body that exhibits no evidence of cell shrinkage. Degenerating neurons characterized by shrunken cell bodies will be excluded. Neuronal density values will be expressed as mean ± SD. Counts are performed by an investigator without knowledge of the treatment history of the rats.

V.2. Data Analysis: Values from experimental and control groups are averaged and compared using analysis of variance ($p<0.05$ to reject the null hypothesis that the group means were equal). Post hoc analyses will use the Tukey test for multiple group comparison. A sample size of 17 animals per group will have 80% power to detect differences between groups of 1.2 standard deviations, based on one-way ANOVA with Tukey's post-hoc multiple comparisons among 3 group means with a 5%, two-sided significance level. Even with death of 8 animals per group, a sample size of 9 animals per group will have 80% power to detect differences between groups of 1.6 standard deviations, based on one-way ANOVA with Tukey's post-hoc multiple comparisons among 3 group means with a 5%, two-sided significance level.

V.3. Laboratory Animals Required and Justification: Chemical warfare agents or nerve agents are some of the most lethal compounds known to mankind. Nerve agents induce severe seizures, brain damage and death. Anticholinergic drugs are only effective if given within 5 minutes after the initiation of seizures. Thus, these agents have limited value in protecting the brain against nerve agent-induced seizures. We have convincing data indicating that linolenic acid, a dietary supplement that can be

purchased over the counter, is an efficacious neuroprotective compound against soman-induced neuropathology.

Mortality Rate:
The protocol involving the use of soman was developed by Dr. (b)(6) my collaborator at (b)(6) Dr. (b)(6) is a senior scientist at (b)(6) and an established investigator in the nerve agent field. According to Dr (b)(6) the dose of soman used to inject the animals is the dose that elicits seizures in 100% of the animals. Animals must seize for 40 min in order for the brain to be damaged. If the animals don't seize, they have to be euthanized and cannot be used for further study. The dose of soman used in this study is 1.6 x LD_{50}. The LD_{50} is the dose that kills 50% of the animals so 1.6xLD_{50} will result in more than 50% death in soman-treated animals alone. You can see from Dr (b)(6) publications that he uses 2xLD_{50} often to determine efficacy (21-26). Also, our work showing that alpha-linolenic acid is protective against soman-induced neuropathology was recently published as well using the method listed in this animal protocol (27).

V.3.1. **Non-animal Alternatives Considered**:
Because we are studying cellular mechanisms and responses, there are currently no non-animal alternatives that can meet our needs for these studies.

V.3.2. **Animal Model and Species Justification**: The male Sprague-Dawley rats for the *in vivo* studies were selected because this is the common gender and species of rat used in the literature. This allows us to compare our results directly with the many published results from other laboratories using chemical warfare agents or other acetylcholinesterase inhibitors such as paraoxon.

V.3.3. **Laboratory Animals**

		Species #1	Species #2
V.3.3.1.	**Genus & Species**:	Rattus norvegicus	
V.3.3.2.	**Strain/Stock**:	Sprague-Dawley	
V.3.3.3.	**Source/Vendor**:	(b)(4)	
V.3.3.4.	**Age**:	adult	
V.3.3.5.	**Weight**:	250-275 gm	
V.3.3.6.	**Sex**:	male	
V.3.3.7.	**Special Considerations**:	N/A	

V.3.4. **Number of Animals Required (by Species)**: 86

V.3.5. **Refinement, Reduction, Replacement (3 Rs)**:

V.3.5.1. Refinement: All surgeries will be performed under appropriate anesthesia. Any rat exhibiting signs of pain or impairment beyond that from this model will be euthanized at an early endpoint. No other refinement alternatives were considered. All animals will be weighed daily. During the first 24 hours after soman injection, laboratory personnel will stay with animals in LAM. After the first 24 hours, laboratory personnel will check animals every 8 hours. All animals will receive Lactate Ringer's (5 ml, sc) as needed (up to 25 ml/day), wet mash, apple slices and gel squares. We will determine the survival rate of all animals and quantify the results just prior to perfusion (the day after the behavioral measures are completed).

V.3.5.2. Reduction: We are using 17 rats/group which provides a sufficient number to determine statistical significance.

V.3.5.3. Replacement: Using rats will allow us to study whether linolenic acid protects against soman-induced neuropathology without using higher species. No other replacements were considered.

V.4. Technical Methods:

V.4.1. Pain / Distress Assessment:

V.4.1.1. APHIS Form 7023 Information:

V.4.1.1.1. Number of Animals:

	Species #1	Species #2
V.4.1.1.1.1. Column C:	18	
V.4.1.1.1.2. Column D:		
V.4.1.1.1.3. Column E:	68	

V.4.1.2. Pain Relief / Prevention:

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization:

Anesthesia for placement of external jugular catheter:
Rats will be placed in an induction chamber then anesthesia will be induced with 3-4% isoflurane from a precision vaporizer delivered in 1-2 Liters per minute of oxygen. Once the rats are in lateral recumbancy, they will be moved to a mask and prepared for surgery. Maintenance anesthesia will be delivered at 1-3% isoflurane in 0.5 to 1 Liter per minute of oxygen. Anesthesia will be adjusted based on response to toe pinch and depth of respirations. Once animal is adequately anesthetized (no response to toe pinch) then surgical procedures will begin. All rats except for naïve will have external jugular catheters placed for injection of either vehicle or linolenic acid.

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions: Animals will have 7 days to acclimate to their surroundings once delivered to USUHS and before being

used for any *in vivo* experiments. Rats will be observed by the PI or technician to ensure they appear healthy prior to undergoing surgery.

Animal monitoring. The animals will be watched continuously for 1h and then checked every 30 min until the animal is able to move. Researcher personnel will monitor the rats twice a day beginning on the following day after soman. Monitoring will be performed in the rat's home cage, and will continue every day up to the point they areeuthanized Any animals that show unexpected neurologic signs following soman injection or hunched posture, lethargy, anorexia, or other clinical signs potentially indicative of infection may be euthanized at an early endpoint or treated at the discretion of the veterinarian and/or PI. Research personnel will also weigh rats once a day to ensure they have not lost >20% of their body weight compared to baseline weights. Supplemental feeding in the form of wet mash will be provided by LAM personnel at the request of the PI or as directed by the LAM Veterinarians and fluids (5 ml Lactated Ringer's sc 2 to 3 times a day) will be administered to rats injected with soman by research personnel. Gel squares will also be placed on the floor of each cage and replaced every day by laboratory personnel.

Supplemental (alternative method) feeding. LAM personnel may place wet mash/chow on the cage floor for rats that may not be able to gnaw pellets to get food.

Soman-induced seizures: The animals will not receive anesthesia or analgesia during the time the animals seize following injection of soman. Rats receiving soman will be injected with the oxime HI-6 (125 mg/kg, ip) and 30 min later will receive soman (180 ug/kg, sc) and post-exposure treatment with AMN (2 mg/kg, im, 1 min after soman. All soman-treated animals will receive diazepam (10 mg/kg im) 40 min after onset of status epilepticus.

V.4.1.2.3. Paralytics: N/A

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures: There is no alternative for inducing brain damage in rats that mimics the damage caused by soman to determine whether the proposed research plan using linolenic acid protects against soman-induced brain damage or improves functional outcome. The only way to carry out the research plan is to allow the animals to seize for 40 min as recommended by Dr. (b)(6) at (b)(6) followed by injection of diazepam to stop the seizures.

V.4.1.3.1. Sources Searched: BRD, DTIC Private STINET, NIH Reporter

V.4.1.3.2. Date of Search: December 1, 2012

V.4.1.3.3. Period of Search: 1980-2012

V.4.1.3.4. Key Words of Search: rat, pain, kainic acid, seizure, hippocampus, piriform cortex, amygdala, neuronal damage, brain damage, gluatamate receptor, glutamate receptor, animal welfare, BHLHB2, alternative, reduce, refine, prevent, control, manage, eliminate, alleviate, decrease, diminish.

V.4.1.3.5. Results of Search:

DTIC Private STINET: 520 hits. One study discussed seizures as it relates to chemical warfare agents and measuring seizures on the battlefield. These studies offered no advantage over the proposed methods.

BRD: no hits

NIH Reporter: 17 hits. Several discussed reduce or refine but were not relevant to the proposed study.
Soman-induced convulsions: The treatment plan for inducing status epilepticus by soman in rats is a standard procedure that is routinely performed by many laboratories including our laboratory and outlined in the scientific literature. Sprague-Dawley rats have been used in the literature.

Interpretation: There presently is no alternative to employment of rat as an *in vivo* animal model to study the role of multiple doses of linolenic acid to improve neuroprotection against soman-induced neuropathology or to determine whether improved neuronal survival in linolenic acid-treated rats improves overall functional outcome by behavioral testing.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification: Sixty eight male Sprague-Dawley rats will receive soman at a dose that will induce seizures, an effect that is seen in humans exposed to nerve agents. The rats will experience some level of seizure or physical stress and discomfort for some period of time during the experiments. Analgesic, sedatives and/or anesthetic agents cannot be used because they will modify the pain and seizure threshold preventing us from fully evaluating the effect of soman and as such we will not be able to draw any conclusions on the proposed effect of linolenic acid on neuronal survival or functional outcome. The objective of this study is to determine whether the increase in neuronal survival in linolenic acid-treated rats improves functional outcome. Without exposing the animals to soman, it is not possible for us to conduct these studies. These studies are justified because the use of soman is a model for nerve agent-induced seizures, a expected effect of nerve agent exposure of military personnel in international conflicts and civilian populations. Identification of new neuroprotective agents is highly relevant to enhance treatment response capabilities. Thus, the knowledge obtained from the proposed investigations may benefit many active duty personnel as well as civilians.

V.4.2. Prolonged Restraint: N/A

V.4.3. Surgery: N/A

V.4.3.1. Pre-surgical Provisions:
Surgeons will wear sterile gloves, mask, lab coat or scrub top. A general assessment of physical and behavioral health will be carried out on each rat before surgery. LAM veterinarians will be consulted should any sign of abnormality in appearance and/or behavior be observed.

V.4.3.2. Procedure: Rats will be anesthetized and maintained with isoflurane in oxygen by nosecone (see **V.4.1.2.1.**). After the induction of anesthesia, the rats (with the nosecone) will be placed in lateral recumbancy and prepared for surgery. Maintenance anesthesia will be delivered at 1-3% isoflurane in 0.5 to 1 Liter per minute of oxygen. Anesthesia will be adjusted based on response to toe pinch and depth of respirations. Once animal is adequately anesthetized (no response to toe pinch) then surgical procedures will begin. Only sterile instruments will be used. A supplemental heat source, such as an electric heating pad or circulating warm water blanket, will be used to keep the rats warm throughout the duration of anesthesia. Rats will be monitored for dermal burns.

Placement of external IV catheter. Anesthetized rats will be placed in dorsal recumbancy. Fur will be clipped from the ventral neck and interscapular region. Skin will be prepared for aseptic surgery using either betadine or alcohol or chlorhexidine scrub. The animal will be draped using sterile towels. A 1.5 to 2 cm long incision will be made in the ventrolateral aspect of the neck using a scalpel, parallel and approximately 0.5 cm lateral to midline. The external jugular vein will be dissected free of surrounding tissue and stabilized with a proximally placed tie of 4-0 suture. A catheter introducer will be used to guide the placement of the IV catheter. A 4-0 ligature will be placed at the distal end of the catheter to secure it in place. Tissue adhesive may also be used to help stabilize the catheter in the jugular vein. Catheter will be tested for patency by flushing with sterile saline. The catheter will then be tunneled subcutaneously to exit via an approximately 2.5 cm incision in the interscapular region. Wound clips or suture material will be used to close the interscapular area. Tissue glue or sterile 4 O silk will be used to close the ventral neck incision.
If placement in one side of the jugular area is problematic, the procedure will be repeated on the opposite jugular vein.

V.4.3.3. Post-surgical Provisions:
Immediate post-operative care will be provided by the investigators and rats will be monitored continuously until they are ambulatory. Animals are expected to ambulate. Animals will be returned to their cages post-surgery only after they have recovered sufficiently from anesthesia. Food and water will be provided ad libitum. Room maintenance and climate control is as per LAM SOP. Investigators will perform daily weights, provide supplemental calories (as appropriate) via wet mash and sc lactate ringers (5 ml) if weight loss is greater than 20% until study completion. Following surgery, rats will be monitored continuously until they are ambulatory. The incision site will be monitored daily for signs of infection (erythema, edema, presence of an exudate, induration etc). Because the catheter will be inserted into the external jugular vein, we will also examine the area for signs of bleeding. Catheters will remain in place for about 3 weeks (Specific Aim 3). Each catheter will be flushed once daily with heparinized saline to prevent clotting of the tip.

In addition to Center for LAM SOP's, study personnel will monitor animals using the checklist for animals exhibiting pain/distress beyond expectations of this study. If LAM personnel notice any of the following: constant convulsions or tremors, self mutilation, continuous circling, or persistent labored breathing, and study personnel are

unavailable, the LAM veterinarian may make the decision to euthanize the animal. If animals continue to lose weight despite supplements (wet mash etc) or remain comatose for more than 24 hours, these animals will be euthanized by laboratory personnel or LAM.

V.4.3.4. Location: (b)(6)

V.4.3.5. Surgeon: Dr. (b)(6) (competent in placement of jugular vein catheter)
Ms. (b)(6) (graduate student)

V.4.3.6. Multiple Major Survival Operative Procedures: N/A

V.4.3.6.1. Procedures:

V.4.3.6.2. Scientific Justification:

V.4.4. Animal Manipulations:

V.4.4.1. Injections:

Soman treatment (Specific Aims 3). Male Sprague-Dawley rats (250-300 gm) receiving nerve agent will be injected with the oxime HI-6 (125 mg/kg, ip) and 30 min later will receive soman (180 ug/kg, sc) or saline and post-exposure treatment with atropine methyl nitrate (AMN, 2 mg/kg, im, 0.16-0.19 mL), 1 min after soman. These treatments, HI-6 (125 mg/kg, ip) and 30 min later soman (180 ug/kg, sc) and post-exposure treatment with ANM (2 mg/kg, im) 1 min after soman, have been shown to reliably produce electrographic seizure activity within approximately 10 min. Rats are allowed to seize for 40 min and then treated with 10 mg/kg, im, diazepam (25 gauge needle, 0.67-.74 ml) to stop/attenuate the seizures (as per Dr. (b)(6) protocol at (b)(6)

Linolenic acid will be injected via catheter. We will use a needle size ranging from 22 to 25 gauge and the injected volume is 0.3-35 mL.

Lactate Ringer's solution. After the first 24 hours, laboratory personnel will check animals every 8 hours. All animals will receive Lactate Ringer's (5 ml, sc) or more if the rats are not drinking up to 25 ml/day, wet mash, apple slices and gel squares.

Transcardial perfusion. When rats are euthanized, they will be placed under deep pentobarbital (50-75 mg/kg, i.p.) anesthesia. Once adequate anesthesia is achieved (lack of response to toe pinch, slow even respirations), a midsternal thoracotomy will be performed to expose the heart and the rats will undergo transcardial perfusion with cold PBS and 10% formalin. Generally, about 200 cc of each solution is sufficient per animal, but, more will be used if required.

V.4.4.2. Biosamples:

In vivo experiments. The brains from the male Sprague-Dawley rats will be collected at the time of euthanasia Brain will be preserved for future studies. Hippocampi may need to be removed to determine activated NF-κB levels, a biomarker of linolenic acid.

V.4.4.3. Adjuvants: N/A

V.4.4.4. Monoclonal Antibody (MAbs) Production: N/A

V.4.4.5. Animal Identification:

A patch will be shaved on each animal's back and then marked with non-toxic permanent ink with an individual ID. Sometimes, the ink fades in which case the ID will be re-inked on the patch. All cages have cage cards per LAM. Rats that receive nerve agent injection will be checked for their ink mark labels prior to injection of nerve agent to make sure they are clearly labeled.

V.4.4.6. Behavioral Studies:

Activity and Movement: General activity, movement, and coordination can be used as indices of overall health and well-being of rodents. Activity and movement serve as negative controls (brain areas relevant to movement should not be disrupted in the current study), and as a covariates for the other behavioral tasks that rely on animal locomotion for task completion. The locomotor and rotarod tasks have been used reliably for these purposes in Dr. (b)(6) lab for many years.

Open field locomotor activity. Locomotor activity is measured using an Omnitech Electronics Digiscan infrared photocell system. One-hour activity measurements are obtained (preferably during animals' active or dark cycle). Animals are placed singly in a 40 X 40 X 30 cm clear Plexiglas arena covered by a perforated Plexiglas lid. Data are automatically gathered and transmitted to a computer via an Omnitech Model DCM-I-BBU analyzer. The interfaced software measures 21 activity variables, including total distance and horizontal and vertical activity. Chambers are cleaned between subjects with 35% isopropyl alcohol solution.
The duration of locomotor activity testing is a maximum of 60 min per day and can be performed on multiple days throughout the duration of the experiment.

Rotarod: The rotarod test measures an animal's ability to maintain balance by coordinating movement and making postural adjustments. It also measures the ability to improve these skills with practice. Each rat rotarod treadmill (Med Associates, Inc, St. Albans, VT) consists of a motor-driven drum with constant speed or accelerating speed modes of operation. The drum (7.0 cm diameter) allows each animal to maintain a suitable grip. It is divided into four test zones (8.9 cm wide) so that up to four animals may be tested at the same time. The device consists of a smooth hard plastic cylinder with concentric circular plastic sides (39.7 cm diameter) to prevent the rat from laterally climbing off the cylinder.
Rats are placed on the device facing the wall with the rod rotating in the direction opposite from the animal (so that the rat uses its paws to pace forwards and avoid

falling off the rod). When a rat falls off the rotating drum (height of 26.7 cm), it breaks a photobeam, stopping the timer associated with that zone. In each trial, the speed of rotation is increased from 0 revolutions per minute (rpm) to 35 rpm for a maximum of 3 or 5 min. The mean duration on the device (based on 3 consecutive trials) is recorded. The procedures are based on reports in the literature (6-9). Chambers are cleaned between subjects with 35% isopropyl alcohol solution. The duration of rotarod measurement is 9 or 15 min per day can be performed on multiple days throughout the duration of the experiment.

Activation of the amygdala, a brain region vulnerable to soman-induced neuronal cell death, is involved in anxiety and stress-related behaviors. This can be measured using the total time spent in the center of an open field arena or number of entries into the center of the field.

Anxiety

Open field center time. The interfaced software measures time spent in the center vs. the margin of the open field. More time spent in the center of the apparatus is indicative of lower anxiety because the center of an open field may be more dangerous than the sides and corners. Chambers are cleaned between subjects with 35% isopropyl alcohol solution. The duration of open field center time measurement is 60 minutes per day, and data is gathered at the same time as general activity described above under "Open field locomotor activity" and can be performed on multiple days throughout the duration of the experiment.

Research in humans and animals has clearly established that the hippocampus is involved in learning and memory (2). Rats lesioned in the hippocampus have a difficult time acquiring active avoidance responses (3,4) and retaining passive avoidance responses over a period of time (3-5).

Learning and Memory

Passive avoidance: Animals are trained and tested using an automated avoidance training system (Med Associates, St. Albans, VT) consisting of two 21 x 25 x 17 cm chambers separated by a vertically-sliding door. This task consists of a training day and a consecutive testing day. During training, the animal is placed in one chamber of the darkened apparatus. After a delay of 60 seconds, a light comes on and the door to the other, still darkened chamber, opens. Naive rats instinctively move quickly from the lit chamber into the dark chamber. When the rat crosses completely into the darkened chamber, the door closes, latency to cross is recorded by the interfaced computer, and a 0.8 mA (mild, non-damaging) shock is delivered through the grid floor for 1 sec. The rat is left in the darkened chamber in which the shock has been delivered for 30 sec to facilitate the formation of memory for the aversive event, and then removed. The procedure on testing day is identical except that the shock is not delivered if/when the animal crosses into the darkened chamber. Memory is presumed to have occurred if the animal does not cross into the chamber in which it previously was shocked, or if latency to cross is significantly longer during the testing trial than during the training trial. The duration of passive avoidance testing is 5 min on each of two consecutive days,

and is only performed once during an experiment. Chambers are cleaned with 35% isopropyl alcohol between animals.

Active Avoidance: The active avoidance task is a fear-motivated associative avoidance test based on electric current as a source of punishment. In this task, a rodent learns to predict an aversive event (0.8 mA shock for 1 sec; **1 shock on day of training and 1 shock on testing day if they don't remember the cue that they will be shocked**) based on the presentation of a specific stimulus (lit chamber becomes darkened), and avoid the aversive event by actively moving into a lit compartment (10-11). **The total number of shocks each animal receives on the training day is one. If the animal remembers the cue that he will be shocked on the testing day, the rat does not get shocked. If he doesn't remember, the rat gets shocked only once. Maximum number of shock sessions is 2 (one training day and one testing day).**
The measures recorded are: number of avoidances (rodent crossing to other compartment during stimulus signal), number of non-responses (rodent failing to cross during stimulus signal), and response latency (latency to avoid aversive stimulus). These measures serve as an index of learning and allow memory to be assessed. This task takes place in the shuttlebox apparatus described above for passive avoidance. It is performed on 2 consecutive days once during an experiment. Chambers are cleaned with 35% isopropyl alcohol between animals.

The prefrontal cortex is involved in complex executive function, including planning, decision making, and controlling social behavior in humans. The social interaction paradigm has been used in rats to assess functioning of the prefrontal cortex in a rat model of schizophrenia (12). Further, rodent social interaction is correlated with neuronal morphology in the prefrontal cortex (13). The piriform cortex, also called the olfactory cortex, is related to processing of olfactory cues. Because rodent-rodent interaction involves sniffing and smelling one another, the social interaction paradigm will also be used to assess piriform cortex function.

Interaction with Conspecifics
Social interaction observation: Social interaction is videotaped in a 40 X 40 X 30 cm clear Plexiglas arena. A shield made of cardboard measuring 45 cm in height is placed around three sides of the test arena at a distance of 10 cm to minimize subject distraction. The camera is placed 30 cm away from the unshielded side of the arena. Video cables connect cameras to taping equipment nearby. Following each social interaction, arenas are cleaned with 35% isopropyl alcohol solution. Animals are paired for testing with another animal of the same sex and in the same experimental condition. Pairs are determined so that body weights are comparable. Prior to taping of the interaction, animals are placed in opposite corners of the arena and a slotted Plexiglas lid is placed on top of the arena. Social interactions are observed or videotaped for 10 min for later scoring and analyses. We have not observed fighting to occur during the social interaction test. Animals typically engage in a range of social behaviors, including grooming, following and sniffing one another, and wrestling behavior (similar to wrestling behaviors exhibited by cage mates) but we have never seen an instance of biting. Animals are monitored continuously during the test both on video monitor and by listening for vocalizations (because fighting generally is accompanied by vocalizations). Should fighting occur, animals will be separated immediately and the test will be

terminated. The duration of the social interaction test is 10 min and can be performed multiple times throughout the experiment.
Live scoring and/or videotapes made during the testing sessions will be quantified by a sampling procedure in which the behavior of each animal is scored by a trained rater once every three seconds for the entire 10 min period. Behaviors are separated into three categories for analysis: Exploratory, Social, and Other. These procedures are based on classic protocols used to score and analyze behavior of children interacting in pairs (57, 58) and we have applied these same scoring categories to analyses of social interactions by rats (14, 15).

Human and animal studies have shown that the amygdala may be implicated in depressive states and expression of depressive behaviors. In humans, increased amygdale volumes positively correlated with depressive symptoms in temporal lobe epilepsy (67). Rodent models have found that greater depressive-like behavior on the forced swim test is correlated with amygdala activation (16).

Depression
Swim test: The Porsolt swim test is widely used as an index of learned helplessness or depression (17-20). The procedure involves a repeated procedure in which rats are placed into a cylinder (approximately 65 cm tall and 25 cm diameter cylinder filled to a height of 48 cm with water that is between 28-32 °C on the first day for 15 minutes. After 15 minutes of swimming, the rats are removed from the water and are dried and warmed with towels and heat lamps. On subsequent days, rats are retested for 5 minutes under identical conditions to determine the latency to become immobile (i.e., the rat initiates a stationary posture that does not reflect attempts to escape from the water), amount of time spent immobile, and number of times the animal becomes immobile, as determined by video analysis software (AnyMaze, Stoelting, Wood Dale, IL). After 5 minutes, the animals are removed and then dried and warmed with towels and heat lamps. On the second day of testing, shorter latencies to assume an immobile, floating position, more instances of immobility, and longer durations of immobility are interpreted as increased helplessness or depression. All rats are monitored the entire time and are removed from the water if they cannot swim or show signs of distress. Feces will be removed from the water between animals, and water will be replaced if it becomes too murky. The test lasts 15 minutes on the training day, and 5 minutes the consecutive testing day. This procedure can be performed several times throughout the experiment.
Seizure Observation
Animals will be placed into a cage separate from their homecage for observation and video analysis (AnyMaze, Stoelting, Wood Dale, IL) of seizure activity. Seizure activity is manually keyed for the duration of the seizure. AnyMaze software can analyze the video for latency to seize, seizure duration, and number of seizure occurrences.

Seizure Observation
Animals will be placed into a cage separate from their homecage for observation and video analysis (AnyMaze, Stoelting, Wood Dale, IL) of seizure activity. Seizure activity is manually keyed for the duration of the seizure. AnyMaze software can analyze the video for latency to seize, seizure duration, and number of seizure occurrences.

Timing of behavioral Tests

Day 1	Day 2	Day 3	Day 4
Open field activity (training) Rotarod	**Open field activity testing Passive Avoidance training**	**Passive avoidance testing Forced Swim Test training**	**Forced swim testing**

Behavior tests are performed 14 days after soman exposure. We are performing four behavior tests: rotarod, open field activity, passive/active avoidance and the forced swim test. On any given day, animals are subjected to 1 training and testing/day or a training combined with the rotarod because rotarod does not require training. Animals that undergo testing for the forced swim test are not subjected to any other training or testing during the remainder of the day. All behavior tests are completed in four days/group of animals.

V.4.4.7. Other Procedures:

Transcardial perfusion. When rats are euthanized they will be placed under deep pentobarbital (50-75 mg/kg) anesthesia as described above. Once adequate anesthesia is achieved (lack of response to toe pinch, slow even respirations), a midsternal thoracotomy will be performed to expose the heart and the rats will undergo transcardial perfusion with cold PBS and 10% formalin. Generally, about 200 cc of each solution is sufficient per animal, but, more will be used if required. Transcardial perfusion will be performed in (b)(6)

Animal transportation: All animals will be transported to (b)(6) on the morning soman is to be injected with soman in accordance with the LAM transportation SOP. Animals will be pre- or post-injected with linolenic acid or saline. **An animal protocol will also be submitted to** (b)(6) **for approval.** The rats will be brought back from (b)(6) to LAM by lab personnel on the day of nerve agent injection where they will be placed in home cages (1 rat/cage).

General histological procedures. For each brain studied, we will place two sections per slide and prepare 60 slides per rat. Every other slide will be stained with cresyl violet and every other slide will be stained with FluoroJade. Nissl-positive undamaged neurons and fluorescent-positive degenerating neurons are counted in the six brain regions [piriform cortex, hippocampus (CA1, CA3), cerebral cortex, amygdala, thalamus, caudate/putamen]. Counts will be performed without knowledge of the treatment history of the rats.

Cresyl Violet staining. Dried slides will be stained with cresyl violet in the following manner:

Treatment	Time
95% ETOH	15 min.
70% ETOH	1 min.

50% ETOH	1 min.
DH2O	2 min.
DH2O	1 min
Cresyl Violet Stain*	2 min.
DH2O	1 min.
50% ETOH	1 min.
70% acid ETOH**	2 min.
95% ETOH	2 min
95% ETOH	a few dips
100% ETOH	1 min
Histoclear	mounting media

*Cresyl violet preparation: add 1.25g cresyl violet acetate and 0.75 ml glacial acetic acid to 250 ml warm DH20, cool and filter. **2 ml glacial acetic acid in 200 ml 70% ETOH. Note: Some people find histoclear vapor to be irritating and may require a mask.

Histofluorescent labeling of degenerating neurons with Fluoro-Jade B (Specific Aim 1 and 2). Formalin-fixed brains will be prepared as outlined above (Perfusion of rats for brain fixation) and brain sections will be cut through the designated brain regions on a cryostat.
The sections will be collected in 0.1M neutral phosphate buffer and mounted on 2% gelatin coated slides and then air dried on a slide warmer at 50 □C for at least 30 min. The slides will be transferred to a solution of 0.06% potassium permanganate for 10 minutes on a shaker table to insure consistent background suppression between sections. The slides will be rinsed in distilled water for 2 minutes. From this point forward, the protocol is performed as much as possible away from the light. The staining solution will be prepared from a 0.01% stock solution for Fluoro-Jade B (10 mg of Fluoro-Jade B in 100 mL of distilled water). To make up 200 mL of staining solution, 20 mL of stock solution will be added to180 mL 0.1% acetic acid (180 µL Acetic Acid in 180 mL distilled water). This results in a final dye concentration of 0.001%. The stock solution is stable for 2 months when stored at 4 □C but the freshly made staining solution is prepared within 10 minutes of use and will not be reused. After 30 minutes in the staining solution in the dark, the slides will be rinsed for one minute in each of three distilled water washes. Excess water will be removed by briefly (about 15 seconds) draining the slides vertically on a paper towel. The slides will be rapidly placed on a slide warmer, set at approximately 50 °C, until they are fully dry (about 5-10 minutes). The dry slides will be cleared by immersion in xylene for at least one minute before coverslipping with DPX (Sigma-Aldrich, St. Louis, MO), a non-aqueous non-fluorescent plastic mounting media. Sections spaced 125 µm apart will be viewed under fluorescein (FITC) optics in an Axiovert Zeiss microscope equipped for epifluorescence and photographed (10x magnification) using Axiovision software. A grid (170 x 170 µm) will be placed over a representative field in each of the six brain regions and the number of fluorescent cells will be counted, providing an estimate of the mean number of degenerating neurons for each animal. The mean number of Fluoro-Jade B-positive neurons ± SD will be calculated and graphed as a histogram.

V.4.4.8. Tissue Sharing: The brains from Specific Aim 1-3 will be collected at the time of euthanasia and remain available for future studies. All other tissues (organs etc) will be made available to other investigator upon request.

V.4.5. Study Endpoint: The study endpoint for rats used for Specific Aim 1-3 is survival until the pre-determined post-operative time point, after which they will be euthanized. Prior to euthanization rats will be anesthetized then euthanized for tissue collection as indicated above.

V.4.6. Euthanasia:

Experiment 1-3: Research personnel will perform all euthanasias except in cases where a LAM veterinarian makes the decision that a particular animal needs to be euthanized. At the indicated endpoint, each mouse will be deeply anesthetized with Pentobarbital (60-75 mg/kg ip). Animals should be deeply anesthetized within 30 minutes. A midsternal thoracotomy will be performed to expose the heart and the mice will undergo transcardial perfusion with PBS and the 10% formalin in PBS. This procedure results in euthanasia from exsanguination under deep nembutal anesthesia.

Rats that reach an early endpoint (see **V.4.5**) will be euthanized via cylinderized CO_2. Research personnel or the PI will perform this early euthanasia. The apparatus for euthanasia by CO_2 is located in (b)(6) Alternately, if requested by the PI, animals will be euthanized by Center for LAM personnel) using cylinderized CO_2 in compliance with the 2008 AVMA Guidelines on Euthanasia. Euthanasia will be performed in the LAM CAF. If possible, animals will be euthanized in their home cage. If not, a clean rodent cage will be used. Animals will be placed in the cage so that it is not overcrowded (each animal can place all four feet on the bottom of the cage.) With animals in the chamber, the flow rate of CO2 will displace at least 20% of the chamber volume per minute. Gas flow will be maintained for at least one minute after respiration has stopped before removing animals from the cage. A supplemental method to ensure death (cervical dislocation or bilateral thoracotomy) may be used.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol.

V.5.1.1. Study Room:

Building(s) (b)(6) Room Number(s) (b)(6)

V.5.1.2. Special Husbandry Provisions:

Food Restriction:	Yes	_____	No	x
Fluid Restriction:	Yes		No	x

V.5.1.3. Exceptions: All animals will be housed individually after insertion of IV catheter. Animals injected with soman will be given apple slices, wet mash and gel squares as food supplements on the floor of each cage.

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care:

V.5.2.2. Emergency Veterinary Medical Care: All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: Except as indicated below, all animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents.

V.5.3.2. Enrichment Restrictions:

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
small animal surgery, Drug injections, tissue dissection, euthanasia, transcardial perfusion	(b)(6)	1 year experience with animal surgery; 3 + years rodent handling and 3 years experience with tissue dissection and transcardial perfusion	Investigator course and rodent handling course (July, 2012)
Catheter placement, small animal surgery, drug injections, tissue dissection, euthanasia, transcardial perfusion, brain section cutting, brain section staining and counting		15 year experience in rodent handling, surgery and tissue dissection, 5 years experience in transcardial perfusion	Investigator course and rodent handling course (1 June 2007)

Animal handling, agent injections, drug injections	(b)(6)	39+ years rodent handling, surgery and tissue dissection; 15 years in EEG electrode emplacement in primates; 39 years EEG electrode emplacement in rodents	Occ Health/zoonotic disease (01/05/04), Rodent Handling (02/05/04), aseptic techniques and rodent anesthesia (November 2006), Anesthesia (March 2006) and XCSM (nerve agent) custodian
Euthanasia via transcardial perfusion		30+ yr rodent handling, surgery, tissue dissection, euthanasia	30 + years experience and on-the-job training in handling small laboratory animals, anesthesia, guillotine usage, perfusion. Rodent handling course and investigator training course at NIH
Animal handling, tissue dissection, drug injections, transcardial perfusion		30+ yr rodent handling, surgery and tissue dissection; 3 yr experience on transcardial perfusion	Investigator training course at USUHS (Nov 1993).
Collaborator for behavioral measures		Animal handling 25+ yrs experience in: injections, drug administration, surgical implant/expaint of osmotic mini-pumps, behavioral measures, biological sample collection anesthesia, decapitation	USUHS investigator Training and Animal Handling courses (several sessions, including sessions in 1980 and in early 1990s); NIH/NIMH training courses (several in mid 1980s); 25+ years experience with rats and other rodents.
Animal Handling, drug injections		Animal handling 3+ years,	USUHS investigator Training and Animal Handling courses; 2010; 5 + years experience with rats.

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

(b)(6) _____ 01 | 08 | 13

Principal Investigator Signature Date

G. Training: The following personnel will attend the next USUHS Investigator/Animal User Training Course:

_____ _____

_____ _____

H. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely, "Responsibility" for implementing animal use alternatives where feasible and conducting humane and lawful research.

(b)(6) _____ 01 | 08 | 13

Principal Investigator Signature Date

I. Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL or WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

X. PROTOCOL ABSTRACT:

A. Animal Protocol Number: (b)(6)

B. Animal Protocol Title: Linolenic Acid: An omega 3 fatty acid that protects against soman-induced neuropathology in Sprague-Dawley rats

C. Principal Investigator: (b)(6)

D. Performing Organization: USUHS

E. Funding: DTRA

F. Objective and Approach: The objective is to develop innovative and safe strategies to protect the brain against soman-induced neuropathology. The approach is to inject multiple doses of linolenic acid as a post-treatment strategy and determine neuronal survival. We will determine whether the neuroprotective effect of linolenic acid translates in an improvement of functional outcome through behavioral testing.

MEMORANDUM FOR DR. (b)(6) DEPARTMENT OF NEUROLOGY

SUBJECT: IACUC Approval of Protocol – Initial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on April 1, 2014:

Animal Protocol Title: "Possible involvement of Alpha-liolenic acid-induced neuroplastic effects against soman-induced brain damage"

USUHS Protocol Number: (b)(6)

Expiration Date: March 31, 2017

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6). The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6). This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. NON-TECHNICAL SYNOPSIS:

Nerve agents represent a key threat to the United States military and civilian populations. These agents block a crucial brain enzyme, acetylcholinesterase, which in turn leads to brain hyperactivity. Brain hyperactivity results in seizures. A severe type of seizure is status epilepticus, seizures lasting more than 5 minutes, and is commonly observed following exposure to chemical warfare agents. Status epilepticus is a medical emergency because it can lead to severe brain damage and/or death. The current therapy for nerve agent-induced status epilepticus is ineffectual in preventing the brain damage. Thus, compounds that protect the brain against nerve agents are required to attenuate or prevent damage and improve outcome.

α-Linolenic acid (LIN) is an omega-3 fatty acid found in vegetable products such as flax and pumpkin seeds. Linolenic acid is a dietary supplement that can be purchased over the counter. α-Linolenic acid has been shown to significantly protect against the brain damage caused by status epilepticus induced by kainic acid, a compound that is found in a particular type of seaweed. Therefore, we tested whether linolenic acid may protect against soman-induced brain damage caused by status epilepticus. Our data show that administration of a single dose of α-linolenic acid injected intravenously either before or after soman significantly protects vulnerable brain cells against soman-induced brain damage twenty four hours after nerve agent injection. Our most recent results provide convincing evidence that three doses of α-linolenic acid administered by intravenous injection after soman significantly protects against soman-induced brain damage. Brain networks were examined through behavioral testing. Administration of 3 doses of α-linolenic acid injected after soman exerts an anti-depressant-like activity as measured by the Porsolt swim test, significantly improved performance on the rotarod as well as memory consolidation and memory processes (see below).

Catheters will be placed into a medium sized vein and patency of the catheters will be maintained by a heparin-saline solution. The oxime, HI-6, ill be administered before and atropine and diazepam will be administered after injection of the nerve agent, soman. HI-6, atropine and diazepam improve survival of animals exposed to soman. The

neuroprotective agent, α-linolenic acid, will be injected into the animals three times over a 7 day period via the catheters after nerve agent.

We now wish to test the hypothesis that the well-established *in vivo* α-linolenic acid-induced neuroplastic effects contribute at least in part to the observed increase in animal survival, neuronal survival and improvement in functional outcome by activating the mammalian target of rapamycin in the hippocampus.

II. BACKGROUND:

II.1. Background:

Nerve agents and neurodegeneration. Nerve agents irreversibly inhibit the cholinesterase enzyme. Inhibition of acetylcholinesterase (AchE) results in elevated acetylcholine (Ach) levels in synapses in the peripheral and central nervous system (CNS) leading to the progression of toxic signs including hypersecretions, tremors, seizures, respiratory distress and ultimately death.

It is established that prolonged seizures are responsible for the neuropathology caused by nerve agents. Termination of seizures within 10 min results in no neuronal cell death whereas 20 minutes of seizure activity results in mild neuronal cell death; further delay in controlling seizures dramatically increases the neuropathology in animal models. Moreover, the longer seizures continue the higher the probability for the development of status epilepticus, a serious complication of seizure activity defined as a prolonged seizure or continuous seizures lasting more than five minutes without regaining consciousness. The brain region that shows the most severe damage is the amygdala followed by the piriform cortex, hippocampus, cortex, thalamus, and caudate/putamen. Anticonvulsants such as benzodiazepines decrease seizure activity and improve outcome but their efficacy to attenuate or abolish nerve agent-induced seizures depends upon the administration time post-exposure of the nerve agent. For example, the mean latency for seizure termination by midazolam (the most effective anticonvulsant) given five minutes after the induction of seizure activity induced by either soman or sarin was twenty minutes. Thus, even under the most ideal conditions, there is attendant brain damage (McDonough et al., 1997). In addition, benzodiazepines such as midazolam can cause respiratory depression and exacerbate nerve agent-induced respiratory depression leading to increased brain injury and/or death.

Glutamate and excitotoxicity. Neurodegeneration caused by prolonged seizure activity is an example of hypoxic-ischemic neuronal injury. The primary event in nerve agent-induced seizures is the excessive accumulation of Ach in synapses which results in the release of the excitatory amino acid glutamate. Glutamate, the endogenous neurotransmitter required for normal physiological excitation, is involved in the pathophysiology of hypoxic-ischemic neuronal injury. Although this neuropathological process can be mediated by any of the excitatory amino acid receptors, the N-methyl-D-aspartate (NMDA) glutamate receptor subtype plays a crucial role. Overactivation of postsynaptic NMDA receptors is thought to result in a massive influx of calcium leading to biochemical and metabolic events that result in neurodegeneration. This process is

referred to as excitotoxicity. The NMDA glutamate receptor subtype plays a crucial role in neuronal cell death mediated by nerve agents. These results confirm the role of NMDA receptors in nerve agent-induced neurodegeneration and validate the mechanism of neuronal cell death.
The vulnerable brain regions that are involved in nerve agent-induced neuropathology would be expected to impair learning and memory (hippocampus, dorsal medial nucleus of the thalamus), emotional memory (amygdala), cognition (cortex) and movement (caudate/putamen). Because of the long latency required to terminate seizures, soldiers are at high risk for developing the neuropathology. Thus, it is essential to develop effective neuroprotective treatments and preventative therapies.

Linolenic acid is an essential polyunsaturated fatty acid (PUFA) and the only omega-3 fatty acid found in vegetable products. It is most abundant in flaxseed oil. It is commercially available and can be purchased over the counter as a nutritional supplement. Protective effects of α-linolenic acid have been convincingly demonstrated in models of stroke, spinal cord injury and brain damage due to status epilepticus induced by kainic acid. PUFAs also have beneficial effects on mood as alpha-linolenic acid has been shown to exert an anti-depressant effect in women. Our most recent work demonstrated that three doses of α-linolenic acid increases neurogenesis, synaptogenesis, synaptic function and brain-derived neurotrophic factor (BDNF) levels in brain.

We have demonstrated previously that administration of a single dose of alpha-linolenic acid injected intravenously into adult male Sprague-Dawley rats either 3 days before or 30 minutes after soman protects significantly against soman-induced brain damage (Pan et al., 2012). We now have convincing evidence that administration of three doses of alpha-linolenic acid injected 30 min, 3 days and 7 days after soman increases animal survival, neuronal survival and improves functional outcome.

Alpha-linolenic acid (LIN) exerts an anti-depressant-like activity. Administration of 3 doses of LIN exerts an anti-depressant activity in soman-treated animals. Groups of animals were administered soman (1.6xLD50 s.c.) followed by α-linolenic acid (500 nmol/kg, iv; LIN500) at 30 min, 3 days and 7 days after soman.
Control groups consisted of saline for soman and vehicle (0.05% ethanol) for LIN500; vehicle (veh) was injected intravenously.
Two weeks after soman/veh exposure, all groups of animals were subjected to the Porsolt forced swim test (Porsolt et al., 1977). The forced swim test (FST) is a behavioral despair test and is the most widely used test to screen antidepressant drugs. Exposure to soman significantly increased immobility time; post-treatment with three doses of LIN500 following soman elicited a significant antidepressant-like effect, producing a 3.8-fold decrease in the FST immobility time compared with soman/vehicle (Figure 1). The locomotor activity in LIN500-injected rats

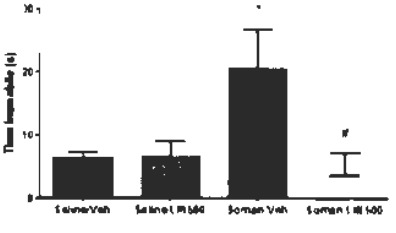

Figure 1. Three doses of α-linolenic acid exert an anti-depressant effect in soman-treated animals. Performance in the Porsolt forced swimming test was measured as time spent being immobile in seconds (s). FST was conducted two weeks after administration of soman/veh. *p < 0.05 vs saline/veh (vehicle) or saline/LIN (α-linolenic acid) group. #p <0.05 vs soman/veh (n = 8-10 animals/group).

was comparable with that observed in vehicle-treated animals ensuring that the increased active behaviors in FST were not secondary to a nonspecific increase in motor activity. These results demonstrate for the first time that 3 doses of α-linolenic acid exert an anti-depressant effect on animals damaged by soman.

A critical mechanism in the modulation of antidepressant treatment response occurs through increased brain-derived neurotrophic factor (BDNF) synthesis and its signaling pathways in brain. Converging lines of evidence have shown that the mechanisms of antidepressants are related to several mechanisms of neuroplasticity, ranging from changes in gene expression (including neurotrophic mechanisms) to synaptic transmission and plasticity, and neurogenesis (Lemaire et al., 2000; Racagni et al., 2008; Shors et al., 2001). Our previous results demonstrated that three doses of LIN500 administered intravenously over a seven day period increased BDNF levels, neurogenesis synaptogenesis and synaptic function in specific brain regions (Blondeau et al., 2009), properties well known for the efficiency of antidepressant drugs (Castren et al., 2007).

Research activities focusing on neural stem cells have shown that promoting their proliferation or grafting/infusing them by different routes into the brain leads to neurological improvement in different brain disease models (Capone et al., 2007; Maysami et al., 2008; Nomura et al., 2005; Pallini et al., 2005; Bramham, 2008; Cohen and Greenberg, 2008). This benefit does not come only by their capacity to replace lost neurons. They can also trigger several other mechanisms, such as the induction of survival-promoting neurotrophic factors or promote the restoration of synaptic transmitter release function by integrating into existing synaptic networks, and thus improve the functional circuitry. Three doses of α-linolenic acid promote neural stem cell proliferation, synaptogenesis and synaptic function (Blondeau et al., 2009). It is worth noting that neural stem cells can induce the transcription of protective factors, such as BDNF, which would be expected to modify the ischemic environment and promote neuroprotection. The in vitro and in vivo studies show that the expression of BDNF levels was increased after α-linolenic acid treatment in neural stem cells, hippocampal mature neurons, and in cortical/hippocampal tissue (5). BDNF is a potent enhancer of neurogenesis in intact (Lee et al., 2002) and ischemic brains (Liu et al., 1998; Zhu et al., 2011). Soman-induced status epilepticus would be expected to create an ischemic environment and it has been demonstrated that neurogenesis is impaired in this model (Joosen et al., 2009). The increase of mature BDNF, enhanced neurogenesis, synaptogenesis and synaptic function (see below) induced by α-linolenic acid may lead to increased brain protection and an environmental change favorable toward recovery of functional network circuitry.

In a mouse model of stroke, a single injection of α-linolenic acid, after the onset of stroke, significantly reduced infarct size and improved the neurological score 24-h post-ischemia. Although the single injection of α-linolenic acid did not improve long-term survival rate, repeated α-linolenic acid injections significantly improved survival, suggesting that subchronic α-linolenic acid treatment triggers other protective pathways (Heurteaux et al., 2006). Mature BDNF protein levels increased in the cortex and hippocampus following the injection of three doses of α-linolenic acid given iv (day 1, day 3, day 7) in control mice (Blondeau et al., 2009). BDNF is widely expressed in brain

where it carries out diverse functions including neuronal maintenance, learning and memory, enhanced neuronal survival in vivo and in vitro (Acheson et al., 1995; Fawcett et al., 1998; Ghosh et al., 1994; Gottschalk et al., 1998; Jiang et al., 2005; Korte et al., 1995; Lu and Figurov, 1997; Marini et al., 1998; Mattson et al., 2006; Miller and Kaplan, 2001; Suen et al., 1997; Tong et al., 1998; Yan et al., 1992); BDNF mediates these effects through its high affinity receptor, TrkB (Aloyz et al., 1999; Friedman and Greene, 1999; Kafitz et al., 1999; Kaplan and Miller, 2000; Klein et al., 1991; Soppet et al., 1991). It has been previously shown that BDNF increases neurogenesis, synapse formation and synaptic transmission (Katoh-Semba et al., 2002; Lee et al., 2002a; Lee et al., 2002b; Pencea et al., 2001).

Administration of three doses α-linolenic acid given intravenously on day 1, day 3 and day 7 in control mice also enhanced neurogenesis over baseline levels on day 10 in the hippocampus. Western blot experiments showed a 1.7 and 3.2-fold increase in synaptophysin in the cortex and hippocampus respectively. Increases in the expression of synaptobrevin and soluble synaptosomal-associated protein of 25kD (SNAP-25) by approximately 2-fold were also found in the cortex and hippocampus. Both proteins play a key role in exocytosis by participating in the fusion process. The protein expression of vesicular glutamate transporters V-GLUT1 and V-GLUT2 increased in the cortex and hippocampus; both are expressed in adult brain (Blondeau et al., 2009). Neuronal injury itself can lead to neural proliferation as a compensatory mechanism for cell death in the hippocampus (Gould and Tanapat, 1997; Liu et al., 1998) and growth factors such as BDNF play a prominent role in promoting neuronal differentiation and survival (Lowenstein and Arsenault, 1996). α-Linolenic acid may further promote the restoration of synaptic transmitter release function thus improving the function of damaged circuits. We hypothesize that chronic treatment with α-linolenic acid restores network circuitry damaged by soman via enhanced neurogenesis, synaptic function and synaptogenesis in the hippocampus and cortex, two major brain regions involved in plasticity and heavily damaged after nerve agent exposure.

We now show that three doses of α-linolenic acid administered 30 min, 3 days and 7 days after soman exposure increases animal survival.

The neuroprotective effect of 3 doses of α-linolenic acid administered intravenously (i.v.) 30 min, 3 days and 7 days after soman (soman/LIN500) is accompanied by a 2-fold increase in survival rate 21 days after soman (soman/Veh) exposure (Figure 2). We observed no increase in survival when α-linolenic acid (LIN500) was injected once, 30 min after soman exposure. There were no deaths in control groups (saline/veh; saline/LIN500). These results are comparable to our previous results where a single injection of LIN500 failed to improve animal survival following middle cerebral artery occlusion model

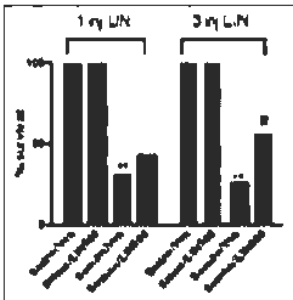

Figure 2. Administration of three injections of α-linolenic acid (LIN) significantly improves survival rate. Young male Sprague-Dawley rats were injected with α-linolenic acid intravenously (500 nmol/kg; LIN500) or vehicle (0.05% ETOH; veh) 30 min (1 injection; 1 inj), or 30 min, 3 days and 7 days (3 injections; 3 inj) after soman exposure. Controls consisting of saline in place of soman were also incorporated into the experiment. Survival rate was measured on day 21. **p < 0.001 *vs* saline/veh or saline/LIN500 group and #p < 0.05 *vs* soman/veh group by Fisher exact test. n=13-15/group.

(MCAO) of stroke but where three injections (30 min, 3 days, 7 days) after MCAO increased animal survival 3-fold (Blondeau et al., 2009).

We hypothesize that enhanced neurogenesis, synaptogenesis, synaptic neurotransmission and BDNF levels in cortex and hippocampus, play a critical role in the observed increase in animal survival and anti-depressant-like activity in animals that received three doses of α-linolenic acid after soman. We further hypothesize that one of the known downstream targets of BDNF via its high affinity receptor, TrkB, is the mammalian target of rapamycin (mtor).

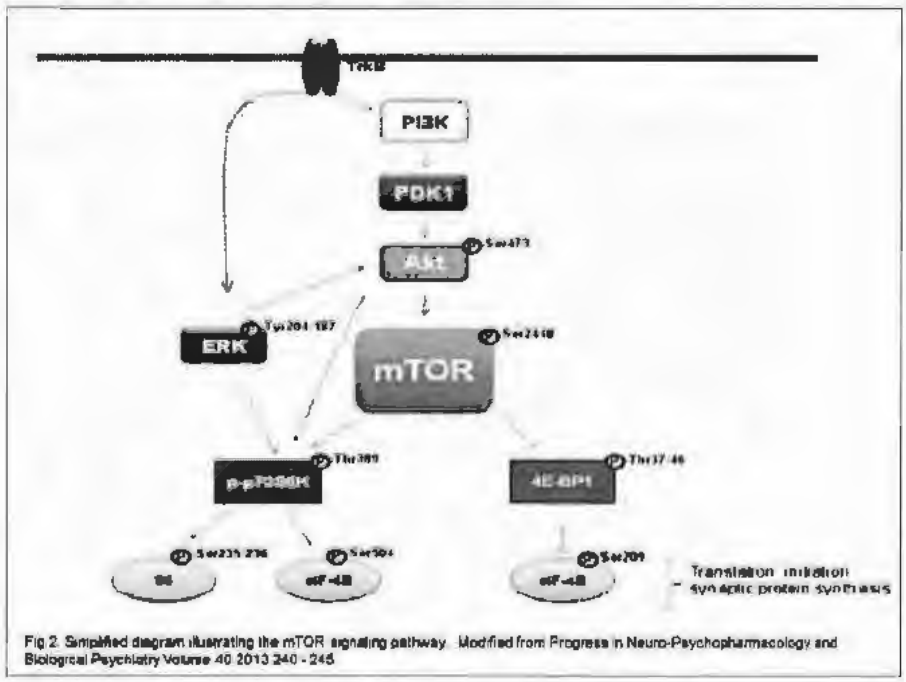

Fig 2. Simplified diagram illustrating the mTOR signaling pathway. Modified from Progress in Neuro-Psychopharmacology and Biological Psychiatry Volume 40 2013 240 - 245

BDNF-induced activation of TrkB lead to the activation of three main intracellular signaling pathways: 1) the phospholipase Cγ (PLCγ) pathway, which leads to activation of protein kinase C; 2) the mitogen-activated protein kinase [MAPK, or extracellular signal related kinase (ERK)] pathway, which activates several downstream effectors; and 3) the phosphatidylinositol 3-kinase (PI3K) pathway that activates the serine/threonine kinase Akt. MAPK and PI3K play crucial roles in neuronal survival, protein-synthesis dependent plasticity and neurogenesis.

The MAPKs are a specific class of serine/threonine kinases which respond to extracellular signals such as growth factors, mitogens, cellular stress and mediate proliferation, differentiation, and cell survival in mammalian cells. One of the MAPKs within mammalian cells is the extracellular signal-related kinases (ERKs). Several investigations have indicated that ERK promotes cell survival and proliferation. ERK is a threonine-glutamic acid-tyrosine (Thr-Glu-Tyr) motif divided into two subtypes: ERK1 and ERK2. Activation of ERK by neurotrophins stimulates ras, which activates MAPKKK, MAPKK and ERK [Lu and Chow, 1999; Mcallister et al., 1999; Tyler et al., 2002; West et al., 2001]. The PI3Ks are enzymes that initiate signaling cascades. Akt is a serine/threonine protein kinase and a major downstream target of PI3K. This pathway is known for regulating metabolism, cell growth and survival and recently has been associated with synaptic plasticity and antidepressant behavior.

Low expression of Akt has been related to neurodegeneration, whereas the increased activation of Akt is neuroprotective [Lee et al., 2006]. The phosphorylation of Thr308 and Ser473 of Akt fully activates Akt, which then phosphorylates a diverse number of

protein substrates containing the consensus sequence of RXRXXS/T [LaPiccolo et al., 2008]. Akt phosphorylation at ser473 is associated with neuroprotection after seizure-induced neuronal death [Piermartiri et al., 2009]. The substrates activated by Akt include Bcl-2-associated death promoter (BAD), Caspase 9, mammalian target of rapamycin (mTOR), IκB kinase (IKK), NF-Kappa B, glycogen synthase kinase 3β (GSK-3β), cAMP response element-binding (CREB) among others. The phosphorylation of these substrates eventually elicits multiple biological responses.

The PI3K–Akt and ERK are the two pathways involved in the activation of the mammalian target of rapamycin (mTOR) signaling (Fig 2) [Chandran et al., 2013). The mTOR is a large serine-threonine kinase that exists in two distinct heteromeric protein complexes referred to as mTOR complex 1 (mTORC1) and mTOR complex 2 (mTORC2). The mTORC1 is sensitive to the selective inhibitor rapamycin and it is activated by phosphorylation of serine 2448 in the canonical PI3K- Akt pathway after growth factor stimulation. However, additional signaling cascades also activate mTOR [Chong et al., 2012]. Rapamycin does not directly inhibit mTOR kinase activity; instead, it binds to FKBP12 and disrupts the mTOR-RAPTOR interaction, e.g. the complex of mTORC1. By contrast, mTORC2 is resistant to rapamycin, and recent studies have suggested that mTORC2 may phosphorylate Akt at S473 [Sarbassov et al., 2005; Sarbassov et al., 2004] but its mechanisms in brain plasticity and neurogenesis are not well understood.

The role of mTORC1 in neurological disorders. Treatments that activate Akt and mTOR mediate neuroprotective effects against ischemic brain injury [Koh, 2008], and contribute to recover motor function after spinal cord injury [Hu et al., 2010]. Activation of AKT/ERK/mTOR signaling pathway in the brain mediates protein-dependent synaptic plasticity [Slipczuk et al., 2009], neural differentiation and proliferation during neurogenesis [Han et al., 2008; Otsegi et al., 2006; Paliouras et al., 2012], and has been proposed to be part of the mechanism underlying antidepressant effects (Marsden, 2012). The antidepressant effect in rats is abolished when animals are treated with either rapamycin or with the PI3K inhibitor (LY294002) or the ERK inhibitor (U0126), an effect possibly related to concomitant inhibition of synaptogenesis [Li et al., 2010].
However, hyperactive mTOR leads to epilepsy, and inhibition of mTOR has antiepileptogenic properties in some model of epilepsy [Zeng et al., 2008; McMahon et al., 2012; Buckmaster et al., 2011]. But chronic inhibition of mTOR has been reported to induce prodepressant effects in a rat model of absence epilepsy [Russo et al., 2013]. In a recent extensive review of mTOR and epilepsy, Russo et al. [Russo et al., 2012] concluded that the activation status of mTOR is "complex and variable" and "might be limited to certain types of epilepsy and epileptogenic process", suggesting that the nature of the brain insult may contribute to the degree of mTOR activation.
The activation of mTOR signaling by neurotrophins increases the translation of synaptic proteins, which is essential for synaptic plasticity, by two mechanisms. First, mTORC1 phosphorylates and inactivates the eIF4E-binding protein (4E-BPs), which facilitates translation initiation by releasing the inhibition of eukaryotic initiation factor 4E (eIF4E), a crucial initiation factor in cap-dependent translation. The association of 4E-BPs with eIF-4E inhibits the ability of eIF-4E to associate with eIF-4G and initiate translation. Second, it activates p70S6 kinase, an enzyme that controls translation at a number of

levels, including synthesis of the S6 ribosomal subunit, phosphorylation of RNA helicase cofactor eIF4A and inhibition of eukaryotic elongation factor 2 (eEF2) kinase [Kuhn et al., 1996]. The p70S6 kinase and 4E-BP are also regulated by MAPK/ERK to control protein-synthesis dependent plasticity [Hartman et al., 2012], and p70S6 can further phosphorylate mTOR setting up an autoregulatory mechanism. Protein-dependent synaptic plasticity strengthens the neuronal connection and helps to regulate memory storage in the brain. On the other hand, excessive protein synthesis results in behavioral deficits, instead of improving neuroplasticity, suggesting a temporal window to where mTOR should be carefully modulated (Troca-Marin et al., 2012). Taken together, the LIN-induced increase in BDNF to enhance neuronal survival, synaptic plasticity and neurogenesis may play a central role in ameliorating the soman-induced neuronal damage and cognitive impairment in rodents.

II.2. Literature Search for Duplication:

II.2.1. Literature Source(s) Searched: PubMed, DTIC, BRD, ToxNet, NIH Reporter

II.2.2. Date of Search: January 27, 2014

II.2.3. Period of Search: 1980-2013

II.2.4. Key Words and Search Strategy: alpha-linolenic acid, soman, rat, neuropathology, brain damage, excitotoxicity

II.2.5. Results of Search:

BRD: no hits
DTIC: no hits
PubMed: 3 hit. One paper (Lauritzen et al., 2000) described the neuroprotective effect of linolenic acid against kainic acid-induced status epilepticus and another paper described that the protective effect against ischemic stroke requires activated NF-κB (Blondeau et al., 2001). The third paper (b)(6) which was published in the journal Neurotoxicology in 2012 (33(5):1219-29). The current project is an extension of our work where we have convincing data indicating that three doses of alpha-linolenic acid increase animal survival, neuronal survival in four major brain regions known to be vulnerable to soman and an improvement in functional outcome in animals exposed to a highly toxic dose of soman.

III. **OBJECTIVE\HYPOTHESIS:** The objective of this project is to determine the role of the known alpha-linolenic acid-induced neuroplastic effects in the observed increase in animal survival, neuronal survival and the improvement in functional outcome in soman-induced brain damage.

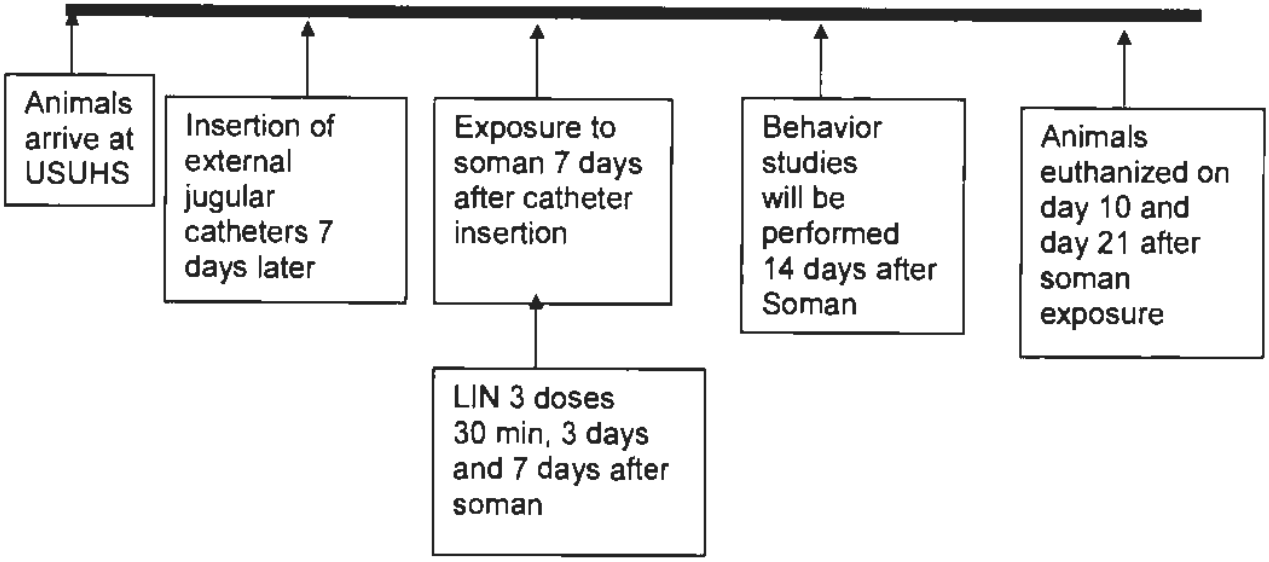
IV. **MILITARY RELEVANCE:**
These studies are justified because the use of soman is a model for nerve agent-induced seizures, an expected effect of nerve agent exposure of military personnel in international conflicts and civilian populations. Identification of new neuroprotective

agents is highly relevant to enhance treatment response capabilities. Thus, the knowledge obtained from the proposed investigations may benefit many active duty personnel as well as civilians.

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures:

Experimental Design:



Experimental Design: On either day 10 or day 21 after soman exposure, rats will be euthanized, brains fixed and sectioned for immunohistochemistry. A subset of rats will be euthanized 10 days after soman exposure, the brains harvested and stored at -80°C for western blot analysis. The brain regions investigated will be the hippocampus and prefrontal cortex. Another group of rats will be subjected to behavior studies and will be euthanized on day 21.

Experiment 1) Investigation of BDNF/TrkB and signaling pathways: western blot will be performed to determine changes in expression of BDNF, the presynaptic proteins synaptophysin-1, SNAP25 and postsynaptic density protein-95 (PSD-95).

Experiment 2) Correlation of mTOR signaling pathway with neurogenesis, synaptic plasticity and behavior: We will further test the role of the activation of mTOR in the well-known neuroplastic effects of LIN and correlate mTOR signaling to LIN-induced neuroprotection by blocking mTOR pathway with rapamycin (an mTOR antagonist),

Drug treatment

All of the procedures for exposing the animals to soman and post-treatment with LIN are described below. LIN will be administered 30 min, 3 days and 7 days after soman exposure by intravenous injection via an external jugular catheter.

Soman-induced seizures: The animals will not receive anesthesia or analgesia during the time the animals seize following injection of soman. Rats receiving soman will be injected with the oxime HI-6 (125 mg/kg, ip) and 30 min later will receive soman (180 ug/kg, sc) followed by post-exposure treatment with atropine methyl nitrate [AMN] (2 mg/kg, im, 1 min after soman. All soman-treated animals will receive diazepam (10 mg/kg im) 40 min after onset of status epilepticus.

Additional drug treatments are alpha-linolenic acid, BrdU, rapamycin and paraformaldehyde for perfusion (see V.4.4.1. Injections)

Histological procedures include cresyl violet staining, immunohistochemistry, FluroJade C staining.

V.1.1. Experiment 1: Determine neurogenesis in the subgranular zone of the dentate gyrus induced by Linolenic acid after soman exposure.

V.1.2. Experiment 2: To determine the role of the mTOR pathway in LIN-induced neuroprotection and improved functional outcome following soman exposure.

V.2. Data Analysis: Immunohistochemistry, Western blot and behavioral outcomes will be compared between groups using analysis of variance (ANOVA) followed by post-hoc t tests for specific comparisons of interest. Data will be examined for normality and constant variance and will be transformed if necessary, and nonparametric tests, e.g. Kruskal-Wallis and Mann-Whitney will be used if transformation is not sufficient. A sample size of 6 per group will have 80% power to detect a difference of 1.8 standard deviations between groups based on a two-group t test with a 5%, two-sided significance level. Differences of this magnitude have been observed in previous studies in this laboratory.

Experiment 1. Determine neurogenesis induced by Linolenic acid after soman exposure.

BrdU administration and Measurement of Neurogenesis: This experiment is divided in two sections:
1) In the first part the animals will receive two BrdU injections (i.p.). BrdU is a nucleotide analog, after injection BrdU is permanently incorporated into replicating DNA in place of thymidine, in the S-phase of cell cycle. BrdU-labeled cells can undergo apparently normal division, differentiation, migration and process integration in studies of adult neurogenesis [Bondeau et al., 2009).

2) The second part is the BrdU staining after the animals are euthanized. Neurogenesis will be quantified in the subgranular zone (SGZ) of the dentate gyrus (DG) of the

hippocampus. Fluorescent BrdU labeling can be imaged on a standard fluorescent microscope after immunohistochemistry to positively identify the number of BrdU-positive (anti-BrdU) cells. The phenotype of the BrdU-positive cells will be determined using fluorescent double-labeling with double cortin (DCX), an immature neuronal marker, NeuN (Feminizing Locus on X-3, Fox-3, or Hexaribonucleotide Binding Protein-3), a marker that is expressed in mature neurons, and GFAP (glial fibrillary acidic protein), an astrocyte marker.

Experiment 2. To determine the role of the mTOR pathway in LIN-induced neuroprotection and improved functional outcome following soman exposure. Rationale: Soman exposure results in profound cognitive deficits in humans and rodents. The mammalian target of rapamycin (mTOR) is a key mediator of protein-dependent synaptic plasticity (e.g. synaptogenesis), an important mechanism for memory storage in the brain. The mTOR inhibitor, rapamycin has been shown to impair cognitive function, disrupting memory consolidation and processing in the hippocampus. Moreover, mTOR has been reported to promote neuronal differentiation during neurogenesis. Increased synaptic plasticity and neurogenesis in the adult brain are necessary for positive behavioral effects of antidepressant drugs in rodent models of depression. The mTOR pathway can be activated by growth factors such as BDNF through the activation of TrkB receptors, and downstream activation of Akt and ERK signaling. Previous results from our group have demonstrated that repeated LIN treatment per se increases BDNF levels, synaptogenesis, neurogenesis and antidepressant effect, but the intracellular signaling mechanism(s) remain unclear. Hence I want to investigate whether soman–induced neurodegeneration is associated with changes in BDNF, TrkB and the downstream pathways i.e. PI3K, MAPK and mTOR in the hippocampus and propose to address whether 3 doses of LIN treatment (500 nmol/kg, iv) modulates these pathways to exert, in part, its neuroprotective effect to improve neuronal survival and functional outcome after soman exposure.

Treatment Groups and Group Sizes for Experiments 1 and 2

Table 1 LIN Treatment Group and Group Sizes for Experiment 1 (neurogenesis)

Treatment Group	Soman 0 min, Atropine min	Treatment (time after seizure onset)	Group Size	Pain Category
Group 1 Adult Male rats	HI-6→Soman→atropine →seizure→diazepam	LIN (30 min, 3 da 7 days), BrdU on day 9 and day 10 and 2 time points (10 days and 21 days)	12 Male Rats (6 for each time point)	**E**

V.3. Laboratory Animals Required and Justification: Because we are studying cellular mechanisms and responses, there are currently no non-animal alternatives that can meet our needs for these studies.

V.3.1. Non-animal Alternatives Considered: Because we are studying cellular mechanisms and responses, there are currently no non-animal alternatives that can meet our needs for these studies.

V.3.2. Animal Model and Species Justification: The male Sprague-Dawley rats for the in vivo studies were selected because this is the common gender and species of rat used in the literature. This allows us to compare our results directly with the many published results from other laboratories using chemical warfare agents or other acetylcholinesterase inhibitors such as paraoxon.

V.3.3. Laboratory Animals

	Species #1	Species #2
V.3.3.1. Genus & Species:	Rattus norvegicus	
V.3.3.2. Strain/Stock:	Sprague-Dawley	
V.3.3.3. Source/Vendor:	(b)(4)	
V.3.3.4. Age:	Young adult	
V.3.3.5. Weight:	250-275 gm	
V.3.3.6. Sex:	Male	
V.3.3.7. Special Considerations:	N/A	

V.3.4. Number of Animals Required (by Species): 288

V.3.5. Refinement, Reduction, Replacement (3 Rs):

V.3.5.1. Refinement: All surgeries will be performed under appropriate anesthesia as stated in section V.4.1.2.1. Any rat exhibiting signs of pain or impairment beyond that from this model will be euthanized at an early endpoint. No other refinement alternatives were considered.
All animals will be weighed daily. During the first 24 hours after soman injection, laboratory personnel will stay with animals in LAM. After the first 24 hours, laboratory personnel will check animals every 8 hours. All animals will receive Lactate Ringer's (5 ml, sc) by research staff as needed (up to 25 ml/day), wet mash, apple slices and gel

squares. We will determine the survival rate of all animals and quantify the results just prior to perfusion.

V.3.5.2. Reduction: All animals that are injected with soman will receive drugs to improve their survival (HI-6, atropine and diazepam). By using these drugs, survival is improved thereby reducing the overall number of animals required for this work.

V.3.5.3. Replacement: Computer modeling or lower animals such as worms cannot be used for these studies because we are quantifying cellular and molecular changes that can only be measured in living brain cells. The rat has been used extensively for cellular and molecular studies involving nerve agents and we will be able to compare our results with the existing literature.

V.4. Technical Methods:

V.4.1. Pain / Distress Assessment: In addition to Center for LAM SOP's, research personnel will monitor animals using the checklist (in section VIII, Enclosures) for animals exhibiting pain/distress beyond expectations of this study. If LAM personnel notice any of the following: constant convulsions or tremors, self-mutilation, continuous circling, or persistent labored breathing, and study personnel are unavailable, the LAM veterinarian may make the decision to euthanize the animal. If animals continue to lose weight despite supplements (wet mash etc) or remain comatose for more than 24 hours, these animals will be euthanized by laboratory personnel or LAM.

V.4.1.1. APHIS Form 7023 Information:

V.4.1.1.1. Number of Animals:

	Species #1	Species #2
V.4.1.1.1.1. Column C:		
V.4.1.1.1.2. Column D:	144	
V.4.1.1.1.3. Column E:	192	

V.4.1.2. Pain Relief / Prevention:

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization:

Anesthesia for placement of external jugular catheter: Rats will be placed in an induction chamber then anesthesia will be induced with 3-4% isoflurane from a precision vaporizer delivered in 1-2 Liters per minute of oxygen. Once the rats are in lateral recumbancy, they will be moved to a mask and prepared for surgery. Maintenance anesthesia will be delivered at 1-3% isoflurane in 0.5 to 1 Liter per minute of oxygen. Anesthesia will be adjusted based on response to toe pinch and depth of respirations. Once animal is adequately anesthetized (no response to toe pinch) then

surgical procedures will begin. All rats except for naïve will have external jugular catheters placed for injection of either vehicle or linolenic acid.

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions: Animals will have 7 days to acclimate to their surroundings once delivered to USUHS and before being used for any in vivo experiments. Rats will be observed by the PI or technician to ensure they appear healthy prior to undergoing surgery.

Animal monitoring. The animals will be watched continuously for 1h and then checked every 30 min until the animal ambulatory Research personnel will monitor the rats three times a day beginning on the following day after soman. Monitoring will be performed in the rat's home cage, and will continue every day up to the point they are euthanized. Any animals that show unexpected neurologic signs following soman injection or hunched posture, lethargy, anorexia, or other clinical signs potentially indicative of infection may be euthanized at an early endpoint or treated at the discretion of the veterinarian and/or PI. Research personnel will also weigh rats once a day to ensure they have not lost >20% of their body weight compared to baseline weights. Supplemental feeding in the form of wet mash will be provided by LAM personnel at the request of the PI or as directed by the LAM Veterinarians and fluids (5 ml Lactated Ringer's sc 2 to 3 times a day) will be administered to rats injected with soman by research personnel. Gel squares will also be placed on the floor of each cage and replaced every day by laboratory personnel.

Supplemental (alternative method) feeding. LAM personnel may place wet mash/chow on the cage floor for rats that may not be able to gnaw pellets to get food. They may also provide apple slices once animals are awake and moving around their home cage.

Soman-induced seizures: The animals will not receive anesthesia or analgesia during the time the animals seize following injection of soman. Rats receiving soman will be injected with the oxime HI-6 (125 mg/kg, ip) and 30 min later will receive soman (180 ug/kg, sc) followed by post-exposure treatment with atropine methyl nitrate [AMN] (2 mg/kg, im, 1 min after soman. All soman-treated animals will receive diazepam (10 mg/kg im) 40 min after onset of status epilepticus.

V.4.1.2.3. Paralytics: N/A

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures:

V.4.1.3.1. Sources Searched: BRD, DTIC Private STINET, NIH Reporter

V.4.1.3.2. Date of Search: December 31, 2013

V.4.1.3.3. Period of Search: 1980-2013

V.4.1.3.4. Key Words of Search: rat, pain, kainic acid, seizure, hippocampus, piriform cortex, amygdala, neuronal damage, brain damage, gluatamate receptor, glutamate

receptor, animal welfare, alternative, reduce, refine, prevent, control, manage, eliminate, alleviate, decrease, diminish

V.4.1.3.5. Results of Search:

There is no alternative for inducing brain damage in rats that mimics the damage caused by soman to determine whether the proposed research plan using linolenic acid protects against soman-induced brain damage or improves functional outcome. The only way to carry out the research plan is to allow the animals to seize for 40 min as recommended by Dr. (b)(6) at (b)(6) followed by injection of diazepam to stop the seizures.

DTIC Private STINET: 520 hits. One study discussed seizures as it relates to chemical warfare agents and measuring seizures on the battlefield. These studies offered no advantage over the proposed methods.

BRD: no hits

NIH Reporter: 17 hits. Several discussed reduce or refine but were not relevant to the proposed study.
Soman-induced convulsions: The treatment plan for inducing status epilepticus by soman in rats is a standard procedure that is routinely performed by many laboratories including our laboratory and outlined in the scientific literature. Sprague-Dawley rats have been used in the literature.

Interpretation: There presently is no alternative to employment of rat as an in vivo animal model to study the role of multiple doses of linolenic acid to improve neuroprotection against soman-induced neuropathology or to determine whether improved neuronal survival in linolenic acid-treated rats improves overall functional outcome by behavioral testing.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification:

One hundred and forty-four male Sprague-Dawley rats will receive soman at a dose that will induce seizures, an effect that is seen in humans exposed to nerve agents. The rats will experience some level of seizure or physical stress and discomfort for some period of time during the experiments. Analgesic, sedatives and/or anesthetic agents cannot be used because they will modify the pain and seizure threshold preventing us from fully evaluating the effect of soman and as such we will not be able to draw any conclusions on the proposed effect of linolenic acid on the neuroplastic effects or functional outcome. The objective of this study is to determine the role of LIN-induced neuroplastic effects in the observed increase in neuronal survival, animal survival, and improvement in functional outcome. Without exposing the animals to soman, it is not possible for us to conduct these studies.

V.4.2. Prolonged Restraint: N/A

V.4.3. Surgery:

V.4.3.1. Pre-surgical Provisions:
Surgeons will wear sterile gloves, mask, lab coat or scrub top and use aseptic technique. A general assessment of physical and behavioral health will be carried out on each rat before surgery. LAM veterinarians will be consulted should any sign of abnormality in appearance and/or behavior be observed.

V.4.3.2. Procedure: Rats will be anesthetized and maintained with isoflurane in oxygen by nosecone (see V.4.1.2.1.). After the induction of anesthesia, the rats (with the nosecone) will be placed in lateral recumbancy and prepared for surgery. Maintenance anesthesia will be delivered at 1-3% isoflurane in 0.5 to 1 Liter per minute of oxygen. Anesthesia will be adjusted based on response to toe pinch and depth of respirations. Once animal is adequately anesthetized (no response to toe pinch) then surgical procedures will begin. Only sterile instruments will be used. A supplemental heat source, such as an electric heating pad or circulating warm water blanket, will be used to keep the rats warm throughout the duration of anesthesia. Rats will be monitored for dermal bums.

Placement of external IV catheter. Anesthetized rats will be placed in dorsal recumbancy. Fur will be clipped from the ventral neck and interscapular region. Skin will be prepared for aseptic surgery using either betadine or alcohol or chlorhexidine scrub. The animal will be draped using sterile towels. A 1.5 to 2 cm long incision will be made in the ventrolateral aspect of the neck using a scalpel, parallel and approximately 0.5 cm lateral to midline. The external jugular vein will be dissected free of surrounding tissue and stabilized with a proximally placed tie of 4-0 suture. A catheter introducer will be used to guide the placement of the IV catheter. A 4-0 ligature will be placed at the distal end of the catheter to secure it in place. Tissue adhesive may also be used to help stabilize the catheter in the jugular vein. Catheter will be tested for patency by flushing with sterile saline. The catheter will then be tunneled subcutaneously to exit via an approximately 2.5 cm incision in the interscapular region. Wound clips or suture material will be used to close the interscapular area. Tissue glue or suture material (sterile 4 O silk) will be used to close the ventral neck incision. If placement in one side of the jugular area is problematic, the procedure will be repeated on the opposite jugular vein.

V.4.3.3. Post-surgical Provisions:

Immediate post-operative care will be provided by the investigators and rats will be monitored continuously until they are ambulatory. Animals are expected to ambulate. Animals will be returned to their cages post-surgery only after they have recovered sufficiently from anesthesia. Food and water will be provided ad libitum. Room maintenance and climate control is as per LAM SOP. Following surgery, rats will be monitored continuously until they are ambulatory. The incision site will be monitored daily for signs of infection (erythema, edema, presence of an exudate, induration etc). Because the catheter will be inserted into the external jugular vein, we will also examine the area for signs of bleeding. Each catheter will be flushed once daily with heparinized saline to prevent clotting of the tip by research personnel or PI.

Soman-injected animals: Food and water will be provided ad libitum. Room maintenance and climate control is as per LAM SOP. Investigators will perform daily weights, provide supplemental calories (as appropriate) via wet mash and sc lactate ringers (5 ml) four times a day while comatose after soman. Once the animal is awake, research personnel will watch animals for their ability to drink from their water bottle. Those animals that have difficulty drinking due to poor ambulation will be injected with lactate ringers (5 ml) s.c. 2-4 times per day until animals are able to drink on their own.. Early Endpoints: In addition to Center for LAM SOP's, research personnel will monitor animals using the checklist for animals exhibiting pain/distress beyond expectations of this study. If LAM personnel notice any of the following: constant convulsions or tremors, an animal that is comatose for more than 2 hours, self-mutilation, continuous circling, persistent labored breathing, or behavior that LAM personnel feels is causing the animal to suffer, and research personnel are unavailable, the LAM veterinarian may make the decision to euthanize the animal. If animals continue to lose weight despite supplements (wet mash etc) or remain comatose for more than 24 hours, these animals will be euthanized by laboratory personnel or LAM.

V.4.3.4. Location: (b)(6)

V.4.3.5. Surgeon: Dr (b)(6) (competent in placement of jugular vein catheter)
Ms. (b)(6) (graduate student)

V.4.3.6. Multiple Major Survival Operative Procedures:

V.4.3.6.1. Procedures:

V.4.3.6.2. Scientific Justification:

V.4.4. Animal Manipulations:

V.4.4.1. Injections:

Soman treatment. Male Sprague-Dawley rats (250-300 gm) receiving nerve agent will be injected with the oxime HI-6 (125 mg/kg, 250 mg/ml (0.15 ml for 300 gram rat/1 ml syringe and 25 gauge 1/2 inch needle) ip) and 30 min later will receive soman (180 ug/kg, 360 ug/ml (0.15 ml for 300 gram rat/1 ml syringe and 25 gauge1/2 inch needle; sc) or saline and post-exposure treatment with atropine methyl nitrate (AMN, 2 mg/kg, 4 mg/ml (0.15 ml for 300 gram rat/1 ml syringe 25 gauge 1/2 inch needle) im into right thigh muscle,), 1 min after soman. These treatments, HI-6 (125 mg/kg, ip) and 30 min later soman (180 ug/kg, sc) and post-exposure treatment with ANM (2 mg/kg, im) 1 min after soman, have been shown to reliably produce electrographic seizure activity within approximately 10 min. Rats are allowed to seize for 40 min and then treated with 10 mg/kg, im, diazepam (0.6 ml for 300 gram rat/1 ml syringe 25 gauge 1/2 inch needle,injected into left thigh muscle) to stop/attenuate the seizures.

Alpha-Linolenic acid (500 nmol/kg) or vehicle will be injected via catheter 30 min, 3 days and 7 days after soman exposure. We will use a needle size ranging from 22 to 25 gauge and the injected volume is 0.3-0.35 mL.

Rapamycin: Rapamycin (LC Labs, Woburn, MA, USA) is initially dissolved in 100% ethanol to prepare a stock solution of 20mg/ml and stored at −20°C. As previously described [(Hartman et al., 2012), immediately prior to use, rapamycin will be diluted to a final concentration of 4% ethanol and 1 mg/ml rapamycin in a vehicle solution containing 5% Tween 80 (sigma), 5% PEG 400 (low-molecular-weight grade of polyethylene glycol) (Sigma). Rats will receive daily administration of rapamycin by intraperitoneal injection in the right lower quadrant (25-26 gauge needle, a total volume of 1.12 ml) x 7 days. The rapamycin dose of 4.5 mg/kg proposed in this major modification has been demonstrated to inhibit mTOR activity in the hippocampus [Hartman et al., 2012]. The dose which inhibits mTOR without blocking soman-induced seizures and neuronal degeneration will be used in this proposal. Control groups will receive an equal volume of vehicle. After blocking this signaling pathway, a subset of the rats will be euthanized on day 10 to identify changes in synaptic proteins and neurogenesis (n= 6 rats/per group). Another group will be submitted to behavioral tests and euthanized on day 21 (n= 6 rats/per group).

Bromodeoxyuridine (BrdU): A stock solution of BrdU will be diluted in saline to a final concentration of 20 mg/ml and the pH adjusted to 7.4. The solution will be filtered sterilized prior to injection. BrdU will be injected at a dose of 300 mg/kg on day 9 and day 10 after soman exposure. To maintain BrdU availability during a full cell cycle, which has 24.7 hours, BrdU or vehicle will be administered to rats by intraperitoneal injection in the right lower quadrant by restraint (25-26 gauge needle, a total volume of 4.5 ml/300 gram rat) prior to euthanasia (Blondeau et al., 2009). This high dosage has been demonstrated to maximize BrdU incorporation into proliferating cells in the subgranular zone of the dentate gyrus in rats allowing specific and quantitative assessment [Cameron and McKay, 2001].

Transcardial perfusion. When rats are euthanized, they will be placed under deep Fatal Plus (60-75 mg/kg) anesthesia. Once adequate anesthesia is achieved (lack of response to toe pinch, slow even respirations), a midsternal thoracotomy will be performed to expose the heart and the rats will undergo transcardial perfusion with cold PBS and 10% formalin. Generally, about 200 cc of each solution is sufficient per animal, but, more will be used if required.

Euthanasia for western blot experiments: Rats will be placed under deep Fatal Plus (60-75 mg/kg, i.p.) anesthesia. Once adequate anesthesia is achieved (lack of response to toe pinch, slow even respirations), the animal will be decapitated using a sharp blade to avoid tissue-altering effects of gases and anesthetics. Many euthanization methods have been shown to influence protein expression levels and confound interpretation of protein expression results. For example, the use of carbon dioxide or ether has been shown to distress animals and deoxygenate blood. Thus, the physiological effects associated with hypoxia and hypercapnia would alter protein expression profiles.

V.4.4.2. Biosamples:

In vivo experiments. The brains from the male Sprague-Dawley rats will be collected at the time of euthanasia. Brain will be preserved for future studies. Hippocampi may need to be removed to determine activated NF-κB levels, a biomarker of linolenic acid.

V.4.4.3. **Adjuvants**: N/A

V.4.4.4. **Monoclonal Antibody (MAbs) Production**: N/A

V.4.4.5. **Animal Identification**:

A patch will be shaved on each animal's back and then marked with non-toxic permanent ink with an individual ID. Sometimes, the ink fades in which case the ID will be re-inked on the patch. All cages have cage cards per LAM. Rats that receive nerve agent injection will be checked for their ink mark labels prior to injection of nerve agent to make sure they are clearly labeled.

V.4.4.6. **Behavioral Studies**: Behavior studies will be conducted 14 days after soman exposure.

Behavior Outline:
One group of 48 animals

Day 14	Day 18	Day 19
Rotarod test	Forced swim pretest 15 min in water	Forced Swim test 5 min in water

Second group of 48 animals

Day 14	Day 15	Day 19	Day 20
Open field (accommodation)	Open field testing	passive avoidance training day	Passive avoidance testing day

Each group of treated (6 animals/group) and control animals (6 animals/group) will undergo only two behavior tests. There are 8 groups (treated and control) of animals (see table 17 through 24). Therefore, 48 animals will be subjected to the open field behavior test and the passive avoidance task. Another group of 48 animals (treated and controls) will be subjected to the rotarod task and forced swim task. A period of four days will separate the two behavior measurements to reduce any influence of one test on another. Interactions with co-specifics will not be performed in this study and this section was deleted.

Activity and Movement: General activity, movement, and coordination can be used as indices of overall health and well-being of rodents. Activity and movement serve as negative controls (brain areas relevant to movement should not be disrupted in the current study), and as a covariates for the other behavioral tasks that rely on animal

locomotion for task completion. The locomotor and rotarod tasks have been used reliably for these purposes in Dr. (b)(6) lab for many years.

Open field locomotor activity. Locomotor activity is measured using an Omnitech Electronics Digiscan infrared photocell system. One-hour activity measurements are obtained (preferably during animals' active or dark cycle). Animals are placed singly in a 40 X 40 X 30 cm clear Plexiglas arena covered by a perforated Plexiglas lid. Data are automatically gathered and transmitted to a computer via an Omnitech Model DCM-I-BBU analyzer. The interfaced software measures 21 activity variables, including total distance and horizontal and vertical activity. Chambers are cleaned between subjects with 35% isopropyl alcohol solution.
The duration of locomotor activity testing is a maximum of 60 min per day and can be performed on multiple days throughout the duration of the experiment.

Rotarod: The rotarod test measures an animal's ability to maintain balance by coordinating movement and making postural adjustments. It also measures the ability to improve these skills with practice. Each rat rotarod treadmill (Med Associates, Inc, St. Albans, VT) consists of a motor-driven drum with constant speed or accelerating speed modes of operation. The drum (7.0 cm diameter) allows each animal to maintain a suitable grip. It is divided into four test zones (8.9 cm wide) so that up to four animals may be tested at the same time. The device consists of a smooth hard plastic cylinder with concentric circular plastic sides (39.7 cm diameter) to prevent the rat from laterally climbing off the cylinder.
Rats are placed on the device facing the wall with the rod rotating in the direction opposite from the animal (so that the rat uses its paws to pace forwards and avoid falling off the rod). When a rat falls off the rotating drum (height of 26.7 cm), it breaks a photobeam, stopping the timer associated with that zone. In each trial, the speed of rotation is increased from 0 revolutions per minute (rpm) to 35 rpm for a maximum of 3 or 5 min. The mean duration on the device (based on 3 consecutive trials) is recorded. The procedures are based on reports in the literature (6-9). Chambers are cleaned between subjects with 35% isopropyl alcohol solution. The duration of rotarod measurement is 9 or 15 min per day can be performed on multiple days throughout the duration of the experiment.

Activation of the amygdala, a brain region vulnerable to soman-induced neuronal cell death, is involved in anxiety and stress-related behaviors. This can be measured using the total time spent in the center of an open field arena or number of entries into the center of the field.

Anxiety

In our recent study, we did not find evidence of anxiety in rats exposed to soman. Therefore, we will not determine open field center time in this protocol.

Research in humans and animals has clearly established that the hippocampus is involved in learning and memory (2). Rats lesioned in the hippocampus have a difficult

time acquiring active avoidance responses (3,4) and retaining passive avoidance responses over a period of time (3-5).

Learning and Memory

Passive avoidance: Animals are trained and tested using an automated avoidance training system (Med Associates, St. Albans, VT) consisting of two 21 x 25 x 17 cm chambers separated by a vertically-sliding door. This task consists of a training day and a consecutive testing day. During training, the animal is placed in one chamber of the darkened apparatus. After a delay of 60 seconds, a light comes on and the door to the other, still darkened chamber, opens. Naive rats instinctively move quickly from the lit chamber into the dark chamber. When the rat crosses completely into the darkened chamber, the door closes, latency to cross is recorded by the interfaced computer, and a single 0.8 mA (mild, non-damaging) shock is delivered through the grid floor for 1 sec. The rat is left in the darkened chamber in which the shock has been delivered for 30 sec to facilitate the formation of memory for the aversive event, and then removed. The procedure on testing day is identical except that the shock is not delivered if/when the animal crosses into the darkened chamber. Memory is presumed to have occurred if the animal does not cross into the chamber in which it previously was shocked, or if latency to cross is significantly longer during the testing trial than during the training trial. The duration of passive avoidance testing is 5 min on each of two consecutive days, and is only performed once during an experiment. Chambers are cleaned with 35% isopropyl alcohol between animals.

The prefrontal cortex is involved in complex executive function, including planning, decision making, and controlling social behavior in humans. The social interaction paradigm has been used in rats to assess functioning of the prefrontal cortex in a rat model of schizophrenia (12). Further, rodent social interaction is correlated with neuronal morphology in the prefrontal cortex (13). The piriform cortex, also called the olfactory cortex, is related to processing of olfactory cues. Because rodent-rodent interaction involves sniffing and smelling one another, the social interaction paradigm will also be used to assess piriform cortex function.

Depression

Swim test: The Porsolt swim test is widely used as an index of learned helplessness or depression (17-20). The procedure involves a repeated procedure in which rats are placed into a cylinder (approximately 65 cm tall and 25 cm diameter cylinder filled to a height of 48 cm with water that is between 28-32 °C on the first day for 15 minutes. The rationale for the 15 min pretest is to induce a state of behavioral despair since the animals become more immobile as the test progresses during the 15 min pretest (Porsolt et al., 1978). As defined, immobility is floating in the water using only movements necessary to keep the animal's nose above the surface. Immobility time and latency to the initial immobility period are the primary dependent measures in this task (Castagne et al., 2009).

After 15 minutes of swimming, the rats are removed from the water and are dried and warmed with towels and heat lamps. On subsequent days, rats are retested for 5 minutes under identical conditions to determine the latency to become immobile (i.e.,

the rat initiates a stationary posture that does not reflect attempts to escape from the water), amount of time spent immobile, and number of times the animal becomes immobile, as determined by video analysis software (AnyMaze, Stoelting, Wood Dale, IL). After 5 minutes, the animals are removed and then dried and warmed with towels and heat lamps. On the second day of testing, shorter latencies to assume an immobile, floating position, more instances of immobility, and longer durations of immobility are interpreted as increased helplessness or depression. All rats are monitored the entire time and are removed from the water if they cannot swim or show signs of distress. Feces will be removed from the water between animals, and water will be replaced if it is difficult to observe the animals in the water. The test lasts 15 minutes on the training day, and 5 minutes on the consecutive testing day.

Seizure Observation
Animals will be placed into a cage separate from their homecage for observation and video analysis (AnyMaze, Stoelting, Wood Dale, IL) of seizure activity. Seizure activity is manually keyed for the duration of the seizure. AnyMaze software can analyze the video for latency to seize, seizure duration, and number of seizure occurrences.

V.4.4.7. Other Procedures:

Transcardial perfusion. When rats are euthanized they will be placed under deep Fatal Plus (50-75 mg/kg) anesthesia as described above. Once adequate anesthesia is achieved (lack of response to toe pinch, slow even respirations), a midsternal thoracotomy will be performed to expose the heart and the rats will undergo transcardial perfusion with cold PBS and 10% formalin. Generally, about 200 cc of each solution is sufficient per animal, but, more will be used if required. Transcardial perfusion will be performed in (b)(6)

Animal transportation: All animals will be transported to (b)(6) on the morning soman is to be injected in accordance with the LAM transportation SOP. Animals will be post-injected with linolenic acid or saline. Laboratory personnel who will transport animals to and from (b)(6) include: (b)(6) (b)(6) USUHS laboratory personnel will not be "working" on the animals at (b)(6) as only (b)(6) employees can handle nerve agents. Animals will be transported to and from (b)(6) using the LAM van. The rats will be brought back from (b)(6) to LAM by lab personnel on the day of nerve agent injection where they will be placed in home cages (1 rat/cage).

It is important to note that this study cannot be conducted without the use of the nerve agent, soman. Dr. (b)(6) will be submitting an IACUC protocol to (b)(6) The experiments using animals that will receive soman will commence when we receive approval of the animal protocol at (b)(6)

V.4.4.8. Tissue Sharing: The brains from Experiments 1-2 will be collected at the time of euthanasia and remain available for future studies. All other tissues (organs etc) will be made available to other investigator upon request.

V.4.5. Study Endpoint: The study endpoint for rats used for Experiments 1-2 is survival until the pre-determined post-operative time point, after which they will be euthanized. Prior to euthanization rats will be anesthetized then euthanized for tissue collection (V.4.4.7).

Early endpoints: Any of the following endpoints will represent a reason for early euthanasia: persistent seizures, persistent tremors, comatose for more than 2 hours after exposure to soman, self mutilation, continuous circling, persistent labored respiration. These signs, if observed by LAM personnel and no study personnel can be reached, may be taken by the LAM veterinarian as cause for euthanasia.

V.4.6. Euthanasia:

Experiment 1-2: Research personnel will perform all euthanasias except in cases where a LAM veterinarian makes the decision that a particular animal needs to be euthanized. At the indicated endpoint, each rat will be deeply anesthetized with Fatal Plus (60-75 mg/kg ip). Animals should be deeply anesthetized within 30 minutes. A midsternal thoracotomy will be performed to expose the heart and the mice will undergo transcardial perfusion with PBS and the 10% formalin in PBS. This procedure results in euthanasia from exsanguination under deep nembutal anesthesia.

Rats that reach an early endpoint will be euthanized via cylinderized CO_2. Research personnel, PI or a LAM veterinarian will perform this early euthanasia. The apparatus for euthanasia by CO_2 is located in (b)(6) Only one animal will be placed in the apparatus located in (b)(6) for euthanasia. With one animal in the apparatus, the flow rate of CO_2 will displace at least 20% of the apparatus volume per minute. Gas flow will be maintained for at least one minute after respiration has stopped before removing animals from the cage. A supplemental method to ensure death (cervical dislocation or bilateral thoracotomy) may be used. Alternately, if requested by the PI, animals will be euthanized by Center for LAM personnel) using cylinderized CO_2 in compliance with the 2013 AVMA Guidelines on Euthanasia. Euthanasia will be performed in the LAM CAF.

Euthanasia for western blot. Rats will be placed under deep Fatal Plus (60-75 mg/kg, i.p.) anesthesia. Once adequate anesthesia is achieved (lack of response to toe pinch, slow even respirations), the animal will be decapitated using a sharp blade to avoid tissue-altering effects of gases and anesthetics.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol.

V.5.1.1. Study Room:

Building(s) (b)(6) Room Number(s) (b)(6)

V.5.1.2. Special Husbandry Provisions:

Food Restriction: Yes _____ No __x__

Fluid Restriction: Yes No x

V.5.1.3. Exceptions: All animals will be housed individually after insertion of IV catheter. Animals injected with soman will be given apple slices, wet mash and gel squares as food supplements on the floor of each cage.

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care: Animals will be monitored for health, humane treatment, and husbandry considerations, twice daily by LAM staff during routine weekday rounds and at least once on weekends/holidays. This is in addition to, and not in place of, the monitoring that is done by the PI and their staff. In the event of a debilitating illness or adverse reaction, the decision to treat or euthanize an animal will be made by either the veterinarian and/or the PI.

V.5.2.2. Emergency Veterinary Medical Care: All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: Except as indicated below, all animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents; balls, toys and food enrichment treats for large animal species.

V.5.3.2. Enrichment Restrictions:

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
Insertion of external jugular venous catheters, i.p. injection, euthanasia	(b)(6)	More than 15 years experience in in vivo rodent procedures including perfusions. 7 years experience inserting jugular catheters	Investigator course and rodent handling (1 June 2007)
small animal surgery, Drug injections, tissue		2 years experience with animal surgery; 3 + years rodent	Investigator course and rodent handling course (July, 2012)

dissection, euthanasia, transcardial perfusion	(b)(6)	handling and 3 years experience with tissue dissection and transcardial perfusion	
Animal handling, agent injections, drug injections		39+ years rodent handling, surgery and tissue dissection; 15 years in EEG electrode emplacement in primates; 39 years EEG electrode emplacement in rodents	Occ Health/zoonotic disease (01/05/04), Rodent Handling (02/05/04), aseptic techniques and rodent anesthesia (November 2006), Anesthesia (March 2006) and XCSM (nerve agent) custodian
Animal handling, tissue dissection, drug injections, transcardial perfusion		30+ yr rodent handling, surgery and tissue dissection; 4 yr experience on transcardial perfusion	Investigator training course at USUHS (Nov 1993).

VII. BIOHAZARDS/SAFETY: All personal protective equipment (PPE) will be properly disposed of in LAM or the laboratory. Waste gas is scavenged by appropriate filters in LAM-designated surgery rooms. All sharps will be placed in Sharps containers and disposed of properly. There are no precautions necessary for animals exposed to soman.

Protocol for pain/ distress checklist (based on Kirsch 2002)

1. Appearance score:

Score of 0: Normal. Haircoat normal: smooth, lies flat, normal sheen. Eyes clear, open, no discharge/staining. Normal posture/movements

Score of 1: Lack of grooming apparent (i.e., animal does not clean off eye lubricant). No other marked changes

Score of 2: Haircoat roughened. Eyes and nose discharges or porphyrin (red) staining

Score of 3: Haircoat very roughened. External orifices ungroomed. Abnormal posture not explainable by brain damage. Eyes pale, sunken, glazed. Pupils enlarged.

2. Respiratory score

Score of 0: Respiration even and frequency unchanged. Limbs and feet warm. Mucous membranes (gums and anus pink), and extremities normal (ears and feet pink)

Score of 1/2: Respiration uneven. Shallow breathing, more abdominal breathing evident.

Score of 3: Respiration visibly labored. Limbs and feet cold. Mucous/membranes and/or extremities abnormal.

3. Unprovoked behavior score

Score of 0: Normal behavior pattern (i.e., exploring cage, grooming, feeding). Animal bright, alert, responsive.

Score of 1/2: Abnormal behavior. Less mobile, alert, responsive than normal. Inactive when hyperactivity expected (nighttime, feeding time). Guarding potentially painful area (i.e., leg, head, neck). Twitching, lameness.

Score of 3: Unsolicited vocalization, self-mutilation, expiratory grunts, grinding teeth, teeth chattering, salivating, very restless or does not move. Exaggeration of score 2 signs. Unresponsive, unaware of extraneous activity.

4. Reactive behavior score

Score of 0: Behavioral responses normal for expected conditions (i.e., reaching into cage, handling animal, response to tapping on cage, response to holding food pellet in grommet opening, taking rectal temperature).

Score of 1: Shows minor depression or minor exaggeration of responses.
Score of 2: Shows moderate signs of abnormal responses. There may be behavioral changes (i.e., animal more aggressive or more docile).
Score of 3: Animal overreacts to external stimuli, has weak responses as in pre-comatose state, or is non-responsive.

5. Body weight score (only at ≥24 hours): monitor body weight, skin turgor

Score of 0: body weight (BW) maintained or increased with respect to baseline. Skin hydration unchanged (pinch test – skin should "snap" back)
Score of 1: loss of BW < 10%
Score of 2: loss of BW 10-20%
Score of 3: loss of BW >20%

Body weight score and skin turgor will be checked daily until animals are euthanized.

Whenever a subscore of 3 or a total score of >10 is reached, the PI and/or veterinarian will be contacted and the rat will be considered for euthanasia.

5. Body weight score (only at ≥24 hours): monitor body weight, skin turgor

Score of 0: body weight (BW) maintained or increased with respect to baseline. Skin hydration unchanged (pinch test – skin should "snap" back)
Score of 1: loss of BW < 10%
Score of 2: loss of BW 10-20%
Score of 3: loss of BW >20%

Body weight score and skin turgor will be checked daily until animals are euthanized.

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

I. Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL or WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

X. PROTOCOL ABSTRACT:

Alpha-linolenic acid (ALA) is an omega-3 polyunsaturated fatty acid shown to exhibit potent neuroprotective properties against various animal models of hypoxic-ischemic neuronal cell death. This compound is found in vegetable products such as flaxseed, rapeseed and pumpkin seeds and can be purchased over-the-counter. Humans can consume large quantities (up to 6 grams) of alpha-linolenic acid without side effects. We have shown previously that administration of a single intravenous injection of ALA given either 3 days prior or 30 min after soman reduces soman-induced brain damage. We now show that three doses of ALA given over a seven day period reduces brain damage, improves functional outcome and increases animal survival. In this proposal, we wish to test whether the well-established neuroplastic effects of ALA contribute to the reduction in soman-induced brain damage, improved functional outcome and increased animal survival.

A. Animal Protocol Number:

B. Animal Protocol Title: The possible involvement of LIN-induced neuroplastic effects against soman-induced brain damage in Sprague-Dawley adult rats

C. Principal Investigator: (b)(6)

D. Performing Organization: USUHS

E. Funding: NIH

F. Objective and Approach: The objective of this project is to determine whether the known alpha-linolenic acid-induced neuroplastic effects contribute to the observed increase in animal and neuronal survival, the anti-depressant-like activity and the improved functional outcome.

Indexing Terms (Descriptors): rat, soman, neurogenesis, synaptogenesis, synaptic function, rapamycin, BrdU, Porsolt forced swim test, hippocampus, BDNF, mammalian target of rapamycin.

February 24, 2016

MEMORANDUM FOR DR. (b)(6) DEPARTMENT OF NEUROLOGY

SUBJECT: IACUC Approval of Protocol – Initial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on February 24, 2016:

Animal Protocol Title: "Traumatic Brain Injury Recovery with n-3 Highly Unsaturated Fatty Acids (HUFAs) in Mice: A Biomarker Driven Approach"

USUHS Protocol Number: (b)(6)

Expiration Date: February 23, 2019

Supporting Grant(s) Number: TBD

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. NON-TECHNICAL SYNOPSIS: Traumatic brain injury (TBI) is a major cause of mortality and morbidity in civilian and military populations. In pre-clinical animal models, therapies aimed at modulating excitatory neurotransmission, inflammation, oxidative stress, and neurotrophic factors, among others, have been effective in limiting secondary neurodegeneration and improving neurological outcome. However, none of these therapies has proved effective when tested in Phase III clinical trials. A major reason for the failure to translate the preclinical findings to the bedside is that human TBI is heterogeneous, and there is a lack of appropriate biomarkers that correlate to outcome. The discovery of useful biomarkers for TBI severity will allow for better diagnosis and treatment. Development of non-invasive measures of drug efficacy in pre-clinical models will allow for easy translation into early phase clinical trials. Polyunsaturated fatty acids (PUFAs) of the omega-3 type, such as docosahexaenoic acid (DHA) and eicosapentaenoic acid (EPA) are abundant in cell membranes of the brain and are released after injury. Free DHA has neuroprotective and neuroreparative effects. DHA supplementation in mice improves recovery from experimental TBI. The typical human diet is deficient in DHA while lab mouse chow is abundant in DHA. We have modified lab mouse chow to match a human DHA diet to accurately measure efficacy of DHA as a neuroprotective therapy in a mouse model of TBI. DHA is thus a potentially viable drug treatment for TBI. Additionaly, blood biomarkers and neuroimaging of the injured, DHA-deficient mice may allow for the discovery of non-invasive and accurate biomarkers that can readily be translated into clincal settings. This study aims to investigate non-invasive imaging biomarkers for DHA deficiency and TBI, as well as elucidate the neuroprotective value of DHA as a treatment for TBI.

II. BACKGROUND:

II.1. Background:

Traumatic Brain Injury (TBI):
In the United States, approximately 230,000 patients are hospitalized each year with TBI, in addition to 1.5 million cases of milder TBI that do not require hospitalization (Langlois, et al. 2004). A large number of molecular events have been postulated, primarily on the basis of experimental animal models, to influence the response of neural tissue to brain injury (Siesjo 1993). In animal models, therapeutic interventions aimed at modulating several of these molecular steps have been successful in limiting the extent of injury and improving neurologic recovery (McIntosh 1993; McIntosh, et al. 1998). These experimental observations constitute a convincing demonstration of the principle that not all neural damage occurs at the time of injury, and that a window of opportunity exists for therapeutic intervention. However, Phase III clinical trials of several of these therapies in patients with severe brain injuries have failed to demonstrate efficacy (Doppenberg and Bullock 1997). Differences between animal models of brain injury and human TBI account for part of the failure to translate these important preclinical observations to the bedside (Narayan and Michel 2002). Further, the molecular mechanisms involved in neurodegeneration resulting from focal contusions may differ from those triggered by diffuse injuries (Maxwell, et al. 1997), and past clinical trials have made no attempt to identify injury mechanism or stratify by injury type. Thus, it is likely that further advances in the therapy of TBI will require a detailed understanding of the injury subtypes involved, and targeting of therapies to specific pathologic mechanisms (Stiefel, et al. 2004). MRI holds much promise as a tool for identifying such mechanisms.

Translation of Preclinical TBI Studies to the Clinic:
The failure of multiple Phase 3 clinical trials in TBI has forced a re-thinking of the approach to early phase human clinical trials. The conclusions of several workshops convened by DoD and NIH over the past several years is that biomarker-driven approaches are needed, in order to prove that the therapy is engaging its proposed molecular target and to provide proof of principle by demonstrating efficacy on a pharmacodynamic biomarker. Since the biomarker is mechanistically closer to the biological effect of the therapy than clinically relevant outcome measures, such studies can achieve adequate power with modest sample sizes, and can be useful for fine-tuning important issues such as dose, timing, and duration of therapy before launching large and expensive Phase 3 trials. This approach, while in principle straightforward, has very rarely been attempted. This is primarily because of a low level of collaboration between preclinical scientists and clinical investigators. Most preclinical studies use outcome measures such as histopathology and behavioral function which are not appropriate for human clinical trials. Additionally, important issues such as timing, dosing, duration of therapy, pharmacokinetics and pharmacodynamics are infrequently addressed in animal models. CNRM is ideally positioned to overcome this gap between preclinical and clinical investigators. Investments in preclinical and clinical imaging, as well as in preclinical and clinical blood-based biomarkers show substantial promise for identifying pharmacodynamic biomarkers in parallel between animal and human studies. Omega-3 fatty acids are nutritional supplements which have been extensively studied for the treatment of cardiovascular disease, stroke, and neurodegenerative disorders. It is recognized to have an excellent safety profile. In animal models of experimental TBI, omega-3 fatty acids has been shown to be effective in improving

outcome after impact acceleration injury and controlled cortical impact. The therapeutic window in rats is at least 24 hours, indicating that it is a feasible agent for human therapy.

DHA as a Neuroprotective Agent for TBI:

Among polyunsaturated fatty acids (PUFAs) of the omega-3 type, such as docosahexaenoic acid (DHA) and eicosapentaenoic acid (EPA), DHA is particularly abundant in the brain where it is primarily found in membrane phospholipids (Kim 2007). Immediately after injury, tissue phospholipases are activated, leading to an increase in free fatty acids. Free DHA has several prominent effects promoting neuroprotection and neurorepair, including promoting neurite outgrowth, synaptogenesis, and activating transcriptional activity via interaction with retinoid acid X receptors (Cao, et al. 2009; de Urquiza, et al. 2000). Further, DHA is converted to anti-inflammatory, neuroprotective, synaptogenic and pro-neurogenic mediators such as synaptamide, resolvins, and protectins (Hong, et al. 2003; Bazan 2005; Kim, et al. 2011; Rashid, et al. 2013), while AA-derived eicosanoids are often pro-inflammatory, exacerbating the initial injury (Farooqui and Horrocks 2006). In rats, omega-3 FA supplementation post-injury reduced axonal injury, microglial activation, and improved behavioral function after impact acceleration TBI and fluid percussion injury (FPI) (Mills, et al. 2011; Bailes and Mills 2010). Raising brain DHA by dietary supplementation of omega-3 fatty acids improves recovery from controlled cortical impact (CCI) injury in mice (Desai, et al. 2014). Interestingly, DHA levels in mice fed standard lab chow are significantly higher than in the human brain (Hamazaki, et al. 2010), and in our optimized mouse model the diet can be modified to match DHA levels found in humans. In this proposal we will develop these measures of efficacy of DHA as a neuroprotective therapy in a mouse model of TBI. DHA has an excellent safety profile, and has been widely tested in humans with cardiovascular disease, stroke, and neurodegenerative diseases. Only a few small trials have tested DHA supplementation after TBI, with widely publicized but anecdotal results. DHA is thus a potentially viable drug treatment for patients with TBI. The next steps for the pre-clinical investigation are to develop measurements of drug efficacy through measurements of biomarkers in serum, and imaging studies, which can be used as noninvasive indications of efficacy in early phase clinical trials. Our objective is therefore to determine whether DHA supplementation alters plasma levels of bioactive lipids known to be neuroprotective, anti-inflammatory, and neuroregenerative, such as synaptamide, 17-hydroxy-DHA, resolvins and endocannabinoids, the mechanisms through which DHA supplementation is proposed to improve recovery from TBI.

MR imaging of DHA treatment after TBI:

The failure of over 30 drugs in clinical trials for TBI suggests the need for different processes to evaluate suitability of potential therapies. Identification of pharmacodynamic biomarkers in the laboratory and then translation of those biomarkers to early phase human studies has not yielded successful therapies. One suggested change is the development of non–invasive measures of drug efficacy in pre-clinical models. Non-invasive measures, such as MRI, can easily be transferred to early phase clinical trials, in order to demonstrate that the therapy is engaging the molecular target and resulting in a biologic effect.

This program proposal is centered on the evaluation of supplementing diet with omega-

3 fatty acids (FA), such as docosahexaenoic acid (DHA), as a potential therapeutic strategy for traumatic brain injury (TBI). An extensive literature suggests a neuroprotective role for omega-3 FA in stroke, neurodegenerative diseases, and traumatic spinal and brain injury (Michael-Titus and Priestley 2014; Lee, et al. 2015; Sorg, et al. 2015; Wilde, et al. 2015). There is also evidence of improved recovery of motor functions and lower anxiety in mice with adequate supplementation of DHA versus DHA depleted mice after TBI induced by controlled cortical impact (Desai, et al. 2014). Nothing is known, however, about potential Magnetic Resonance Imaging (MRI) biomarkers of structural brain changes induced by omega-3 FA. As omega-3 FA alter the chemical composition of the plasma membrane of neuronal cells it is reasonable to assume that MRI measurable brain tissue properties such as T1 and T2 relaxation times and diffusion properties may be altered. Preliminary experiments from our laboratory in mice where brain tissue omega-3 FA levels have been enriched or depleted by dietary manipulations shows significant changes in diffusivity and relaxometry. Moreover, if omega-3 FA dietary intake affects the outcome of TBI, MRI metrics should be able to document different levels of severity of the structural damage in the injured brain depending on the therapeutic regime. Finally, MRI metrics may help elucidate the mechanisms of improved recovery, revealing potential effects of omega-3 FA on edema, inflammation, gliosis, and neuroregeneration. Parallel histological assessment and ex-vivo MRI scanning will enable us to elucidate the biological substrate of the structural changes detected using the MRI techniques.

II.2. Literature Search for Duplication:

II.2.1. Literature Source(s) Searched: PubMed, PowER Search through USUHS Library, DTIC database, and NIH RePorter

II.2.2. Date of Search: 11/2/2015

II.2.3. Period of Search: Pubmed: 1950-present
PowER Search: 1916-present
DTIC database: all available
NIH RePorter: 1990-2015

II.2.4. Key Words and Search Strategy: The PubMed database was searched using the following strategy:

#1: TBI AND DHA
#2: TBI and MRI and omega-3 fatty acid

The following keywords were used in PowER Search:

Traumatic brain injury
Omega-3 fatty acids
DHA
Magnetic resonance imaging

Diffusion tensor imaging
Neuroprotective
Biomarker
Mouse/ Mice

The following keywords were used for DITC database:

TBI
DHA
Mouse
MRI

The following keywords were used for the

TBI
DHA
Mouse
MRI

II.2.5. Results of Search: Search strategy 1 for Pubmed yielded several studies that investigate DHA as a neuroprotective treatment for TBI (16 publications). Only one publication utilizes MRI in combination with DHA supplementation after TBI (search strategy 2 for Pubmed, 1 publication.) This publication is a case study, as opposed to a scientific experiment, of 1 patient that utilizes MRI throughout the patient's recovery (Lewis, et al. 2013). PowER Search through the USUHS library did not yield a similar study. DTIC database yielded 0 studies when all keywords were searched together. When MRI was excluded from the search (TBI and DHA and Mouse) one study came up from our collaborator Dr. (b)(6) researching DHA metabolites after TBI. However that study did not have the same scope regarding MRI biomarkers and study time points as the current study. The NIH RePorter searched yielded 0 projects/matches. After a thorough literature search, there was no indication of duplication efforts to answer the particular questions posed in our aims and no comparable use of methods. There are currently no drug treatments or accurate biomarkers for TBI. It is thus important that we work towards studying the potential for DHA and Synaptamide as pharmacodynamic biomarkers for TBI outcome as well as a potential therapeutics.

III. OBJECTIVE\HYPOTHESIS:

Hypothesis: Our hypothesis is that DHA supplementation after TBI is neuroprotective and this neuroprotection can be detected via blood biomarkers and advanced magnetic resonance imaging strategies. We will show this with the following specific aims:

Aim 1: Innovative imaging study, designed to determine whether advanced neuroimaging strategies, including diffusion imaging and relaxometry, are sensitive to the omega-3 fatty acid content of brain membranes. In this study we propose to use quantitative MRI techniques to identify potential biomarkers of brain

changes induced by Omega-3 fatty acids in animals. We plan to investigate the effects of DHA intake on the brain in mice that are chronically depleted of Omega-3 FA vs. animals with an Omega-3 FA enriched diet, using a model based on the one developed by Desai et al. (2014) in Dr (b)(6) lab. We will acquire MRI data of mice *in vivo* prior to DHA supplementation and then longitudinally. The MRI measures we plan to apply are quantitative and informative about different tissue properties (a detailed description of the MRI techniques can be found in the research plan section). Ex-vivo, high resolution MRI scanning will be performed on the same brains studied with histological techniques. The histological analysis will enable us to elucidate the biological substrate of the structural changes detected using MRI.

Aim 2: Preclinical project designed to identify MRI biomarkers sensitive to omega-3 supplementation after TBI. Such MRI and blood biomarkers could readily be translated to clinical trials. These include measurements of bioactive lipids in plasma and RBC membranes such as synaptamide, 17-hydroxy-DHA, D-resolvins, endovanilloids, and endocannabinoids. These bioactive lipids have potent anti-inflammatory and pro-neurogenic effects that will simultaneously be tested in a parallel clinical study. Our collaborators at (b)(6) will be conducting parallel studies aimed to: (1) Reproduce neuroprotective effect of DHA in mice with humanized tissue levels of omega-3 FA. To determine which bioactive lipids are altered by DHA after TBI in mice. C57BL/6 mice will be raised in a special chow designed to produce brain tissue omega-3 FA levels comparable to what is found in human brain tissue. Eight-10 weeks old male mice will be injured by an experimental TBI model, moderate controlled cortical impact in the parietal cortex. DHA and Synpatamide supplementation (40 mg/kg) will start 6 hours after injury and continue for 30 days. Blood will be collected at sacrifice. Accessible biological tissues (plasma, serum, RBC membranes, potentially others) will be assayed using sensitive HPLC-Mass Spectrometry (MS) assays in Dr (b)(6) lab. Several bioactive lipids will be measured. The focus will be on bioactive lipids which are products of DHA and have anti-inflammatory and pro-neurogenic properties, such as synaptamide, D-resolvins, and 17-hydroxy-DHA. We expect to see an increase in tissue and plasma levels of neuroprotective bioactive lipids. Our lab will acquire MRI data of mice *in vivo* prior to injury and then longitudinally after TBI induced by controlled cortical impact to investigate the effects of DHA treatment. We will apply the same in-vivo and ex-vivo MRI techniques from aim 1, as well as histological characterization of the brains after injury.

IV. MILITARY RELEVANCE:

At present there are no effective treatments for TBI, other than stabilizing the patient, preventing excessive intracranial pressure and symptomatic relief. Military physicians and their patients are in desperate need of interventions that will lessen the initial lesion, before the process of regeneration and repair can begin. This study is focused on furthering development of treatment with a naturally occurring dietary supplement, omega-3 fatty acids. Over 30 drugs that were effective in animal TBI models have failed in clinical trials for TBI suggesting that different tactics are required for establishing efficacy of a drug both in animal models, and within the clinical trial. A recent pharmaceutical working group convened by (b)(6) supported the development of pharmacodynamic biomarkers, proteins that could be easily measured in blood, that

would demonstrate the efficacy of the drug. Non-invasive biomarkers, such as MRI abnormalities, are also promising. These non–invasive measures of drug efficacy in pre-clinical models can be transferred to early-phase clinical trials, in order to demonstrate that the therapy is engaging the molecular target and resulting in a biologic effect. This proposal seeks to establish blood biomarkers to determine the efficacy of candesartan action by non-invasive measures. It therefore will link seamlessly with early phase clinical trials to provide better measurements for assessing efficacy in patients. These experiments therefore are developing a new methodology for assessing suitable therapies in pre-clinical models, in order to allow clinical trials to have different outcome measures. This proposal will therefore have direct relevance to recovery from TBI for military service members as it seeks to develop a functional working therapy with a widely available and safe dietary supplement. The experiments will provide more complete information to decide whether to proceed to phase III clinical trials with omega-3 fatty acid supplementation. Additionally, the knowledge of blood and MRI biomarkers associated with different outcomes and responses to the therapy would be very important for the clinical management of service members suffering from TBI.

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures:

Specific Aim 1: Innovative imaging study, designed to determine whether advanced neuroimaging strategies, including diffusion imaging and relaxometry, are sensitive to the omega-3 fatty acid content of brain membranes.

Specific Aim 2: Innovative imaging study, designed to determine whether advanced neuroimaging strategies, including diffusion imaging and relaxometry, are sensitive to the omega-3 fatty acid content of traumatically injured brain membranes and structures.

V.1.1. Experiment 1: 1) To measure quantitative MRI parameters in the brain of healthy mice that received adequate amount of dietary Omega-3 FA, versus animals that were chronically depleted.

Two-week pregnant dams will be purchased from an approved vendor and housed at USUHS. Control dams and pups will receive a diet with adequate DHA levels throughout the experiment. Experimental dams will receive a DHA-deficient feed once they arrive in the animal facility and throughout the rest of their pregnancy (see v.5.1.2). The pups will be fed the DHA-deficient diet throughout the experiment. We expect approximately 8 pups per litter (based on normative data for C57/6 mice) 50% male and 50% female. We intend to use all mouse pups for this study.

Mice will either receive DHA (40 mg/kg), Synaptamide (40 mg/kg), DHA plus Synaptamide, or vehicle injections. Animals will begin receiving supplement injections at 3 months of age. Animals will receive daily injections for a maximum of 30 days. The MRI will be performed both in vivo at 7 or 30 days. Then the brain will be fixed via cardiac perfusion and removed for ex-vivo high resolution scanning. After scanning the entire brain would be available to Dr. (b)(6) team for histological

characterization.

Total: N=140 (Class D)	**Aim 1**	**Aim 1**	**Aim 1**	**Aim 1**	**Aim 1**
Imaging Time Point	**Sufficient Dietary DHA**	**DHA-Deficient, vehicle injected**	**DHA-deficient, DHA supplemented**	**DHA-deficient, Synaptamide supplemented**	**DHA-deficient, DHA/Synaptamide supplemented**

Chronic (30 days)	Male=7 Female=7	Male=7 Female=7	Male=7 Female=7	Male=7 Female=7	Male=7 Female=7

V.1.2. Experiment 2: To measure quantitative MRI parameters in the brain of mice with TBI and assess potential effects of dietary Omega-3 FA on outcome and brain structural recovery. Two groups of animals will be included, mice which received adequate amount of dietary Omega- 3 FA, versus animals which were chronically depleted. This aim includes both in vivo, and ex-vivo scanning at high resolution. The in-vivo component will investigate the effects of Omega-3 FA on the evolution of the TBI lesion.

Two-week pregnant dams will be purchased from an approved vendor and housed at USUHS. All dams will receive a DHA-deficient feed once they arrive in the animal facility and throughout the rest of their pregnancy. The pups will be fed the DHA-deficient diet throughout the experiment. Our plan is to scan *in-vivo* all animals before inducing the lesion and then at selected time-points after experimental TBI. The injury will be produced via the controlled cortical injury experimental TBI model on 8-10 week old DHA-deficient mice. One group of CCI mice will receive supplemental DHA, synaptamide, or DHA plus synaptamide injections. The other group of CCI injured mice will receive vehicle injections. Animals will be scanned at various time points, then immediately euthanized via transcardial perfusion. For transcardial perfusion, animals will be injected with Pentobarbital Na. When they are nonresponsive to toe pinch, the animnals will be perfused with phosphate buffered saline and 4% paraformaldehyde and the brain extracted. The brains will undergo high resolution ex vivo MRI and then they will be cut at 40 um thickness and undergo immunohistochemistry to reveal astrogliosis, axonal number, myelin thickness and neurons. The brains will then be scanned via high-resolution *ex-vivo* MRI. Then the brain will be histologically characterized. This will enable direct comparison of *in vivo* scanning with high resolution *ex-vivo* scanning and histology.

Fifty additional animals will come directly from our collaborator, Dr. [b)(6) redacted] to be scanned at USUHS and sacrificed immediately after scanning. These animals will not be housed at USUHS, however, will be transferred to USUHS according to LAM protocol.

Magnetic Resonance Imaging of CCI and DHA-deficiency: In vivo Animal MRI acquisitions will be performed in the 7 Tesla Bruker scanner at the CNRM Translational imaging facility, while high resolution ex-vivo scans of fixed brains will be performed on the NIH vertical bore scanners. We plan to focus on three quantitative MRI acquisition methods: 1) Diffusion MRI with Diffusion Tensor (DTI) dual compartment DTI assessment as proposed by Pierpaoli et al. (2004), (2) High resolution DESPOT-based T1and T2 and myelin water compartment assessment as proposed by Deoni et al., (2008), and, in ex-vivo animal brains, 3) High Angular Resolution Diffusion Image (HARDI) analysis using the MAP-MRI approach suggested by Ozarslan et al. (2013) for high quality investigations of diffusion properties.

The first task for diffusion MRI development is to improve the anatomical quality of the images, implementing optimal diffusion MRI (DWI) sequences that would allow correction for distortions in Echo planar Images. While DWI has opened up a new window on studying brain architecture, some brain regions and structures are still invisible in conventional DWI acquisitions. In particular, EPI, the most widely used sequence to acquire clinical DWI data, produces almost no measurable signal in brain areas near the sinuses and oral cavities, making white matter pathways there difficult to study. We plan to work on reducing these artifacts in EPI. The current version of our processing software TORTOISE (www.tortoise.org) corrects distortion from susceptibility artifacts by warping the EPI images to a unwarped reference image (usually a fast spin-echo echo image). The method works very well in most regions, but it is unable to correct regions of "signal pileup".

V.2. Data Analysis:

Magnetic Resonance Imaging: We plan to focus on three quantitative MRI acquisition methods: 1) Diffusion MRI with Diffusion Tensor (DTI) dual compartment DTI assessment as proposed by Pierpaoli et al. (2004), (2) High resolution DESPOT-based T1and T2 and myelin water compartment assessment as proposed by Deoni et al., (2008), and, in ex-vivo animal brains, 3) High Angular Resolution Diffusion Image (HARDI) analysis using the MAP-MRI approach suggested by Ozarslan et al. (2013) for high quality investigations of diffusion properties. If MAP-MRI will prove informative in the animal model, an appropriate clinical implementation of the MAP-MRI sequences will be also be used for the clinical studies.

The following parameters will be used for the diffusion studies in the animal experiments, both in vivo and ex-vivo are.

In-vivo diffusion acquisition. Images will be acquired using a single-shot 2D EPI pulse sequence with slice and spatial dimensions to attempt isotropic voxel sizes (approximately 250 microns isotropic). Multiple repetitions will be used with a single average and a "blip-up/blip-down" approach will be used where half of the repetitions will have a reversed phase encode direction. Diffusion parameters will be multiple non-weighted reference images (b=0s/mm2) and for DTI diffusion weighting, a b-value of 800-1000 s/mm2 will be used with 14-32 directions. For MAP-MRI an optimized diffusion-weighting paradigm will be used with multiple shells in q-space (likely 4 shells ranging from 1000-5000 s/mm2).

Ex-vivo diffusion acquisition. Fixed brain tissue will be imaged at either 7T or 14T using a 10-15mm volume coil. A segmented 3D EPI pulse sequence will be used to rapidly acquire each diffusion weighted volume (4-8 minutes per image volume) at high resolution (100 microns isotropic). A blip- up/blip-down approach will also be used for this acquisition as described in the previous section. The diffusion parametes will include a set of low b-value image volumes (100-1000s/mm2) for use in calculating the reference image and multiple shells in q-space including b(in s/mm2)/#directions=1700/32, 3800/32, 6700/56 and 10,000/87. Gaussian DTI will use only the reference images and b=1700 s/mm2 shell, while non-Gaussian DTI and MAP-MRI will use the entire sampled q-space.

Diffusion image processing. In-vivo and ex-vivo images will be processed offline using our TORTOISE software package (www.tortoise.org) including: blip-up/blip-down correction for geometric distortions, registration-based correction of motion and eddy-current artifacts, alignment with a standard template, non-linear estimation of the diffusion tensor, modeling of MAP-MRI parameters. HARDI and mcDESPOT (Deoni 2008) analysis will be performed. Each processing modality offers different information regarding the water diffusion magnitude, direction, and restriction; providing a more complete picture of the underlying microstructure of the brain.

The data acquired from this study will also be used to improve existing DWI techniques and processing protocols. Removing cerebral spinal fluid signal (CSF), distinguishing myelin from other aniostotropic regions, lack of contrast in certain grey matter regions, correcting for "signal pileup", and interpreting diffusion parameters in relation to biological mechanisms are some of the current issues with conventional DWI that need further development. Our lab has already made progress in correcting distortion from susceptibility artifacts by warping the EPI images to an unwarped reference image (usually a fast spin-echo echo image) using the current version of our processing software TORTOISE (www.tortoise.org). The method works very well in most regions, but it is unable to correct regions of "signal pileup." "Signal pileup" occurs when the amount of distortion changes in such a way that a single voxel in the reconstructed image contains signal from a region containing several voxels in the undistorted image. In this case, information is lost and no correction method can restore an undistorted image. The lost information can be recovered by acquiring a second image of the same slice with the polarity of the phase encode blips reversed. The two images together

contain all the information required to reconstruct an undistorted image. We have developed methods and written code to efficiently correct image distortion using information from blip-up and blip-down images, and we intend to include both blip-up and blip-down image acquisitions in our protocol. We expect this correction method will increase the geometrical fidelity of our images, reduce the systematic error in the DTI results, and increase our ability to correlate imaging findings to histopathology.

The dual compartment DTI method we plan to use has enhanced tissue characterization capabilities compared to conventional DTI. It will enable us to extract specific information about the parenchymal water compartment by removing the effect of CSF contamination. Diffusion measurements in brain tissue adjacent to CSF-filled cavities suffer from CSF partial volume contamination. As the diffusivity of water in CSF is 3 times larger than in normal brain parenchyma, even a small amount of CSF can severely bias diffusion measurements in the cortex and periventricular areas. As the cortical thickness is ~2mm, it is virtually impossible to obtain diffusion data in the cortex unaffected by CSF contamination at the image resolution of clinical DTI. In animal experiments image resolution is higher (in this project we expect to collect in vivo brain DTI data with isotropic voxels of 300 microns) but still significant CSF contamination at interfaces can occur. One additional interesting feature of this approach is the handling of the vascular signals that in conventional DTI contaminates the measured diffusivity of the parenchyma. With the dual compartment DTI analysis, vascular spins will affect the diffusivity and the volume fraction of the CSF water compartment, not that of the parenchymal compartment. This is particularly important for this experiment in which subtle diffusivity changes are expected due to plastic changes in the brain. We expect to be able to differentiate plasticity that may affect the vasculature, which will be reflected in the fast diffusivity water compartment from changes that will affect the brain tissue, either glial cells or neurons, which will be reflected in the low diffusivity, parenchymal water compartment.

Magnetization transfer imaging (MTI) and DTI provide information related to myelin, however, these measures are non-specific (the MTI signal is generally related to lipid content, and significant diffusion anisotropy is observed even in non-myelinated white matter). Currently, multi-component relaxometry (MCR) is the most direct means of quantifying myelin volume, with estimates having strong agreement with histopathological assessments. In conventional T2 MCR, the measured MRI signal is decomposed into contributions from two water pools, which in brain tissue, are attributed to an intra/extra-cellular pool and water trapped between the hydrophobic bilayers of the myelin sheath. The T1 and T2 MCR method we plan to use is based on rapid steady-state imaging techniques. Unlike conventional T2 MCR approaches which suffer lengthy acquisition times and poor spatial resolution (typically more than 16 minutes for a single image slice with 1 mm3 voxels), this new mcDESPOT technique permits reproducible whole-brain high-resolution myelin quantification in a clinically reasonable time-frame (less than 20 minutes), presenting the first opportunity for whole-brain quantitative evaluation of myelin in vivo in human subjects. The importance of myelin in the pathophysiology of TBI and the role of myelin products as potential biomarkers in TBI are reported in several recent studies (Schumacher 2007; Hergenroeder 2008; Ottens 2008). We hypothesize that the diffusion anisotropy changes that have been measured in white matter following learning paradigms could

be related to changes in the degree of myelination of existing axons rather then in the number of axonal projections. This view is supported by recent work by (b)(6) at the NIH who has demonstrated that electrical activity signals oligodendrocytes to trigger the initial events in formation of myelin. This mechanism would preferentially myelinate electrically active axons (Wake 2011). The use of mcDESPOT to assess myelin-specific changes in brain plasticity is a completely novel approach, and we believe that it would be more informative than previously used MRI methods.

Overall the use of these quantitative MRI metrics, in conjunction with histopathological validation, will represent a first step in achieving biological specificity in the characterization of plastic brain changes that are affected by Omega-3 FA intake. An important aspect of this project is that we aim at using the same quantitative acquisitions in both the animal and clinical portion of the project so that the results of the histological assessment performed by Dr (b)(6) lab would be valuable for the interpretation of MRI findings obtained in the clinical setting.

Histological Characterization: All brains will be sections at 40-30 microns and stained for markers of neurodegeneration and neuroinflammation. After staining, digital images of the whole section will be acquired. The digital images will be analyzed using imageJ software.

Statistical Analysis: Histology and DTI differences between treatment groups at different times will be analyzed using two-way repeated measures ANOVA. Male v. Female differences will be analyzed via one-way ANOVA both within groups and within time points. Correlation plots will then be done to compare DTI metrics with histology markers.

Statistical power analysis: Number of animals for each experiment was determined via a power-based assessment. The sample sizes (for each group) are considered for an alpha=.05 and power=.80. Experiment 1 has 5 treatment groups and 2 time points. Experiment 2 has 4 treatment groups and 4 times points. Assuming an effect size of 1.25, experiment 1 requires n=7 and experiment 2 requires an n=9. These groups were then doubled to include both male and female mice as separate groups per treatment and time point.

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered:

We study the impact of injury on the molecular mechanisms and structural integrity of the brain which requires an accurate representation of the structure and biology of the brain. Since this study requires a specific structural and molecular biology that is not reproducible in non-animal models, we are required to use an animal model. Culture and *in vitro* techniques as well as computer models are applied to this research whenever possible.

V.3.2. Animal Model and Species Justification:

CCI is a highly reproducible and widely studied model for traumatic brain injury. There is a large literature studying the effects of CCI on the neurobiology of mice, which will assist in understanding our results later on. Additionally, the previous research studying the effect of DHA on the brain was done in CCI injured mice.

V.3.3. Laboratory Animals

		Species #1	Species #2
V.3.3.1.	**Genus & Species**:	*Mus musculus*	*Mus musculus*
V.3.3.2.	**Strain/Stock**:	C57Black/6	C57Black/6
V.3.3.3.	**Source/Vendor**:	1) (b)(4)	1) Weaned from pregnant dams at USUHS 2) (b)(6)
V.3.3.4.	**Age**:	~8 weeks	8-10 weeks
V.3.3.5.	**Weight**:	25-30g	~30g
V.3.3.6.	**Sex**:	Female, 2-weeks pregnant	Male and Female
V.3.3.7.	**Special Considerations**:	Given special chow: See v.5.1.2	Given special chow: See v.5.1.2

V.3.4. Number of Animals Required (by Species): Species 1: 71
Species 2: 500
plus 50 animals from (b)(6)

V.3.5. Refinement, Reduction, Replacement (3 Rs): also see CNRM SOP #1

V.3.5.1. Refinement:
The experiments are conducted with every effort to eliminate the possibility of pain. Animals will be anesthetized prior to exposure to CCI to minimize animal distress at the time of injury. Immediately following CCI, the animals will be monitored for at least two hours for signs of pain and/or distress i.e. changes in appearance, respiration, provoked and unprovoked behavior, and changes in body weight. Body weight will be measured once before surgery and then weekly after that. A total body weight loss of >10% from baseline weight for a sustained period of 1 week will constitute a sign of excess pain or distress. Animal handlers will adjust animals to new environments or experimental situations by allowing animal to acclimate to the new environment for at least 15 minutes prior to the experiment. New environments include the USUHS MRI facility and the surgery rooms.

V.3.5.2. Reduction:
The number of animals used in these experiments is dictated by considerations of statistical power. We will use the same animal to test multiple potential TBI biomarkers, which includes blood and MRI biomarkers.

V.3.5.3. Replacement:
No adequate replacement for live animal use was identified for this study. We have considered use of in vitro techniques and computer simulations whenever possible, however, these approaches cannot address the complex structural and molecular interactions required to study how DHA treatment effect's the brain after injury, and have therefore been rejected.

V.4. Technical Methods:

V.4.1. Pain / Distress Assessment:
Depth of anesthesia will be checked prior to any potentially painful procedure by administration of a foot-pinch test. The test should not elicit a response from the animal. Assessment of pain will be accomplished by close visual monitoring both during and after potentially painful procedures by trained study personnel. Signs of excessive pain or distress will result in immediate removal from the study and euthanasia.

V.4.1.1. APHIS Form 7023 Information:

V.4.1.1.1. Number of Animals:

	Species #1	Species #2
V.4.1.1.1.1. Column C:	71	0
V.4.1.1.1.2. Column D:	0	212
V.4.1.1.1.3. Column E:	0	338

V.4.1.2. Pain Relief / Prevention:

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization: see CNRM SOP #1
Isoflurane will be the anesthetic. Mice will be anesthetized in an induction chamber with isoflurane + 100% oxygen containing (4% isoflurane.) After anesthesia is induced (indicated by non-responsiveness to toe pinch and decreased respiratory rate), the isofluorane is reduced to 1.5-2% and the animals will be maintained via nose cone.

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions:
Animals will be gently handled for approximately 3min daily for 3-5 days prior to the start of the experiments to reduce stress on the animal. A general assessment of physical and behavioral health will be carried out on each mouse before any procedure. A veterinarian will be consulted should any sign of abnormality in appearance and/or

behavior be observed. Animals will be housed in a static cage in a room with stable temperature and humidity and on a reversed 12-h light/dark cycle per LAM SOP. Food and water will be *ad libitum*. For at least two hours following exposure to CCI, mice will be observed for signs of pain and distress and/or gross neurologic deficits. Assessment of pain will be accomplished by close visual monitoring both before and during potentially painful procedures by trained study personnel. Specifically, animals will be observed for changes in appearance, respiration, and provoked and unprovoked behavior. If recovery is not complete by the end of two hours, observation will be continued until recovery is complete. If the animal is having difficulty moving about the cage, gel packs, which provide complete nutrition will be placed on the bottom of the cage to allow easier access to food. If the animal shows signs of unusually high levels of pain and discomfort, it will be euthanized

V.4.1.3.1. Sources Searched: ALTBIB and PubMed

V.4.1.3.2. Date of Search: 8/27/15

V.4.1.3.3. Period of Search: all available

V.4.1.3.4. Key Words of Search:

Keywords for PubMed:

#1: Pain AND traumatic brain injury AND in vitro
#2: MRI AND traumatic brain injury AND in vitro
#3: MRI AND traumatic brain injury AND cell culture
#4: traumatic brain injury AND pain

V.4.1.3.5. Results of Search:

There is a small selection of brain injury research conducted in vitro and in computer models. These studies address specific bioengineering questions or specific cell injury questions. The only way to address the specific aims proposed in this study is to keep the cellular organization and biochemical interactions of the entire brain intact. This requires using an in vivo model and reducing the anesthetics and analgesics being administered. This search lead to a review article that discusses the need for in vivo experimental TBI and careful consideration of how anesthetic and analgesic agents can affect the experimental outcome (Rowe, et al 2013).

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification:

See CNRM SOP #1

The goal of the current study is aimed at understanding the benefits of n-3 fatty acid supplementation for brain development and recovery after traumatic brain injury. Analgesics and anesthetics commonly used during animal surgery have neuroprotective and anti-inflammatory side effects (Rowe, et al. 2013; Graham, et al. 2004; Zohar, et al. 2006; Zhang, et al. 2002). The efficacy of n-3 fatty acids after TBI may be a result of their effect on anti-inflammatory pathways (Calder 2005). N-3 fatty acids, specifically DHA, decreases the products of cyclooxygenase 1 and 2 (COX-1 and COX-2) (Norris, et al. 2012). The non-steroidal anti-inflammatory drugs (NSAIDs) typically used after animal surgery (i.e. meloxicam) work by inhibiting COX (Botting 2000; Tacca, et al. 2002). Another commonly used analgesic for animal surgeries is acetaminophen. Acetaminophen has been reported to inhibit prostaglandin synthesis, a prominent molecular product of the COX-inflammatory pathway (Graham and Scott, 2005). DHA and the former analgesics would exhibit similar biochemical footprints when investigating the COX inflammatory pathway. Opioids, like Buprenorphine, have been reported to show anti-inflammatory effects such as decreasing TNF (Walker 2003; Lufty, et al. 2004). Neuroinflammatory pathways are an important site of inquiry in this study. The neuroprotection and anti-inflammatory actions of additional post-operative analgesics may confound and mask n-3 fatty acid effects on brain biochemistry and repair. Avoiding additional analgesics is recommended until a better understanding of the effects of n-3 fatty acids on reparative brain mechanisms and development is acquired

V.4.2. Prolonged Restraint: N/A

V.4.3. Surgery:

V.4.3.1. Pre-surgical Provisions: see CNRM SOP #1
Mice will be fed a diet deficient in DHA. The present study will be conducted to establish the neuroprotective potential of n-3 fatty acids/DHA in traumatic brain injury model. Modified diet will be used as one of the sources to expose the animal to different levels of fatty acids. In these diet studies, the animals will be fed one of four defined diets (AIN-93) that consist of varying ratios of n3 and n-6 fatty acids prior to euthanasia and tissue collection. The supplementation entails only a substitution in fats, with the rest of the dietary composition maintained at normal levels. Since linoleic acid is considered an essential fatty acid, all diets will include at least 0.5 energy percent of this fatty acid. Therefore, animals will receive proper nutrition throughout the experiment and there will be no water restriction. Two-week pregnant dams will be placed on a special diet through the pregnancy as well as after delivery in the lactation period. After weaning, the male and female offspring will be placed on the same diet as had by the respective dams for a further 8-10 week period. For both series of experiments, the animals will be subjected to CCI when they are 8-10 weeks old and continued with their respective diet regime for about another week.

V.4.3.2. Procedure: see CNRM SOP #1 for

CCI: Mice will be induced in 100% oxygen and 4% isoflurane. Once mouse is unresponsive to toe pinch, the anesthesia will be maintained at 2.5% isoflurane. The head will be secured via ear bars and the top of the head will be shaved. Iodine will be

applied to the shaved area. A midline incision using a scapel will be performed to expose the parietal bone of the skull. The craniotomy will be 4 mm made over the left cerebral hemisphere between the lambda and the bregma marks about 1 mm from midline. An impact velocity of 3.5 m/s with a penetration depth at 1.5 mm and impactor dwell time of 500 ms will be used. After the injury, the wound will be covered with Surgicel (Johnson & Johnson, Arlington, TX, USA) and the craniotomy closed using cyanoacrylate. The incision will be sealed with non-absorbable nylon sutures (Ethilon Nylon Suture, Ethicon, Johnson & Johnson) and then the animal will be removed from anesthesia. Once the animal regains righting reflex, the animal will be returned to their home cage and monitored for excessive pain and discomfort. Any sutures that do not fall out naturally while the incision is healing post-surgery, will be removed when the incision is fully sealed (approx. 1 week post surgery.)

MRI: One set of mice will be housed at USUHS and taken to the USHUS Animal MRI facility directly for imaging. Another set of mice will arrive from Dr. (b)(6) (b)(6) . These mice will be transported to USHUS for MRI imaging via the LAM vehicle and euthanized immediately after imaging in the fume hood in Rm (b)(6) For MRI imaging, mice will be anesthetized in an induction chamber with 100% oxygen containing 4% isofluorane. After anesthesia is induced (indicated by loss of toe pinch reflex, decreased respiratory rate), the isofluorane is reduced to 1.5-2% and the animals will be maintained via nose cone in a stereotaxic setup. Core body temperature is monitored by a thermistor type rectal temperature probe (or an MR compatible fiber optic rectal probe) that is lubricated and inserted into the rectum. A target body temperature of 37 is maintained by a feedback controlled circulating warm water blanket. Plane of anesthesia will be monitored by anesthetic gas levels, and changes in physiological parameters that may include heart rate, respiratory rate, end tidal CO2 and body temperature (via rectal probe). ECG may be monitored if necessary.

For MR imaging of the brain, the head of the anesthetized mouse will be restrained with ear bars and a bite bar in a configuration similar to commercial stereotaxic devices. MR may be performed for up to 3 hours to include a T2 anatomical scan, Diffusion tensor imaging, relaxometry measures and other scans as deemed necessary.

V.4.3.3. Post-surgical Provisions: see CNRM SOP #1
The mouse will be recovered in a clean cage on a circulating warm water heating pad. It will be visually monitored until it is awake and ambulatory. Animals will be given ad lib access to food on the floor of their cage for 24 hours after anesthesia. Animals will be monitored daily for signs of pain and distress not associated with the surgical injury.

V.4.3.4. Location:
CCI will take place at the CCI apparatus in the LAM facilities at USUHS
MRI will take place at the animal MRI facility at USUHS
Cardial perfusion will take place in the fume hood in Rm (b)(6) USUHS campus

V.4.3.5. Surgeon:
(b)(6) Ph.D

V.4.3.6. Multiple Major Survival Operative Procedures: N/A

V.4.3.6.1. Procedures: N/A

V.4.3.6.2. Scientific Justification: N/A

V.4.4. Animal Manipulations:

V.4.4.1. Injections: See CNRM SOP #1
Using a 27 gauge needle, animals will receive an intraperitoneal (i.p.) injection (approximately 200-400 µL) of either DHA (16mg/kg), Synaptamide (5-20 mg/kg), DHA plus Synaptamide, or vehicle. DHA and Synaptamide are immiscible in saline, therefore the vehicle will be DMSO. A similar study in rat administered a daily dose i.p. injection of 16 mg/kg of DHA for just short of one month (21 days) (Harvey et al. 2014). No issues of toxicity relating to the DHA (16mg/kg) in DMSO injection were reported in that study. There is no literature available on the toxicity of synaptamide injections in vivo. Our collaborator, Dr. (b)(6) is working on toxicity and tolerability of synaptamide in vivo and will inform us of a safe and effective dose. Her lab has currently administered a daily synaptamide dose of 25 mg/kg to mice for 3 days without any signs of pain or distress and no mortalities (Desai, personal communication, Feb 2016). The synaptamide dose will be between 5-20 mg/kg. In our study, animals will initially be dosed 6 hours after injury and then once a day for the following 30 days. IP injection sites will alternate sides of the abdomen from day to day. Animals that do not receive injury (experiment 1) will begin injections at 3 months of age. For transcardial perfusions, animals will be injected IP with an overdose of Na Pentobarbital or Euthasol (50-70 mg/kg) before the non-survival transcardial perfusion procedure begins.

V.4.4.2. Biosamples:
All brains will be removed for ex-vivo imaging and histological characterization.

V.4.4.3. Adjuvants: N/A

V.4.4.4. Monoclonal Antibody (MAbs) Production: N/A

V.4.4.5. Animal Identification: Animals will be identified via ear punch and hand written notes on cage cards regarding group and treatment.

V.4.4.6. Behavioral Studies: No behavioral studies will be performed for these experiments.

V.4.4.7. Other Procedures:
Transcardiac Perfusion: All mice will receive cardiac perfusions. Each mouse will be overdosed with Na Pentobarbital (50-70mg/kg) and be checked for reflex using a pinch test. In the instances when Na Pentobarbital is not available the commercially available euthanasia solution Euthasol® (50-70 mg/kg) will be used as an alternative. Once the animal is deeply anesthetized (as indicated by lack of response to pinch test), they will be cut from the bottom of the rib cage to the top of the sternum to expose thoracic organs. An appropriate size needle (26-27 G for mice) will be punctured through the left

ventricle of the heart into the right atrium. Saline will be pushed through the heart either by way of syringe or tubing. Once the blood has cleared, (measured by the aorta and liver color) then 4% buffered paraformaldehyde plus 4% glucose in phosphate buffer solution will be pushed through the heart. The brain will then be removed and immersed in paraformaldehyde solution or frozen. This procedure will occur in the fume hood in Rm (b)(6) USUHS campus.

Ear Punch: All mice will receive ear punch for identification in a cage. Mice in experiment 1 will be randomly assigned to experimental groups. Before drug administration begins, each mouse will be scruffed and quickly receive a 1 mm hole in their ear from a disinfected mouse ear punch in the appropriate identification location. The ear punch device will be disinfected initially in an autoclave and then rubbed down with 70% ethanol before the punch. Mice in experiment 2 will receive an ear punch for identification during the time of surgery, while the mouse is still anesthetized.

V.4.4.8. Tissue Sharing: N/A

V.4.5. Study Endpoint:
All animals will be euthanized at the time points indicated in the protocol. Any animal showing signs of excessive pain or distress will be euthanized before the experimental study endpoint and removed from the study. Signs of excessive pain or distress include hunched posture, self-mutilation, aggressive vocalization, ataxia, lethargy, soiled hair coat, and excessive body weight loss. Body weight will be measured once before surgery and then weekly after that. A total body weight loss of >10% loss from baseline weight for a sustained period of 1 week will constitute a sign of excess pain or distress. Any animal that shows these symptoms will be carefully observed for several days. If symptoms attenuate, the animal will be kept in the study. Excessive pain or distress will involve the any of the above symptoms lasting for more than a week and will necessitate removal from the study.

V.4.6. Euthanasia: Euthanasia for animals in the experiment will consist of transcardial perfusion as describe earlier. All animals needing to be euthanized for other reasons, such as excessive pain and distress, will be euthanized following AVMA guidelines and will consist of CO_2 inhalation from a 100% CO_2 compressed gas cylinder. Animals will be placed in an induction chamber and the tank will be filled with CO_2 gas at an approximate rate of 0.5-1 liter per minute. Gas will be maintained for 1 minute after respiration has stopped to prevent unintended recovery (approximately 3-4 minutes total.)

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol.

V.5.1.1. Study Room:
Building(s) USUHS (b)(6) Room Number(s) (b)(6)

V.5.1.2. Special Husbandry Provisions:

Food Restriction:	Yes	_____	No	X
Fluid Restriction:	Yes		No	X

V.5.1.3. Exceptions: Special Diet: The present study will be conducted to establish the neuroprotective potential of n-3 fatty acids/DHA in a traumatic brain injury model. Modified diet will be used as one of the sources to expose the animal to different levels of fatty acids. In these diet studies, the animals will be fed one of four defined diets (AIN-93) that consist of varying ratios of n3 and n-6 fatty acids prior to euthanasia and tissue collection. The supplementation entails only a substitution in fats, with the rest of the dietary composition maintained at normal levels. Since linoleic acid is considered an essential fatty acid, all diets will include at least 0.5 energy percent of this fatty acid. Therefore, animals will receive proper nutrition throughout the experiment and there will be no water restriction. Two-week pregnant dams will be placed on a special diet through the pregnancy as well as after delivery in the lactation period. After weaning, the male offspring will be placed on the same diet as had by the respective dams for a further 8-10 week period. For both series of experiments, the animals will be subjected to CCI when they are 8-10 weeks old and continued with their respective diet regime throughout the experiment.

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care: Veterinary staff at LAM will check on animal cages 2 times per day. Animal cages will be changed out for clean cages 2 times per week. Any animals that look ill or distressed will be reported to a Veterinarian for further assessment. The veterinarian's diagnosis of the animal will be reported and the animal will be monitored for worsening or improving of symptoms. If treatment of the animal is required, protocol staff will be notified for approval of the treatment.

V.5.2.2. Emergency Veterinary Medical Care: All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekends and holidays.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: Except as indicated below, all animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents.

V.5.3.2. Enrichment Restrictions: None

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
Planning and interpreting CCI experiments; will not be handling animals	(b)(6)	Over 20 years of experience working in pre-clinical and clinical TBI	USUHS PI Training,
Planning and interpreting MRI experiments; will not be handling animals		Over 20 years of experience in MRI	Will take USUHS PI training
CCI		Postdoc, 5 yr experience performing CCI	Rodent Handling Training, 5 Nov 2015 USUHS PI Training, 5 Nov 2015
MRI		Postdoc, 5 yr experience handling rodents and trained on performing in vivo MRI by experienced technicians	MIF Safety Course, 2015 fMRI Summer Course, 2015
MRI		Postdoctoral fellow, 6+ years experience scanning various animals	Rodent Handling Training, 8 Jan 2013 USUHS PI Training, 6 Feb 2013
Perfusion		Postdoc, 5 yr experience in perfusion of rodents	Rodent Handling Techniques Course, 5 Nov 2015 USUHS PI Training, 5 Nov 2015
Intraperitoneal Injection		Postdoc, 5 yr experience performing IP injection	Rodent Handling Techniques Course, 5 Nov 2015 USUHS PI Training, 5 Nov 2015
CCI and Perfusion		Research Assistant, works on numerous projects in Dr (b)(6) (b)(6) lab, 2 years previous experience working	Rodent Handling Techniques Course, 4 February 2016 USUHS PI Training, 4 February 2016

		with mice	

VII. BIOHAZARDS/SAFETY:

PPE: All technicians will wear scrubs/lab coat, gloves, closed-toed shoes, and a mask while handling animals. When working with biologically hazardous materials, technicians will wear a lab coat, gloves, closed-toed shoes, goggles, and a mask.
Waste gas: Waste anesthetic gases will be exhausted using an active scavenging system.
Paraformaldehyde: Paraformaldehyde will be worked with in a fume hood. Waste will be collected and disposed of as chemical waste.

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

(b)(6) Sept 18, 2015

Principal Investigator Signature Date

G. Training: The following personnel will attend the next USUHS Investigator/Animal User Training Course:

(b)(6) MD, PhD

H. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely, "Responsibility" for implementing animal use alternatives where feasible and conducting humane and lawful research.

I. Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

X. PROTOCOL ABSTRACT:

A. **Animal Protocol Number**: To be assigned

B. **Animal Protocol Title**: Traumatic brain injury recovery with n-3 highly unsaturated fatty acids (HUFAs) in mice: A biomarker-driven approach

C. **Principal Investigator**: (b)(6)

D. **Performing Organization**: Uniformed Services University for the Health Sciences

E. **Funding**: Center for Neuroscience and Regenerative Mediicne

F. **Objective and Approach**: **Hypothesis**: Our hypothesis is that DHA supplementation after TBI is neuroprotective and this neuroprotection can be detected via blood biomarkers and advanced magnetic resonance imaging strategies. We will show this with the following specific aims:

Aim 1: Innovative imaging study, designed to determine whether advanced neuroimaging strategies, including diffusion imaging and relaxometry, are sensitive to the omega-3 fatty acid content of brain membranes. In this study we propose to use quantitative MRI techniques to identify potential biomarkers of brain changes induced by Omega-3 fatty acids in animals. We plan to investigate the effects of DHA intake on the brain in mice that are chronically depleted of Omega-3 FA vs. animals with an Omega-3 FA enriched diet, using a model based on the one developed by Desai et al. (2014) in Dr. (b)(6) lab. We will acquire MRI data of mice *in vivo* prior to DHA supplementation and then longitudinally. Ex-vivo, high resolution MRI scanning will be performed on the same brains studied with histological techniques.

Aim 2: Preclinical project designed to identify MRI biomarkers sensitive to omega-3 supplementation after TBI. Such MRI and blood biomarkers could readily be translated to clinical trials. These include measurements of bioactive lipids in plasma and RBC membranes such as synaptamide, 17-hydroxy-DHA, D-resolvins, endovanilloids, and endocannabinoids. These bioactive lipids have potent anti-inflammatory and pro-neurogenic effects that will simultaneously be tested in a parallel clinical study. Eight-10 weeks old male mice will be injured by an experimental TBI model, moderate controlled cortical impact in the parietal cortex. DHA and Synpatamide supplementation (40 mg/kg) will start 6 hours after injury and continue for 30 days {3136}. Accessible biological tissues (plasma, serum, RBC membranes, potentially others) will be assayed using sensitive HPLC-Mass Spectrometry (MS) assays in Dr (b)(6) lab. Our lab will acquire MRI data of mice *in vivo* prior to injury and then longitudinally after TBI induced by controlled cortical impact to investigate the effects of DHA treatment.

G. **Indexing Terms (Descriptors)**: Traumatic brain injury

MEMORANDUM FOR DR (b)(6) DEPARTMENT OF PATHOLOGY

SUBJECT: IACUC Approval of Protocol - Triennial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on April 23, 2012:

Animal Protocol Title: "Regulation of Anti-Infectious Immunity (Mice)"

USUHS Protocol Number: (b)(6)

Expiration Date: April 22, 2015

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. NON-TECHNICAL SYNOPSIS:

Infections with extracellular bacteria are a major source of global morbidity and mortality. This fact, and the increasing incidence of antibiotic-resistance of bacterial strains make the development of vaccines against these agents of high clinical importance for both the civilian and military sectors. Immunity to this class of pathogens is mediated by antibody that facilitates the uptake and subsequent killing of bacteria by phagocytic cells such as neutrophils and macrophages. In order to optimize the design of effective vaccines against these agents, it is important to understand the basic immunologic parameters that regulate antibody production in vivo in response to immunization or infection with an intact bacterial pathogen.

Our laboratory studies the in vivo protein- and polysaccharide-specific immunoglobulin isotype response to intact Gram-positive (e.g. *Streptococcus pneumoniae, Streptococcus agalactiae, Staphylococcus aureus*) and Gram-negative (e.g. *Neisseria meningitidis, Acinetobacter baumannii*) extracellular bacteria or antigens derived from these pathogens, using the mouse as a model system. These bacteria continue to cause substantial global health problems. We currently have two major funding sources (see above) that collectively are integrated to explore this general issue in a complementary fashion. Hence, these respective projects, which are conducted in Rooms (b)(6) (b)(6) in the Department of Pathology, are subsumed under this one animal protocol, given that the methodologies related to the use of mice are widely overlapping among the projects.

Areas of study include the role of dendritic cells and macrophages, B and T lymphocytes, innate immunity including Toll-like receptors, cytokines, chemokines, and T cell costimulatory molecules, in the ability to elicit humoral immunity to intact extracellular bacteria, or purified bacterial antigens and novel adjuvants. Regarding the use of mice, methodologies include 1) utilizing athymic nude mice for a) making monoclonal antibody-containing ascites and b) as a model of T cell-deficiency for immunologic studies, 2) immunization of mice with heat-killed intact bacteria or bacterial antigens, by i.p., i.v. and

s.c. routes; in selected experiments alum or Toll-like receptor (TLR) ligand adjuvants are used, 3) tail vein bleeds to obtain sera for measurement of antigen-specific Ig isotype titers and cytokines by ELISA, and for obtaining circulating immune cells, 4) removal of lymphoid tissue for obtaining cells for various *in vitro* immunologic studies and for confocal fluorescence microscopy, 5) infection of mice with live extracellular bacteria for studies on immunologic protection or induction of humoral immunity, 6) use of various mouse strains as recipients in immune cell adoptive transfer experiments, and 7) gamma irradiation of immune cells to act as antigen-presenting cells for stimulating T cells, or of live mice to create bone marrow chimeras. Heavy use is made of transgenic and knockout mice (listed below) in which we have established breeding colonies for some strains, in LAM. As will be described, although these extracellular bacteria are human pathogens, their use experimentally at worst poses minimal health concerns that can easily be addressed using routine microbiologic precautions.

II. BACKGROUND:

II.1. Background:

Various extracellular bacteria, listed in this protocol, are major causes of global morbidity and mortality. Systemic adaptive immunity to these bacterial pathogens is mediated by antibody, especially IgG specific for the capsular polysaccharide (PS), but also for bacterial proteins. **Our long-term goal is to elucidate the cellular mechanisms that underlie the distinct differences that exist between *in vivo* anti-PS and anti-protein Ig responses between distinct extracellular bacteria, and between intact bacterial pathogens and bacteria-derived soluble vaccines, These studies will aid in the development of improved vaccines and to an understanding of physiologic humoral immune responses during bacterial infections.**

In contrast to the current dogma, based on using purified PS antigens, that IgG anti-PS responses are T cell-independent, we demonstrated that the IgG anti-PS responses to intact extracellular bacteria are heavily dependent on $CD4^+$ T cells. However, distinct bacteria elicit distinct types of T cell-dependent anti-PS responses in vivo. Further, IgG anti-PS responses to intact bacteria appear to be regulated by distinct cellular parameters relative to IgG anti-PS responses to soluble PS-containing vaccines. In light of these data, **the central hypothesis that underlies our proposed research is that distinct physical parameters and combinations of antigenic and immune-modulating moieties intrinsic to various intact bacteria and vaccines distinguish both *physiologic* anti-PS and anti-protein Ig responses to intact bacteria, as well humoral immunity to intact bacteria versus soluble bacterial vaccine antigens.** We will demonstrate that these parameters differentially impact on 1) the temporal usage of responding B cells, T cells, and APCs within the spleen, 2) the cellular interactions of the responding B cells with these other immune cell types, and the recruitment of regulatory innate immune processes. As a result we will provide a mechanistic basis that will elucidate the nature of the in vivo humoral immune responses observed.

II.2. Literature Search for Duplication:

II.2.1. **Literature Source(s) Searched**:
Biomedical Research Data Base (BRD)
Federal Research in Progress (FEDRIP)
Pub Med

II.2.2. **Date of Search**: December 23, 2011

II.2.3. **Period of Search**: 2001-2011 (FEDRIP); 2001-2011 (BRD)

II.2.4. **Key Words and Search Strategy**:
Search#1. Extracellular bacteria, mouse, and humoral immunity.
Search#2. Extracellular bacteria, mouse, and vaccine.
Search#3. Extracellular bacteria, mouse, and humoral immunity
Search#4. Polysaccharides, mouse, and antibody
Search#5. Extracellular bacteria, mouse, and polysaccharides
Search#6. Polysaccharides, mouse, and vaccine

II.2.5. **Results of Search**:
Although extensive work is being conducted in the more general areas subsumed under each search, and thus multiple hits too numerous to detail were obtained, the searches did not reveal any projects investigating the specific ideas outlined in this protocol including detailed studies investigating the differential regulation of anti-protein and anti-polysaccharide responses to intact extracellular bacteria or bacteria-derived antigens.

III. OBJECTIVE\HYPOTHESIS:

1. We will determine the nature and relationships of B cell and APC cell subsets, and CD4$^+$ T cells that differentially mediate *in vivo* anti-PS and anti-protein Ig isotype responses to systemic immunization with intact extracellular bacteria. We will utilize magnetic bead or high speed electronic cell sorting and adoptive transfer of wild-type and genetically altered immune cells or bacteria, and bacteria-derived soluble vaccine antigens, combined with ELISPOT and ELISA analyses of antigen-specific Ig isotype production to accomplish this aim. In addition, selective manipulation of immune cells in vivo will be accomplished by creation of bone marrow chimeric mice, in which mice are first irradiated to ablate the hematopoietic system, then reconstituted with bone marrow cells from genetically altered mice.

The bacteria selected for these studies are those that account for major morbidity and mortality in the human populations, and in which vaccines are either available (although requiring improvements) or being developed. The bacteria include 1) *Streptococcus pneumoniae* 2) *Streptococcus agalactiae* (Group B Strep [GBS]), 3) *Staphylococcus aureus*, 4/5) *Neisseria meningitidis*, group A and C, and 6) *Acinetobacter baumannii*. The justification for the use of these bacteria is that they include both Gram-positive and Gram-negative bacteria, which may behave differently in regard to the nature of the immune response elicited. **Thus, these studies represent a systematic approach to understanding intact bacterial pathogens as immunogens for elicitation of antibody responses specific for bacterial protein**

and polysaccharide antigens. For each bacteria, a corresponding conjugate vaccine is evaluated to further study if and how these conjugates differ from intact bacteria in eliciting humoral immunity. **Thus, the relatively large number of mice requested, reflects the systematic and comprehensive nature of these analyses, which have not previously been undertaken by others and which have potential clinical significance.** The time points chosen are based on our extensive experience on the kinetics of the immune response obtained from our previous studies on *Streptococcus pneumoniae*.

2. We will determine the *mechanism* by which B cells, APCs, and $CD4^+$ T cells differentially orchestrate anti-PS and anti-protein responses within a spatiotemporal context. We will utilize B cells from PS- and protein-specific B cell receptor transgenic mice and T cells from $CD4^+$ T cell receptor (TCR) transgenic mice with specificity for a bacteria-expressed peptide to accomplish this aim. These cells will be used to conduct *in vitro* functional studies and confocal microscopic analyses of splenic and lymph node tissue sections from mice immunized *in vivo*.

3. We will determine the mechanism by which distinct extracellular bacteria exert immunoregulatory effects on humoral immune responses to co-immunized soluble antigens. During infections with extracellular bacteria, the immune system likely encounters a variety of microbial components in soluble form, as well as those associated with the intact bacterium. Although soluble and particulate antigens may exhibit distinct immunologic properties, their potential cross-regulatory effects on the humoral immune response, following concomitant immunization, as might occur during bacterial infections, is unknown. We will determine the innate cellular mechanisms by which intact bacteria alter antibody responses to co-immunized proteins antigens, through the use of genetically altered bacteria and mice, immune cell adoptive transfer studies, and bone marrow chimeric mice.

These studies are the first to systematically determine the mechanisms that distinguish anti-PS from anti-protein responses to an *intact* bacterium, elucidate the differences between humoral immune responses to intact bacteria versus soluble bacterial antigen-derived vaccines, determine the mechanisms by which bacteria alter immune responses to heterologous antigens, and provide novel basic immunologic insights with direct relevance to the development of anti-bacterial vaccines.

IV. MILITARY RELEVANCE:

Infections with extracellular bacteria continue to exact significant morbidity and mortality among members of the military population. Although these infections can be treated with antibiotics, the increasing development of antibiotic-resistant strains has made necessary the development of new vaccines for host protection. Protective vaccines for extracellular bacteria necessitate the elicitation of high titers of antigen-specific IgG antibodies against select microbial antigens. The rational design of vaccines requires an understanding of the basic immunologic parameters that elicit antibody production in response to either an intact pathogen or purified soluble microbial antigens. The work subsumed under this protocol should provide useful new information on the basic humoral immune response to extracellular bacteria and their

relevant antigens, which will help guide the development of new anti-bacterial vaccines that will have immediate use among the military population that are at risk for these infections, both as natural pathogens, as well as potential bioterrorist agents. In addition, direct clinical applications will be explored through the development of novel adjuvants for stimulating immunity to various antigens derived from these bacterial pathogens.

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures:

Two major types of experiments will be performed:

1) In vivo-in these experiments mice are immunized i.p., i.v., s.c., or i.n. with either intact bacteria, purified antigen, or specific types of purified immune cells (e.g. dendritic cells, macrophages, T cells, and B cells) with or without additional immunoreagents such as adjuvant (i.e. alum, TLR ligands), monoclonal antibodies or fusion proteins specific for soluble mediators or cell surface structures. At varying times thereafter, several parameters of the immune response will be determined such as;

a) blood levels of bacteria [counting on agar plates] and lethality,

b) serum titers of antigen-specific Ig isotypes [ELISA] or numbers of specific Ig-producing B cells [ELISPOT].

c) phenotypic changes and localization of various immune cell types found within intact lymphoid organs or freshly explanted [fluorescence confocal microscopy and flow cytometry],

d) cytokine and chemokine production [ELISA, ELISPOT, flow cytometry, immunohistochemistry, RT-PCR]

Generally, *in vivo* experiments are performed using 7 mice per experimental group based on our consultation with a professional statistician (see below: "V.2. Data Analysis"), as well as having long experience working in this research area. As such, this number of mice is crucial for meaningful statistics. The typical experiment covers 4-5 weeks (i.e. primary immunization followed by secondary immunization 2-3 weeks later, with an additional 1-2 weeks of follow-up analyses).

2) **In vitro**- Mice will also be used as a source of immune cell types for both in vitro stimulation and in vivo adoptive transfer experiments. Cells include:

a) dendritic cells and macrophages obtained from bone marrow, cultured initially in GM-CSF or M-CSF, respectively to increase cell numbers.

b) T cells, B cells, dendritic cells, or macrophages obtained from spleen or lymph node and then purified by either magnetic or electronic cell sorting and used either for in vitro studies or for adoptive transfer into new mice for in vivo studies.

c) Macrophages obtained via peritoneal lavage and used immediately.

The number of mice required for these experiments strictly depends on the nature of the experiment and the particular cell type or subset under study; different cells are found in different relative proportions and thus heavily influence the number of mice needed to obtain sufficient numbers for the experiment. Details of these experiments now follow:

V.1.1. Experiment 1: The T cell, costimulatory, and B cell subset requirements for induction of in vivo PS-specific and protein-specific IgG responses to intact bacteria and conjugate vaccines. We previously conducted a series of in vivo immunologic studies to determine the cellular and costimulatory parameters that mediated the antibody response to intact, heat-killed *Streptococcus pneumoniae*, capsular type 14 (Pn14) versus a soluble pneumococcal conjugate vaccine. To develop a broader view of how different Gram-positive and Gram-negative bacteria regulate an anti-capsular polysaccharide response in vivo, we will significantly extend our studies using the Gram-positive bacteria, *Streptococcus agalactiae* (Group B Streptococcus [GBS]) and *Staphylococcus aureus* (SA) and the Gram-negative bacteria, *Neisseria meningitidis* group A and group C (MenA and MenC, respectively) and *Acinetobacter baumannii* (AcB). Soluble conjugate vaccines utilizing the purified capsular PS from these bacteria, will also be evaluated in a similar fashion to better understand the differential parameters governing responses to particulate intact bacteria versus soluble bacterial conjugate vaccines.

The justification for these studies is the hypothesis that the unique structural and biochemical features between these bacteria, as well as conjugate vaccines, will result in distinctive anti-polysaccharide (PS) responses in vivo. All bacteria will be heat-killed and injected into mice i.p. and thus we anticipate no pain, suffering, or lethality from these series of studies, nor any risk to the investigator. 7 mice per group will be used to statistically power these studies. Serum will be obtained from tail vein bleeds at day 0 (pre-bleed), 21 (primary) and 28 (secondary) for determination of serum titers of PS-specific and whole bacterial protein-specific IgM and IgG.

a. Kinetics of the systemic primary and secondary IgM and IgG anti-PS responses to heat-killed bacteria. Wild-type (BALB/c, C57BL/6, FVB) mice will be injected i.p., i.v., or s.c. with 2 different doses (2×10^8 CFU/mouse and 1×10^9 CFU/mouse) of the respective bacteria in saline and boosted with the same dose on day 21. Following determination of serum titers of antigen-specific antibody, the mice will be euthanized. Thus, each experiment is expected to last ~35 days. All experiments will be planned to performed 3x for reproducibility, with the assumption that some experiments may fail and that at least 2 successful experiments are needed publishable data. On the basis of these studies we will choose a single dose of bacteria and a single route of immunization for subsequent studies. Since we plan to subsequently use genetically altered mice on either the BALB/c or C57BL/6 background

Total BALB/c: 5 types bacteria x 2 doses x 3 immunization routes x 7 mice x 3 experiments=630

Total C57BL/6: 5 types bacteria x 2 doses x 3 immunization routes x 7 mice x 3 experiments=630

Total FVB: 5 types bacteria x 2 doses x 3 immunization routes x 7 mice x 3 experiments=630

b. Kinetics of the systemic primary and secondary IgM and IgG anti-PS responses to soluble bacterial conjugate vaccine. A similar series of studies as described in 1.a. will be performed using a single standard dose (10 micrograms per mouse) of soluble conjugate vaccine containing a PS from the bacteria indicated above covalently attached to an immunogenic protein. Only two experiments each are proposed using C57BL/6 and FVB strains in this instance, since we consider that these will be largely confirmatory of the data obtained using the BALB/c strain.

Total BALB/c: 5 types conjugate x 1 dose x 3 immunization routes x 7 mice x 3 experiments=315

Total C57BL/6: 5 types conjugate x 1 dose x 3 immunization routes x 7 mice x 2 experiments=315

Total FVB: 5 types conjugate x 1 dose x 3 immunization routes x 7 mice x 2 experiments=315

c. PS-specific IgG memory response. To determine intact bacteria or conjugate vaccine induce memory B and/or CD4+ T cells specific for the IgG anti-PS and/or IgG anti-protein response, RAG-/- mice (BALB/c or C57BL/6 background) which lack B and T cells, will be used as recipients for adoptive transfer of B cells and CD4+ T cells from either naïve or bacteria/conjugate primed BALB/c mice or C57BL/6 mice. Reconstituted RAG-/- mice will be immunized with either intact bacteria or conjugate and serum titers of IgG anti-PS will be determined by ELISA. If memory cells for an IgG anti-PS response are produced by the initial immunization, then it is predicted that recipient RAG-/- mice will demonstrate substantially higher serum anti-PS titers when donor cells are from primed as opposed to naïve mice. Cells from one donor will be transferred into one recipient.

BALB/c, RAG-/-: 5 bacteria x 7 mice x 3 experiments=105 BALB/c, 105 RAG-/-

BALB/c, RAG-/-: 5 conjugate x 7 mice x 3 experiments=105 BALB/c, 105 RAG-/-

C57BL/6, RAG-/-: 5 bacteria x 7 mice x 3 experiments=105 C57BL/6, 105 RAG-/-

C57BL/6, RAG-/-: 5 conjugate x 7 mice x 3 experiments=105 C57BL/6, 105 RAG-/-

d. T cell-dependence of IgG anti-PS response to bacteria or conjugate vaccine. BALB/c or T cell-deficient (athymic nude) mice (7/group) will be immunized with heat-inactivated bacteria and boosted. Additional BALB/c mice will receive 1 mg of a depleting rat IgG2b anti-mouse CD4 mAb (clone GK1.5), rat IgG2b anti-mouse CD8 mAb (2.43) or species/isotype-matched negative control mAb (clone J1.2), 24h prior to immunization. Serum will be collected for primary and secondary IgM and IgG anti-PS and anti-protein responses by ELISA.

BALB/c mice: 5 types bacteria x 7 mice/group x 3 experiments x 3 Ab + 1 saline treatments=420

BALB/c mice: 5 types conjugate x 7 mice/group x 3 experiments x 3 Ab + 1 saline treatments=420

Athymic nude mice: 5 types bacteria x 7 mice/group x 3 experiments=105

Athymic nude mice: 5 types conjugate x 7 mice/group x 3 experiments=105

e. B cell subsets. Three complementary approaches will be utilized to determine the potential role of marginal zone B cell (MZB) and follicular B cells (FB) in the IgG anti-PS and anti-protein response to intact bacteria versus conjugate vaccine. **(i) Lsc-/- mice (ii) adoptive transfer of sort-purified FB or MZB cells, as well as CD4+ T cells, into RAG-/- mice**; 1 mouse as donor cells into 1 mouse as recipeint (41), and (iii) **selective depletion of MZB using anti-LFA-1 ($\alpha_L\beta_2$) + anti-α4-CD49d mAbs with rat IgG as control Ab.**

i. Lsc-/-: 5 types bacteria or conjugate (10) x 7 mice/group x 3 experiments=210

C57BL/6 control: 5 types bacteria or conjugate (10) x 7 mice/group x 3 experiments=210

ii. BALB/c: 5 bacteria or conjugate (10) x 7 mice [donor+recipient]/group (14) x 3 experiments=420

iii. BALB/c: 5 bacteria or conjugate (10) x 7 mice x 2 Abs or saline (3) x 3 experiments=630

f. T cell costimulation. If as expected, the IgG anti-PS response to intact bacteria and conjugate is dependent on CD4+ T cells, the T cell costimulatory requirements will be determined as follows: **(i) B7-dependence:** CD28-/- vs wild-type (WT) mice, and injection of CTLA4Ig or *control* L6 into WT mice, **(ii) ICOS-dependence:** ICOS-/- vs WT mice, and blocking rat IgG2a anti-mouse ICOSL (clone HK5.3) vs *control* rat IgG2a anti E coli β-galactosidase (clone GL117), and **(iii) CD40/CD40L**: CD40L-/- vs WT mice, and blocking hamster IgG anti-mouse CD40L mAb (clone MR-1) vs *control* hamster IgG. The use of knockout mice and corresponding blocking/depleting mAbs are important complementary, validating approaches.

i. C57BL/6: 5 bacteria/5 conjugate (10) x 7 C57BL/6 (WT) x 3 experiments=210
   CD28-/-: 5 bacteria/5 conjugate (10) x 7 CD28-/- x 3 experiments=210
   BALB/c: 5 bacteria/5 conjugate (10) x 7 BALB/c (CTLA4Ig) x 3 experiments=210
   BALB/c: 5 bacteria/5 conjugate (10) x 7 BALB/c (L6) x 3 experiments=210

ii. C57BL/6: 5 bacteria/5 conjugate (10) x 7 C57BL/6 x 3 experiments=210
   ICOS-/-: 5 bacteria/5 conjugate (10) x 7 ICOS-/- x 3 experiments=210
   BALB/c: 5 bacteria/5 conjugate (10) x 7 BALB/c (anti-ICOSL) x 3 experiments=210
   BALB/c: 5 bacteria/5 conjugate (10) x 7 BALB/c (control Ab) x 3 experiments=210

iii. CD40L-/-: 5 bacteria/5 conjugate (10) x 7 CD40L-/- x 3 experiments=210
   BALB/c: 5 bacteria/5 conjugate (10) x 7 BALB/c (WT) x 3 experiments=210
   BALB/c: 5 bacteria/5 conjugate (10) x 7 BALB/c (anti-CD40L) x 3 experiments=210
   5 bacteria/5 conjugate (10) x 7 BALB/c (hamster IgG) x 3 experiments=210

V.1.2. Experiment 2: Role of inflammatory monocytes and conventional dendritic cells (DC) in anti-PS responses to intact bacteria and conjugate vaccines. Transgenic mice expressing the Diphtheria toxin receptor (DTR) dependent on the activity of the CD11b or CD11c promoter (i.e. CD11b-DTR and CD11c-DTR mice, respectively) are used to selectively deplete a subset of CD11b+ (inflammatory monocytes) or total CD11c+ cells (conventional DC) following DT injection. To prevent lethality following DT administration, DT must be administered to bone marrow (BM) chimeric mice, made by injecting BM cells from either CD11b-DTR mice into lethally-irradiated wild-type FVB or C57BL/6 mice, or BM cells from CD11c-DTR mice into lethally-irradiated BALB/c mice, for reconstitution of the hematopoietic system expressing the respective transgene. C57BL/6 recipients will be used selectively, and thus in few numbers) for additional experiments involving other genetically altered cells from strain-matched mice. These BM chimeric mice can thus be used to study the role of inflammatory monocytes and conventional (c)DC in regulating anti-PS and anti-protein responses to intact bacteria and conjugate vaccines in adjuvant. Preliminary studies from our laboratory demonstrated that depletion of inflammatory monocytes markedly inhibits the anti-PS response to intact Pn14 (*Streptococcus pneumoniae*, capsular type 14) while enhancing the protein response. Further preliminary studies indicated that depletion of cDC results in an unexpected *enhancement* in both the anti-PS and anti-protein responses to intact Pn14.

In this series of studies we will determine (i.) whether the results observed for Pn14 apply to additional, distinct bacteria, as well as to different soluble conjugate vaccines. (ii.) whether inflammatory monocytes and or cDC play a role in innate host protection

against live bacteria by performing lethality studies using a dose of bacteria that we have determined is sub-lethal in WT mice. To minimize the use of mice in lethality studies, preliminary dosing to establish a sub-lethal challenge will entail the use of 3 mice per group to establish the dose of live bacteria of a given strain, that is minimally lethal as a prelude to performing more extensive lethality studies. Three-fold increments in bacterial dose will be tested based on historical doses previously used in published studies, so as to minimize the number of groups needed. For these experiments, two irradiated recipient mice can be reconstituted with BM from 1 CD11b-DTR or CD11c-DTR mice. Only 1 experiment is proposed using C57BL/6 mice since we consider this study relatively straightforward and confirmatory of the data using FVB, for the purpose of using the CD11b-DTR model,. Three experiments each are proposed for BALB/c mice since this strain is being used in conjunction with a different mouse model (i.e. CD11c-DTR).

The strains of *N. meningitidis* type A or C use in our curren studies are from ATCC and classified as BSL2 agents. However, in light of case studies (see below) reporting a risk of infection for laboratory workers with exposure to live *N. meningitidis* type A or C (used in our laboratory) [attack rate estimated at 13/100,000], we will take the following precautions: 1) The laboratory worker will be required to read the relevant published reports on potential risk. 2) The laboratory worker will be required to receive the tetravalent meningococcal conjugate vaccine before handling live meningococcus. If that individual refuses, they will not utilize these bacteria. 3) Handling of bacteria will require working both in a class II biological safety cabinet (currently in our lab) and wearing of a surgical mask in order to prevent exposure to droplets and aerosols, according to the published recommendations.

V.1.3 Experiment 3. **Regulation of in vivo antibody responses to soluble protein antigens by co-immunized distinct intact, heat-killed bacteria**. During infections with extracellular bacteria, the immune system likely encounters a variety of microbial components in soluble form, as well as those associated with the intact bacterium. Although soluble and particulate antigens may exhibit distinct immunologic properties, their potential cross-regulatory effects on the humoral immune response, following concomitant immunization, as might occur during bacterial infections, is unknown. Preliminary studies from our laboratory demonstrate that co-immunization (i.v.) of soluble chicken ovalbumin (cOVA) in alum adjuvant with intact, heat-killed unencapsulated *Streptococcus pneumoniae* (strain R36A) markedly inhibits the subsequent IgG anti-cOVA response, and that this depends on the expression of phosphorylcholine in the R36A cell wall. In contrast, unencapsulated Group B Streptococcus (GBS) or unencapsulated *Neisseria meningitidis*. group C (MenC), which do not express PC, significantly enhances the IgG anti-cOVA response.

We will conduct a series of experiments to better understand the mechanisms underlying these effects. We will determine: (i.) whether Toll-like receptors mediate the stimulatory effects of intact bacteria by using MyD88-/- mice; MyD88 is a critical adaptor molecule for TLR signaling, (ii.) the effects on CD4+ T helper cells specific for cOVA by co-immunized bacteria; cOVA-specific transgenic CD4+ T cells (D011.10 x RAG-/- [BALB/c background] or OT-II x RAG-/- [C57BL/6 background]) will be adoptively transferred into WT BALB/c or C57BL/6 mice for immunization studies; 1 transgenic mouse can be used as a donor for two WT recipients. Two different strains of mice are used (C57BL/6 and BALB/c) to accommodate the further use of additional strain-matched genetically altered immune cells. The transgenic CD4+ T cells will be evaluated by flow cytometry at days 0, 1, 2, 3, 7, 8, and 14 (7 time points) for T cell activation, proliferation, differentiation, and memory cell development, with each assay performed using 3 recipient mice each (iii.) the effect of TLR4 on the R36A-mediated inhibition of the IgG anti-cOVA response, in light of previous reports that the inhibitory action of phosphorylcholine (PC) may be mediated by TLR4; both TLR4-/- mice [C57BL/6 background] and C3H/HeJ (TLR4-mutated, C3H/HeN background) will be used in complementary studies (iv.) the role of suppressive, IL-10-producing B1 cells, which express specificity for PC, on the R36A-mediated inhibition of the IgG anti-cOVA response; x.i.d. mice which selectively lack B1 B cells will be used, (v.) the effects of bacteria on the IgG anti-cOVA utilizing the s.c. route (i.e. lymph node-mediated versus i.v. route which is mediated by the spleen), with splenectomy performed to rule out splenic contributions following s.c. immunization. The bacteria to be utilized will include R36A, R36A without PC (R36Apc-), GBS, and MenC.

i. MyD88-/-: 4 bacteria x 7 mice/group 2 immunizations (cOVA alone versus cOVA + bacteria) x 3 experiments=168
   C57BL/6: 4 bacteria x 7 mice/group x 2 immunizations x 3 experiments=168
ii. BALB/c: 4 bacteria x 3 mice/group x 2 immunizations x 7 time points x 3 experiments=504
   C57BL/6: 4 bacteria x 3 mice/group x 2 immunizations x 7 time points x 3

experiments=504
D011.10 x RAG-/-: 252 (donor cells)
OT-II x RAG-/-: 252 (donor cells)

iii. TLR4-/-: 4 bacteria x 7 mice/group x 3 experiments=84
C57BL/6: 4 bacteria x 7 mice/group x 3 experiments=84
C3H/HeJ: 4 bacteria x 7 mice/group x 3 experiments=84
C3H/HeN: 4 bacteria x 7 mice/group x 3 experiments=84

i.v. x.i.d.: 2 bacteria x 7 mice/group x 2 immunizations x 3 experiments=84
CBA/CaJ (control): 2 bacteria x 7 mice/group x 2 immunizations x 3 experiments=84

v. BALB/c: 4 bacteria x 7 mice/group x 2 immunizations [s.c] (cOVA alone versus cOVA + bacteria) x 3 mouse groups (WT, sham-splenectomized, splenectomized) x 3 experiments=504

V.1.4. Experiment 4. Adoptive transfer of transgenic B cells (PspA-specific and PPS14-specific [BALB/c background] and PC-specific (M167-Tg [C57BL/6 background]) and T cells (PspA-Tg, and D10.11 [cOVA-specific] (BALB/c background) and OT-II [cOVA-specific] (C57BL/6 background) into recipient mice (athymic nude, or BALB/c wild-type). In these studies, transgenic B cells and/or T cells will be transferred into recipients in order to study their ability to induce antigen-specific Ig isotype production (by ELISA and ELISPOT assay) in response to challenge with Pn (wild-type or expressing fusion PspA-cOVA) or conjugate vaccines, as well as transgenic B and T cell localization and migration within the spleen (by fluorescence confocal microscopy) following Pn and conjugate challenge. Isolation of adoptively transgenic B and T cells, by electronic cells sorting, following Pn and conjugate immunization for in vitro analyses will also be conducted. We anticipate using an average of 10 mice from each strain mentioned above every 1 month (6 strains) in order to obtain sufficient numbers of purified B and T cells for adoptive transfer and to have a sufficient number of recipient mice for analysis. In all adoptive transfer studies both donors and recipients must be on the same strain background (i.e. BALB/c or C57BL/6). These studies will be ongoing for upcoming 3 year period. Through the use of antigen-specific transgenic B and T cells we can transfer into recipients a sufficient number of antigen-specific cells that can then be visualized with confocal immunohistochemistry and flow cytometric analyses. These cells can be further isolated for the study of additional cellular as well as molecular and biochemical parameters in order to determine how their behavior differs when exposed to different forms of antigen (e.g intact bacteria, soluble protein or polysaccharide, or conjugate vaccine).

Total mice: 10/month x 9 strains x 36 months=3,240 mice (360 of each strain): 360 PspA-BCR-Tg,, 360 PPS14-BCR-Tg, 360 M167-Tg, 360 PspA-TCR-Tg,, 360 D10.11 x RAG-/-, 360 OT-II x RAG-/-, 360 athymic nude, 360 BALB/c 360 C57BL/6.

Mice in pain category "E" are in EXP2.ii as follows: FVB (210 mice), BALB/c (210 mice), and C57BL/6 (70 Mice).

Total mice required for upcoming 3 years=17,016 (see Table next page)

V.2. Data Analysis:

We have consulted with a professional statistician (Dr. (b)(6) in the Department of Preventive Medicine and Biometrics, at USUHS. As per her advice, we applied a formula, obtained from "Van Belle Statistical Rules of Thumb" (Wiley 2002, page 35) to determine the number of mice needed per experimental group in order to generate 80% power at 0.05% significance for a 3-fold difference between control and experimental groups. 80% power indicates that 4 out of every 5 experiments will show a statistically significant difference, if in fact a difference exists. This determination is based on calculating a coefficient of variation that quantifies differences in serum titers of Ig between individual mice in the same experimental group. The formula is as follows: $N=8CV^2/FC^2$ $(1+ [1-FC]^2)$ where N=number of required mice, CV=coefficient of variation (standard deviation/mean), FC=fold-change. We calculated a set of CVs for 3 separate, *in vivo* experiments using intact Pn, involving several different (1) time points primary response (days 0, 7, 14) and secondary response (days 21 and 28), (2) antigens (PC, PPS14, and PspA), (3) isotypes (IgM, IgG) and (4) strains of mice (BALB/c, C57BL/6, and B6129). Collectively, the average CVs for the 3 experiments were 0.4 (using 5 mice per group, B6129), 0.51 (using 10 mice per group, BALB/c), and 0.53 (using 8 mice per group, C57BL/6). The number of required mice ('N") to generate 80% power to these studies was compatible with our typical use of 7 mice per group. Thus, these numbers clearly provides the power necessary to reproducibly detect significant changes anticipated in these studies, and is consistent with mouse numbers used by others for *in vivo* studies. Dr. (b)(6) agreed with our use of the student-T-test for determination of statistical significance, and the use of standard error of the mean for expressing variation, and suggested that geometric means would be preferable to arithmetic means, even though the latter are also acceptable.

V.3. Laboratory Animals Required and Justification:

An itemized justification of the number of animals required is found in section V.1. under the respective descriptions of each set of experiments, based on the internal logic of each subsection.

V.3.1. Non-animal Alternatives Considered:

As state in V.3.2 below the studies described herein cannot be performed using long-term cell lines or modeling, but must directly assess the reactivity of the intact host.

V.3.2. Animal Model:

Mice

Species Justification:

Collectively, these studies are designed to evaluate an immune response to either a whole pathogen or purified antigen in the intact host. In light of the vast complexity of an intact immune system, including the spatio-temporal organization of multiple cell types and cell surface and soluble mediators, a true understanding of the physiology of an immune response to a pathogen can only be studied in an intact host. The mouse model is ideal for studying the physiology of an in vivo immune response because: 1) it is the most widely studied animal model and hence a vast amount of information is already known in this species and 2) there are numerous immunoreagents available specific for use in the mouse.

Strain Justification:

1. **Conventional wild-type mice: BALB/c, C57BL/6, FVB, C3H/HeN and CBA/CaJ**. These mice will, in part, serve as controls for genetically altered mice that have been created on these respective strain backgrounds. Additionally, each of these wild-type strains have certain unique host response patterns to immunization that make them of interest for studies involving the intact immune system.

2. **Athymic nude mice (mice lacking T cells).** These mice have a natural mutation leading to the loss of thymic development. As a result, these mice are markedly deficient in T cells. Hence they serve as a convenient recipient for T cell transfer studies.

3. **RAG-/- [BALB/c and C57BL/6 background] (mice lacking both B cells and T cells).** RAG-/- mice are genetically deficient in a key protein involved in the formation of the antigen receptors for B cells and T cells. On this basis, RAG-/- mice fail to develop B cells and T cells, but otherwise develop in a relatively normal fashion. These mice thus serve as a convenient recipient for injecting B cells and/or T cells exhibiting specific

alterations, in order to determine if these alterations have an effect on an immune response.

4. **OVA-specific T cell receptor transgenic mice: D10.11 x RAG-/- (BALB/c background), OT-II x RAG-/- (C57BL/6 background.** These mice are transgenic for a rearranged T cell receptor that recognizes a chicken ovalbumin (cOVA) peptide in association with MHC class-II. As such, a large percentage or 100% (on RAG-/- background) of the T cells in these mice are specific for cOVA-MHC class-II on the surface of antigen-presenting cells. Since wild-type Pn does not express this peptide, these T cells will be used as negative controls in transfer experiments in which transgenic T cells with an anti-Pn peptide specificity (i.e. PspA-specific T cell transgenic mice are used to determine the role of such T cells in the anti-Pn humoral response. Alternatively, cOVA-specific T cells will be used to deliver specific cognate help to genetically altered Pn which expresses a PspA-cOVA fusion protein in its cell wall, but not wild-type Pn.

5. **Phosphorylcholine (PC)-specific B cell receptor transgenic mice: M167 Tg.** PC is a determinant on the cell wall C-polysaccharide (teichoic acid) of Pn. Thus, the B cells from M167 Tg mice will specifically recognize Pn through this determinant. B cells from these mice will be used to study the functional B cell response to Pn.

6. **Immunoglobulin transgenic mice: PPS14 light chain, PPS14 heavy chain, double PPS14 heavy/light chain, PspA light chain, PspA heavy chain, double PspA heavy/light chain.** These mice are currently being created in our lab. The immunoglobulin heavy chain and light chain encoding a B cell receptor specific for either the Pn cell wall protein, PspA, or the Pn capsular polysaccharide, PPS14 has been isolated and will be used to create BCR transgenic mice. This will lead to the creation of mice possessing large numbers of PspA-specific or PPS14-specific B cells. These B cells will be used in studies of the B cell functional response to intact Pn during an immune response.

7. **PspA-specific T cell receptor (TCR) transgenic (Tg) mice (PspA-TCR-Tg).** These mice are currently being created in our lab. They will posses rearranged T cell receptor genes encoding for a PspA peptide/MHC class-II specificity. These mice will possess a large number of CD4+ PspA-specific T cells useful for studying the T cell response to intact Pn during an immune response.

8. **Lsc-/- mice**. These mice lack the cytoplasmic signaling protein Lsc, which results in an inability of antigen-specific splenic marginal zone B cells (MZB) to migrate from the marginal zone to the T cell areas of the spleen following immunization. This results in a defect in MZB obtaining CD4+ T cell help during an immune response. Thus, these mice have been useful in defining B cell subset utilization in T cell-dependent humoral immune responses to intact bacteria versus soluble bacterial-derived antigens.

9. **MyD88-/-, TLR4-/- mice**. These mice are genetically deficient in the TLR adaptor protein MyD88 or the Toll-like receptor 4 [TLR4]. A role for these proteins in mediating in vivo innate and adaptive immune responses to Pn has been demonstrated.

10. **C3H/HeJ mice**. These mice have an inactivating mutation in the TLR4 gene leading to the expression of a non-signaling TLR4 molecule, and are used in a complementary fashion with TLR4-/- mice, which lack the TLR4 gene.

11. **CD11c-DTR and CD11b-DTR mice**. These mice express the Diphtheria toxin receptor in cells expressing either CD11c (dendritic cells) or CD11b (inflammatory monocytes), respectively. Injection of diphtheria toxin selectively depletes these cells allowing for studies on their functional role in humoral immunity.

Both male and female mice (6-12 weeks of age) will be used. The gender of the mouse has been shown by us previously not to significantly bias the phenomena under study and thus use of both genders represents a substantial savings in money. Nevertheless, when genetically-altered mice of one gender is used, the control mice will be of the same gender to maintain a strict control. The age range of the mouse is chosen in order to use mice with a mature and vigorous immune system, in a timely way.

Justification for performance of lethality studies:

Prevention of lethality from infectious agents following vaccination continues to be among the "gold-standards" of vaccine validation using mouse models. Introduction of live pathogens via the i.p., i.v., or i.n. route are considered standard, straightforward approaches. Below, are several representative samples of numerous recent citations in mainstream, peer-reviewed scientific journals in which lethality studies using extracellular bacteria were considered a major aspect of the reported project:

1. Cao, J., D. Chen, W. Xu, T Chen, S. Xu et al. 2007. Enhanced protection against pneumococcal infection elicited by immunization with the combination of PspA, PspC, and ClpP. *Vaccine* 25: 4996-5005.

V.3.3. Laboratory Animals

V.3.3.1. Genus & Species: Mouse

V.3.3.2. Strain/Stock: BALB/c, C57BL/6, FVB, RAG-/- (BALB/c background), RAG-/- (C57BL/6 background), Athymic nude, Lsc-/-, CD28-/-, ICOS-/-, CD40L-/-, CD11b-DTR (FVB), CD11b-DTR (C57BL/6), CD11c-DTR (BALB/c), MyD88-/-, D011.10 x RAG-/-, OT-II x RAG-/-, TLR4-/-, C3H/HeJ, C3H/HeN, x.i.d., CBA/CaJ, PspA-BCR-Tg, PPS14-BCR-Tg, M167-Tg, PspA-TCR-Tg.

V.3.3.3. **Source/Vendor**: (b)(4)

V.3.3.4. **Age**: 6-12 weeks
V.3.3.5. **Weight**: N/A
V.3.3.6. **Sex**: Male and Female
V.3.3.7. **Special Considerations**: None.

V.3.4. **Number of Animals Required (by species)**: 17,016 mice (see above)

V.3.5. **Refinement, Reduction, Replacement (3 Rs)**:

V.3.5.1. **Refinement**:

Strict endpoint criteria have been defined to euthanize mice at the earliest appropriate time in order to minimize pain and suffering. Mice will be examined three times daily (8 AM, 1 PM, and 6 PM). Mice will be infected ~6 PM since most mice that are not protected by vaccination will develop pre-terminal signs from 14h-24h post-infection. Thus, the majority of mice that will eventually die, can be identified when they are pre-terminal (as described above), in order to euthanize these mice to minimize distress. As discussed and cited in this protocol the use of anesthetics and analgesics is contraindicated for these studies, given the known effects of these agents on altering immune function and hence potentially obscuring the data obtained.

V.3.5.2. **Reduction**:

A minimal number of mice have been chosen for each experimental group based on the innate mouse-to-mouse variability of the humoral immune response to a bacterial agent in the context of maximizing our ability to discern statistical significance ($p \leq 0.05$). A further reduction is realized by using only 3 mice per group to establish the dose of live bacteria of a given strain, that is minimally lethal as a prelude to performing more extensive lethality studies.

V.3.5.3. **Replacement**:

As indicated in this protocol, the mouse is the lowest species on the phylogenetic scale in which to conduct detailed studies on the immunologic response of the intact host to a bacterial agent.

V.4. **Technical Methods**:

V.4.1. **Pain / Distress Assessment**:

V.4.1.1. **APHIS Form 7023 Information**:

V.4.1.1.1. **Number of Animals**:

	Species #1	Species #2
V.4.1.1.1.1. Column C:	16,190	
V.4.1.1.1.2. Column D:	336*	
V.4.1.1.1.3. Column E:	490**	

*These mice (BALB/c) will be undergoing splenectomy, involving survival of a surgical procedure.

**These mice (FVB=210, C57BL/6=70, BALB/c=210) will be involved in lethality studies, in which mice not protected by vaccination and/or unvaccinated mice will die from the infection.

V.4.1.2. Pain Relief / Prevention: In bacterial lethality and other studies described above, no measures will be performed to relieve the distress the mice may encounter as this would represent a serious potential impediment to the interpretation of these studies, given that any such measure could impact on the ultimate functioning of the host immune system.

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization: N/A
See justification in V4.1.3.5.

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions:

Lethality studies-The end-point of lethality studies will be whether or not the mouse becomes moribund, a condition from which the mice do not recover. The moribund status will be defined by any of the following criteria: 1) inability to ambulate, 2) inability to eat or drink, 3) hunched posture, and 4) unresponsiveness to external stimuli. If any of these signs are present, the mouse will be euthanized by cervical dislocation as described in our protocol. Mice are checked 3x/day for moribund symptoms by (b)(6) (b)(6)

Mice will be monitored at 8:00 AM (14 h post-infection), 1:00 PM, and 6:00 PM. A log will be maintained documenting the date and time the mice were checked and by whom, the number of mice appearing moribund (including those which required euthanasia) and the number of mice found dead. When the lethality experiment is completed the findings will be reported to IACUC in order to evaluate the efficacy of this modified approach. If no improvement is observed in decreasing the number of mice found dead (versus moribund) we will consider other methods, including adding an additional time point for monitoring.

Mouse irradiation and establishment of bone marrow chimeric mice- Mice will be gamma irradiated at USUHS at 900-1000 Rads for the purpose of making bone marrow chimeras. Specifically, irradiation of wild-type mice will eliminate their hematopoietic cells, to be replaced with mutant donor (i.e. CD11b-DTR and CD11c-DTR) [DTR=Diphtheria toxin receptor] hematopoietic cells, via injection, i.v., of bone marrow cells from mutant mice. These "chimeric" mice will thus have a wild-type non-hematopoietic system and mutant hematopoietic system. This approach is being taken based on published observations that these mutant non-

hematopoietic phenotypes confer unwanted lethality under the experimental conditions being used (i.e. following DT [Diphtheria toxin] injection [see below]), which is designed to study the mutant hematopoietic cells.

Transfer of bone marrow cells rescues mice from the lethal effects of the irradiation. Chimeras are stably established and ready to use experimentally at 4-6 weeks. If donor cells don't repopulate bone marrow, mice will die in about 10 days. Donor bone marrow cells (10 million cells per mouse in 150 microliters) must be injected i.v. within 24h of irradiation. Mice are maintained on antibiotics in their drinking water (Ditrim [sulfadiazine/trimethoprim] or Sulfatrim [sulfamethoxazole/trimethoprim; 5ml/200ml) for 2 weeks following irradiation. Subsequently, mice will switched to regular water without antibiotics. The antibiotic treatment should have no effect on the data generated from these studies. No anesthesia nor other methods to alleviate pain/suffering are required. Identification of moribund mice (if, in the unlikely occasion, bone marrow cells fail to re-establish the hematopoietic system) with subsequent sacrifice of animals by cervical dislocation has already been described in our current protocol.

V.4.1.2.3. Paralytics: N/A

V.4.1.3.1. Sources Searched: Medline

V.4.1.3.2. Date of Search: 03/01/2012

V.4.1.3.3. Period of Search: 1980-2012

V.4.1.3.4. Key Words of Search: Animal, mouse, immunity, bacteria, pain, in vivo.

V.4.1.3.5. Results of Search:

opioids-opioids such as morphine have been reported to produce a number of immunomodulatory effects in both laboratory animals and humans. In vitro exposure of murine lymphocytes and macrophages to morphine and its metabolites at a wide range of concentrations resulted in suppressed B cell proliferation, suppression of IL-2, IL-4, and IL-6, and inhibited cytotoxic T lymphocytes function [(ref 1)]. Fentanyl and buprenorphine, both opioid analgesics, also have immunomodulatory attributes in mice. Both opioids have shown a dose dependent attenuation of the serum TNF-α response in mice as a result of exposure to LPS and results in a significantly lower LPS-induced serum TNF-α increase. Morphine also suppresses T and B cells, depresses NK cell activity, and decreases the primary antibody response[(ref 2)]. Narcotic analgesics can cause histamine release and respiratory depression which could alter the pathogenic and clinical response to infection[(ref 3)]

B. **Non-steroidal anti-inflammatories (NSAIDs)**-The cyclooxygenase inhibiting NSAIDs have been shown to produce progressive alterations of parameters of the thrombocyte vessel system of hemostasis, decreased ability of thrombocytes to aggregate, and activation of lipid peroxidation processes in rabbits injected with bacterial endotoxin[(ref 4)]

In summary-Steroidal and non-steroidal anti-inflammatories are contra-indicated in many protocols due to their interference with the inflammatory pathway which is critical in the normal pathogenesis of many physiological processes, including immunity.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification:

Pain will not be alleviated in the studies described in this protocol, except for splenectomized mice post-surgery (see below: V.4.3 "Surgery") since steroidal and non-steroidal anti-inflammatories are contra-indicated in these experiments due to their interference with the inflammatory pathway which is critical in the normal pathogenesis of many physiological processes, including immunity. However, animals listed under Category C that do show evidence of significant pain or distress, in the opinion of the attending veterinarian and after consultation with the PI or his staff if they can be reached, will be euthanized immediately". The projects described above are designed to study the immune response of the intact mouse to various types of immunization. These encompass essentially classical cellular immunologic approaches to studying the immune system including injections for immunization and bleeding to obtain sera for measuring antigen-specific Ig isotype titers. All members of the lab are trained and experienced in these procedures and this in turn minimizes the actual pain and discomfort inflicted.

V.4.2. Prolonged Restraint: N/A

V.4.3. Surgery: Splenectomy. The procedure is performed as follows (adapted from Griffith and Farris, 1942): Mice are anesthetized with a combination of ketamine, xylazine, and acepromazine, respectively at 30mg/kg BW IM, 6 mg/kg BW IM, and 1mg/kg BW IM (O'Rourke et al. 1994). The mouse is laid on its back with its tail towards the investigator. The abdominal cavity is exposed through a midline incision extending posteriorly for about half of the abdomen. Alternatively, a dorso-ventral incision can be made near to the costal border of the thorax, on the right of the investigator. The prominent splenic vein with an accompanying small artery courses through the pancreatic tissue and splits into several small vessels just before entering the spleen. A ligature is placed around the splenic blood vessels just before they divide; they are severed distal to the ligature and the spleen is removed before closing the incision.

Postoperative care includes analgesic given SC bid for 24 hrs (Buprenorphine at

0.05-0.10 mg/kg BW, as recommended by Flecknell, 1991). In addition, a single dose will be given during surgery. No adverse changes in body temperature were reported in the published protocol. Mice should remain healthy provided they are not infected with Bartonella muris, a blood parasite which produces a fatal microcytic anemia in splenectomized animals. If necessary, infection can be controlled with an i.m. injection of Neoarsphenamine at a dose of 140 mg/kg body weight. The pain level is "D".

V.4.4. Animal Manipulations:

V.4.4.1. Injections:

Mice are immunized either s.c., i.p., or i.v. with either heat-killed or viable intact *S. pneumoniae*, soluble purified protein and/or polysaccharide antigens with or without alum or TLR adjuvant and/or immune cells. For immunizations, mice will be immobilized manually and 0.25-0.5 ml of PBS containing bacteria, antigen (+/- adjuvant) and/or cells will be injected using a 28 gauge needle. For i.v. injections mice will first be subjected to heating by infrared heat lamp, with close monitoring to prevent heat exhaustion, in order to increase blood flow to the tail vein to facilitate injections. After various time periods, sera may be collected by obtaining blood from the tail vein. The maximum number of blood collections from immunized mice is typically 3 per mouse. Approximately 0.2 ml of blood is collected from the tail vein of each mouse, 7 days apart. We have taken this approach for many years and have noticed no ill effects on mouse health. To accomplish this, a small transverse cut is made to puncture the tail vein allowing blood to drip into an eppendorf tube. Blood is collected until the bleeding stops spontaneously, which is not life threatening to the mouse. None of these procedures requires prior measures to relieve distress.

V.4.4.2. Biosamples:

Sera will be obtained by tail vein bleed and stored at –20°C. Spleen, lymph node, and bone marrow will be obtained after mouse euthanasia by cervical dislocation. These tissues will either be used immediately as a source of immunologic cells and/or frozen in liquid nitrogen for subsequent immunohistochemistry studies.

V.4.4.3. Adjuvants:

Alum (Aluminum hydroxide) or select Toll-like receptor ligands (e.g. CpG-ODN), will be used for enhancing immune responses. The use of these adjuvants historically has had no discernible adverse effects on mice at the dosages and frequencies described in this proposal.

V.4.4.4. Monoclonal Antibody (MAbs) Production:

1. All mAb production currently planned in-house will be done using in vitro methodologies. There are occasions when relatively large quantities of mAb are required necessitating the use of an outside vendor to make mAb using in vitro

bioreactors. These mAbs will be screened for pathogens prior to use in the USUHS animal facility as per IACUC policy 023.

V.4.4.5. Animal Identification:

In selected experiments individual mice are specifically identified using metal ear tags (purchased from the National Band and Tag Company). Otherwise all animals are identified by cage cards.

V.4.4.6. Behavioral Studies: N/A

V.4.4.7. Other Procedures: N/A

V.4.4.8. Tissue Sharing:

Cells, tissue, and sera are available for sharing when appropriate.

V.4.5. Study Endpoint:

Bacterial lethality studies (Experiment: V.1.2.ii)-Mice will be infected i.p with viable extracellular bacteria that will be sub-lethal in a wild-type mouse. Changes in blood levels of live bacteria over time will be measured by counting colonies on agar plates, and the ability of the mice to recover from the infection will be graphed as number of deaths on the ordinate versus days after initial infection on the abscissa. The end-point of the study will be whether or not the mouse becomes moribund, a condition from which the mice do not recover. The moribund status will be defined by any of the following criteria: 1) inability to ambulate, 2) inability to eat or drink, 3) hunched posture, and 4) unresponsiveness to external stimuli. If any of these signs are present, the mouse will be euthanized by cervical dislocation as described in our protocol.

Mouse immunizations (Experiments: V.1.1-V.1.4)-Mice are immunized one or more times with either intact bacteria or purified bacterial antigens. At varying periods of time after immunization, as described in detail above, sera is obtained through tail vein bleeds for measurement of antigen-specific Ig isotype titers and/or cytokines. When the period of the immune response under study is completed, mice are euthanized by cervical dislocation. In other studies, mice are similarly immunized, and at select periods of time thereafter, are euthanized by cervical dislocation whereupon lymphoid tissue (i.e. spleen and lymph nodes) is removed for immunologic analyses. In some studies, naïve mice are euthanized by cervical dislocation and bone marrow cells are obtained for the in vitro generation of dendritic cells or macrophages, or as donor cells for bone marrow chimeric mice.

V.4.6. Euthanasia:

Mice will be euthanized by cervical dislocation.

Justification for select circumstance to use cervical dislocation instead of C02 asphyxiation for mouse euthanasia. A major concern of using CO_2 asphyxiation, which is not a concern when using cervical dislocation, is its potential effect on immune cell function. My laboratory routinely isolates immune cells from euthanized mice for further immunologic study in vitro or for adoptive transfer into naïve mice, and several studies indicate a potential for immune cell parameters to be altered by prior euthanasia with CO_2. In an article by Howard et al (ref 1) C02 euthanasia was associated with alterations in *in vitro* lymphoproliferation and cytotoxic T cell function, not observed after cervical dislocation. In an article by Butler et al (ref 2) CO_2 euthanasia was associated with alterations in prostacyclin production, an arachidonic acid metabolite with potential direct and indirect immune modulating properties (ref 3). Finally, a study by Pecaut et al (ref 4) demonstrated that CO_2 euthanasia can alter circulating CD8+ T cell numbers and spontaneous blastogenesis of blood and splenic leukocytes. The members of my laboratory have had prior experience in the procedure of cervical dislocation, which will assure the virtually instantaneous euthanization of the mouse, thus avoiding significant distress to the animal.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol.

V.5.1.1. Study Room: (b)(6)

V.5.1.2. Special Husbandry Provisions:

Food Restriction:	Yes	_____	No	X
Fluid Restriction:	Yes		No	X

V.5.1.3. Exceptions: None _____ _____

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care:

All animals will be housed in LAM. The USUHS maintains a modern, AAALAC - accredited, Central Animal Facility of approximately 40,000 square feet. The facility and the University's animal care and use program, are managed by the Department of Laboratory Animal Medicine (LAM). LAM is directed by a veterinarian who is an ACLAM Diplomate and is staffed with two other veterinarians, a graduate of animal husbandry, and approximately 30 technicians. The University is able to provide appropriate care for a wide variety of laboratory animal species, from invertebrates to lower vertebrates, to higher vertebrates, including non-human primates and domestic livestock, as well as the more commonly used species such as rodents and rabbits."

V.5.2.2. Emergency Veterinary Medical Care: All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: Except as indicated below, all animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents; balls, toys and food enrichment treats for large animal species.

V.5.3.2. Enrichment Restrictions: None

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
iv (tail vein), ip, and s.c. injections, tail vein bleeds, lethality studies, and euthanasia.	(b)(6)	Associate Prof 16 yrs; 10 yrs doing lethality studies.	2000 rodent handling
iv (tail vein), ip, and s.c. injections, tail vein bleeds, lethality studies, and euthanasia.		Res Assoc 11 yrs; 6 yrs doing lethality studies. Will perform splenectomy according to published protocol and prior consultation with LAM. Has had extensive experience in mouse handling and invasive procedures.	2001 rodent handling

VII. BIOHAZARDS/SAFETY:

Laboratory use of extracellular bacteria, discussed in this protocol, does not pose a significant health hazard for immunocompetent adults when standard laboratory precautions are taken as stated in the catalogue published by the American Type Culture Collection (ATCC, Manassas, VA). Indeed, most adults are already colonized with these bacteria. Hence, these bacteria are considered a "biohazard level 2" requiring investigator handling with gloves and a lab coat. Facial masks are to be worn upon entering animal rooms. The following types of individuals should not be exposed to these bacteria: 1) asplenic, 2) immunodeficient 3) children and elderly, 4) cancer. Areas in which these bacteria are stored should have appropriate biohazard labels. Mice receiving live, virulent extracellular bacteria are to be kept in filter-top cages as a precaution against transmission to other mice, although mouse to mouse transmission is "extremely rare". All cages that contained infected mice are to eventually be autoclaved before re-use. Dead mice are placed in a bag and either autoclaved immediately, or placed in the LAM cold room until autoclaved.

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

B. **Animal Protocol Title**: Regulation of anti-bacterial immunity (mice)

C. **Principal Investigator:** (b)(6) M.D., Professor, Dept. of Pathology, USUHS.

D. **Performing Organization:** Uniformed Services University of the Health Sciences 4301 Jones Bridge Road; Bethesda, Maryland 0814

E. **Funding:** NIH, USUHS

F. **Objective and Approach:**

Infections with extracellular bacteria are a major source of global morbidity and mortality. This fact, and the increasing incidence of antibiotic-resistance of bacterial strains make the development of vaccines against these agents of high clinical importance for both the civilian and military sectors. Immunity to this class of pathogens is mediated by antibody that facilitates the uptake and subsequent killing of bacteria by phagocytic cells such as neutrophils and macrophages. In order to optimize the design of effective vaccines against these agents, it is important to understand the basic immunologic parameters that regulate antibody production in vivo in response to immunization or infection with an intact bacterial pathogen.

Our laboratory initially conducted extensive studies on the in vivo protein- and polysaccharide-specific immunoglobulin isotype response to intact *Streptococcus pneumoniae* or vaccine antigens derived from *S. pneumoniae*, using the mouse as a model system. Recently, additional extracellular bacterial species have been added to our scope of investigation, including *Staphylococcus aureus, Streptococcus agalactiae (Group B Streptococcus, GBS), Acinetobacter baumannii, and Neisseria meningitides, groups A and C.* These extracellular bacteria continue to cause substantial global health problems. We currently have two major funding sources (see above) that collectively are integrated to explore this general issue in a complementary fashion. Hence, these respective projects, which are conducted in Rooms (b)(6) in the Department of Pathology, are subsumed under this one animal protocol, given that the methodologies related to the use of mice are widely overlapping among the projects.

Areas of study include the role of dendritic cells and macrophages, B and T lymphocytes, innate immunity including Toll-like receptors, cytokines, chemokines, T cell costimulatory molecules, in the ability to elicit humoral immunity to distinct, polysaccharide-encapsulated extracellular bacteria, and conjugate vaccines containing specific capsular polysaccharide derived from these bacteria. Regarding the use of mice, methodologies include 1) utilizing athymic nude mice as a model of T cell-deficiency for immunologic studies, 2) immunization of mice with heat-killed intact bacteria or bacterial antigens, by i.p., i.v. and s.c. routes; in selected experiments alum or Toll-like receptor (TLR) ligand adjuvants are used, 3) tail vein bleeds to obtain sera for measurement of antigen-specific Ig isotype titers and cytokines by ELISA, and for obtaining circulating immune cells, 4) removal of lymphoid tissue for obtaining cells for various *in vitro* immunologic studies and for confocal fluorescence microscopy, 5) infection of mice with live extracellular bacteria for studies on immunologic protection, 6) use of $RAG^{-/-}$ (B cell-deficient + T cell-deficient) mice as recipients in immune cell adoptive transfer experiments, and 7) gamma irradiation of immune cells, to act as antigen-presenting cells for stimulating T cells, and gamma irradiation of mice for making bone marrow chimeras. Heavy use is made of transgenic and knockout mice in which, for some, we have established breeding colonies in LAM. As will be described, although the extracellular bacteria described in this protocol are human

pathogens, their use experimentally at worst poses minimal health concerns that can easily be addressed using routine microbiologic precautions.

G. Indexing Terms (Descriptors): Animal, bacteria, antibody, polysaccharide, mouse, dendritic cell, macrophage, T-cell, B-cell, innate, adaptive, costimulation, Toll-like receptor, oligodeoxynucleotide, vaccine.

MEMORANDUM FOR DR. (b)(6) DEPARTMENT OF PATHOLOGY

SUBJECT: IACUC Approval of Protocol - Triennial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on October 9, 2013:

Animal Protocol Title: "Role of MicroRNAs in Mild Traumatic Injury and Posttraumatic Stress Disorder: Identification of Biomarkers and Therapeutic Targets in Mice"

USUHS Protocol Number: (b)(6)

Expiration Date: October 8, 2016

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. **NON-TECHNICAL SYNOPSIS:** Traumatic brain injury (TBI) is described as an insult to the head by a violent force. Mild traumatic brain injury (mTBI) is one of the most common types of injury sustained in the war zones. mTBI is also called signature injury of war in Iraq and Afghanistan. Recent advancement in the knowledge of mTBI has shed light on the role of immune and repair response generated by the body in response to mTBI. Dysregulated inflammatory responses following mTBI are increasingly being discovered at the core of the mTBI induced brain injury resulting in the loss of cognitive skills and neurobehavioral disorders. mTBI injury usually go unnoticed due to lack of any outward sign of injury. There are no diagnostic markers for identifying mTBI injury at early stages. In the proposed study we will sought to determine early serum based biomarkers to detect mTBI. In this regard we will evaluate the expression pattern of microRNAs (miRNA) in the blood of the animals that sustain mTBI. MiRNA are a class of small oligonucleotide molecules that have come to be known as key regulators of gene expression and thereby cellular processes. Their presence in blood has been reported after organ injury such as of liver and muscle and in cancer such as of colon and pancreas. mTBI injury will be induced by an free falling impactor (333gm) from a height of 2 cm. This has been demonstrated to induce a clinically relevant mTBI injury that results in cognitive and neurobehavioral deficits. MiRNA expression will be evaluated in the blood and the brain of these animals and their expression and significantly modulated miRNAs will be determined. These significantly modulated miRNA will then be restored to their normal levels either by using a mimic (a molecule similar to the miRNA made by the body) or an antagonist (a molecule that will stop the miRNA made by the body). Restoration to normal levels of

miRNA will then be correlated with improvement in the cognitive and neurobehavioral deficits.

II. BACKGROUND:

II.1. Background:

Traumatic Brain Injury (TBI) is defined as a blow or jolt to the head or a penetrating head injury resulting in the disruption of brain function. Mild TBI (mTBI) is generally referred to as the minor injury caused to the head. This is defined as alterations or loss of consciousness lasting 30min to 24hr post injury (Vasterling et al 2009, www.dvbic.org). Mild TBI is much more difficult to define and diagnose and early identification usually involves a history of direct trauma to the head and brief loss of consciousness. Clinical symptoms of mTBI include headache, dizziness, inability to concentrate, loss of memory and other neuropsychiatric and cognitive complaints. Most of the symptoms associated with mTBI resolve within days or weeks of injury with substantial recovery in most cases. However approximately 10-20% of patients reported continued problems and 44-50% experienced three or more symptoms in a year post injury (Bigler 2008, Wood 2004, Vasterling et al 2009). These kind of reoccurring symptoms are termed as persistent post concussive syndrome (Bigler 2008).

mTBI often goes undiagnosed because of the lack of visible wound and lack of diagnostic markers (Belanger et al 2005, 2007 and 2009). Traditionally, neuroimaging techniques i.e. computed tomography (CT) And magnetic resonance imaging (MRI) is used to diagnose the brain injury. In case of mTBI these two diagnostic tools have limitations due to sensitivity of detection of minor brain tissue alterations (Le et al 2009). Development of minimally invasive assays for biomarkers capable of detecting and managing mTBI is urgently needed to reduce high morbidity associated with it.

MicroRNAs (miRNAs) are a class of small (19-28nt) endogenous RNA molecules that regulate gene expression at post transcriptional level either by translational repression. MicroRNA binds to the complementary sequences in the mRNA and blocks its translation and accelerates mRNA decay (Brown et al 2009). MiRNAs play important role in development and functioning of the brain. More than 1000 miRNA have been identified in the brain and have been shown to differential expressed in brain during the developmental stages (Forero et al 2010, Shao et al 2010, Sempre et al 2004, Nelson et al 2006, Krichevsky et al 2003, Kosik and Krichevsky 2005, Liu et al 2011). MiRNA have also been shown to regulate memory and learning by modulating dendrite spine formations and synaptic plasticity (Bredy et al 2011, Konopka et al 2010, 2011, Edbauer et al 2010, Rajasetjupathy et al 2009). Addiction to drug such as cocaine and its effect on cognition, memory and learning has also been suggested to be mediated by miRNAs and miRNAs have also been shown to regulate learning and memory associated genes (Chandrasekar and Dreyer et al 2011, Gao et al 2010, Spadaro et al 2012).

Biomarker is "a measurable substance in an organism whose presence is indicative of some phenomenon such as disease, infection, or environmental exposure".. MiRNAs have emerged as novel diagnostic biomarkers for various diseases. MiRNA changes in the serum have been suggested as a potential marker of disease and injury (Mayr et al 2013, Allegra et al 2012, Wahid et al 2010). MiRNA modulations in patients with TBI have also been reported (Redell et al 2009). Earlier we have reported that miRNA modulation occurs in the serum of rats exposed to repetitive blasts (Balakathiresan et al

2012). Serum miRNA expressions can also reflect the miRNA modulation that may occur in the CNS following TBI, which was indicated by the simultaneous up-regulation of Let-7i in the blood and brain of rats with TBI (Balakathiresan et al 2012).

As mentioned earlier, mTBI is under diagnosed at present; therefore a non invasive test for biomarker of mTBI is needed for the diagnosis of mTBI. The presence of specific miRNAs in blood following organ injury including brain facilitates the use of miRNAs a biomarker of mTBI. Simple and non invasive tests such as blood test will prove extremely useful in diagnosis of mTBI. We hypothesize that upon induction of mTBI, miRNAs will be modulated which result in inflammatory response in the brain. These miRNAs will cross the BBB to enter the blood and hence can be detected in blood plasma and utilized as biomarkers for mTBI.

II.2. Literature Search for Duplication:

II.2.1. Literature Source(s) Searched: Medline, Defense Technical Information Center (DTIC), DoD Biomedical Research Database (BRD) and Research Portfolio Online Reporting Tools (RePORT).

II.2.2. Date of Search: June 28-July1 2013

II.2.3. Period of Search: 1980 – current

II.2.4. Key Words and Search Strategy: Traumatic brain injury (TBI), microRNA, biomarkers, Post traumatic stress disorders (PTSD), War and TBI, Operation Enduring Freedom (OEF), Operation Iraqi Freedom (OIF), miRNA and brain injury, miRNA and blood, miRNA and plasma, circulating miRNA and brain injury, brain injury and blood brain barrier (BBB), brain and miRNA antagomirs, brain and miRNA mimics, miRNA as biomarkers etc.

II.2.5. Results of Search: No duplication of the proposed study was found in the above mentioned database. Below is the summary of the search results:

1.) Incidence of TBI has increased significantly in the current conflicts of OEF and OIF over the previous wars. Untill Q1 of 2013 the total incidence of TBI in US troops is 273, 859.

2.) mTBI is a signature injury of OEF and OIF.

3.) There is no reliable diagnostic test available to detect mTBI at early stages though some putative protein based biomarkers such as S100B, UCH-L1, GFAP and its breakdown products and neuronal elonases etc have been described but there use in diagnosing the mTBI and its prognosis is unknown.

4.) Circulating miRNAs have been describes as potential biomarkers in various organ injury and cancers.

5.) BBB is breached after mTBI and brain specific miRNAs have been detected in the circulation when an injury results in BBB breach.

6.) miRNA expression pattern signature may be used as a potential biomarkers after an injury.

7.) RePORT database search with key words "traumatic brain injury" return 1310 results, further filtering using key word "biomarker" returned 51 results. Combination of TBI and microRNA return 6 results. Careful examination of these

results revealed funded projects in microRNA and brain function but no duplication of proposed research effort was found.

III. OBJECTIVE\HYPOTHESIS:

The central hypothesis of the proposed study is that miRNA profile of the serum will change after mTBI. This altered pattern of serum miRNAs may then be used as diagnostic marker of mTBI injury. Some of the identified miRNA can also be used as therapeutic molecules for treating mTBI. The overall objective of the proposed study is to establish miRNA as diagnostic markers for mTBI and to develop miRNAs as therapeutic moleculaes for treating mTBI.

The first objective is to evaluate the expression profile of miRNAs in the blood of mouse following an mTBI. Evidence in the literature suggests that miRNA modulation occur upon injury to brain either caused by stroke or by traumatic events (Liu et al 2009, Lei et al 2009). Our working hypothesis is that, a mild injury to the brain is going to cause a focused as well as diffused injury which will cause a modulation of expression of miRNAs which then results in an inflammatory response throughout the brain. Mild TBI also cause disruption of BBB which would allow the miRNAs of brain to enter the blood stream. These circulating miRNAs in blood plasma can be used as a biomarker for mTBI.

From previous studies on mTBI, we know that inflammation plays a major role in the pathophysiology of mTBI. Gene involved in inflammatory response would be modulated and along with them the miRNAs which regulate them would also be modulated. We expect to find significant modulation of miRNAs in brain which are involved in regulating the inflammatory and neuronal repair and regeneration pathways.

Reconstitution of aberrantly expressed miRNAs in diseased conditions using antagomirs and expressing miRNA through plasmid vector "mimic" has been successfully shown in many studies as discussed before. The working hypothesis here is that due to mTBI, miRNA expression is altered which results in a persistent inflammation and reduced neuronal repair and development. Restoring the altered levels of miRNAs expression may be important in reducing the inflammation in the brain and would enhance repair process in damaged neurons. In this study, we will design specific antagomirs and plasmid vector expressing pre-miRNAs for the miRNA over expressed and repressed during mTBI.

IV. MILITARY RELEVANCE:

Traumatic brain injury (TBI) is a significant concern amongst military personnel who are currently or were previously deployed in Iraq and/or Afghanistan. Among the causes of war-related TBI are exposures to blast, gunshot and shrapnel wounds, falls and motor vehicle accidents. Mild TBI (mTBI) that is also commonly referred to as concussions occurs when the head is hit or shaken leaving a person dazed, confused or with loss of consciousness for a short period of time. About 22 % of the wounded soldiers in the current conflicts have sustained TBI and approximately 43,000 and 39,000 cases of TBI and PTSD have been recorded by military health system (MHS) in the year 2008. The cost associated with the diagnosis and treatment of TBI and posttraumatic stress disorder (PTSD) is huge and about $2 billion was spent in the FY

2010 on the diagnosis, treatment and care recent veterans with TBI and PTSD (A CBO Study: The Veterans Health Administration's Treatment of PTSD and Traumatic Brain Injury Among Recent Combat Veterans, February 2012)).

Symptoms of mild TBI can appear in days, weeks to months post injury. Clinical symptoms of mTBI are wide ranging and include sleep disturbances, fatigue, trouble in decisions making, headaches, depression, memory loss, short attention span, difficulty organizing and completing the tasks, irritability, anger, impulsive behavior and sensitivity to lights and sound. These conditions not only degrade the quality of life among veterans it also have detrimental effect on their family social and mental health. Morbidity due to mTBI also affects a soldiers potential for redeployment and the ever growing numbers of TBI may also affect the military operational readiness.

Mild TBI often goes undiagnosed because of the lack of visible wound and lack of diagnostic markers. Traditionally, neuroimaging techniques have been used for the diagnosis of TBI which have several limitations for the detection of mTBI. MicroRNAs have been successfully shown as circulating biomarkers in various neurodegenerative disease models and tissue injury models. Diagnosis of mTBI using miRNAs as biomarker will be an easy, non invasive and inexpensive method. Upon successful evaluation of miRNAs in this study, it can be easily tested in mTBI patients and integrated in military for diagnosis in a significantly short period of time.

The experimental models to create mTBI injury in mice that will be employed in the proposed study have been well characterized. This model replicates all the pathophysiological changes such as cerebral edema and decreased blood pressure that is seen in the soldiers sustaining mTBI injury. Secondary neuronal damage such as diffuse axonal injury and excitotoxicity and inflammation that is implicated in the brain tissue damage following mTBI is also reproduced in this model. Cognitive and neurobehavioral deficits associated with mTBI are also reproduced in this model. Further, we are using a closed head injury model which also replicates the kind of injury which is often associated the soldiers and war veterans who experience mTBI.

The proposed study has significant military relevance and importance as there is no specific biomarker for diagnosis and effective treatment available for mTBI and PTSD. There is a greater prevalence of PTSD in veterans who had suffered mTBI. Both the conditions contribute towards the morbidity and loss of quality life in veterans returning from the war zones and also have significant financial burden on the military in terms of diagnosis, treatment and care of veterans. Social and mental stress on veterans and their families is far greater than the civilian population. This project therefore addresses the task area "diagnosis and treatment of brain injury" where we will evaluate the capability of miRNAs as biomarkers for mTBI and treatment of mTBI by targeting aberrantly expressing miRNAs during mTBI. We have assembled a team of experienced investigators with significant expertise and capabilities, as documented in their biographical sketches, to investigate miRNA as biomarker for mTBI and to evaluate the neuroprotection by targeting modulated miRNAs in brain upon mTBI. The environment, resources and various centers involved in TBI and PTSD research at USUHS offer an added advantage and will enhance the chances of success.

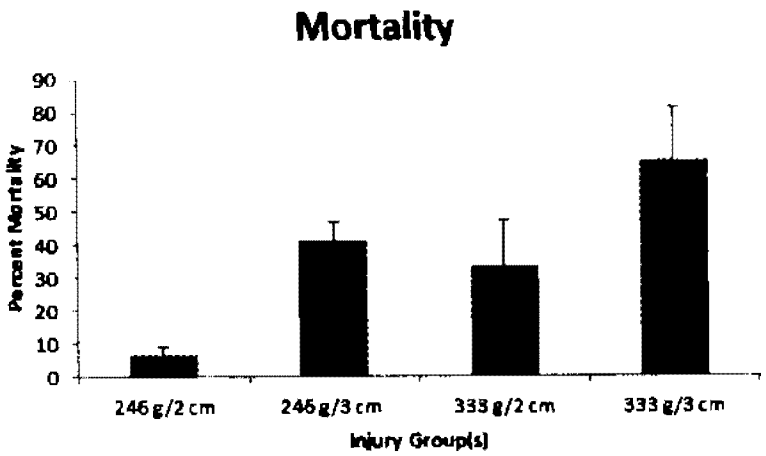
V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures:

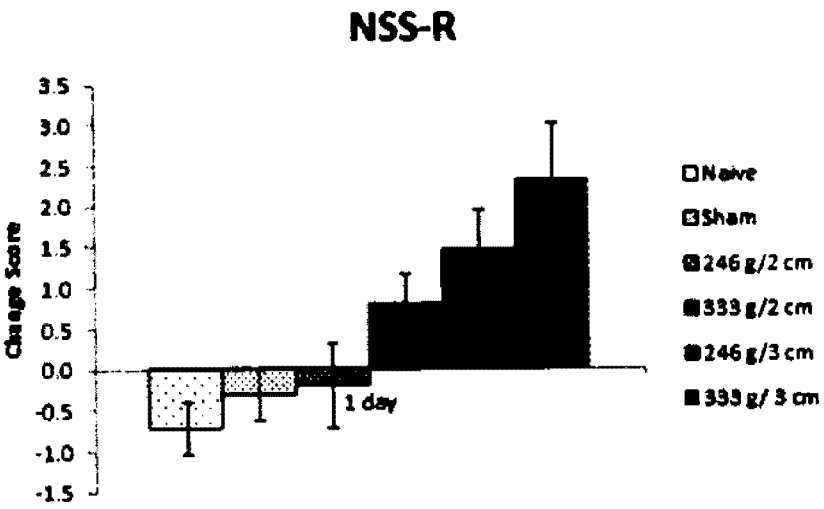
V.1.1. Experiment 1: To evaluate the mild TBI in mouse induced with the injury using a free falling weight that is restricted to stop at the depth of 4-5 mm from the point of impact.

From our previous experiments, it was observed that mild injury with 333g, weight and falling height of 2 cm and 3cm result in high percentage of mortality (Fig 1A). Resulting injury causes mild injury with acute neurological and behavioral alterations at day 1 (Fig 1B). This may be due to compression of brain in between the hard surface of the falling rod and solid plastic base. Therefore, in the proposed experiment we will restrict the falling weight to stop at the depth of 4-5mm from the point of contact (Fig 2). In a preliminary experiment, the mortality associated with the injury was reduced to 20% in 333g/3cm weight injury. Further contusion on the brain that result in a mild injury may not cause a full skin depth cut wound, therefore in one subset of animals injury will be induced on the head over the left parietal lobe area without the scalp incision. For this subset, skin over the head will be stretched to minimize the slipping of falling rod.

A



B



Groups	mTBI by weight Drop method	# iteration/ group/ method	Total animals	Pain category
No Injury with scalp incision	6	3	18	E
Injury (333g/3cm) with scalp incision	6	3	18	E
No Injury without scalp incision	6	3	18	C
Injury (333g/3cm) without scalp incision	6	3	18	E
Total animals required			72	

Total animals required [6 animals/group x 4 groups x 3 iterations/ group/ method =72 mice]

Anticipated results/problems and alternative approach: Based on our previous experience we expect that the described model (333g/3cm) will produce a mild traumatic brain injury while significantly reducing the associated mortality that is seen if weight is dropped unrestricted under gravity. If, mTBI is not reproduced as per the described parameters we will increase the height of the falling weight by 0.5 cm until we achieve the desired parameters of mTBI. The above table includes the number of mice (iteration #) that may be needed for the standardization of injury. This pilot study will also predict the percent survival of the mice after receiving the injury.

V.1.2. Experiment 2: **To evaluate the miRNA expression profile in mouse blood and brain upon mTBI using 333g weight falling from a height of 3cm.**

In this experiment animals will be subjected to single mTBI as described above in experiment 1 (please also see Section V.4.3.2 page 24). miRNA expression profile in the brains and blood of mice subjected to mTBI will be evaluated at different time points as described below. A correlation will be done to identify blood miRNA that are common, or not, with the miRNA expressed in the brain. Target prediction to predict the genes that may be modulated by the miRNAs will also be done using Target Scan software.

NOTE: From our previous experiments observation, 333g weight and 3cm height should reproduce the mild TBI. This combination of weight and height will be used in this and rest of the experiments. However, restricted fall may change the outcome. In that case the parameters determined in the experiments 1 will be used to create injury in this and the rest of the experiments.

Test and controls: Following test and control groups will be taken: 1.) No injury-naive control; 2.) mTBI-3hr; 3.) mTBI-1day; 4.) mTBI-4day; 5.) mTBI-7day; mTBI will be induced using weight drop method as described in section V4.3.2. Sham controls (with only the scalp incision) for each of the above time point will also be taken. Mice will be euthanized after the indicated time point post injury and blood and brain samples will be collected as described below.

Groups	No. of Animals	# iteration/group	Total animals	Pain Category
No injury control-naive	6	2	12	C
mTBI-3hr	6	2	12	E
mTBI-Day 1	6	2	12	E
mTBI-Day 4	6	2	12	E
mTBI-Day 7	6	2	12	E
mTBI-Day 14	6	2	12	E
mTBI-Day 30	6	2	12	E
Sham (3hr, Day 1, Day 4, Day 7, Day 14 and Day 30)	6 each group	1	36	E
Total animals required	48	2 (except sham)	**120**	

Total animas required [{6 animals /group x 7 groups x 2 iterations/group = 84 mice} + {6 animals/group x 6 groups x 1 iterations= 36mice} = 120 mice]

Sample collection: Animals will be deeply anesthetized using isoflurane and blood will be collected from animals by cardiac puncture (terminal procedure) into the collection vials (MiniCollect Serum Clot Activator Tubes with Gel Separator (0.8 ml), Greiner Bio-One) and serum will be separated by incubating at RT for 40 min followed by centrifugation at 3000g for 10min. Serum will then be stored at -20°C. Five out of 10 animals will be perfused with 4% neutral buffered formalin and brains will be collected for histological evaluation. Other five animals will be euthanized without perfusion and brains will be collected and freeze immediately for RNA isolation. Other tissues *viz* spleen and liver will also be collected from all the animals and banked for use if need arises.

miRNA analysis: cDNA synthesis for the miRNA will be done using stem-loop multiplex miRNA primer pool (ABI Inc). Analysis of miRNA expression profile will be done using Taqman low density array cards (ABI Inc) in a 384 well format, as per manufacturer's protocol. Total of 10 biological replicates will be used for each time point after the injury for the analysis. The results will be analyzed using Statminer software (Integromics, Inc) for determining the statistically significant miRNAs modulated upon mTBI. We will use Benjamin Hochberg algorithm for adjusting the false discovery rate (less than 5%) to reduce the number of false positive results.

Anticipated results/problems and solution: From the literature we know that miRNAs are candidate biomarkers in various tissue injury models in blood plasma. Since in mTBI blood brain barrier is compromised, we expect to find miRNAs in plasma which have entered the circulation from the brain. The miRNAs expressed exclusively in animals with mTBI and not in the plasma of animals with no injury would be the candidates for biomarkers of mTBI. Further miRNA expression profile of the brain will give us insights

of the dysregulation of miRNA during mTBI. This will enable us to elucidate the role of these miRNAs in various regulatory pathways important with regard to mTBI.

V.1.3. Experiment 3: To reconstitute the expression of specific miRNAs in mouse brain with mTBI by deploying miRNA inhibitors and/or mimics.

Reconstitution of aberrantly expressed miRNAs in diseased conditions using antagomirs and expressing miRNA through plasmid vector "mimic" has been successfully shown in many studies (Thum et al 2008, Krutzfeldt et al 2005). The working hypothesis here is that due to mTBI, miRNA expression is altered which results in a persistent inflammation and reduced neuronal repair and development. Restoring the altered levels of miRNAs expression may be important in reducing the inflammation in the brain and would enhance repair process in damaged neurons. In this study, we will design specific antagomirs and plasmid vector expressing pre-miRNAs for the miRNA over expressed and repressed during mTBI.

Design and synthesis of antagomirs and mimics: From the Experiment#2, we will get the data for specific miRNAs which gets modulated upon induction of mTBI. We will custom design locked nucleic acid (LNA) antagomirs (Exiqon Inc) specific for these miRNAs which are upregulated. LNA oligonucleotides contain one or more of the 2′-O, 4′-C-methylene-β-D-ribofuranosyl nucleosides which results in a conformational lock of the molecule into a near perfect N-type conformation. LNA modified antagomirs are more stable, less toxic and highly specific. MicroRNA mimics will be ordered for specific miRNAs in the form of precursor molecules (Pre-miR™ miRNA Precursor Molecule, Ambion Inc).

Treatment with antagomirs and/ or mimics: Animals will be treated with antagomirs or mimics following the mild TBI (as determined in experiment #2) via intravenous injections in the tail vein. LNA antagomirs will be dissolved in Phosphate buffer saline (PBS) buffer and would be administered at a dose of 80mg/kg of body weight (Krützfeldt et al, 2005). MicroRNA mimics in the form of precursor molecules will be administered at a dose of 50ug/mice in PBS buffer via tail vein injections (Takeshita et al 2009). This treatment will be repeated after 24 and 48hrs post injury.

Following parameters will be evaluated;

(A) Determine the delivery of the miRNA antagomir or mimic: Cy3 labeled LNA antagomirs and/or mimics will be administered intravenously in a separate group of mice to verify the delivery of antagomirs and mimics to brain post mTBI. Brain sections from these mice will be studied using a laser scanning microscope to detect the localization of cy3. Mice will be evaluated every day for 3 days for localization of cy3 signal.

Group	# of animals	Pain Category
Cy3 labeled LNA antagomir and mimic with no injury	18 (n=6/each time point)	C
Cy3 labeled LNA antagomir or mimic with injury	18 (n=6/each time point	E
Total animals required	36	

Total of animals required [18 animals /group x 2 groups = 36 mice]

(B) Effect of miRNA antagomir or mimics treatment on cognitive and neurological dysfunctions following mTBI:

Animals will be treated as described above. Following groups will be taken:

Groups	# of Animals	# of iterations/ group/ function	Total animals	Pain Category
Saline control with Sham (without injury)	6	3	18	E
Saline control with injury	6	3	18	E
Antagomirs / mimics control with sham (without injury)	6	3	18	E
Treatment with antagomirs and/or mimics following mTBI. We anticipate selecting 4 miRNA targets. Represents 4 groups	24 (n=6 for each of the 4 miRNA target groups)	3	72	E
Total Animals	42	3	126	

Number of animals required-

[6 animals/group x 8 groups x 3 iterations/group = 144 mice].

Evaluation of neuro-behavioral deficits: On day 1 post injury three different tasks will be evaluated. Animals will be first evaluated for NSS-r in the morning followed by evaluation of OFL and then ASR in the afternoon. On day 14, only OFL and ASR test will be sequentially done in the afternoon

The above three tests and time points were selected based on our experience with this model. However, it may turn out that as the experiments progress we may have to do specific test for memory, depression or motor activity. Therefore, we have added the Barnes Maze Test, the Morris Water Maze test, Forced Swimming Test, and the Rotarod test, and the under section V4. In case we decide that a specific test is needed, animals under those experiments will undertake only that particular test in addition to NSS-r.

(C) Effect of miRNA antagomir and mimic treatment on the biochemical and histological changes in the brain. This experiment will be undertaken only with the

most effective miRNA antagomir or mimic as determined from the experiment in part B. Animals will treated with the miRNA antagomir or mimic will be euthanized at 3hr, Day 1, 4, and 7 after the last treatment with antagomirs or/mimics as described above. Brains will be isolated from one group of animals and immediately stored at -80°C for biochemical parameter analysis. Another group of animals will be perfused with the 4% formaldehyde solution and brains will be collected for histological studies. Serial sagittal sections of the 1mm thickness will be cut and placed on slides from all parts of the brain.

Groups	# of animals for biochemical parameters	# of animals for histological parameters	# of iterations/ group/ parameter	Total animals	Pain Category
Injury + Treatment with antagomirs and/or mimics following mTBI (For histological and biochemical parameter analysis)	24 (n=6/each time point)	24 (n=6/each time point)	2	96	E
Treatment with antagomir or mimic without injury	24 (n=6/each time point)	24 (n=6/each time point)	2	96	C
Total animals required				192	

Number of animals required- [24 animals/group x 2 groups x 2 iterations/group = 240 mice]

V.2. <u>Data Analysis and Statistics</u>: The statistical framework for designing experiment and estimating the sample size considers the magnitude of the effect in the control group the "additional effect" (over and above the control effect) expected in the treatment group, statistical power to detect this desired difference between the treatment and control, and the alpha level. The laboratory and clinical experiments will be designed with a statistical power of at least 80%. The alpha level is traditionally set at 5%. To observe a treatment effect of 60% with 80% power and 5% alpha level a sample size of 6 mice per group would be necessary and therefore 6 mice per group will be taken in all the experiments. All qualitative variables will be compared between treatment and control groups using Fisher's exact test. Since several variables will be measured in each experiment, analyses of all variables at 5% alpha level will result in inflation of P-value. This inflated P-value may increase the probability of false positive result. Therefore to maintain the experiment wise alpha level of 5% and to control for multiple comparisons in the experiment, we will adjust the P- values using statistical procedures of Holm 1979 and Hochberg 1988. This will rule out any false positive results. USUHS has a Biostatistics Consulting Center (BCC) that provides help with the statistical and graphical analysis of the data. BCC provides advice at all stages of the research process from study design to presentation of results. BCC will be extensively consulted while analyzing the data and its presentation.

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered: Due to the complex nature of the traumatic brain injury and especially in mTBI where there are no outward sign of trauma there are no non-animal alternatives to the experiments involving TBI experiments. Further in the proposed study biomarkers in the circulating blood post mTBI will be evaluated which will require use of animal model and there are no non-animal alternative to this study.

V.3.2. Animal Model and Species Justification: Several animal models such as mouse and rat have been described for studying TBI injury and effect of therapeutic drugs in TBI. We have taken 10-12 week old (weighing 28 gm), male C57BL/6 mice (Jackson Labs) for the proposed study. C57BL/g mouse model have been well characterized for creating mTBI (Flierl et al 2009). Male mice are preferred as progesterone has been shown to have protective effect on TBI in humans (Beauchamp et. al., 2008). Further, other mouse species will require re characterization of the TBI model as the parameters such as weight and the height from which it is dropped will change with the species. Therefore, we have chosen male C57BL/g mouse for the proposed study.

V.3.3. Laboratory Animals

	Species #1	Species #2
V.3.3.1. Genus & Species:	Mouse	
V.3.3.2. Strain/Stock:	C57BL/6	
V.3.3.3. Source/Vendor:	(b)(4)	
V.3.3.4. Age:	10-12 week	
V.3.3.5. Weight:	28 gm	
V.3.3.6. Sex:	Male	

V.3.3.7. Special Considerations:
No special considerations are needed.

V.3.4. Number of Animals Required (by Species): 546

V.3.5. Refinement, Reduction, Replacement (3 Rs):

V.3.5.1. Refinement: The free fall weight drop model originally described in Flierl et.al 2009 caused significant mortality in our hands. Therefore, we will modify the free fall in such a way that the falling weight stops after impacting the brain (please see figure 2). This will help in reducing the compression of brain tissue between the falling weight and the solid surface of the platform on which animals are placed. We expect that such refinement will result in significant reduction in the mortality. Further if any animal show symptom of sever disease such as loss of consciousness for prolonged time (>30min), NSS score of >5 and paralysis, it will be removed from the study and will be humanely euthanized. Animals will be anesthetized before performing any brain injury.

We have deliberated use of rat model in the proposed study but mouse model provided us with greater advantages. Since mouse is much smaller than the rat handling and induction of mTBI will be faster and far easier in this model. Further the miRNA work relating to use of antagomirs and mimics has been extensively carried out and validated *in-vivo* in the mouse model and only a few study has shown this approach in rat. Consideration was given to the number of known miRNA in mouse and their similarity with the known human miRNAs. As listed in the microRNA resource database (www.mirbase.org) number of known mouse microRNAs (579) is much higher than in the rats (325). The number of known human microRNAs is 721. Several microRNAs that are known in both human and mouse are not discovered in the rat yet. Therefore, we believe the advantages of using mouse in the proposed studies outweighed the use of rat model.

V.3.5.2. Reduction: The number of animals to be used is the minimum number of animals needed to achieve scientifically sound conclusions for the experimental objectives. In order to reduce the number of animals in case the defined parameters do not produce the desired injury, we will perform a small pilot study upfront to establish the induction of desired mTBI using the weight drop method. This will significantly reduce the number of animals that otherwise may be needed for successful completion of this study.

V.3.5.3. Replacement: Due to the nature of the study, *in-vitro* and/or computer modeling systems are not available. A whole live animal model is necessary to study and possibly identify specific biomarkers after TBI.

V.4. Technical Methods:

Procedure for induction of mTBI by weight drop method: Please refer to section V4.3.2.

Neurological Severity Scale Revised (NSS-R) (b)(6) Laboratory Version. The Neurological Severity Scale – Revised (NSS-R) is currently being used to characterize traumatic brain injury in rats. Using this assessment will allow for comparisons both between multiple behavioral tests as well as behavioral comparisons between strains.

The Neurological Severity Score (NSS) is a battery of motor and reflex tests used to assess the extent of brain injury in experimental rodents (Shohami et al., 1995; Hamm, 2001; Mahmood et al., 2001). The tests assess reflex suppression, general movement, and postural adjustments in response to a challenge. The NSS includes observations of behaviors and performance measures. The Revised Neurological Severity Scale (NSS-R) is a specific, continuous sequence of behavioral tests and observations. The NSS-R is based on several previous reports but modified to increase standardization.

NSS-R tasks 2, 3, and 10 are based on the methods of Shohami et al. (1995); tasks 1, 3, 6, 8, and 10 are based on the methods of Mahmood et al. (2001); tasks 6 and 10 are based on methods described by Hamm (2001); task 4 is based on the methods of Marti et al. (2005); tasks 7 and 9 are new. The testing is conducted using two empty "guinea pig" polycarbonate cages (46 cm x 36 cm x 20 cm) with no bedding or lid.

Scoring:

In the previous version of the NSS, behavior was scored in a binary fashion with the absence of behavior assigned one point; higher total scores indicated a greater extent of injury. The Shohami system allowed for a total of 24 points and the Mahmood system allowed for a total of 14 points. By contrast, a three-point Likert scale is used in the NSS-R to increase sensitivity, in which a normal, healthy response is assigned a "0," a partial or compromised response is assigned a "1," and the absence of a response is assigned a "2." Therefore, the NSS-R has a scoring range of 0-30, which is designed to increase sensitivity.

In the NSS-R, the mice are scored as follows:

0-presence of reflex or response that is comparable to a normal mouse

1-reflex or response is present but impaired/attenuated

2-absence of reflex or response

Higher scores will reflect greater extent of injury, with the highest score possible being the total number of measures multiplied by three. Following the methods of Shohami et al., two terms will be used to describe the clinical status of the mice:

1. NSS – the total score for performance on a particular test

2. Δ NSS – the difference between the total score immediately post-injury and any subsequent scores.

NSS-R Tests:

1. General balance test

The mouse's ability to walk on a balance beam is assessed. The balance beam is placed lengthwise at above Cage A by placing the ends of the balance beam on top of two pairs of stacked cages. The mouse is gently placed onto the balance beam and observed. The mouse's movement on the balance beam is given a score of 0, 1, or 2. A score of 0 is given if the mouse maintains balance and walks successfully on the beam. A score of 1 is recorded if the mouse balances on the beam but does not walk along the beam. A score of 2 is given if the mouse does not balance or walk on the beam at all. The task is repeated three times and the score is based on the "best" performance. The second test begins immediately after test #1.

2. *Landing test*

In this test, the mouse lands on a flat surface after being dropped from the cage height where the balance beam is placed as described above, and the reflexes of its paws and body posture are observed. The landing test occurs immediately following the general balance test, as the mouse lands on the cage floor. The mouse's landing is observed and rated. A score of 0 is given if the mouse shows normal reflexes when landing. A

score of 1 is given if the mouse shows partial reflexes that are compromised in some way. A score of 2 is given if the mouse does not use landing reflexes when falling off the balance beam, and instead falls flatly onto the cage floor.

3. Tail raise test

Immediately following the landing test, the mouse will be gently lifted by the base of the tail (dorsal side up). When the mouse is lifted, the reflexes of its forelimbs and hind limbs will be observed and scored for the proper flexion and extension. A score of 0 indicates normal reflexes, a score of 1 indicates partial reflexes, and a score of 2 indicates that no reflexes were observed (e.g., the mouse was limp when lifted by the tail). After the tail raise test, the mouse is brought to the second cage, Cage B, to conduct the drag test.

4. Drag test

While continuing to hold the mouse by the base of the tail, the mouse is placed on the floor of Cage B, with the mouse facing and close to one of the shorter walls. Allowing only the mouse's forepaws to remain on the floor of the cage, the mouse is gently dragged backwards at a constant speed (about 20 cm/sec) across the length of the cage. The mouse's behavior while being dragged is observed. A score of 0 indicates extension of forepaws and effort to slow down the drag or to pull away from the drag. A score of 1 indicates some effort to slow down the drag or to pull away. A score of 2 indicates no resistance.

5. Righting Reflex

After the conclusion of the drag test, the mouse remains in Cage B for the Righting reflex test, as well as for the remainder of the reflex tests. The mouse is placed on its back and the mouse is observed. A score of 0 indicates that the mouse gets onto four paws without difficulty. A score of 1 indicates partial "righting" or complete righting with difficulty. A score of 2 indicates inability to right completely.

6. Face Reflex

The face reflex will be tested by lightly touching the head with a long Q-tip or eraser end of a pencil and observing responses. A score of 0 indicates a head shake or movement away from the stimulus. A score of 1 indicates partial response and a score of 2 indicates no response.

7. Eye Reflex

The eye reflex is tested by lightly touching the eye with a Q-tip and observing the response. The response will be scored according to the following criteria: 0 indicates a complete and immediate eye blink; 1 indicates a delayed eye blink; and 2 indicates no response.

8. Sound Reflex

This reflex is a movement in response to the noise of a short, sharp clap of the experimenter's hands. The reflex is observed and rated as follows: 0 for a quick jumpy movement followed by freezing; 1 for a slow movement and/or no freezing; and 2 for no response.

9. *Tail reflex*

This reflex is tested by applying a brief pinch using the experimenter's fingers to the tail for a marked and immediate squeak; 1 for a delayed or weak squeak; and 2 for a no response.

10. Paw flexion reflex

This reflex is tested by briefly applying a pinch with the experimenter's fingers to the hind paw and observing whether a withdrawal response is elicited. The test will be scored as follows: 0 for a limb withdrawal reflex; 1 for a partial or delayed withdrawal reflex; and 2 for no response

Other Neurological behavior tests:

Barnes Maze test: Spatial memory task in rodents after TBI will be evaluated using Barnes Maze test (Barnes 1979, Harrison et al 2006, Doll et al 2009, Maegele et al 2005). The arena consists of a circular platform (122 cm diameter) with 20 holes around the perimeter. One hole is designated as the "escape hole" and has a long box underneath it that extends under the platform. The other 19 holes can be used with or without the false boxes directly underneath the holes, but do not extend out underneath the platform. Bright light is pointed towards the maze to act as an aversive stimulus and induce mice to find the "escape hole". The time line for training and testing using the Barnes Maze test consists of 4-5 consecutive training days and multiple testing days. On the first day, three trials (one acclimatization and two training trials) are given to each animal. Next for four consecutive days each animal receive two training trails. Following the induction of mTBI each animal will be given two test trails each day for seven days to evaluate the spatial memory task. Training is conducted by placing the animals at the center of the platform and ends after the animal has escaped from the "escape hole" or the predetermined time of 300 sec has ended. After the animal has escaped from the maze it is covered for 30sec to reinforce the escape from the aversive stimuli. If the animal fails to escape the maze then it will be led to the escape hole and will be covered for 60sec to reinforce the escape from the aversive stimuli. Platform will be cleaned with 35% isopropyl alcohol in between the training and or testing of each animal to remove any olfactory cues.

Rotarod test: The rotarod test measures the motor skills of an animal. It also measures learning behavior as the animal improves the balancing act by practice (Chen et al 2007, Fujimoto et al 2004). The rotarod treadmill (Med Association) consists of a motor-driven drum divided into four stations. When the animal falls off the rotating drum it breaks a photobeam stopping the timer associated with that chamber. The animals will have three consecutive trials on this device with speed of rotation increasing with each trial from 0 to 35 revolutions per minute for a maximum of 3 min. Average time from three trails will be expressed in seconds and will be recorded for scoring each animal.

Open field locomotion: Open field locomotion will be measured during the dark cycle i.e. the active period of the animals using an Omnitech/Accusan Electronics Digiscan infrared photocell system (Elliott and Grunberg 2005). The system consists of a clear box with infrared beams to measure horizontal and vertical movement of the animal. Activity for each animal will be measured for one hour.

Startle acoustic test: The acoustic startle reflex test in animal will be conducted with a Startle Response Acoustic Test System (Coulbourn Instruments, Columbus, Ohio, USA) (Faraday and Grunberg 2000). The system consists of eight weight sensitive platforms

in a sound-attenuated chamber. A subject's movements in response to stimuli will be transduced into analog signals by the platforms. These signals will then be digitized and stored by a computer. All acoustic stimuli will be given by a loudspeaker mounted 24 cm above the test cage. To minimize the effects of handling and stress on drug testing, animals will be allowed to acclimate to the startle chamber for 2 consecutive days. During acclimation animals are in the chamber for 20 min/each session. The startle baselines will then be tested for each animal the next day on Day -1 before their drug administration or experimental manipulations. During testing mice will be individually placed in an animal holder (E05-15, Coulbourn Instruments, Columbus, Ohio, USA), which will be then placed on a weight-sensitive platform within the chamber. A ventilating fan built into the chamber provides background noise. Following 3-min acclimation period animals will be exposed to six types of sound stimulus trials: 100 and 110 dB alone, both 100 and 110 dB with pre-pulse (84dB), pre-pulse alone and no stimulus. Each trial type will be presented eight times. Trial types will be presented in random order to avoid order effects and habituation. Inter-trial intervals ranged randomly from 15 to 25s. Animals will be tested in the dark cycle; during the experiments the red light will be provided in the dark room. Each animal's responses will be averaged within trial type. Trials during which no stimuli presented will be used as control for normal subject movements on the platform. Amplitudes of each trial type will be derived by subtracting grams (g) of platform displacement on the no-stimulus trials (i.e., body weight of each subject) from g of platform displacement in response to specific stimuli. The remainder resulting from this calculation represented absolute amplitude of ASR to the stimulus (e.g., 100 dB, 100 dB with pre-pulse, 110 dB, 110 dB with pre-pulse). The ASR amplitude tested each time was finally represented as "% of baseline", which was calculated using the equation: % of baseline= (absolute amplitude /baseline absolute amplitude) 100%. For each test day, ANOVAs for repeated measures will be performed on startle amplitudes with factors of stress status and drug dosage. Tukey or Bonferroni test was used to assess significant post-hoc differences between individual groups. The data will be represented as mean ± S.E.M.

Forced swimming test: Forced swim test consists of two phases, a training phase and a test phase on two successive days (Carlezon et al 2002, Pliakas et al 2001). For the training phase animals are placed into a 65cm tall x 25cm diameter cylinders filled with tepid water up to 48 cm for 15 minutes. For testing phase animals are similarly placed into the water for 5 min. Animal is considered immobile in water if 75% of the animal's body is still for at least 5 seconds (as analyzed by video recording software). Total time of immobility, latency to first instance of immobility and number of immobile periods will be recorded for each animal. Animals under stress or showing inability or difficulty in swimming will be immediately removed from the water. All mice will be dried off using paper towels after the test and before placing them back in their respective cages.

Morris Water Maze (MWM) test: Our current neurobehavioral experiments such as open field locomotion and rotarod test indicate that there may be a learning behavior deficit in the mild TBI group as compared to the control. Published literature on mild TBI suggest that Morris Water Maze test may be more sensitive to bring out the learning behavior deficits in mouse as compared to the other neurobehavioral tests. Therefore we would like to conduct MWM test in our studies details of which are given below:

Ten days (day 1 of the training) after TBI or sham procedures, a Stoelting Morris water maze is filled with tap water (25°C) to a depth of 20-30 cm. A clear plastic platform is placed in one of the "quadrants" of the tank floor. On Day 1, a pre-training trial takes place where the mouse is gently placed on the platform in the tank and the mouse remains there for 15 seconds. If the mouse jumps into the water during this time, it is allowed a brief swim (< 60 seconds) before being guided back to the platform. On Days 2-5, training trials take place in which the mouse is placed near the side of the tank in a location away from the platform, and is allotted 60 seconds to swim to the platform, where it remains for 15 seconds before being dried and placed into the home cage under a heating lamp. If the mouse does not reach the platform in the allotted 60 seconds, they are gently guided to the platform. A total of four trials per mouse, separated by 1-2 minutes, are performed each day and the latency to find the platform is recorded for each trial. Finally, on the final day of training (Day 5) about one hour after the last training trial, a single trial is performed with the platform removed from the tank. The time spent in the pool quadrant where the platform was located is measured, compared to time spent in the other three quadrants. The time to reach the platform, distance traveled, and time in each quadrant of the tank is recorded by the Any-Maze video tracking program.

Twenty six days (day one of the 2nd round of training) after the TBI or sham procedure above procedure will be repeated again with following differences. The platform will be moved to a different quadrant of the Stoelting Morris water maze. Training will done for 3 days i.e. day 26, 27 and 28 post TBI or sham procedure. Day 26 training will be similar to day 1 of first round of training as described above. On day 27 and day 28 training will be similar to day 4 and 5 of the 1st round of training respectively. On day 28, a single trial with platform removed will be conducted 1 hour after the last training trail. Data will be measured and analyzed as described above.

Ear punch identification: We have initially proposed in our protocol that a temporary marking on tail with a sharpie marker will be used to identify animals. We have increasingly face problem with this mode of animal identification as many times due to water bottle leak or form other reasons the marking on the tail fades away and it becomes extremely difficult to identify the animals. Therefore we would like to request a more reliable animal identification technique of ear punching. Ear punches will be made on the day of surgery when the injury or sham group of mice will be under anesthesia (as described in the protocol). Scissor style ear punch (Kent Scientific, cat# INS500076) will be used to make ear punch. Animals will be identified in the following manner:

Mouse #1-No holes.
Mouse #2-One hole on the right ear.
Mouse #3-One hole on the left ear.
Mouse #4-One hole on each ear.
Mouse #5-Two holes on the right ear.
Mouse #6-Two holes on the left ear.
Mouse #7-Two holes on the right and one hole on the left.
Mouse #8-Two holes on the left and one hole on the right.
Mouse #9-Two holes on each ear.

Mostly numbering from 1 to 5 five will be required and further identification will be done based on the cage number followed by the animal number.

Perfusion and collection of brain: Animals will be perfused as described before (Sharma et. al., 2009). Briefly, each animal will be euthanized using over dose of isoflurane and will be perfused first with 15ml of ice cold IX PBS (GIBCO Phosphate-Buffered Saline, Invitrogen) containing 12.5U of heparin followed by 15ml of 10% neutral buffered formalin (NBF) (VWR, West Chester, PA). Whole brain will be carefully removed and fixed in the 10% NBF solution.

V.4.1. Pain / Distress Assessment:

V.4.1.1. APHIS Form 7023 Information:

V.4.1.1.1. Number of Animals:

	Species #1	Species #2
V.4.1.1.1.1. Column C:	144	
V.4.1.1.1.2. Column D:	0	
V.4.1.1.1.3. Column E:	402	

Please refer to section V.4.1.4 for details regarding grouping of animals under each category.

V.4.1.2. Pain Relief / Prevention:

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization:

Anesthesia: Animals will be anesthetized by inhalation anesthetic immediately prior to the induction of TBI. General anesthesia will be induced by 2-4 % isoflurane + 100% oxygen using a precision vaporizer via a rodent anesthesia machine in a clear chamber. Mice will then be removed from the chamber and maintained under anesthesia on 0.5-3% isoflurane + 100% oxygen using a nose cone during the procedure. All the procedures such as induction of TBI, euthanasia and perfusion will be performed on mice with no pedal withdrawal reflex. Mice will also be carefully monitored for a stable rate of respiration. Waste anesthetic gases will be scavenged either through the chemical fume hood or passively by the charcoal filter. Anesthetics will be administered by the PI or his staff or by LAM personnel.

Analgesia: None

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions:

Animals will be kept at the animal housing facility of LAM for 10-14 days prior to the induction of mTBI and will receive standard care. Acclimation and baseline measurements for the behavior test will be done in the week preceding the day of injury. Post injury animals will be monitored for any distress. If animal is found to be distressed for reasons other than the mTBI it will be removed from the study and humanly euthanized.

V.4.1.2.3. Paralytics: none

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures:

V.4.1.3.1. Sources Searched: Medline (PUBMED), defense technical information center biomedical research database (BRD) and research portfolio online reporting tools (RePORT)

V.4.1.3.2. Date of Search: June 1-8, 2013

V.4.1.3.3. Period of Search: 1970-current

V.4.1.3.4. Key Words of Search: Traumatic brain injury, mild traumatic brain injury, traumatic brain injury + pain, mild traumatic brain injury + pain, mild traumatic brain injury + distress + pain, mild traumatic brain injury + alternative, mild traumatic brain injury + pain + alternative, mild traumatic brain injury + analgesic, mild traumatic brain injury + analgesic + microRNA, perfusion and tissue fixation, perfusion+ pain, perfusion + pain + alternative, cardiac puncture blood collection, cardiac puncture + pain, tail vein injection, tail vein injection + pain, tail vein injection + pain + alternative.

V.4.1.3.5. Results of Search:

Use of the various key words and their combinations returned several results. These results showed that induction of mTBI by weight drop method, formalin perfusion by cardiac puncture, tail vein injection and blood collection by tail vein nick and cardiac puncture are routinely used technique and are used as per the need of the experiment. We could not find any alternative to the weight drop method to induce mTBI that is minimally invasive in producing contusion. Further the blood collection by cardiac puncture will give greater blood volume as compared to the tail vein nick with minimum stress to the animal as it will be done under anesthesia. Below is the summary of the literature search:

1.) Search using the term "traumatic brain injury" returned 54467, 4825 and 626 results in PUBMED, BRD and RePORT database respectively. Adding "mild" to this search reduced the numbers to 2961, 1316 and 211 in PUBMED, BRD and RePORT database respectively. Search with "mild traumatic brain injury + pain" returned 141, 504 and 171 results in PUBMED, BRD and RePORT database respectively. "Mild traumatic brain injury + alternative" returned 28, 399 and 103 results in PUBMED, BRD and RePORT database respectively. These results show that there is no painless alternative to study mild traumatic brain injury. Most of the results indicate interventions to reduce the associated pain after the injury has happened.

2.) Use of analgesic: Pubmed search of the analgesic (NSAIDS such as aspirin, cyclooxygenase 2 blocker, ibuprofen, Sildenafil, acetaminophen etc) and gene expression showed that analgesics modulate gene expression in the host.

3.) Perfusion: Pubmed search of "perfusion by cardiac puncture" returned 123 results, where as "cardiac perfusion" returned 42445 results. Search for formalin cardiac perfusion returned 80 results. These results showed that perfusion with formalin through cardiac puncture is a well establish methodology. Search for "alternative to formalin perfusion" returned 6 results. All these results showed alternative to use of formalin with some other fixative such as acrolein but did not indicate any painless alternative to the perfusion technique.

4.) Blood collection: Search with key words "blood collection" returned 26909 results which reduced to 507 when the term "cardiac puncture" was added to the first search.

These results indicate that blood collection by cardiac puncture is a well established method.

5.) Tail vein injections: Search for "tail vein injection + mouse" returned 1114 results and addition of microRNA to the above keywords retuned only two results. These results show that tail vein injection is a well established method of administering drugs/ dyes and microRNA can also be delivered by tail vein injection.

V.4.1.4. <u>Unalleviated Painful or Distressful Procedure Justification</u>: All the animals in the experiment 1, 2 and 3, that will be induced with the TBIhave been placed under the unalleviated painful or distress category, category E. Animals that will undergo only the scalp incisions have also been placed under the category E. Total number of animals under this category are 402. This is done due to the concern that analgesics (NSAIDS such as aspirin, cyclooxygenase 2 blocker, ibuprofen, Sildenafil, acetaminophen etc) results in modulation of gene expression in the host. Buprenorphine is a mu-opiod receptor partial agonist and kappa-opiod receptor agonist (Sanchez et al 2008). Detailed molecular mechanism of Buprenorphine action is not fully understood. It has been shown to induce dose dependent affect on myelin associated glycoprotein expression and glycosylation. Buprenorphine engages both mu-opiod receptor and nociceptin/orphanin FQ receptor (NOP receptor) in the oligodendrocytes presumably via modulating activity of Src-family tyrosine kinase Fyn (Sanchez et al 2008, Eschenroeder eta l 2012). Buprenorphine also induce low level of interleukin 4 response in T lymphocytes and has also been reported to induce apoptosis in NG108-15 nerve cells (Borner et al 2013, Kugawa et al 1998). Studies on molecular mechanism of Buprenorphine action are limited. Therefore, it is also not know if buprenorphine treatment will affect the microRNA expression in the serum and brain of mice. The main objective of the proposal is to evaluate mTBI induced miRNA expression in brain and blood so as to use that information as diagnostic marker of mTBI. It is well establish that microRNA modulate the gene expression by acting upstream of the mRNA translation step. Since the analgesics modulate gene expression it will be safe to assume that microRNA expression will also be modulated by these analgesics. Analgesic, acetaminophen is known to modulate the miRNA expression in the serum (Wang et al 2009). Therefore, use of analgesic may interfere with the outcome of the proposed study i.e. identification of microRNA in serum post mTBI and their establishment as mTBI biomarkers, in a way that may result in false identification of miRNAs or inaccurate correlation of miRNA with mTBI. **However, to reduce the pain at the time of injury or only scalp incisions, all procedures will be done under continuous inhalation anesthesia.**

Animals that are placed under the category C (n=144) are the animals that will either be naïve subjects or receive momentary discomfort due to injections of saline or miRNA antagomirs/mimics.

Treatment with miRNA mimics/antagmoirs is expected to alleviate the pathology associated with the induction of mTBI therefore will be expected to alleviate the pain associated with the mTBI. If treatment with microRNA mimic(s) or antagomir(s) would be found effective in treating the mild TBI, then the above categories will be changed as deemed necessary. Such observations will be recorded and reported in the annual report to IACUC.

V.4.2. Prolonged Restraint: None

V.4.3. Surgery: Following section have been adopted from the SOP provided by the CNRM under brain injury models (b)(4)

V.4.3.1. Pre-surgical Provisions: Animals will be kept at the animal housing facility of LAM for 10-14 days prior to the induction of mTBI and will receive standard care.

V.4.3.2. Procedure: All the procedures will be carried out under aseptic conditions at the CNRM's TBI surgical suite in DLAM. Bench space and instrument to be used will be cleaned with 70% ethanol. Following two procedures will be done under the proposed study:

Weight drop induced mTBI: Mice (~28gms) will be anesthetized by inhalation anesthesia as described in section **V.4.1.2.1**. Skin will be cleaned with betadine and a midline scalp incision (~1.0-1.5 cm) will be made in a single cut exposing the skull. Mild closed head injury (CHI) will be induced by weight drop method. 333 gm weight will be dropped from a height of 3 cm causing a mild CHI. An impactor tip of 3 mm diameter at the end of the rod will be used to create the blunt end injury at the predetermined left anterior frontal area. Rod will be retracted immediately to prevent and "rebound injury" that may otherwise result in multiple contusions. Such injury causes a NSS-r) score of 3-4 at Day 1 post injury (figure 1B), which is consistent with the mTBI (Flierl et al 2009, Brody et al 2007). Following injury scalp will be closed with tissue glue. Sham-treated controls will be treated similarly except the impact with the free falling weight.

Controlled cortical impact TBI: This method has been incorporated as a backup to weight drop mTBI method. In case if weight drop mTBI model fails to provide any measurable alteration (biochemical/molecular/behavioral), CCI model for inducing mTBI, which is well established and characterized in the CNRM, will be used to undertake miRNA mimic/antagomir experiments. Mice will be induced and maintained on isoflurane anesthesia as described in section **V.4.1.2.1.** Mouse will be placed in the injury device stereotaxic frame at 0° angle. Skin will be cleaned with Betadine and a small surgical incision in the scalp will be made to expose the skull overlying the right lateral ventricle. A 5.0mm burr hole will be drilled into the skull of the right hemisphere at anterior-posterior = 0 mm, medial-lateral = 2.0 mm from bregma with a hand-held trephine to expose the dura mater. After removal of the bone flap, injury will be produced with the CCI device operated and maintained under the Center for Neuroscience and Regenerative Medicine (CNRM) core services in DLAM. The impact tip (3 mm in diameter) will be slowly lowered to the surface of the dura and a low-voltage detector indicates when the tip contacts the dura (contact will be visually verified). A single contusion will be made and target insult parameters will be a penetration depth of 0.5 mm (mild injury) with a stroke velocity of 5 m/s (Brody et al., 2007). Following CCI, the burr hole filled with bone wax and incision is closed with a Vicryl absorbable suture or with tissue glue. Sham-treated controls will be treated similarly, but the impactor will not be activated. Body temperature will be maintained with the use of a warming pad.

V.4.3.3. Post-surgical Provisions:

Animals will be allowed to recover from the anesthesia on a hot water circulating pad. No analgesic will be given to the animal as it may interfere with the inference of results. Animals will be monitored for 4 hours after the induction of surgery and will be housed singly in their cages. There after animals will be checked once a day by PI's staff. A cage card indicating the date and time of the TBI and the responsible person will be placed on each of the animal cage. Animals will also be assessed for weight loss, absence of grooming and undergo neurological tests to assess the absence/presence of impairment. Animals shown signs of distress not typically associated with the TBI such as muscle rigidity or lack of muscle tone, twitching, trembling, tremor, self-mutilation, or unkempt appearance (erect, matted, or dull hair coat) will be identified. PI will consult with DLAM veterinarians on a case by case basis to determine pain and distress in all animals. Animals deemed to be in distress will be removed from the study and euthanized by DLAM personnel, PI or her/his staff following consultation by LAM vet staff and the PI or his staff.

V.4.3.4. Location: (b)(6) USUHS.

V.4.3.5. Surgeon: PI, (b)(6)

V.4.3.6. Multiple Major Survival Operative Procedures: none

V.4.3.6.1. Procedures: N/A

V.4.3.6.2. Scientific Justification: N/A

V.4.4. Animal Manipulations:

V.4.4.1. Injections: Animals in the experiment #3 will receive three intravenous injections of miRNA antagomirs in the tail vein starting just after the injury, at 24 and 48 hour post injury. LNA Antagomirs (dose of 80 mg/kg) or miRNA mimics (50μg/mice) will be dissolved in PBS and a final volume of 50μl will be injected in the tail vein using a 26(1/2)-27 gauge needle. Control mice will receive only PBS in similar fashion.

V.4.4.2. Biosamples: Animals will be anesthetized as described in the section V.4.1.2.1. Blood samples will be collected from the animals by cardiac puncture while under anesthesia or by tail vein nick. Brains will be isolated after the perfusion (for histology studies) or after the removal of the head (for biochemical and miRNA studies). Other tissues such as spleen and liver will also be harvested and banked for future use is the necessity arises.

V.4.4.3. Adjuvants: none

V.4.4.4. Monoclonal Antibody (MAbs) Production: none

V.4.4.5. Animal Identification: Cage cards, temporary markers and ear punches will be used for animal identification.

V.4.4.6. Behavioral Studies:

V.4.4.7. Other Procedures: NA, no other procedures will be performed on the animals.

V.4.4.8. Tissue Sharing: none

V.4.5. Study Endpoint:

For experiment #1: 4 day post injury.

For experiment #2: 3hr, Day1, 3, 4, 7, 14 & 30 post injury.

For experiment #3: (a): 3days post injury.

(b): 7 day post injury.

(c): 3hr, Day 1, 4 and 7 post last treatment with the antagomir/mimic.

In addition to the above time points animals found to be under duress for reason other than the TBI such as, extensive bite marks and skin lesions from fighting, will be removed from the study and humanely euthanized.

V.4.6. Euthanasia:

Animals will be euthanized at the study end points according to the 2013 AVMA Guidelines on Euthanasia. Mice will be deeply anesthetized as described in section V 4.1.2.1. Deeply anesthetized mice (slow rhythmic breathing with no response to foot pinch) will be euthanized either by cervical dislocation, decapitation or exsanguination during perfusion.

Animals that become paralytic or sustain severe injury due to the creation of TBI will be removed from the study and will be euthanized by CO_2 inhalation by DLAM staff (explanation of this procedure has been adapted from the IACUC policy#13: Rodent Anesthesia with CO2 Prior to Euthanasia (09/08)). Without pre-charging the chamber, animal(s) will be placed in the chamber and 100% carbon dioxide will be introduced. A fill rate of higher than 20% of the chamber volume per minute with CO2, added to the existing air in the chamber will cause rapid unconsciousness with minimal distress to the animals. The expected time to unconsciousness and death is about 2 minutes. Mice will be observed for lack of breathing and pale eye color. If both signs are observed, CO2 will be allowed to flow for another 1 minute. Mice will be removed and will be verified for death after euthanasia and prior to disposal and cervical dislocation and bilateral thoracotomy may be used to ensure death.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol.

V.5.1.1. Study Room:

Building(s) (b)(6) Room Number(s) TBD

V.5.1.2.
Special Husbandry Provisions:

Food Restriction: Yes _____ No X

Fluid Restriction: Yes _____ No X

V.5.1.3. Exceptions: none _____ _____

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care: Mice will be checked on daily basis by the LAM veterinarian and PI staff. All the animals will be checked by the PI's staff twice a day for the first two days after the injury. After that animals will be checked once a day till the end of the study. Routine care such as plentiful chow, water and change of beds will be provided by the DLAM staff. Mice that show increased distress as determined by the veterinarian and described in section 4.3.3 will be removed from the study and will be humanely euthanized by the DLAM staff as described in the section V.4.6.

V.5.2.2. Emergency Veterinary Medical Care: All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: Except as indicated below, all animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents.

V.5.3.2. Enrichment Restrictions: None

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
TBI, anesthesia, and injections.	(b)(6)	PI, >30 years of experience with the mice model. PI in several IACUC rodent protocols at USUHS.	Rodent handling training class 2006, USUHS Investigator Training Course PI training 2003
Neurobehavioral and cognitive functions.		PI in IACUC mice protocols at USUHS evaluating the traumatic brain injury in rodent model.	USUHS Investigator Training Course. PI training 2005
Neurobehavioral and cognitive functions.		PI in several IACUC mice and rat protocols at USUHS evaluating neurobehavioral and cognitive functions in rodent model.	USUHS Investigator Training Course. PI training 2003
Neurobehavioral and cognitive functions.		PI in IACUC rat protocols at USUHS evaluating the neurobehavioral and	USUHS Investigator Training Course PI training 2003

		cognitive functions in rodent model.	
TBI, anesthesia, tail vein injections, perfusions/fixation, serum collection/ tissue harvest	(b)(6)	Research associate, > 10 years of experience with the mice model studying viral disease.	Rodent handling training class 2002 and 2006, USUHS Investigator Training Course (2006),
TBI, anesthesia, tail vein injections, perfusions/fixation, serum collection/ tissue harvest		Graduate student, 5 years of experience handling mice.	Rodent handling training class 2008, USUHS Investigator Training Course 2007,
TBI, anesthesia, injections, Neurobehavioral and cognitive functions.		Graduate student, 3 years of experience handling mice.	Rodent handling training class held on 08/17/2010, USUHS Investigator Training Course 08/17/2010
TBI, anesthesia, injections, Neurobehavioral and cognitive functions.		Graduate student, 3 years of experience handling mice	Rodent handling training class held on 08/17/2010, USUHS Investigator Training Course 08/17/2010
Neurobehavioral and cognitive functions.		3+ years of experience with mice	USUHS Investigator Training Course July 2009.
Neurobehavioral and cognitive functions.		3+ years of experience with mice	USUHS Investigator Training Course 2009.
Neurobehavioral and cognitive functions		2 years experience working with mice and rats	USUHS investigator training course in 2008
Weight drop injury and surgery		>3 year of experience in mice and rat TBI surgery related to her clinical practice as a microsurgeon.	USUHS Investigator Training Course on September 9, 2008. Rodent Handling and Procedural Techniques on September 24th, 2009.
Weight drop injury and surgury		15 years of experience in mice and rat	USUHS Investigator Training Courses on

	(b)(6)	handling, aseptic surgery, and rodent behavior testing	October 28, 2009. Rodent Handling and Procedural Techniques on November 19th, 2009.
TBI, anesthesia, Blood and tissue collection.		Graduate student, 5 years of experience handling mice.	Rodent handling training class 2008, USUHS Investigator Training Course 2007.

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

I. Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

X. PROTOCOL ABSTRACT:

A. Animal Protocol Number: (b)(6)

B. Animal Protocol Title: Role of MicroRNAs in Mild Traumatic Injury and Posttraumatic Stress Disorder: Identification of Biomarkers and Therapeutic Targets in Mice

C. Principal Investigator: (b)(6)

D. Performing Organization: USUHS, Bethesda, MD

E. Funding: DMRDP

F. Objective and Approach: The overall goal of this study is to determine the miRNA modulation in serum and brain post mTBI, to establish miRNAs as early diagnostic markers of mTBI and to determine use of miRNA mimics and antagomirs as therapeutic molecules for treating mTBI. To achieve the proposed objectives we will use a free falling weight drop model to create mild traumatic brain injury (mTBI) in mice. Mice brain and serum samples will be evaluated for changes in the miRNA expression patterns to establish the miRNA expression signature post mTBI. Once these miRNA expression signatures will be established we will determine the significantly modulated miRNAs and will test for their therapeutic potential. This will be achieved by restoring the normal expression pattern (as determined from the sham controls) of the significantly modulated miRNA by using miRNA antagomirs (for inhibiting miRNA) and or mimics (to restore the suppressed miRNA). This will determine the therapeutic potential of these miRNAs. Changes in the miRNA expression pattern will be correlated to the cognitive and neurological dysfunctions that are observed post mTBI. Also the treatment with the miRNA antagomirs and mimics will be correlated with cognitive and neurological behavior changes to establish any beneficial effect of these miRNA antogomirs or mimics.

G. Indexing Terms (Descriptors): mild traumatic brain injury, microRNA, biomarkers, mice, antagomirs and mimics.

MEMORANDUM FOR DR (b)(6) DEPARTMENT OF PATHOLOGY

SUBJECT: IACUC Approval of Protocol - Triennial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on May 7, 2014:

Animal Protocol Title: "Post-transcriptional Silencing of Venezuelan Equine Encephalitis Virus (VEEV) RNA for Developing an Antiviral Therapy against Exposure with VEEV, a Bio-warfare Agent (Mice)"

USUHS Protocol Number: (b)(6)

Expiration Date: May 6, 2017

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. NON-TECHNICAL SYNOPSIS: Alphaviruses have caused widespread outbreaks resulting in significant morbidity in humans and mortality in equines. Currently, there is no safe and effective vaccine or a therapeutic drug against the two important New and Old World alphaviruses, Venezuelan equine encephalitis virus (VEEV) and Chikungunya virus (CHIKV) respectively. The proposed study addresses the research gap that exists to develop effective anti-alphavirus therapeutic drugs. In our earlier studies, we had tested small interfering RNAs (siRNA) for their efficacy against VEEV replication. Two lead siRNA molecules were selected based on the experiments in the cell culture. One hurdle of using the siRNA duplexes in the animals is that these molecules elicit innate immune response of the host after administration. A chemical modification of the siRNA, however, attenuates this property of siRNA. Another problem of using the siRNA in animals is a very short life of the siRNA in the blood circulation. This is addressed by encapsulation of complexing of siRNA molecules to lipid based vesicles that protect the siRNA from the harsh degrading environment of the blood. In this study, we will evaluate the immunostimulatory activity of the non-modified and 2`O methyl modified siRNA duplexes in mice to establish the loss of immunomodulatory activity of modified siRNAs. SiRNA duplexes will be injected either encapsulated/complexed with PEGylated DOTAP vesicles or without any encapsulation in the tail vein of mice. Serum will be isolated from the blood to test for the innate immune response markers. This knowledge will provide information regarding potential use of the modified siRNAs as anti-alphavirus therapy agent. In the second objective, we will evaluate the miRNA changes in the blood of the alphavirus infected mice at the non-symptomatic stages of infection. The miRNA expression will then be analyzed for their use as non-symptomatic and/or prognostic marker of alphavirus exposure. The proposed study, therefore, will address two main research gaps i.e. developing an effective anti-alphavirus therapeutic drugs and diagnostic markers for alphavirus exposure and prognosis.

II. BACKGROUND:

II.1. Background:

Venezuelan Equine Encephalitis Virus (VEEV): VEEV is a New World alphavirus classified under family Togaviridae [Schlesinger 1998]. Genome of 11.7kb single strand message RNA is packed within an icosahedral protein capsid composed of repeated copies of protein C [Strauss et al 1969]. 5' capped two third genome encodes for non-structural polyproteins nsP1-4 (200-300kDa), including the precursor of RNA polymerase required for message amplification. The terminal one third of the genome encodes for structural proteins that are translated from a subgenomic mRNA copy (26S RNA) of full lengths minus strand intermediate. The genomic replication strategy involves a minus strand replicative intermediate and is similar to the strategies used by Picornaviruses, Flaviviruses and Calciviruses [Schlesinger 1998, Flint et al 1969]. Viral RNA dependent RNA polymerase (rdrp) is encoded by the nsp-4 gene of the virus and is central to viral replication in the cells. In this study VEEV rdrp will be targeted using the anti-sense RNA technology.

TC83, a live attenuated strain of VEEV will be used in the proposed experiments. TC83 is highly attenuated and have been **excluded from select agent regulations**. Because of the low level of pathogenicity, this strain can be **safely handled under BSL-2 conditions without vaccination or additional personal protective equipment** (Page 243; Appendix B: BMBL5-section VIIIf).

Chikungunya virus (CHIKV): CHIKV is an Old World alphavirus in the family Togaviridae. Genome organization of CHIKV is same as that of the VEEV with 4 non-structural genes nsp1-4 and 5 structural proteins capsid, 6K, and E1-3. Similar to VEEV Viral RNA dependent RNA polymerase (rdrp) is encoded by the nsp-4 gene of the virus and is central to viral replication and in this study CHIKV rdrp will be targeted using the anti-sense RNA technology.

CHIKV181/25, which is a live attenuated strain of CHIKV, will be used in this study. The United States army had developed and tested CHIKV181/25 for vaccine application. CHIKV181/25 demonstrated an excellent immunogenic profile in Phase II clinical trials (98% seroconversion (Edelman et al 2000). CHIKV is **not a** CDC select agent. **CHIKV181/25 strain can be safely handled under BSL-2 conditions** (see attached document, Doc-2: BMBL5-section VIIIf; Page 235 and Doc-3).

Antiviral potential of RNA Interference Technology: RNA interference (RNAi) or post transcriptional gene silencing (PTGS) was first discovered in plants and later successfully tested in *Drosophila*, *Caenorhabditis elegans*, mammalian cells and against viruses [Bann and Puri 2004]. PTGS is a phenomenon where introduction of double stranded RNA (dsRNA) in the cell system results in a target specific degradation of mRNA resulting in gene silencing. Synthetic short 21-nt RNA duplexes (siRNA) are introduced into the cell. Once inside the cell, siRNAs associate with the RNA –induced silencing complex (RISC), which catalyzes the degradation of complementary cellular mRNA in a highly specific manner. As a result gene expression is reduced both at mRNA and protein level- the hallmark of RNAi. This technique has tremendous potential to be used as a therapeutic strategy in treating the disease involving altered gene expression [Forte et al 2005, Stein et al 1999, Zentilin et al 2004, Xia et al 2002]. Human immunodeficiency virus (HIV), polio virus, hepatitis B virus, hepatitis C virus , West Nile virus, severe acute respiratory syndrome associated coronavirus (SARS-CoV), foot and mouth disease (FMD) virus and Influenza virus (including pandemic

subtypes H5 and H7 and adenovirus infections) have been inhibited both *in vitro* and *in vivo* using virus specific siRNAs [Jacque et al 2002, Ge 2003, Hui et al 2004, Tompskins et al 2004, Wang et al 2004, Giladi et al 2003, Klein et al 2003, Chen et al 2004, Mohanpatra et al 2005, Kahana et al 2004, Sanchez-Vargas et al 2004, Kaliq et al 2010, Eckstein et al 2010). We and others have also shown that siRNA and miRNA targeting the viral nsp4 gene can inhibit VEEV replication *in vitro* [Bhomia et al 2013, O'Brien 2007]. These results suggest that RNA interference may provide a viable therapeutic approach to treat viral infection. Viral RNA polymerase is our target of interest as it is critical for the amplification of VEE viral genome.

Modified SiRNA and Immune Response: Native siRNA duplex when administered in the host is treated as foreign moiety and host demonstrate an innate immune response to the siRNA duplex. 2'O'Me modification of the U and G residues in the sense strand of the siRNA duplex does not interfere with the siRNA efficacy, however, inhibit the innate immune response against the siRNA even when encapsulated with in the SNALPs [Judge et al 2006, Ursic-Bedoya et al 2014].

Encapsulation of siRNA: Naked siRNA show rapid degradation in the blood with in 4hr after injection. However, lipid encapsulated siRNA are protected for more than 24hr at 37^0C. is small nucleic acid lipid particle (SNALP)/lipid-nano particle (LNP) given via systemic administration has been shown to accumulate in the liver and have deliver siRNA to the liver to treat hepatic carcinoma, and in one study a modified SNALP was used to treat dermal carcinoma. Systemically administered SNALP encapsulated siRNA has also been shown to inhibit EBOLA and Marbug infection. Liver is the primary site of virus replication or both EBOLA and Marbug virus [Geisbert et al 2006, Ursic-Bedoya et al 2014].

DOTAP (cationic lipid) liposomes have been used to deliver the siRNA/peptide to dendritic cells after sub-cutaneous injection. These DCs then migrate to the draining lymph nodes (DLN). Particle size of DOTAP based liposomes have been described to be in the range of 100-267 nm. Other studies (non-DOTAP based) have shown that desirable size for lymph node specific delivery of drug range from 20-80nm. However, DOTAP based liposomes have been repeatedly shown to sequester in the DLNs. Further, DOTAP based cationic liposomes have been found to be less toxic than the lipofectamine/SiPORT NeoFX/SiPORT amine based transfection reagents. Incorporation of DOTAP liposomes with DSPE-PEG2000; enhances liposome uptake by resident antigen-presenting cells, accelerates the drainage of DOTAP liposomes into draining LNs, increases deeper distribution of liposomes in lymph nodes and spleen, and prolong their LN retention. DOTAP encapsulated siRNA (non-modified) induce type I and II interferon. DOTAP by itself also act as adjuvant and facilitate CD8+ T cell induction. Cholesterol:DOTAP based cationic lipid liposomes have been used to inhibit HBV and HCV infections *in-vivo*.

MicroRNA and Biomarker: Biomarker is "a measurable substance in an organism whose presence is indicative of some phenomenon such as disease, infection, or environmental exposure". MiRNAs have emerged as novel diagnostic biomarkers for various diseases. MiRNA changes in the serum have been suggested as a potential

marker of disease and injury [Wahid et al 2010]. Earler we have also described the microRNA changes in the brains of mice infected with VEEV [Bhomia et al 2010].

II.2. Literature Search for Duplication:

II.2.1. Literature Source(s) Searched: Medline, Federal Research in Progress, and Defense Technical Information Center and BRD

II.2.2. Date of Search: ~~March~~ April 28~~20~~, 2014.

II.2.3. Period of Search: 1950-2014

II.2.4. Key Words and Search Strategy: Venezuelan equine encephalitis, Venezuelan equine encephalomyelitis, VEEV, CHIKV, Chikungunya virus, siRNA, ~~antiviral treatment~~, innate immune response, 2`O Methyl modification, modified siRNAs, ~~therapy, therapeutic,~~ mice, EMCV, alphavirus, biomarkers, miRNA and biomarkers. One or combination of these keywords was used.

II.2.5. Results of Search:

VEEV/Venezuelan equine encephalitis/Venezuelan equine encephalitis virus + siRNA: Five results: 2 relevant to siRNAs: One published by (b)(6) and one published by another groups; both deal with the anti-VEEV siRNA in-vitro work only. No work with modified siRNA and effect on immunomodulation.

Chikungunya virus+ siRNA: 10 results: One deal with host siRNA response to chikungunya virus; 3 deals with anti-CHIKV activity of siRNAs. None discuss evaluation of modified siRNA against Chikungunya virus and or evaluation of immune modulation by native and chemically modified siRNA sequences.

2`O Methyl modification + siRNAs: 25 results: Non-modified siRNA induces innate immune response via TLR7 activation; 2`O Methyl modification in G and U residues of the siRNAs inhibit host innate immune response; 2`O Methyl modification of G and U residue in sense strand does not effect the anti-gene activity of siRNAs duplex, however, modification in anti-sense strand intereferes with the anti-gene activity of siRNAs. Ebola virus, Marbug virus, hepatitis virus and various host cell genes have been successfully targeted using the 2`O Methyl modified siRNAs.

MicroRNA and VEEV/Venezuelan equine encephalitis virus : 2 results, both from (b)(6) (b)(6) one describe anti-VEEV activity of miRNAs and other described host miRNA response to VEEV in brain. No results describing microRNA as VEEV infection biomarker.

MicroRNA + alphavirus: 10 results including above 2 from (b)(6) Alphaviruses have not been shown to encode for microRNAs. Sindbis virus, eastern equine encephalitis virus and semliki forest virus modulate host miRNA responses in various cell lines. Alphavirus based replicon particles have been utilized to express miRNAs in host cells. No study was reposrted to utilize microRNA as marker of alphavirus infection. No study has proposed usage of host microRNA response to alphaviruses as survelliance biomarker at non-symptomatic stages of infection.

EMCV/ encephalomyocarditis virus + microRNA: 4 results: 2 are relevant to EMCV and microRNA research which deals with mechanistic study regarding the miRNA mediated translation inhibition. EMCV internal ribosome entry sites (IRESes) was used to

describe sensitivity and resistant to miRNA mediated inhibition of gene translation. O study was found to describe host miRNA response to EMCV infection in serum.
MicroRNA + biomarker: 3076 results.
MicroRNA + alphavirus + biomarker: No results. There are two research publications describing the use of siRNA and miRNA for VEEV replication inhibition. One of these is from (b)(6) describing the use of anti-VEEV siRNA *in-vitro* (b)(6),(b)(4) Other paper describes the use of siRNAs to inhibit multiple strains of VEEV *in vitro* [O'Brien 2007]. No literature was found describing use of siRNA mediated interference to inhibit VEEV replication in animals. Ten publications were found to describe microRNA in response to alphaviruses. MicroRNA modulation in response to alphavirus infections have been described however, no literature was found to describe use of microRNA as biomarker of alphavirus infection.

III. **OBJECTIVE\HYPOTHESIS**: The objectives of this proposal are:

1) To evaluate the loss of immunomodulatory activity of 2'O Methyl modified anti-VEEV and CHIKV siRNA duplexes.

2) To evaluate the blood miRNA expression in the mice post alphavirus exposure.

The hypotheses of this project are:

1. *2'O Methyl modified siRNA duplexes will not elicit non-specific innate immune response in the host that is otherwise seen with the non-modified siRNA duplexes.* Non-specific immune response may itself have some protective effect against the alphaviruses and therefore, will hamper the conclusion of any effect by siRNA duplexes. The long term goal of the project is to identify the siRNA duplexes that will inhibit the VEEV replication in the host and any non-specific inhibitory effect will interfere with such interpretation.

2. *Circulatory miRNA expression profile of the host will change after alphavirus exposure. Specific changes in the miRNA expression may predict the type of alphaviral infection.* Since non-symptomatic individuals may act as carriers, a diagnostic marker may help in identifying such individuals and introduction of preventive medical measures can be employed.

IV. **MILITARY RELEVANCE**: VEEV is a CDC category B agent. VEEV has been developed as a biowarfare agent and is infectious through aerosol distribution. Both civilians and soldiers are vulnerable to VEEV exposure as VEEV is endemic in United States and can be potentially used as bio-terrorist agent. Current experimental vaccine is not licensed by FDA and has many non-responders (approximately 20%). Similarly CHIKV is an emerging pathogen that has caused very large outbreaks with significant morbidity in humans. Though CHIKV is not endemic in the continental USA now, states such as Florida with tropical climates and *Ades albopictus* as endemic mosquito population are at high risk of CHIKV spread. Currently there is no antiviral therapy for either VEEV or CHIKV infection. Testing novel strategies like RNA interference may

help in developing treatment for VEEV and CHIKV infection for both civilians and armed forces.

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures:

Two siRNAs targeting VEE nsp4 mRNA and the scrambled siRNA that will be used are as following:

1. **Veev siRNA 1**
   Sense: 5'GCUGCGCAGCUUUCCAAAGUU3'
   Antisense: 5'CUUUGGAAAGCUGCGCAGCUU3'

2. **Veev siRNA 2**
   Sense: 5'AAAGAAAUUGCAACGUCACUU3'
   Antisense: 5'GUGACGUUGCAAUUUCUUUUU3'

Two siRNA targeting the CHIKV nsp4 region of the viral genome will be identified in the *in-vitro* experiments

3. **CHIKV siRNA 1**
   Sequence: to be determined (TBD)

4. **CHIKV siRNA 2**
   Sequence: TBD

5. **ScambledScrambled RNA sequence** 4G 7T 4C 6A (21 nt)
   5' TAGAGCGTAT TACGTATACC T 3'
   Only 76% identical to 2 oryza sativa (rice) genes AP006523 AND AP008208

V.1.1. Experiment 1: To evaluate the loss of immunomodulatory activity of 2'O Methyl modified siRNA duplexes in mice.

SiRNA Formulations:

1.) Without encapsulation: HPLC purified lyophilized siRNA re-suspended in nuclease free autoclaved PBS.

2.) With PEG-DOTAP encapsulation/complex: HPLC purified lyophilized siRNA will be complexed with PEG-DOTAP liposomes in our collaborators laboratory (Dr. (b)(6) NCI, Frederick, MD).

Doses: siRNA dose of 2.5mg/kg body weight will be administered vial the tail vein. This dose is based on the available data in the literature where 2 to 3mg/kg body weight of siRNA has been successfully used in animal studies [Zimmerman et al 2006].

Mice: Male Balb/c, 6 – 8 week-old, 12-16 grams mice will be used in the study.

Sample collection: Blood will be collected at 6hr post siRNA administration via the cardiac puncture. Animal will be deeply anesthetized using cylinderized CO_2 and will be closely observed for respiration to cease; after a period of 10 seconds with no breaths, thoracic cavity will be opened to expose the heart and blood (700-900 µl) will be collected using a 26-1/2 gauge needle mounted on a 1ml syringe. After blood collection cervical dislocation will be performed to ensure the death of animal. Serum will be isolated and tested for an array of innate immune inflammatory cytokines (SABioscience, Qiagen, Frederick, MD).

Animal housing: Animals will be housed in LAM. For this experiment BSL1 housing will be needed for the animals.

Groups	No. of Animals	# iteration/group	Total animals	Pain Category
Control				
Naive	6	2	12	C
Saline	6	2	12	C
Empty PEG-DOTAP Liposomes	6	2	12	C
Non-encapsulated siRNAs				
Veev siRNA 1	6	2	12	C
Veev siRNA 2	6	2	12	C
Chikv siRNA 1	6	2	12	C
Chikv siRNA 2	6	2	12	C
Scrambled siRNA	6	2	12	C
PEG-DOTAP Encapsulated/Complexed siRNAs				
PEG-DOTAP Veev siRNA 1	6	2	12	C
PEG-DOTAP Veev siRNA 2	6	2	12	C
PEG-DOTAP Chikv siRNA 1	6	2	12	C
PEG-DOTAP Chikv siRNA 2	6	2	12	C
PEG-DOTAP Scrambled siRNA	6	2	12	C
Training				
Tail vein injection training using sterile saline solution	20	1	20	C

Total animas required

[{(6 animals /group x 13 groups x 2 iterations/group)} = 156] + [Training animals (20 animals x 1 iteration)=20] = 176

Animals in pain category "C"= ~~156~~176

Experiment 1: In the first experiment none of the mice (n=156) are expected to experience any disease as they will either receive saline or siRNA injections and therefore, are kept under category C.

As tail vein injections are not routinely done in PI's laboratory, a group of 20 mice has been added as training animals. Two personnel from the PI's laboratory will train for tail vein injections using 10 animals each.

V.1.2. Experiment 2: To evaluate the blood miRNA expression in mice post alphavirus exposure.

Mice: Male Balb/c and C57BL/6J, 6 – 8 week-old, 12-16 grams mice will be used in the study.

Virus Infections: TC83, CHIKV181/25 and Encephalomayocarditis virus (EMCV) will be used in this experiment. 1000 PFU of the virus will be injected sub-cutaneous at the back of animal neck. Time of injection will be considered 0 hr.

Sample collection: Blood will be collected at 12hr, 24hr, 48hr and 72hr post infection with the respective viruses. Blood will be collected via the terminal cardiac puncture, therefore, different set of mice (n=6/group) will be used at each of the above indicated time points. at which time animal will be euthanized. At each time point the aanimals will be deeply anesthetized using cylinderized CO_2 and will be closely observed for respiration to cease; after a period of 10 seconds with no breaths, thoracic cavity will be opened to expose the heart and blood (700-900 µl) will be collected using a 26-1/2 gauge needle mounted on a 1ml syringe.will be deeply anesthetized using cylinderized CO_2 and blood will be collected via cardiac puncture. After blood collection at each time point, cervical dislocation will be performed to ensure the death of animal. No repeat cardiac puncture will be performed on the same mouse.

Animal housing: Animals will be housed in LAM. All injection with the viruses will be done in (b)(6) in biosafety cabinet. Animals will return to LAM after the injection procedure and will be housed in LAM for the remainder of the experiment. After virus injections, animals will need BSL-2 housing conditions for the rest of the experiment.

Groups	No. of Animals	# of time points	# iteration/group	Total animals	Pain Category
Uninfected control groups:					
Naïve (Balb/c)	6	4	2	48	C
Saline (Balb/c)	6	4	2	48	C
Naïve (C57BL/6J)	6	4	2	48	C
Saline (C57BL/6J)	6	4	2	48	C
Non-alphavirus infection control group:					
EMCV (Balb/c)	6	4	2	48	E
Alphavirus infection test groups:					

TC83 (Balb/c)	6	4	2	48	~~D~~C
CHIKV181/25 (C57BL/6J)	6	4	2	48	~~D~~C

Total animals required

Balb/c = [6 animals /group x 4 groups x 4 time points x 2 iterations/group] = 192.

C57BL/6J = [6 animals /group x 3 groups x 4 time points x 2 iterations/group] = 144.

Animals in Pain Category C= 288

Animals in Pain Category E= 48

Experiment 2: 192 animals in experiment 2 will either be under naïve group (n=96) or receive saline injection (sub cutaneous) (n=96). Therefore, these animals have been kept under category C.

Two groups will receive live TC83 (n=48) or CHIKV181/25 (n=48) via subcutaneous injection. These two virus strains are live attenuated vaccine strains of the VEEV and CHIKV respectively, and do not cause disease in mice. Therefore, these mice have also been placed under category C.

One group under non-alphavirus control will receive EMCV infection. EMCV causes full blown disease and in our earlier experience cause 100% mortality in mice in 5-6 days post infection. The experiment will be terminated at 3 day post infection and therefore, animals should not suffer with the full blown encephalitis. However, since no analgesic or anti-pyretic drugs will be used, there animals have been kept under category E.

V.2. Data Analysis: The statistical framework for designing experiment and estimating the sample size considers the magnitude of the effect in the control group, the "additional effect" (over and above the control effect) expected in the treatment group, statistical power to detect this desired difference between the treatment and control, and the alpha level. The laboratory and clinical experiments are designed with a statistical power of at least 80%. The alpha level is traditionally set at 5%. To observe a treatment effect of 60% enhancement with 80% power and 5% alpha level a sample size of 6 mice per group would be necessary and therefore 6 mice per group were chosen. To achieve maximum power, animals are randomly allocated to treatment and control groups in equal numbers. Since several variables are measured in each experiment, analyses of all variables at 5% alpha level will result in inflation of P-value. This inflated P-value may increase the probability of false positive result. Therefore, to maintain the experiment wise alpha level of 5% and to control for multiple comparisons in the experiment, we will adjust the P- values using statistical procedures of Tukey's post hoc multiple comparison. Means of quantitative variables will be compared across treatments and time points using 2-way analysis of variance (ANOVA) followed by Tukey's post hoc multiple comparisons. This will minimize the likelihood of any false positive results.

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered: The potency of siRNA to silence/inhibit VEEV replication have been evaluated *in-vitro* and two siRNA duplex were selected out of seven siRNA sequences that were tested. Similar approach will be taken for the anti-CHIKV siRNA and two lead molecules will be selected for *in-vivo* testing. Similarly, for serum miRNA evaluation study, miRNA changes against the CHIKV 181/25 and TC-83 strains were evaluated to determine that viral infection indeed induced differential miRNA expression. However, *in-vivo* environment is more variable as compared to the *in-vitro* cultures and thus *in-vivo* miRNA expression changes will be evaluated in mice.

V.3.2. Animal Model and Species Justification:

Experiment 1:

> **Balb/c mice**: Aim of the study is to evaluate the innate immune response of the mice against the siRNA molecules. Balb/c mice are immunocompetent mice and have been used in similar studies to evaluate the immunomodulatory effect of siRNA [Robbins et al 2007].

Experiment 2:

> **Balb/c mice**: VEEV is endemic in rodents [Day et 1996, Bigler et al 1974] VEE infection in mice induces the bi-phasic disease observed in humans [Jackson A et al 1991, Grieder et al 1995]. Because mice mimic the biphasic disease observed in the humans it is a model of choice to study VEEV pathogenesis. Several murine strains have been described as models such as BALB/c, C3H/Hen and Swiss CD-1 [Paessler et al 2003, Schoneboom et al 2000, Hart et al 1997, Grieder et al 1995, Reynolds et al 1980]. Both BALB/c and CD-1 mice initiate humoral antibody response following subcutaneous vaccination with TC-83 vaccine. Balb/c has also been used to study EMCV infection and prophylaxis studies [Jeoung et al 2011]. Therefore, balb/c will be used to study miRNA expression following TC83 (VEEV) and EMCV infection.
>
> **C57BL/6J mice**: CHIKV infection in adult C57BL/6J mice has been described to mimic the self-limiting arthritis, tenosynovitis, and myositis seen in humans [Gardner et al 2010]. This model is useful in studying the pathogenesis and host responses. Therefore, C57BL/6J mice will be used to study miRNA expression following CHIKV181/25 (CHIKV) infection.

V.3.3. Laboratory Animals

	Species #1	Species #2
V.3.3.1. Genus & Species:	Mouse (mus musculus)	Mouse (mus musulus)
V.3.3.2. Strain/Stock:	Balb/c	C57BL/6J

V.3.3.3. Source/Vendor:	(b)(4)	
V.3.3.4. Age:	6-8 weeks	6-8 weeks
V.3.3.5. Weight:	10-12 gm	10-12gm
V.3.3.6. Sex:	Male	Male
V.3.3.7. Special Considerations:	All animals will be free of common laboratory pathogens, such as MHV.	

V.3.4. Number of Animals Required (by Species): ~~348~~ ——— 368 144

V.3.5. Refinement, Reduction, Replacement (3 Rs):

V.3.5.1. Refinement: *In vitro* experiment models do not replicate the comprehensive host responses to either siRNAs or alphaviruses. We are using the lowest animal in the phylogenetic scale that serves well as an animal model to study alphavirus pathogenesis. Experiments are designed to use noninfectious strain of alphaviruses, thereby reducing the morbidity associated with the alphavirus infection. Further, the study end points are designed to be in the non-symptomatic stage of infection, which will further reduce the morbidity in the animals.

V.3.5.2. Reduction: The number of animals to be used is the minimum number of animals needed to achieve scientifically sound conclusions for the experimental objectives. In order to reduce the number of animals in the study, we tested the efficacy of siRNA to inhibit VEEV replication in cell culture. Only the most effective siRNA duplexes will be used in the proposed animal studies. For biomarker studies, we have confirmed modulation of miRNAs post alpahvirus infection *in vitro*, which has shown differential modulation of miRNAs against TC83 and CHIKV181/25, thereby establishing the proof of concept before beginning the animal experiments.

V.3.5.3. Replacement: We have extensively researched for an alternative to the animal model for studying immune and miRNA modulation by siRNA and alphaviruses, respectively. Due to the nature of the study, *in vitro* experiments will not yield the desired data and animal experiments are required to achieve the successful completion of the study.

V.4. Technical Methods:

V.4.1. Pain / Distress Assessment:

V.4.1.1. APHIS Form 7023 Information:

V.4.1.1.1. Number of Animals:

	Species #1	Species #2
V.4.1.1.1.1. **Column C:**	~~300~~320	144
V.4.1.1.1.2. **Column D:**	0	0
V.4.1.1.1.3. **Column E:**	48	0

Experiment 1: In the first experiment none of the mice (n=~~156~~176) are expected to experience any disease as they will either receive saline or siRNA injections and therefore, are kept under category C.

Experiment 2: 192 animals in experiment 2 will either be under naïve group (n=96) or receive saline injection (sub cutaneous) (n=96). Therefore, these animals have been kept under category C.

Two groups will receive live TC83 (n=48) or CHIKV181/25 (n=48) via subcutaneous injection. These two virus strains are live attenuated vaccine strains of the VEEV and CHIKV respectively, and do not cause disease in mice. Therefore, these mice have also been placed under category C.

One group under non-alphavirus control will receive EMCV infection. EMCV causes full blown disease and in our earlier experience cause 100% mortality in mice in 5-6 days post infection. The experiment will be terminated at 3 day post infection and therefore, animals should not suffer with the full blown encephalitis. However, since no analgesic or anti-pyretic drugs will be used, there animals have been kept under category E.

V.4.1.2. Pain Relief / Prevention: None

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization: None

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions: Animals will be kept at the animal housing facility of LAM for 5-7 days prior to the start of experiments and will receive standard care. Since siRNA duplexes are not toxic by themselves we do not anticipate any adverse effect of siRNA injection in the tail vein or in the brain. We do anticipate a transient localized discomfort due to tail vein injection. Post inoculation, animals will be monitored for any distress. If animal is found to be distressed post siRNA injection, animal will be humanely euthanized. TC83 and CHIKV181/25 are attenuated strain and does not cause disease in mice therefore we do not anticipate any adverse reaction to these virus infections. EMCV causes disease in mice; however, study end point of 3 day post infection is before the symptoms of encephalitis develop. Animals will be humanely euthanized post EMCV injection if any of the following symptoms is observed before the study end point; excitability to sound, more than 20% body weight loss, paralysis or non-responsiveness to touch. A momentary discomfort is expected at the time of virus injections.

V.4.1.2.3. Paralytics: None

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures:

V.4.1.3.1. Sources Searched: PubMed (National Library of Medicine)

V.4.1.3.2. Date of Search: March 26 2014

V.4.1.3.3. Period of Search: 1985-2014

V.4.1.3.4. Key Words of Search: Individual and combination of following words was used; pain, analgesic, mice, alternative, procedure, justification, VEEV, EMCV, CHIKV181/25.

V.4.1.3.5. Results of Search: In regards to alternative to animals for determining loss of immune activity of modified siRNAs, peripheral blood mononuclear cells (PBMCs) have been successfully used. PBMCs demonstrate differential gene expression response to non-modified and 2' O Methyl modified siRNAs. However, to determine the complete host innate immune response, final screening for immune stimulation has been done *in vivo*.

In regards to the alternative to study host miRNA response to alphavirus exposure several models of VEEV infection such as guinea pig, mouse, hamsters and non-human primates. Of these, the mouse model mimics the human biphasic infection of VEEV and the arthralgia of CHIV infection. No alternatives to animal model were found that can comprehensively replicate the host response to alphavirus infection/exposure. Search for EMCV animal model returned around 337 published articles. These describe the use of mouse model for studying EMCV pathogenesis and also for vaccine evaluation. No alternatives to evaluation of host response to EMCV infection other than animal models were found.

Animal model alternatives: Venezuelan equine encephalitis virus + alternate + animal model: 1 result describing adaptation and evolution of VEEV in the mosquitoes and obligate hosts. No *in-vitro* alternative models to mouse and monkey models of VEEV pathogenesis were found. Venezuelan equine encephalitis + animal model + alternative: 4 results; none relevant to alternatives to animal model. Chikungunya virus + animal models + alternatives: No result. EMCV + animal model + alternatives: No results.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification: Majority of the animals in the proposed study are either under category C or D. Only one group of animals that may develop disease is the EMCV group in experiment # 2. The main objective of the exp#2 is to determine miRNA expression changes in the blood of mouse exposed to alphaviruses. EMCV is included as a non-alphavirus control group to increase the sensitivity of the miRNA correlations to alphavirus exposure. EMCV cause disease in mice with a mean survival time of 5-6 days. The end point of the experiment is day 3 post infection, therefore, it is highly unlikely that these mice will experience full blown EMCV disease. However, out of an abundance of caution, these mice have been placed under category E.

No analgesics will be used in the study due to the concern that analgesics (NSAIDS such as aspirin, cyclooxygenase 2 blocker, ibuprofen, Sildenafil, acetaminophen *etc.*) results in modulation of gene expression in the host. Buprenorphine is a mu-opiod

receptor partial agonist and kappa-opiod receptor agonist (Sanchez et al 2008). Detailed molecular mechanism of Buprenorphine action is not fully understood. It has been shown to induce dose dependent effect on myelin associated glycoprotein expression and glycosylation. Buprenorphine engages both mu-opiod receptor and nociceptin/orphanin FQ receptor (NOP receptor) in the oligodendrocytes presumably via modulating activity of Src-family tyrosine kinase Fyn (Sanchez et al 2008, Eschenroeder eta l 2012). Buprenorphine also induce low level of interleukin 4 response in T lymphocytes and has also been reported to induce apoptosis in NG108-15 nerve cells (Borner et al 2013, Kugawa et al 1998). Studies on molecular mechanism of Buprenorphine action are limited. Therefore, it is also not know if buprenorphine treatment will affect the microRNA expression in mice. The main objective of the study is to evaluate host miRNA expression in blood so as to use that information as diagnostic marker of alphavirus exposure. It has been well establish that microRNA modulate the gene expression by acting upstream of the mRNA translation step. Since the analgesics modulate gene expression it will be safe to assume that microRNA expression may also be modulated by these analgesics. In fact analgesic, acetaminophen is known to modulate the miRNA expression in the serum (Wang et al 2009). Therefore, use of analgesic may interfere with the outcome of the proposed study i.e. identification of microRNA in serum post alphavirus exposure and their establishment as biomarkers, in a way that may result in false identification of miRNAs or inaccurate correlation of miRNA with alpahvirus exposure.

Pain + Venezuelan equine encephalitis virus: 4 results: All described VEEV infection in human population. Venezuelan equine encephalitis virus + analgesics: 6 results: None of the six results describe use and effect of analgesic on VEEV pathogenesis and symptoms. MicroRNA + analgesic drugs: 210 results; microRNA + NSAIDS: 105 results; microRNA and opioid receptors: 18 results. Morphine, δ-Opioid receptor activation, cocain, μ-opioid receptor, opioid tolerance and mu-Opioid receptor agonists, have been shown to modulate or modulated by microRNAs. MicroRNAs have also been shown to play role in chronic pain development by regulating nociception and were proposed as biomarker of pain for better patient stratification. Anti-inflammatory molecules such as resveratrol, EGCG and curcumin have also been reported to modulate miRNA expression.

V.4.2. Prolonged Restraint: N/A

V.4.3. Surgery: N/A

V.4.3.1. Pre-surgical Provisions:

V.4.3.2. Procedure:

V.4.3.3. Post-surgical Provisions:

V.4.3.4. Location:

V.4.3.5. Surgeon:

V.4.3.6. Multiple Major Survival Operative Procedures:

V.4.3.6.1. Procedures:

V.4.3.6.2. Scientific Justification:

V.4.4. Animal Manipulations:

V.4.4.1. Injections:

- Experiment # 1: siRNA duplexes with or without encapsulation will be dissolved in nuclease free sterile water and will be injected one time in tail vein using 30 gauge needle in a maximum volume of 25µl.

- Experiment # 2: Virus will be suspended in sterile 1XPBS and will be inoculated subcutaneously using 26 gauage needle in maximum volume of 100 µl dorsally at the back of neck of the mouse.

V.4.4.2. Biosamples:

- Experiment # 1: Blood will be collected at 6hr post siRNA inoculation via the cardiac puncture.

- Experiment # 2: Blood will be collected at 12hr, 24hr, 48hr and 72hr post infection via cardiac puncture.

V.4.4.3. Adjuvants: None

V.4.4.4. Monoclonal Antibody (MAbs) Production: None

V.4.4.5. Animal Identification: Cage cards

V.4.4.6. Behavioral Studies: N/A

V.4.4.7. Other Procedures: N/A

V.4.4.8. Tissue Sharing: N/A

V.4.5. Study Endpoint:

- Experiment # 1: 6hr post inoculation of siRNA duplexes at which time animals will be euthanized and blood will be collected via cardiac puncture.

- Experiment # 2: 12hr, 24hr, 48hr and 72hr post infection at which time animals will be euthanized and blood will be collected via cardiac puncture.
  For animals infected with EMCV, maximum time animal will be held is 72hr post infection. However, if symptoms such as ruffled fur, lethargy, sensitivity to sound, shivering, and paralysis are observed in infected animals, animals will be euthanized and removed from the study.

V.4.6. Euthanasia: Animals will be euthanized at the study end points according to the 2013 AVMA Guidelines on Euthanasia. For terminal blood collection via cardiac puncture animals will be sedated using cylinderized CO_2, after the blood collection cervical dislocation will be done to ensure the death of animal. All euthanasia procedures will be performed in LAM. PI or (b)(6) and authorized LAM personnel will coordinate and will be responsible for the euthanasia. Disposal of BSL-2 carcasses will be handled in the manner described in VII Biohazard/Safety.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol. Animals under experiment #1 will be housed in BSL-1 conditions. Animals under experiment # 2 will be housed in BSL-2 housing conditions.

V.5.1.1. Study Room: LAM
Building(s) (b)(6) Room Number(s) (b)(6)

V.5.1.2. Special Husbandry Provisions:

Food Restriction:	Yes	_____	No	X
Fluid Restriction:	Yes		No	X

V.5.1.3. Exceptions: _____ _____

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care: Animals will be monitored for health, humane treatment, and husbandry considerations, twice daily by LAM veterinary technicians during routine weekday rounds and at least once on weekends/holidays. This is in addition to, and not in place of, the monitoring that is done by the principal investigator and their staff. In the event of a debilitating illness or adverse reaction, the decision to treat or euthanize an animal will be made by either the veterinarian and/or principal investigator. If mice are found showing increased distress such as ruffled fur, hunched posture, weight loss and lethargy, animals will be removed from the study and will be humanely euthanized as described in the section V.4.6.

V.5.2.2. Emergency Veterinary Medical Care: All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays. In the case of an emergency health problem, if the responsible person (e.g. PI) is not available or if the investigator and veterinary staff cannot reach consensus on treatment, the veterinarian has the authority to treat the animal, remove it from the experiment, institute appropriate measures to relieve severe pain or distress, or perform euthanasia if necessary.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: Except as indicated below, all animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents.

V.5.3.2. Enrichment Restrictions:

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
Injections, euthanasia, blood collection.	(b)(6)	PI, >30 years of experience with the mice model. PI in several IACUC rodent protocols at USUHS.	Rodent handling training class 2006, USUHS Investigator Training Course PI training 2003
Tail vein and sub cutaneous injections, injections, euthanasia, blood collection		Research associate, > 10 years of experience with the mice model studying viral disease.	Rodent handling training class 2002 and 2006, USUHS Investigator Training Course (2006).
Tail vein and sub cutaneous injection, euthanasia, blood collection		Post-Doctoral fellow, 7 years of experience handling mice.	Rodent handling training class 2008, USUHS Investigator Training Course 2007.
Injection, euthanasia, blood collection		Post-Doctoral fellow, 7 years of experience handling mice.	Rodent handling training class 2008, USUHS Investigator Training Course 2007.
Injections, euthanasia, blood collection		Graduate student, 3 years of experience handling mice	Rodent handling training class held on 08/17/2010, USUHS Investigator Training Course 08/17/2010

VII. BIOHAZARDS/SAFETY: TC83 and CHIKV181/25 strain of VEEV and CHIKV respectively, are attenuated and have been excluded from select agent regulations.

Because of the low level of pathogenicity, TC83 and CHIKV181/25 can be safely handled under BSL-2 conditions without vaccination or additional personal protective equipment (Page 243; Appendix B: BMBL5-section VIIIf). All the injections with the viruses will be done in the biosafety cabinet in the BSL2 lab (b)(6)

Transport of animals between BSL-2 rooms AND the PI laboratory or LAM Euthanasia room will be carried out as follows. The research staff will decontaminate cages and carts with an appropriate disinfectant (e.g. MB-10) before moving animals though command access areas. Cages will be double-bagged and taped closed in the clear biohazard waste bags kept in the BSL-2 room. The bags will be sprayed with an appropriate disinfectant. Carts will be sprayed down as well, especially the wheels. Allow disinfectant contact time of 3-5 minutes.

Procedures after euthanasia of BSL-2 animals will be carried out as follows. Animal carcasses will be doubled bagged and taped (include burn card) in clear autoclavable biohazard bags. Cages will be double bagged and tapped in clear autoclavable biohazard bags as well, but separate from the carcasses. The downdraft table, C02 lid, instruments and any other surfaces that became contaminated will be disinfected by the person performing the euthanasia (e.g. research staff) and allowed contact time of 3-5 minutes. The double bagged cages and carcasses will be dropped off in autoclave room (b)(6) The bagged carcasses will be placed in the white biohazard container. The bagged cages can be left on the floor. LAM will autoclave the carcasses/cages and dispose of them.

VIII. ENCLOSURES: Appendix A: References
Appendix B: BMBL5-section VIIIf

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

(b)(6) _____ 3/28/14

Principal Investigator Signature Date

G. Training: The following personnel will attend the next USUHS Investigator/Animal User Training Course:

_____ _____

_____ _____

H. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely, "Responsibility" for implementing animal use alternatives where feasible and conducting humane and lawful research.

(b)(6) _____ 3/28/14

Principal Investigator Signature Date

I. Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

(b)(6)

X. PROTOCOL ABSTRACT:

A. Animal Protocol Number:

B. Animal Protocol Title: Post-transcriptional silencing of Venezuelan Equine Encephalitis Virus (VEEV) RNA for developing an antiviral therapy against exposure with VEEV, a bio-warfare agent (in mice).

C. Principal Investigator: (b)(6)

D. Performing Organization: USUHS

E. Funding: Defense Threat Reduction Agency (DTRA)

F. Objective and Approach: The objectives of this proposal are:

1) To evaluate the loss of immunomodulatory activity of 2'O Methyl modified anti-VEEV siRNA duplexes in mice.
2) To determine the miRNA expression in the blood of mice exposed to alphaviruses.

Earlier report have shown that 2'O Methyl modified siRNA duplexes do not elicit a non-specific innate immune response in the host that is seen with the non-modified siRNA duplexes. Non-specific immune response may itself have some protective effect against the VEEV and therefore, will hamper the conclusion of any protective effect by siRNA duplexes. The long term goal of the project is to identify the siRNA duplexes that will inhibit the VEEV replication in the host, any non-specific inhibitory effect thus will interfere with such interpretation. Host miRNAs have emerged as novel diagnostic biomarkers for various diseases. MiRNA changes in the serum have been suggested as a potential marker of disease and injury. In this study, host blood miRNA profile will be determined to identify potential diagnostic and prognostic biomarkers.

G. Indexing Terms (Descriptors): mice, RNA interference, siRNA, VEEV, CHIKV, alphaviruses, biomarkers, miRNAs, diagnostic markers.

Section VIII-F: Arboviruses and Related Zoonotic Viruses

In 1979, the American Committee on Arthropod-Borne Viruses (ACAV) Subcommittee on Arbovirus Laboratory Safety (SALS) first provided biosafety recommendations for each of the 424 viruses then registered in the International Catalogue of Arboviruses, including Certain Other Viruses of Vertebrates.[1] Working together, SALS, the CDC and the NIH have periodically updated the catalogue by providing recommended biosafety practices and containment for arboviruses registered since 1979. These recommendations are based, in part, on risk assessments derived from information provided by a worldwide survey of laboratories working with arboviruses, new published reports on the viruses, as well as discussions with scientists working with each virus.

Table 6, located at the end of this Section, provides an alphabetical listing of 597 viruses and includes common name, virus family or genus, acronym, BSL recommendation, the basis for the rating, the antigenic group[2] (if known), HEPA filtration requirements, and regulatory requirements (i.e., import/export permits from either the CDC or the USDA). In addition, many of the organisms are classified as select agents and require special security measures to possess, use, or transport. (See Appendix F.) Table 4 provides a key for the SALS basis for assignment of viruses listed in Table 6.

Agent summary statements have been included for certain arboviruses. They were submitted by a panel of experts for more detailed consideration due to one or more of the following factors:

- at the time of writing this edition, the organism represented an emerging public health threat in the United States;
- the organism presented unique biocontainment challenge(s) that required further detail; and
- the organism presented a significant risk of laboratory-acquired infection.

These recommendations were made in August 2005; requirements for biosafety, shipping, and select agent registration can change. Please be sure to confirm the requirements with the appropriate Federal agency. If the pathogen of interest is one listed in Appendix D, contact the USDA for additional biosafety requirements. USDA guidance may supersede the information found in this Chapter.

Recommendations for the containment of infected arthropod vectors were drafted by a subcommittee of the American Committee on Medical Entomology (ACME), and circulated widely among medical entomology professionals. (See Appendix E.)

Some commonly used vaccine strains for which attenuation has been firmly established are recognized by SALS. These vaccine strains may be handled safely at BSL-2 (Table 5). The agents in Table 4 and 5 may require permits from USDA/DOC/DHHS.

Table 4. Explanation of Symbols Used in Table 6 to Define Basis for Assignment of Viruses to Biosafety Levels

Symbol	Definition
S	Results of SALS survey and information from the Catalog [1]
IE	Insufficient experience with virus in laboratory facilities with low biocontainment
A	Additional criteria
A1	Disease in sheep, cattle or horses
A2	Fatal human laboratory infection—probably aerosol
A3	Extensive laboratory experience and mild nature of aerosol laboratory infections justifies BSL-2
A4	Placed in BSL-4 based on the close antigenic relationship with a known BSL-4 agent plus insufficient experience
A5	BSL-2 arenaviruses are not known to cause serious acute disease in humans and are not acutely pathogenic for laboratory animals including primates. In view of reported high frequency of laboratory aerosol infection in workers manipulating high concentrations of Pichinde virus, it is strongly recommended that work with high concentrations of BSL-2 arenaviruses be done at BSL-3.
A6	Level assigned to prototype or wild-type virus. A lower level may be recommended for variants with well-defined reduced virulence characteristics.
A7	Placed at this biosafety level based on close antigenic or genetic relationship to other viruses in a group of 3 or more viruses, all of which are classified at this level.
A8	BSL-2 hantaviruses are not known to cause laboratory infections, overt disease in humans, or severe disease in experimental primates. Because of antigenic and biologic relationships to highly pathogenic hantaviruses and the likelihood that experimentally infected rodents may shed large amounts of virus, it is recommended that work with high concentrations or experimentally infected rodents be conducted at BSL-3.

Table 5. Vaccine Strains of BSL-3 and BSL-4 Viruses that May Be Handled as BSL-2

Virus	Vaccine Strain
Chikungunya	181/25
Junin	Candid #1
Rift Valley fever	MP-12
Venezuelan equine encephalomyelitis	TC83 & V3526
Yellow fever	17-D
Japanese encephalitis	14-14-2

Based on the recommendations listed with the tables, the following guidelines should be adhered to where applicable.

Viruses with BSL-2 Containment Recommended

The recommendation for conducting work with the viruses listed in Table 6 at BSL-2 are based on the existence of historical laboratory experience adequate to assess the risks when working with this group of viruses. This indicates a) no overt laboratory-associated infections are reported, b) infections resulted from exposures other than by infectious aerosols, or c) if disease from aerosol exposure is documented, it is uncommon.

Laboratory Safety and Containment Recommendations

Agents listed in this group may be present in blood, CSF, various tissues, and/or infected arthropods, depending on the agent and the stage of infection. The primary laboratory hazards comprise accidental parenteral inoculation, contact of the virus with broken skin or mucous membranes, and bites of infected laboratory rodents or arthropods. Properly maintained BSCs, preferable Class II, or other appropriate personal protective equipment or physical containment devices are used whenever procedures with a potential for creating infectious aerosols or splashes are conducted.

BSL-2 practices, containment equipment, and facilities are recommended for activities with potentially infectious clinical materials and arthropods and for manipulations of infected tissue cultures, embryonate hen's eggs, and rodents.

Large quantities and/or high concentrations of any virus have the potential to overwhelm both innate immune mechanisms and vaccine-induced immunity. When a BSL-2 virus is being produced in large quantities or in high concentrations, additional risk assessment is required. This might indicate BSL-3 practices, including additional respiratory protection, based on the risk assessment of the proposed experiment.

Viruses with BSL-3 Containment Recommended

The recommendations for viruses listed in Table 6 that require BSL-3 containment are based on multiple criteria. SALS considered the laboratory experience for some viruses to be inadequate to assess risk, regardless of the available information regarding disease severity. In some cases, SALS recorded overt LAI transmitted by the aerosol route in the absence or non-use of protective vaccines, and considered that the natural disease in humans is potentially severe, life threatening, or causes residual damage.[1] Arboviruses also were classified as requiring BSL-3 containment if they caused diseases in domestic animals in countries outside of the United States.

Laboratory Safety and Containment Recommendations

The agents listed in this group may be present in blood, CSF, urine, and exudates, depending on the specific agent and stage of disease. The primary laboratory hazards are exposure to aerosols of infectious solutions and animal bedding, accidental parenteral inoculation, and contact with broken skin. Some of these agents (e.g., VEE virus) may be relatively stable in dried blood or exudates.

BSL-3 practices, containment equipment, and facilities are recommended for activities using potentially infectious clinical materials and infected tissue cultures, animals, or arthropods.

A licensed attenuated live virus is available for immunization against yellow fever. It is recommended for all personnel who work with this agent or with infected animals, and those entering rooms where the agents or infected animals are present.

Junin virus has been reclassified to BSL-3, provided that all at-risk personnel are immunized and the laboratory is equipped with HEPA-filtered exhaust. SALS also has reclassified Central European tick-borne encephalitis (CETBE) viruses to BSL-3, provided all at-risk personnel are immunized. CETBE is not a registered name in *The International Catalogue of Arboviruses* (1985). Until the registration issue is resolved taxonomically, CETBE refers to the following group of very closely related, if not essentially identical, tick-borne flaviviruses isolated from Czechoslovakia, Finland and Russia: Absettarov, Hanzalova, Hypr, and Kumlinge viruses. While there is a vaccine available that confers immunity to the CETBE group of genetically (>98%) homogeneous viruses, the efficacy of this vaccine against Russian spring-summer encephalitis (RSSE) virus infections has not been established. Thus, the CETBE group of viruses has been reclassified as BSL-3 when personnel are immunized with CETBE vaccine, while RSSE remains classified as BSL-4. It should be noted that CETBE viruses are currently listed as select agents and require special security and permitting considerations. (See Appendix F.)

Investigational vaccines for eastern equine encephalomyelitis (EEE) virus, Venezuelan equine encephalitis (VEE), western equine encephalomyelitis (WEE) virus, and Rift Valley fever viruses (RVFV), may be available in limited quantities and administered on-site at the Special Immunization Program of USAMRIID, located at Ft. Detrick, Frederick, MD. Details are available at the end of this section.

The use of investigational vaccines for laboratory personnel should be considered if the vaccine is available. Initial studies have shown the vaccine to be effective in producing an appropriate immunologic response, and the adverse effects of vaccination are within acceptable parameters. The decision to recommend vaccines for laboratory personnel must be carefully considered and based on an risk assessment which includes a review of the characteristics of the agent and the disease, benefits versus the risk of vaccination, the experience of the laboratory personnel, laboratory procedures to be used with the agent, and the contraindications for vaccination including the health status of the employee.

If the investigational vaccine is contraindicated, does not provide acceptable reliability for producing an immune response, or laboratory personnel refuse vaccination, the use of appropriate personal protective equipment may provide an alternative. Respiratory protection, such as use of a PAPR, should be considered in areas using organisms with a well-established risk of aerosol infections in the laboratory, such as VEE viruses.

Any respiratory protection equipment must be provided in accordance with the institution's respiratory protection program. Other degrees of respiratory protection may be warranted based on an assessment of risk as defined in Chapter 2 of this manual. All personnel in a laboratory with the infectious agent must use comparable personal protective equipment that meets or exceeds the requirements, even if they are not working with the organism. Sharps precautions as described under BSL-2 and BSL-3 requirements must be continually and strictly reinforced, regardless of whether investigational vaccines are used.

Non-licensed vaccines are available in limited quantities and administered on-site at the Special Immunization Program of USAMRIID. IND vaccines are administered under a cooperative agreement between the U.S. Army and the individual's requesting organization. Contact the Special Immunization Program by telephone at (301) 619-4653.

Enhanced BSL-3 Containment

Situations may arise for which enhancements to BSL-3 practices and equipment are required; for example, when a BSL-3 laboratory performs diagnostic testing on specimens from patients with hemorrhagic fevers thought to be due to dengue or yellow fever viruses. When the origin of these specimens is Africa, the Middle East, or South America, such specimens might contain etiologic agents, such as arenaviruses, filoviruses, or other viruses that are usually manipulated in a BSL-4

PHASE II SAFETY AND IMMUNOGENICITY STUDY OF LIVE CHIKUNGUNYA VIRUS VACCINE TSI-GSD-218

R. EDELMAN, C. O. TACKET, S. S. WASSERMAN, S. A. BODISON, J. G. PERRY, AND J. A. MANGIAFICO

Center for Vaccine Development, University Of Maryland School of Medicine, Baltimore, Maryland; University Health Center, University of Maryland, College Park, Maryland; Diagnostic Systems Division, United States Army Medical Research Institute of Infectious Diseases, Fort Detrick, Frederick, Maryland

Abstract. We conducted a phase II, randomized, double-blind, placebo-controlled, safety and immunogenicity study of a serially passaged, plaque-purified live chikungunya (CHIK) vaccine in 73 healthy adult volunteers. Fifty-nine volunteers were immunized one time subcutaneously with the CHIK vaccine and 14 were immunized with placebo (tissue culture fluid). Vaccinees were clinically evaluated intensively for one month, and had repeated blood draws for serological assays (50% plaque-reduction neutralization test) for one year. Except for transient arthralgia in five CHIK vaccinees, the number and severity of local and systemic reactions and abnormal laboratory tests after immunization were similar in CHIK vaccinees and placebo recipients. Fifty-seven (98%) of 58 evaluable CHIK vaccinees developed CHIK neutralizing antibody by day 28, and 85% of vaccinees remained seropositive at one year after immunization. No placebo recipients seroconverted. This promising live vaccine was safe, produced well-tolerated side effects, and was highly immunogenic.

INTRODUCTION

Chikungunya virus (CHIK) is an alphavirus borne by *Aedes* mosquitoes that produces a dengue-like illness in humans, characterized by fever, rash, painful arthralgia, and sometimes arthritis.[1–5] The virus is widely disseminated throughout sub-Saharan Africa, Southeast Asia, India, and the Western Pacific, and numerous epidemics have been reported in these areas.[6–11] The widespread geographic distribution, recurrent epidemics, and infection of military personnel, travelers, and laboratory staff working with CHIK have indicated the need for a safe and efficacious vaccine.[12–15] Individual strains of CHIK are closely related antigenically,[8,16,17] and infection with one CHIK strain leads to protection against all strains.[18] Reciprocal cross-protection after infection with other alphaviruses occurs in animal models,[19,20] although it is unclear if similar cross protection occurs in humans sequentially exposed to natural infection or live alphavirus vaccines.[21]

An isolate from a patient in Thailand, CHIK strain 15561, was used to develop a small lot of vaccine first passaged in green monkey kidney (GMK) cells and then formalin-inactivated before administration to 16 volunteers.[22] The vaccine produced no untoward reactions and was highly immunogenic. The current live vaccine (Lot 1-85, TSI-GSD-218) was developed at the United States Army Medical Research Institute of Infectious Diseases (USAMRIID) and was produced at the Salk Institute, Swiftwater, PA, from a lot of the GMK-passaged strain 15561 inactivated vaccine by subsequent serial passage in MRC-5 cells.[23] The live vaccine proved to be safe and immunogenic in a phase I trial in 15 alphavirus-naive volunteers.[21] The current phase II, randomized, double-blind, placebo-controlled trial was designed to provide additional safety and immunogenicity data for live CHIK vaccine TSI-GSD-218.

MATERIALS AND METHODS

Vaccine. The live, attenuated, TSI-GSD-218, Lot 1-85, chikungunya vaccine is a lyophilized supernatant from human lung cell cultures (Medical Research Council-5 [MRC-5] cells, certified for vaccine use) infected with an attenuated strain, CHIK 181/Clone 25. This attenuated vaccine seed was originally derived from a serum isolate (CHIK strain 15561) obtained from an infected patient during the 1962 outbreak of CHIK disease in Thailand. Chikungunya strain 15561 was subjected to 18 plaque-to-plaque passages in MRC-5 cultures before CHIK 181/Clone 25 was selected as the vaccine seed.[22,23] The CHIK vaccine elicited neutralizing antibody and protected mice and monkeys against challenge.[23] The vaccine was shown to be safe and immunogenic in humans in phase I trials[21] (Malinowski FJ, unpublished data). The placebo was MRC-5 tissue culture fluid manufactured concurrently with the CHIK vaccine, and diluted identically as the CHIK vaccine. The vaccine and placebo fluids contained less than 0.02 μg neomycin base and 0.25% human serum albumin per ml.

Volunteers. Seventy-three adult volunteers (47 men, 26 women) were recruited by poster, published advertisement, and by word-of-mouth at the University of Maryland, Baltimore, MD and at the University of Maryland, College Park, MD. Healthy volunteers, 18–40 years of age, were screened and included if they had no clinically significant history of medical or psychiatric disease (including Lyme disease and personal and family history of arthritis). Additional screening consisted of a standard but brief physical examination and the usual serum chemistries, urinalysis, and complete blood count. Negative results of serum HIV, hepatitis virus B and C, and alpha virus serology ($PRNT_{50}$ <1:10 for CHIK, Venezuelan equine encephalitis virus [VEE], western equine encephalitis virus [WEE], and eastern equine encephalitis virus [EEE]) were required. In addition, we documented that female volunteers were not pregnant within 48 hours of vaccine administration.

The study was approved by the Institutional Review Boards of the University of Maryland at Baltimore and the University of Maryland at College Park, and by the Human Subjects Research and Review Board, Office of the Surgeon General, United States Army. Informed consent was obtained from all volunteers.

Study design. Volunteers were randomized in blocks of 5 (4 vaccine and 1 placebo recipient) using a computer random-number generator. For logistic reasons, volunteers were

* All differences between CHIK and placebo groups were NS ($P > 0.58$, Fisher's exact test). Clinical reactions were graded and associated with immunization in a blinded fashion before vaccine code was broken.
† Pain, tenderness, erythema, induration, and restricted arm motion.
‡ Malaise, fever, chills, headache, photophobia, myalgia, arthralgia, anorexia, nausea, vomiting, pruritis, and rash.
§ Based on temporal association with immunization 28 days before onset of symptom, and by the absence of another identifiable condition that may have accounted for symptom or symptoms.

divided into five cohorts. In total, 59 volunteers (35 men, 24 women) received the CHIK vaccine, and 14 volunteers (12 men, 2 women) received the placebo preparation. Sixty (82%) of the 73 volunteers were Caucasian, and 13 were either African-American (5 persons), Asian (5 persons), or Hispanic (3 persons).

The vaccine or placebo was administered as a 0.5 ml dose of either the reconstituted vaccine ($\sim 10^5$ plaque-forming units [pfu]/dose) or placebo by injection subcutaneously over the deltoid muscle. Neither the volunteer nor the investigators knew whether virus or placebo fluid was administered until after the completion of the study. After inoculation, all volunteers remained in the vicinity of the clinic for 30 minutes for observation of immediate reactions. Volunteers subsequently returned for clinical checks on study Days 1–4, 10, 14, and 28. Parameters examined and recorded at these times included local pain, tenderness, warmth, erythema, and induration at the inoculation site, and limited range of arm movement. Systemic signs and symptoms noted included temperature, subjective fever or chills, malaise, arthralgia, arthritis, myalgia, rash, pruritus, sore throat, photophobia, headache, anorexia, nausea, and vomiting. Reactions were quantitatively scored on the basis of severity of symptoms: (0 = none, 1 = mild, symptom can be ignored; 2 = moderate, symptom affects activity; and 3 = severe, symptom requires analgesics). Volunteers were given a disposable thermometer and instructed to report to the research nurse or physician whenever they suspected a reaction to the vaccine. A physician investigator was available on a 24-hour basis throughout the study to screen any subject who reported suspected vaccine side effects.

Blood for the safety screen included complete blood counts with differential, platelet count, chemistry panel (electrolytes, glucose, blood urea nitrogen, creatinine, glucose, calcium, phosphorus, aspartate aminotransferase (AST), alanine aminotransferase (ALT), total bilirubin, and alkaline phosphatase) and urinalysis obtained on Days 0, 14, and 28 after inoculation. Clinical laboratory tests were performed by licensed, commercial pathology laboratories approved by the American College of Pathology. Blood for CHIK serology was obtained on Days 0, 14, 28, 42, 180, and 365 after vaccination.

Serologic procedures. Sera were assayed for 50% plaque-reduction neutralization test ($PRNT_{50}$) antibody,[26] modified for use with the vaccine strain of CHIK.[20] The assays were performed by the Diagnostic Systems Division at USAMRIID. A positive antibody titer was considered to be ≥1:20 by the $PRNT_{50}$ assay. The end-point titer was expressed as a reciprocal of the highest initial dilution that demonstrated ≥50% reduction in the number of plaques for the average viral dose. Less than 50% neutralization by the initial serum test dilution of 1:10 was reported as 5.

Statistical methods. Each volunteer's clinical reactions and serological results were entered into the computer before the study code was broken. Both the clinical and the clinical laboratory responses to vaccine versus placebo were compared using Fisher's exact tests, evaluated at two-tailed ($P = 0.05$).

RESULTS

Volunteer retention. One volunteer whose serum interfered non-specifically with the antibody assay was not included in the serological analysis. Thus, 72 volunteers (58 of 59 CHIK vaccinees and all 14 placebo vaccinees) were evaluated serologically and all 73 volunteers were evaluated for side effects. Only three of 365 scheduled blood specimens were obtained off schedule, each from a different volunteer. One Day 180 serum was donated on Day 270, one Day 365 serum was donated on Day 385, and one Day 365 serum was not obtained.

Local reactions. The number of volunteers who experienced one or more local symptoms or signs was 12 (20%) of 59 CHIK vaccinees, and 3 (21%) of the 14 placebo controls (Table 1). The few reactions noted at the immunization site were invariably mild, except one CHIK volunteer who developed moderate intermittent pain in her inoculated arm between 12 and 48 hours after immunization that was associated with a mildly pruritic eczema-like rash at the vaccination site.

Systemic reactions. The CHIK vaccine was well tolerated. Except for transient arthralgia, systemic symptoms were no more frequent or severe in CHIK vaccinees than in placebo recipients (Table 1). The only severe systemic symptoms reported after CHIK vaccination occurred in two individuals who treated their headaches with analgesics for one day. Nineteen (32%) of CHIK vaccinees had symptoms judged to be possibly associated with immunization, compared to 4 (29%) of placebo recipients. Of these immunization-associated reactions, no CHIK vaccinee developed a

TABLE 2
Arthralgia in volunteers immunized with the chikungunya vaccine

Volunteer no.	Description of arthralgia
11	Mild intermittent pain in the left elbow beginning Day 4 (lasted 24 hours)
19	Moderate pain in the left wrist on Day 1 (lasted 10 minutes)
22	Mild arthralgia in the left hand on Day 13 (lasted 3 hours)
32	2–3 bouts of episodic pain lasting 15 minutes in left elbow and wrist on Days 1, 2, and 4 that limited typing
43	Mild left knee and thigh pain on Day 1 (lasted 6 hours)

temperature elevation > 100.0°F, and afebrile, flu-like symptoms occurred with similar frequency in vaccinated and placebo recipients (Table 1). Five (8%) of CHIK vaccinees (3 men, 2 women) had transient arthralgia without arthritic signs or associated flu-like symptoms (Table 2). The most severely affected volunteer (No. 32, Table 2) suffered pain in her left elbow and wrist which required her to stop typing episodically over three days. No placebo recipient reported arthralgia at any time, and no CHIK vaccinee reported joint symptoms between Day 14 and Day 360, the period of passive surveillance.

Clinical laboratory results. No clinically significant abnormal laboratory tests were noted in any volunteer. No significant difference existed in the percentage of CHIK and placebo-group volunteers who had abnormal laboratory tests at baseline or at post-vaccination (data not shown).

Serological results. Fifty-seven (98.3%) of 58 Chik volunteers seroconverted (≥1:20 by $PRNT_{80}$) by Day 28, and although antibody levels declined somewhat over time, 85% of CHIK vaccinees were still seropositive at one year (Figure 1A). The highest geometric mean titer (GMT) (1:582) was reached at Day 28 and declined slowly to 1:105 on Day 360 (Figure 1B). Maximum titers reached 1:10,240 on Days 28 and 42, and declined to 1:1,280 on Days 180 and 360. No placebo recipient seroconverted.

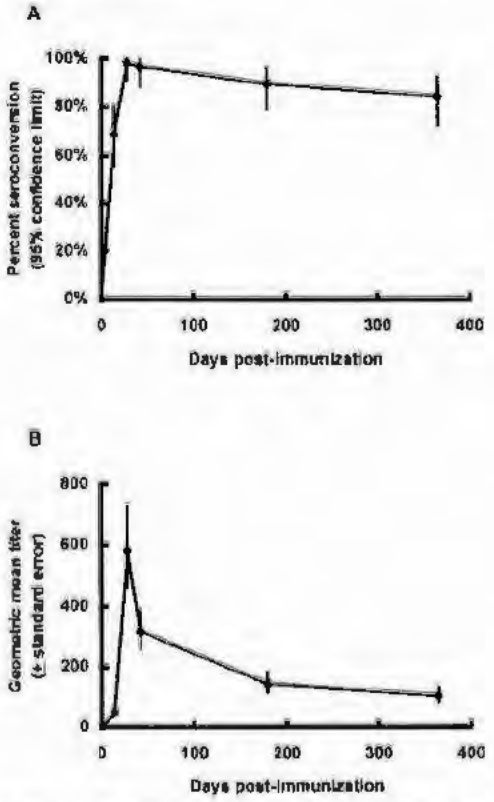

FIGURE 1. Chikungunya virus (CHIK) 80% plaque reduction neutralization test ($PRNT_{80}$) antibody titers in the sera of 58 alphavirus-naive volunteers after immunization with attenuated CHIK vaccine. Serum was obtained on Days 0, 14, 28, 42, 180, and 360. (A) Percent seroconversion (≥1:20 $PRNT_{80}$), 95% confidence intervals. (B) Geometric mean titer ± standard error. No placebo recipients seroconverted (data not shown).

DISCUSSION

This phase II, double-blind study was designed to examine the safety and immunogenicity of the live CHIK vaccine TSI-GSD-218 in healthy adult volunteers. Side effects experienced by vaccinee and placebo volunteers who were followed actively and passively for one year were compared. The neutralizing antibody response was also studied for one year. This study confirms the encouraging clinical reaction profile and antibody response noted in a phase I study of 15 alphavirus-naive volunteers immunized with this vaccine,[7] and in several phase I trials conducted at USAMRIID (Malinoski FJ, unpublished data). In the current blinded phase II study, the number and severity of adverse clinical signs and symptoms were similar in the vaccine-immunized and placebo-inoculated volunteers. No CHIK volunteer developed clinically important reactions to the vaccine. Clinical laboratory abnormalities were also comparable in both volunteer groups in the current study, although minor differences in hematologic values were noted in the previous phase I trial.[7]

Because virulent chikungunya virus can cause acute arthralgia and arthritis,[1,3,21,26] which on occasion may persist for months or years, we were particularly interested in enumerating joint symptoms. Five of 59 CHIK vaccinees developed transient arthralgia without other known cause (Table 2), while none of 14 controls developed arthralgia ($P = 0.33$). The incidence of arthralgia in vaccine recipients compared to controls may have reached statistical significance had we conducted a larger study. Three of 5 volunteers noted arthralgia one day after immunization, which is earlier than predicted based on the fact that CHIK vaccine viremia occurred in previous trials on Day 2–4 as reported by McClain and others[21] and noted by FJ Malinoski, (unpublished data). Nevertheless, it is plausible medically that some of the arthralgia episodes were caused by the attenuated CHIK virus. No volunteer reported symptoms of arthralgia or arthritis during passive surveillance conducted between 1 and 12 months after immunization. One Army volunteer complained of mild, intermittent small-joint pains without evidence of arthritis or abnormal laboratory studies after long-term follow-up (Malinoski FJ, unpublished data). The sum of the safety data in the current phase II trial and in the phase I

Army trials summarized above strongly suggest that the live CHIK vaccine is safe and well-tolerated and that it produces no more severe or more frequent symptoms than found in placebo recipients.

Mild hemorrhage limited to petechia, epistaxis, and bleeding gums, or severe hemorrhage characterized by melena, hematemesis, hemoptysis, or hematuria, have occurred in up to 10% of patients during outbreaks of CHIK infection, depending of the locale.[1,11,27,28] Some of the more severe cases of hemorrhage may have been caused by dengue virus infection.[27] Rarely, death in children and the aged has been associated with outbreaks of CHIK;[28] CHIK was isolated from the blood of one Ceylonese child who died.[29] Nevertheless, because of the rarity of CHIK isolations and because the live CHIK vaccine is highly attenuated for man, hemorrhagic disease and death are not considered to be vaccine risks.

Although chikungunya viral disease is not known to adversely affect the pregnant woman or fetus and no reports of teratogenicity or increased abortion have been associated with massive epidemics of CHIK, there is a theoretical potential that any replicating vaccine virus will adversely affect the developing fetus. This vaccine has not been tested for teratogenicity or abortogenicity in animal models.

The theoretical risk of transmission of the attenuated CHIK vaccine virus to mosquitoes is considered to be remote. Because of the transient low level of viremia produced in inoculated volunteers, it is unlikely that mosquitoes would become infected by feeding on a person inoculated with the CHIK vaccine.[30] Moreover, although the vaccine was successfully transmitted by mosquitoes after intrathoracic inoculation, there was no evidence of reversion to a virulent phenotype.[30] Studies to detect possible revertant isolates from vaccine recipients indicated that most isolates retain the biological characteristics of the vaccine virus. One isolate from a volunteer in an Army study had suckling mouse lethality intermediate between the vaccine (0%) and parent (100%) viruses and induced viremia in monkeys that was higher than that produced by the parent vaccine virus. However, the viremia in the volunteer was probably too low to infect a feeding mosquito (Malinowski FJ, unpublished data).

The CHIK vaccine was highly immunogenic. Forty vaccinees (69%) seroconverted by Day 14, and 57 vaccinees (98%) seroconverted by Day 28 (Figure 1A). Neutralizing antibody was still detected in 85% of volunteers after 12 months. Long-term follow-up studies would be needed to determine the durability of the immune response. The GMT of the vaccinees was high (Figure 1B). All 15 alphavirus-naive individuals seroconverted in the single published phase 1 trial.[31] By contrast, seroconversion in laboratory workers who had previously been immunized with the VEE TC-83 vaccine was only 36%,[21] suggesting that the VEE TC-83 vaccine interferes immunologically with the live CHIK vaccine. These and other investigations suggest that sequential attenuated alphavirus immunization is detrimental to the development of neutralizing antibody and may impair the development of protective responses to subsequent CHIK immunization. It is unknown if previous attenuated alphavirus vaccines can interfere with subsequent infection and illness caused by virulent CHIK.[2]

In summary, the live CHIK vaccine was safe, produced well-tolerated side effects such as transient arthralgia in 5 (8%) of 59 volunteers, and was highly immunogenic. It is, therefore, a promising vaccine for use in alphavirus naive individuals.

Acknowledgments: The authors thank the participation of the study volunteers in Baltimore and College Park, Maryland. Skilled research nursing was provided by Kathleen Palmer, Helen Secrest, and JoAnna Becker. Dr. Alvin Sills provided clinical support, and Julie Hile and Denoise Danner assisted in performing $PRNT_{90}$ assays. We thank Dr. David J. McClain, Dr. Phillip R. Pittman, and Dr. Frank J. Malinoski for reviewing the paper and sharing unpublished data.

Financial support: The study was supported by Contract No. DAMD17-92-C-2058 (Task Order 94-008) to the University of Maryland by the United States Army Medical Research Acquisition Activity, Fort Detrick, Frederick, MD.

MEMORANDUM FOR DR. (b)(6) DEPARTMENT OF PATHOLOGY

SUBJECT: IACUC Approval of Protocol – Initial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on June 1, 2016:

Title of Application: "Deinococcus Radiodurans Mn2+Complexes: A Revolutionary Approach to Radioprotection and Vaccine Production (in mice)"

USUHS Protocol Number: (b)(6)

Expiration Date: May 31, 2019

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. NON-TECHNICAL SYNOPSIS:

Studies have found that the resistance towards radiation, an ability to grow in a high radiation environment, in the bacteria called *Deinococcus radiodurans* comes from high concentration of Manganese (Mn^{2+}) complexes found inside this bacteria. These Mn^{2+} complexes work by protecting the bacterial machinery which repair its genome damaged by the radiations, thus helping the bacteria to survive in the high radiation environment. In the proposed animal studies we will utilize this protein protecting ability of the Mn^{2+} complexes to 1) to test the safety and potential of viruses inactivated in presence of Mn^{2+} complexes for usage as vaccine candidates; and 2) determine the efficacy of topical application of Mn^{2+}-complex to improve wound healing post irradiation. Response to vaccine administration that results in the production of protective antibodies against a pathogen is a complex process. It requires several different processes inside the body to work together. Similarly, process of wound healing is also a complex processes that require a cascade of tightly controlled events to occur for normal healing. These processes cannot be truly replicated in the culture therefore, require use of animals. In the proposed experiments we will use small animal model i.e. mouse for the above mentioned studies. Mouse models for these studies are well established and have been routinely used. This multi-disciplinary research holds the prospect of formulating novel radio protectors, with applications ranging from pre-exposure prophylactic interventions to post-exposure therapeutics, and expediting vaccine production during epidemic outbreaks, bioterrorist attacks and other biothreats.

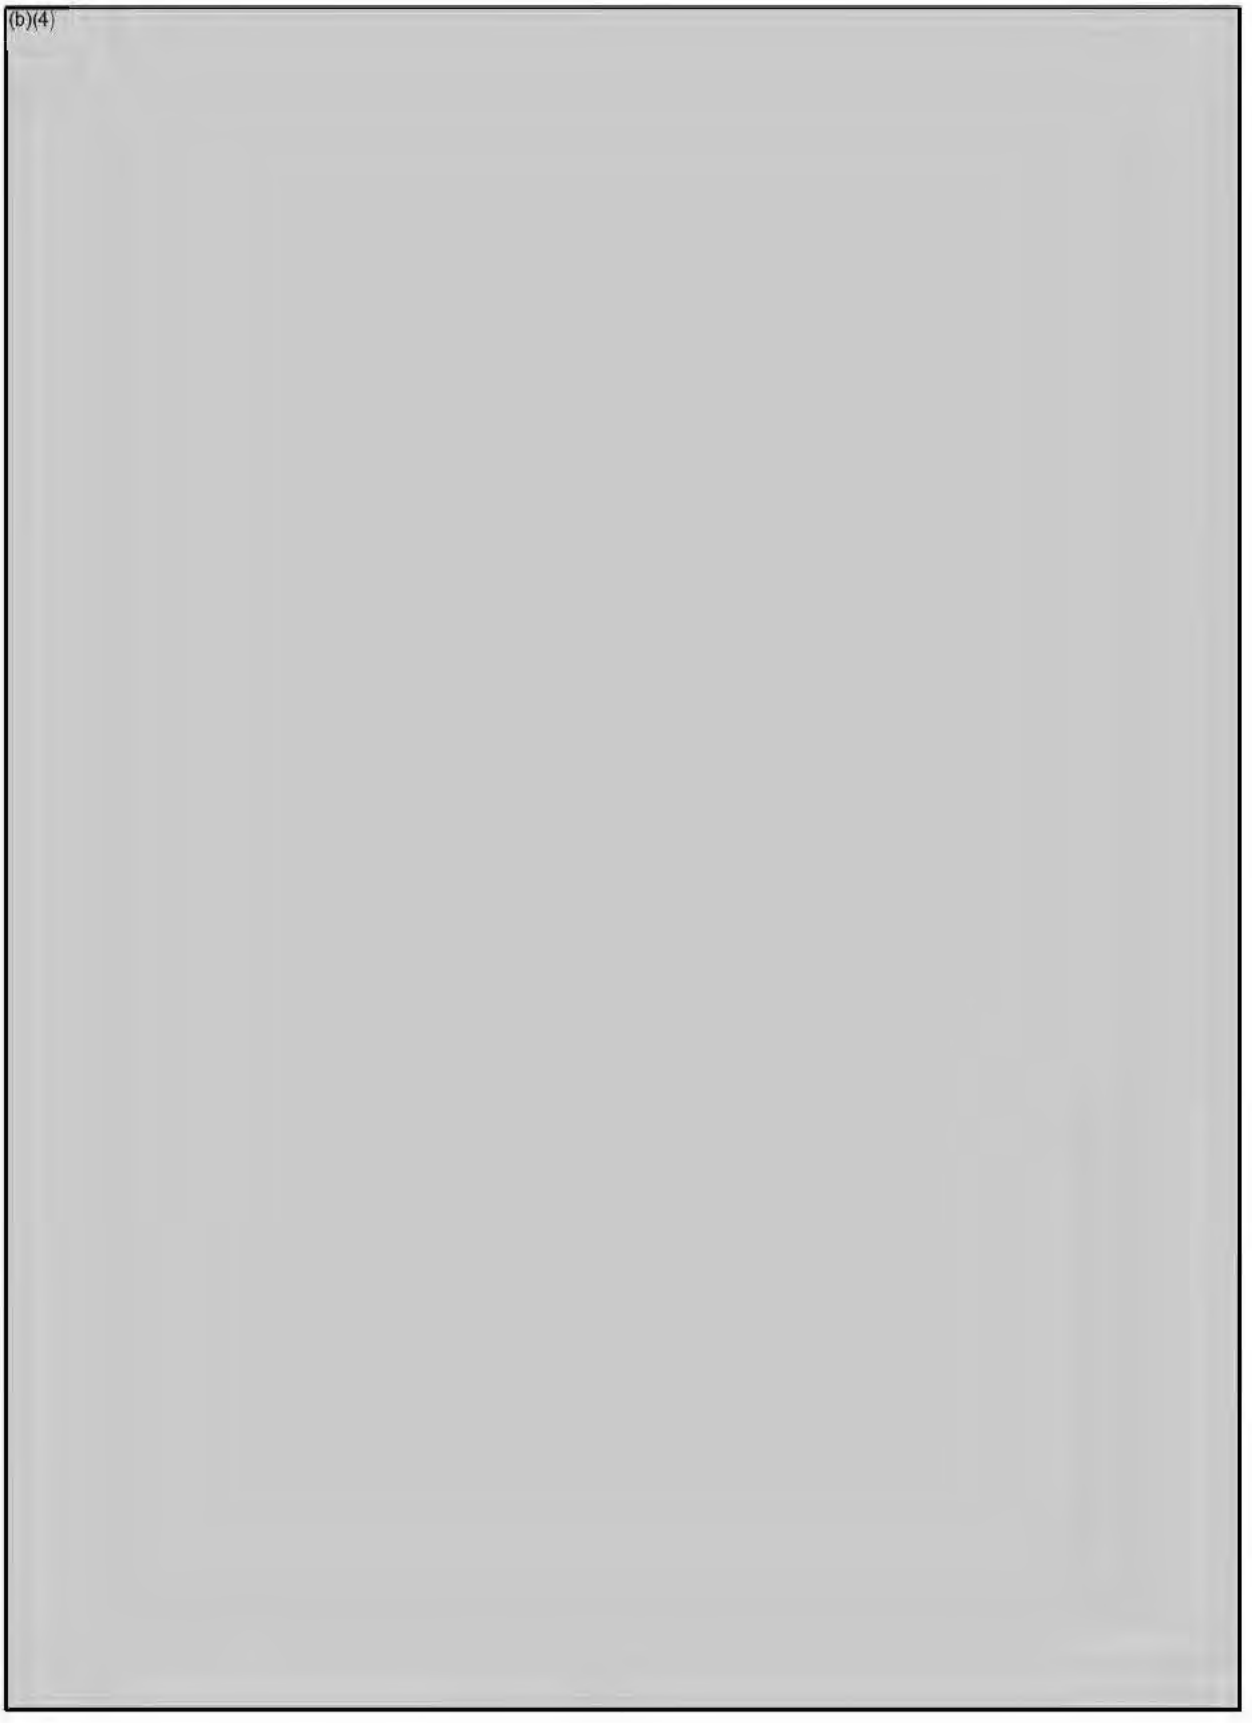
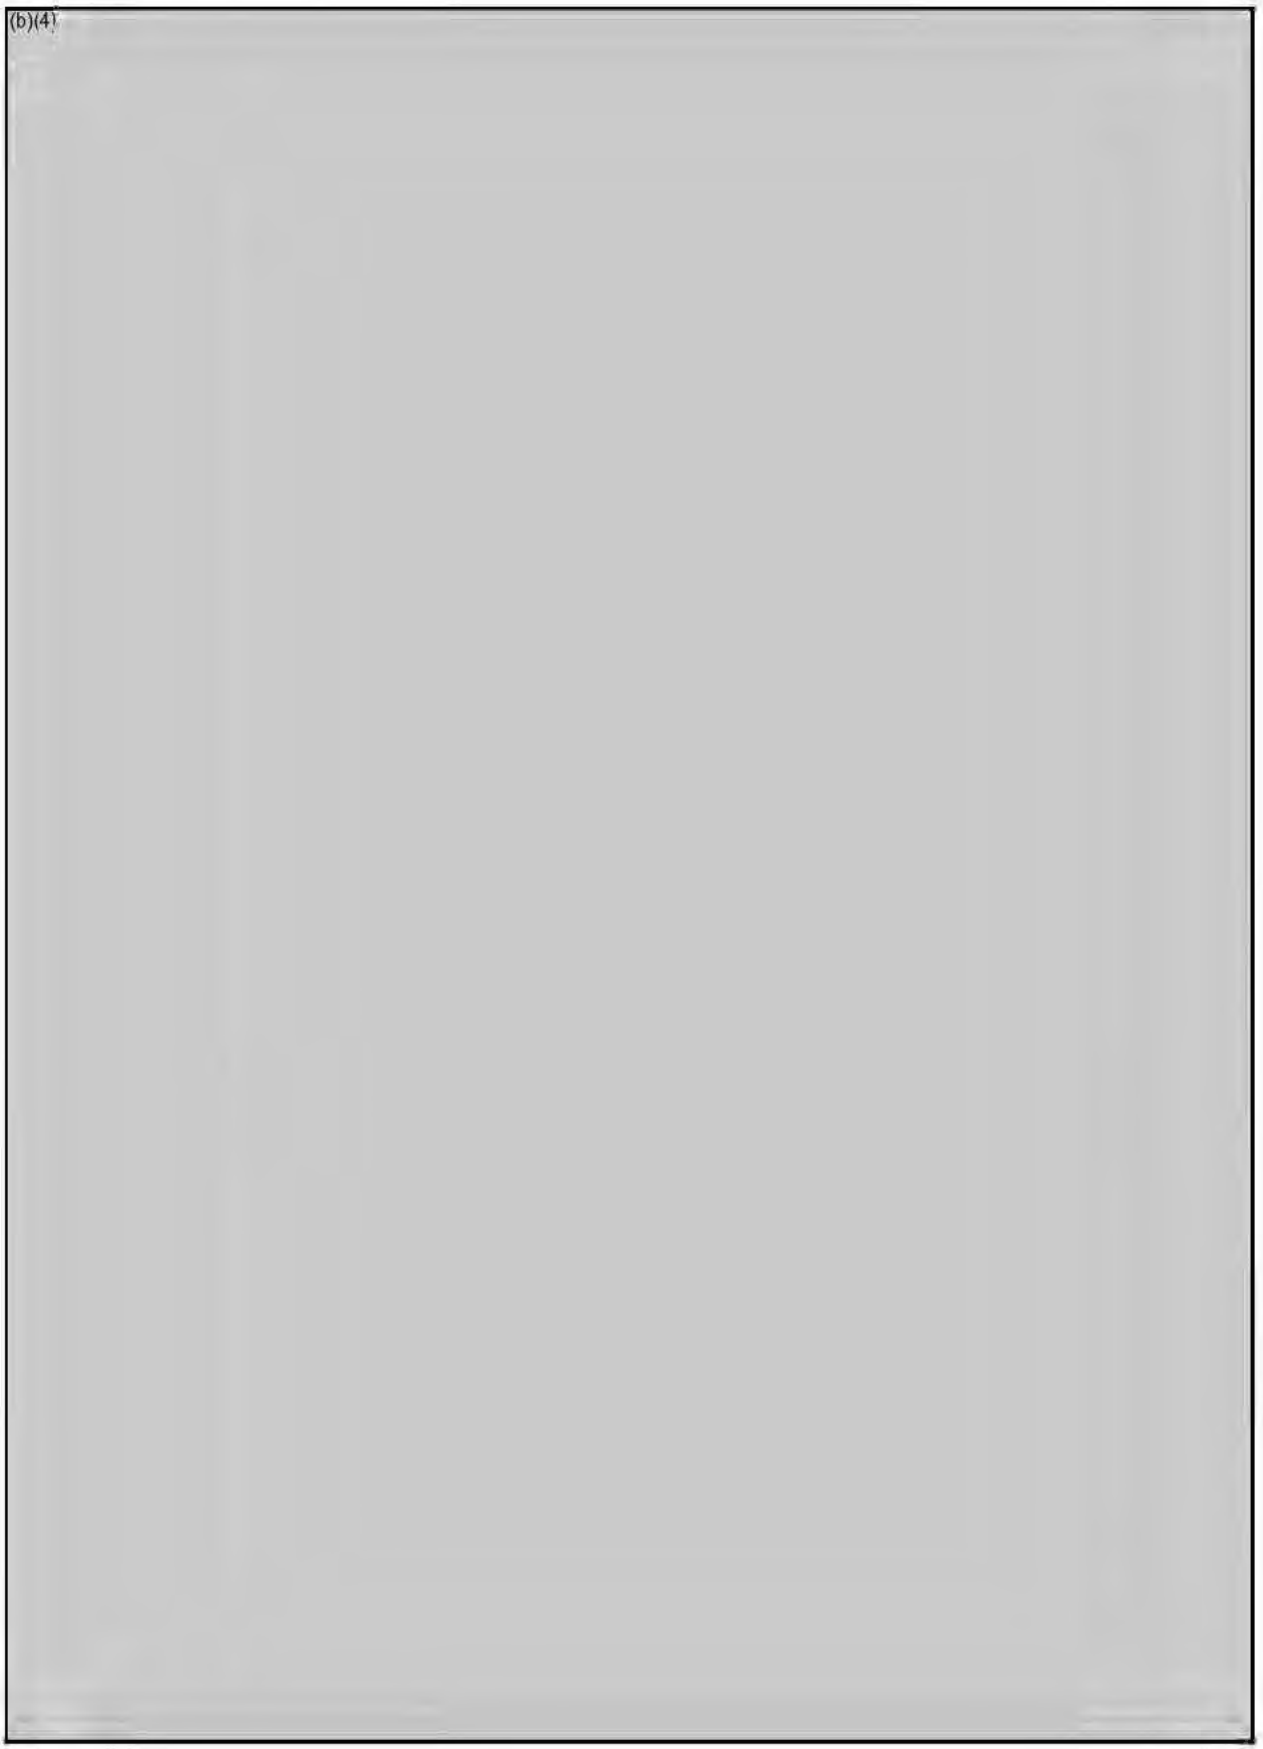
(b)(4),(b)(6)

(b)(4),(b)(6)

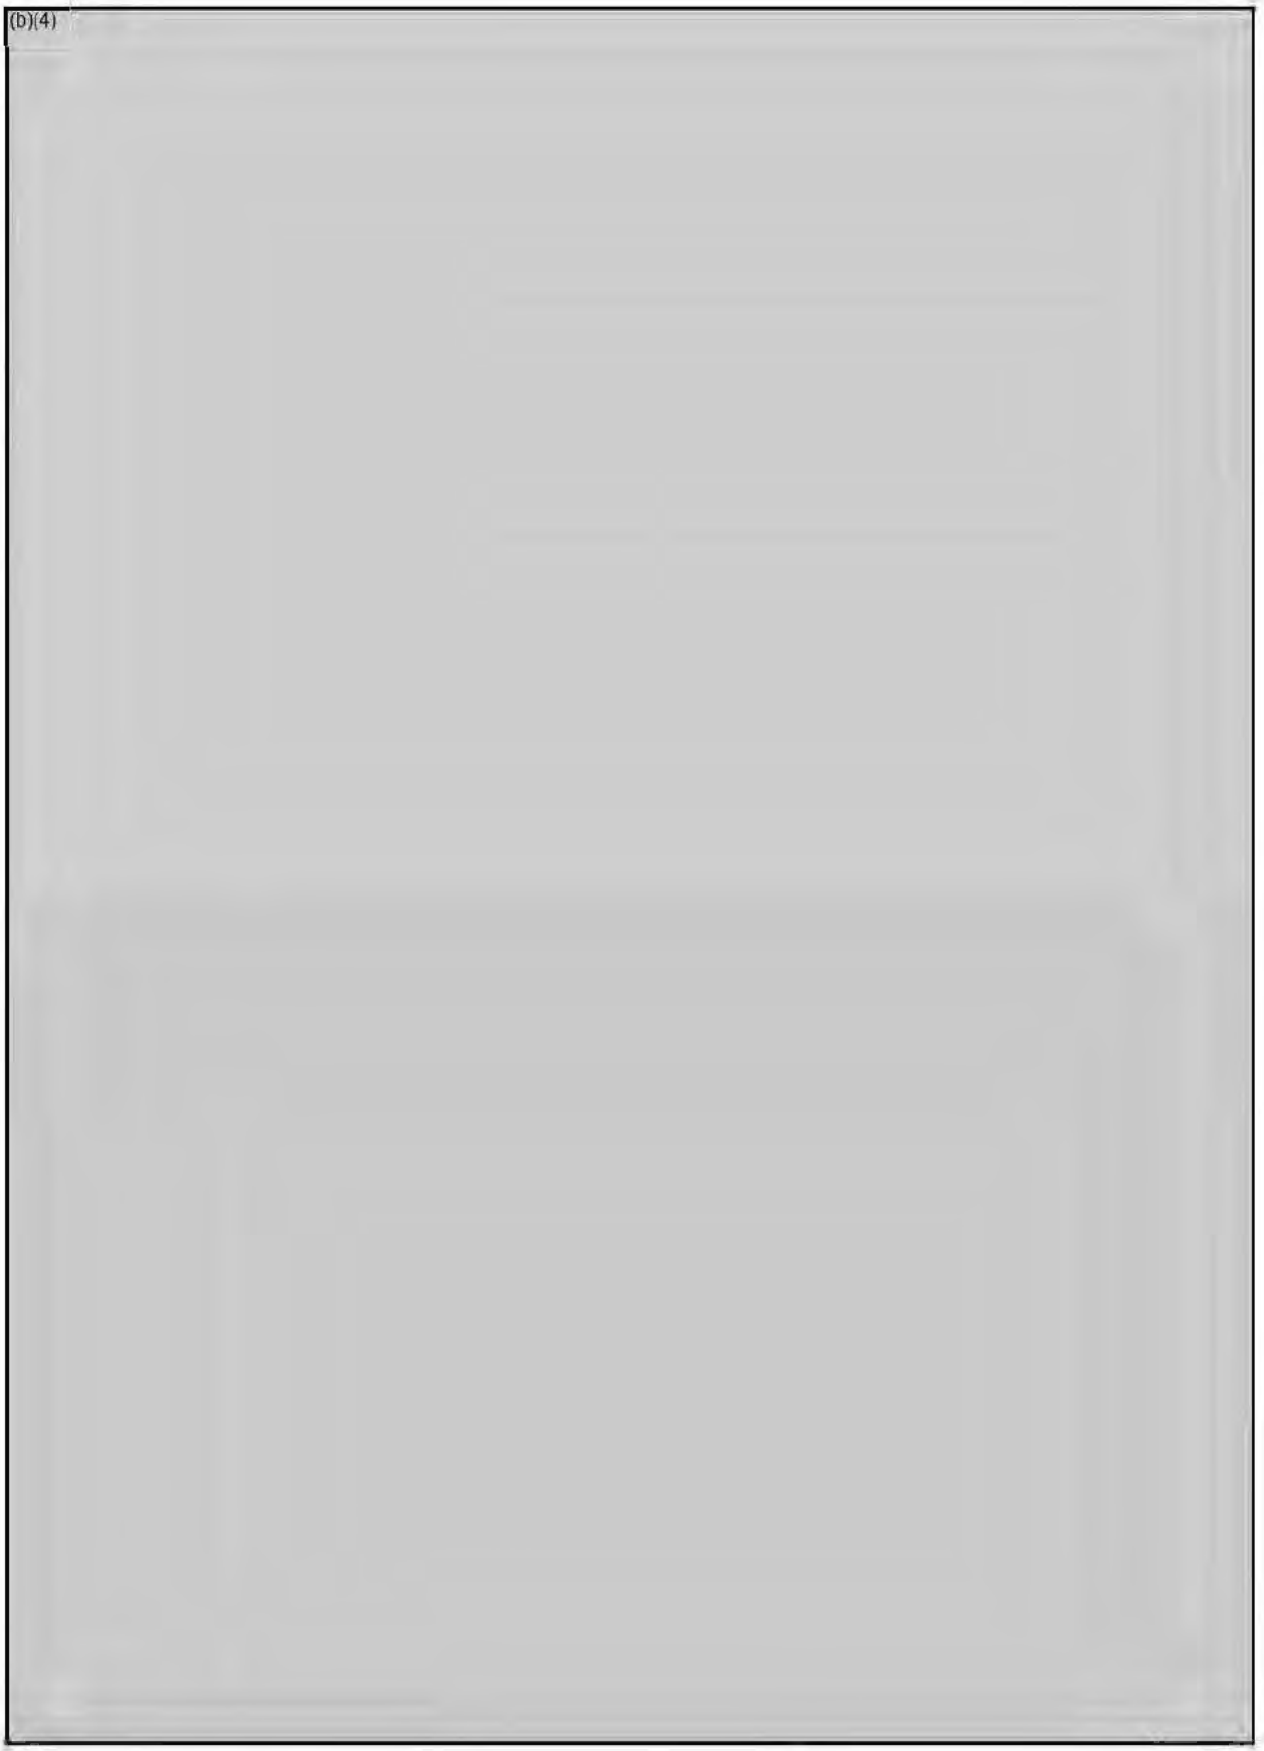
(b)(4)



(b)(4)



(b)(4)



IV. MILITARY RELEVANCE:

Successful completion of the proposed study holds the prospect of identifying and characterizing highly radioprotective compounds against acute and chronic forms of ionizing radiation, thereby helping to sustain military operations in "WMD environments". Dr. (b)(6) previous and current work clearly demonstrates that Mn2+ complexes of *D. radiodurans* are protective against acute exposures to γ-rays (acute and chronic) when applied *ex vivo* to mammalian cells and bacteria. Most importantly, once fully characterized, these Mn2+ complexes could be further developed into novel radioprotective drugs used both by military and domestic authorities in the event of WMD incidents.

Another important potential application of *D. radiodurans* Mn2+ complexes is the production of irradiated viral vaccines. To date, γ-irradiation is the most effective way of sterilizing materials – hence, the widespread use and success of industrial-scale 60Co-sterilization technologies. Other approaches of chemical inactivation such as formalin have resulted in incomplete inactivation and also loss of immunogenicity, which also occurs with inactivation by γ-irradiation. Utilizing *D. radiodurans* Mn2+ complexes for protecting irradiated viral envelope proteins, while at the same time achieving complete inactivation, would have a profound impact on generating inactivated viral vaccines in general. If successful, it would avoid the major disadvantage of epitope loss that occurs during γ-irradiation. CHIKV is an emerging infectious agent and poses great threat to

our troops deployed in CHIKV endemic areas. Additionally, several recent cases of locally transmitted CHIKV infection have also been detected in US. Currently, there is no FDA approved licensed vaccine for prophylaxis against CHIKV. The proposed research would identify and characterize novel Mn^{2+} complex formulations that preserve virus immunogenic epitopes during high-dose irradiation, thus reducing the loss of antigenicity. Prospectively, this approach would help reduce the amount of virus needed for vaccination and thereby reduce the time required to produce mass vaccine in the event of a CHIKV infection outbreak.

Injections, euthanasia, blood and tissue collection.		Post-doctoral fellow, 5 years of experience handling animal samples	Rodent handling training class held on 08/17/2010, USUHS Investigator Training Course 08/17/2010

VII. BIOHAZARDS/SAFETY:

According to BMBL 5th edition CHIKV181/25 shall be handled at BSL2 conditions. We would like to emphasize that no live attenuated virus will be used in the proposed experiments. Only gamma irradiation inactivated viruses will be used to immunize the animals.

Standard BSL2 precautions will be taken while performing the experiments utilizing the viruses. In accordance to BMBL5 recommendation the personal protective equipment worn at the time of handling the live attenuated virus (CHIKV181/21) or handling the mice given the vaccination are lab coats, gloves and face mask. Live attenuated virus will be handled inside a certified biosafety cabinet in a BSL2 laboratory. Irradiation of the virus will be done in an enclosed airtight tube (screw cap tubes) incubated on ice. All the trash generated such as pipette tips, used tubes *etc.* will be autoclaved before discarding. Animal carcasses will be disposed as per LAM SOP. NOTE that none of the animals in the proposed experiments will receive any live attenuated virus all the animals will receive inactivated attenuated virus. Sharps such as needles will be disposed in the designated sharp containers. No recapping of the needles will be done. All the biohazard material generated from the animals work except the animal carcasses will be packaged in the red biohazard bag, autoclaved and packaged in the designated biohazard box and disposed as biohazard material.

VIII. ENCLOSURES:

1. Doc-1: BMBL 5th edition section VIIIf. This section specifically state that V3526 and CHIK181/25 can be handled at BSL2 level.
2. Doc-2: Research publication outlining the phase-II trail of CHIKV181/25.

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

(b)(6) _____ 3/22/16

Principal Investigator Signature Date

G. Training: The following personnel will attend the next USUHS Investigator/Animal User Training Course:

_____ _____

_____ _____

H. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely, "Responsibility" for implementing animal use alternatives where feasible and conducting humane and lawful research.

(b)(6) _____ 3/22/16

Principal Investigator Signature Date

I. Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

X. PROTOCOL ABSTRACT:

A. Animal Protocol Number:

B. Animal Protocol Title: Deinococcus radiodurans Mn^{2+} Complexes: A Revolutionary Approach to Radioprotection and Vaccine Production (in mice).

C. Principal Investigator: Dr. (b)(6)

D. Performing Organization: USUHS, Bethesda, MD.

E. Funding: Defense Threat Reduction Agency.

F. Objective and Approach:

The specific objectives of the proposed study are:

1. To determine the immunogenic potential of the γ-MDP-CHIK181/25.
2. To determine the protective efficacy of topical application of MDP complex on full thickness cutaneous wound post irradiation.

Recently, we along with Dr (b)(6) group (Gaidamakova et al 2012) have shown the protective efficacy of the peptide (DEHGTAVMLK) isolated from the bacteria *Deinococcus radiodurans* against exposure to high level radiations for inactivating VEEV. This peptide preserves the activity of multimeric proteins at doses that obliterate the nucleic acid. This property of the peptide will be used to inactivate CHIKV181/25. The hypothesis is that viruses treated with the above peptide and irradiated at 50,000Gy will retain the structural protein; however, the viral genome will be destroyed. Therefore, such virus particles will not be infectious but should elicit protective antibody response. We will also test the radioprotective potential of this complex when administered *in vivo* against radiation induced delay in wound healing

G. Indexing Terms (Descriptors): *Deinococcus radiodurans,* live attenuated chikungunya virus, radioprotection, Manganese(Mn^{2+})-Decapeptide-Phosphate complex, antibody response, immune response, protein protection.

MEMORANDUM FOR DR. (b)(6) DEPARTMENT OF PATHOLGY

SUBJECT: IACUC Approval of Protocol – Initial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on June 1, 2016:

Title of Application: "Deinococcus radiodurans Mn2 Complexes: A Revolutionary Approach to Radioprotection (in mice)"

USUHS Protocol Number: (b)(6)

Expiration Date: May 31, 2019

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. NON-TECHNICAL SYNOPSIS:

Development of effective therapies for treatment or protection from radiation injury has been a long-sought goal. The potential threat of the wide spread destruction that can be caused by the use of dirty bombs by rogue nations or terrorists, and accidents like the recent release of nuclear material from the Fukushima Daiichi nuclear power plant in Japan, reflects the urgency to develop safe and efficient radiation countermeasures.

Deinococcus radiodurans, is a microorganism that can survive high doses of radiation. Its radiation-resistance is attributed to high intracellular concentration of manganese present in complex with phosphate and other biological materials such as peptides or nucleosides present inside the cell.

We have recently shown that when artificially reconstituted, such a complex, called MDP complex, can protect mice against lethal radiation exposure. An MDP complex consists of Manganese + decapeptide + phosphate and is made spontaneously when the three constituents are mixed together in a test tube. Under the proposed studies, we plan to further investigate the radioprotective efficacy of MDP complex in a mouse model. Following parameters will be investigated: the maximum radiation that MDP complex can protect from; the route of treatment *i.e.*, oral consumption vs injection under the skin, the changes occurring in blood cell count, cytokine, protein and tissue pathology upon treatment with MDP complex. These experiments will help in understanding the cellular and molecular mechanisms involved in MDP mediated radioprotection.

II. BACKGROUND:

II.1. Background:

Proteins in *D. radiodurans* are exceptionally resistant to oxidation, but they are not inherently radiation-resistant. When purified from *D. radiodurans*, proteins are rendered as susceptible to γ-radiation-induced ROS as proteins in naturally radiation-sensitive cells. Proteome protection in *D. radiodurans* and other resistant prokaryotes is mediated

by the accumulation of small-molecule Mn antioxidants which can functionally substitute enzymes such as superoxide dismutase and catalase, which scavenge superoxide ($O_2^{\bullet-}$) and hydrogen peroxide (H_2O_2), respectively. In *D. radiodurans*, Mn-antioxidants make up approximately 70% of the cytosolic Mn^{2+} (0.2 - 1 mM), forming complexes with orthophosphate (Pi) (~12 mM) and peptides (~3 mM). These complexes specifically protect proteins from ROS generated by abiotic and biotic processes arising from exposure to γ-radiation, ultraviolet (UV) radiation, and desiccation. When applied ex vivo, naturally-occurring Mn-peptide-Pi complexes in protein-free cell extracts of *D. radiodurans* protected cultured human cells and Escherichia coli bacteria from extreme cellular insults caused by γ-rays, and preserved the activities of enzymes irradiated or desiccated in vitro. Subsequently, under this project, rational design of the peptide-component of *D. radiodurans* Mn antioxidants yielded a synthetic complex named Mn-DP1-Pi (referred to here simply as MDP, or MDP complex), which forms spontaneously when the decapeptide-1 (b)(4) Pi and Mn^{2+} are combined. Under aqueous conditions, MDP preserved the structure and function of irradiated proteins exposed to massive doses of γ-radiation, but did not significantly protect DNA or RNA. For example, when applied in vitro at physiologically-relevant concentrations, (b)(4)

(b)(4)

and massively increased the in vitro inactivation-dose of the DNA repair enzyme T4 DNA ligase from ~200 Gy to >60,000 Gy; but MDP did not protect DNA or RNA in vitro or in vivo.

The trends in prokaryotes which support the primacy of function (proteome) over information (genome) in radiation toxicity parallel several trends emerging for irradiated mammalian cells. For example, the relationship between DSB yields and γ-ray dose in human cells is about the same as in all other cell-types (0.005 DSBs/Gy/Mbp). In cultured mouse cells exposed to γ-rays, protein oxidation precedes DNA damage, and is implicated as a critical and very early event in radiotoxicity. Moreover, mouse cells which maintain low levels of ROS, either naturally or by treatment with antioxidants, are consistently more resistant to ionizing radiation than cells with high ROS levels, but with no overt effects on DSB yields. However, the degree to which protein oxidation is expected to influence recovery of irradiated mammalian cells is greater than for bacteria because of the impact of genome size. For example, 8 Gy does not cause genomic DSBs in radiation-sensitive bacteria such as *E. coli* (~4.6 Mbp), and any oxidative damage to DSB repair proteins in *E. coli* exposed to 8 Gy would be inconsequential. Not so for most human cells, where a typically lethal dose of 8 Gy is expected to cause approximately 120 DSBs per haploid genome (0.005 × 8 Gy × 3,000 Mbp), and where any oxidative damage to DSB repair proteins is expected to lower DNA repair efficiency. We have shown that proteome activity in human Jurkat T cells exposed to 200 Gy in vitro is protected by MDP administered pre- or post-irradiation, and that mice treated with MDP and exposed to 9.5 Gy all survived. These results give realistic hope that *Deinococcus* Mn-antioxidants will confer radiation resistance on humans, and that antioxidant treatments based on MDP which target the proteome of mammalian cells may be the basis for countermeasures development against acute radiation syndrome

(ARS), a constellation of health effects which present within 24 hours of exposure to acute doses of ionizing radiation.

Preliminary Studies:

Surplus Mn^{2+} in *D. radiodurans* forms ROS-scavenging complexes which protect proteins from ionizing radiation [redacted] studies on protein-free cell extracts of *D. radiodurans* [redacted] have shown that they are armed with low-molecular-weight (<3 kDa) ROS-scavenging Mn^{2+} complexes which consist mainly of peptides bound to Mn^{2+} and orthophosphate (Pi). When reconstituted *in vitro* at physiologically relevant concentrations, Mn^{2+}, Pi, and peptides display multifactorial antioxidant synergism. Using an *in vitro* approach based on the ROS-sensitive enzyme glutamine synthetase (GS) [redacted] demonstrated distinct antioxidant mechanisms involved in protein protection - where Mn^{2+}-Pi alone, or organic metabolites alone (*e.g.*, peptides, amino acids, nucleosides) provided moderate levels of radioprotection [redacted] However, when peptides, Mn^{2+} and Pi were combined, the complexes were substantially more protective [redacted] Yet, the same reconstituted Mn^{2+} complexes afforded little protection on irradiated DNA preparations [redacted] In summary, surplus Mn^{2+} (*i.e.*, the portion of a cell's Mn^{2+} budget which is not bound to proteins) appear to form ROS-scavenging complexes with various metabolites (Daly et al 2010), which provide global protein protection and preserve the quaternary structures and activities of irradiated enzymes (Daly et al 2010).

Protein-free cell extracts of D. radiodurans are radioprotective of human Jurkat T cells: [redacted] recently demonstrated that protein-free cell extracts of *D. radiodurans* are radioprotective of human Jurkat T cells grown and then irradiated in liquid culture [redacted] In collaboration with [redacted] have shown that the same *D. radiodurans* decapetide-Mn^{2+}-Pi complex which is highly protective of glutamine synthetase is also extraordinarily protective of irradiated human Jurkat T cells.

The MDP complex is non-toxic in vivo: Several in vitro assays [Daly et al., 2010, and Patent Publication # WO/2013/098743] have shown that the MDP complex is non-toxic to mammalian cell cultures and when applied to rats and mice, at concentrations much higher than what would be used in the studies proposed here. In the third year of this project, we showed that there is no toxicity when the [redacted] complex was administered intracranial or intramuscular to mice; i.e. [redacted] The MDP-treated mice developed normally, like the saline-treated mice. We also determined the toxicity profile of the MDP complex in our mouse model via subcutaneous (s.c.) and oral (p.o.) routes of administrations for up to 7 days. This confirmed that MDP is not toxic to mice. Indeed, all the MDP-treated animals gained weight and developed normally. A detailed evaluation of the extent of toxicity/injury from MDP in mice was conducted in serum-samples of the mice on day-21, using a hepatic injury marker panel consisting of ALT, AST, ALKP, GGT, total bile and total protein; a renal injury marker panel consisting of creatinine, phosphorus, sodium, potassium, chlorine, calcium, carbon dioxide, urea

nitrogen and glucose; and another injury marker panel consisting of albumin, LDH, CK, amylase, lipase, cholesterol, direct HDLC, triglycerides and uric acid. Importantly, no significant adverse effects of MDP administration were observed in comparisons to the vehicle-treated mice. These observations demonstrate that the MDP complex (300 mg/kg) is safe *in vivo*.

MDP complex protected mice against radiation injury: (b)(6) recently shown that a synthetic *Deinococcus* decapeptide, which spontaneously forms antioxidant complexes with Mn2+ and inorganic phosphate (MDP) is nontoxic and protected B6D2F1/J mice from acute radiation syndromes when administered at 300 mg/kg. 100% of the mice exposed to 9.5 Gy and treated with MDP pre- and post-irradiation survived 30 days with a significantly lower clinical score, versus the irradiated untreated control group which displayed 63% lethality, significant morbidity and loss of body weight (Figure-1). Moreover, our evaluation indicates that the MDP plays an important role in the early protection of white blood cells, and in the attenuation of radiation-induced bone marrow damage, splenomegaly and hematopoietic damage via G-CSF and GM-CSF modulation (data not shown).

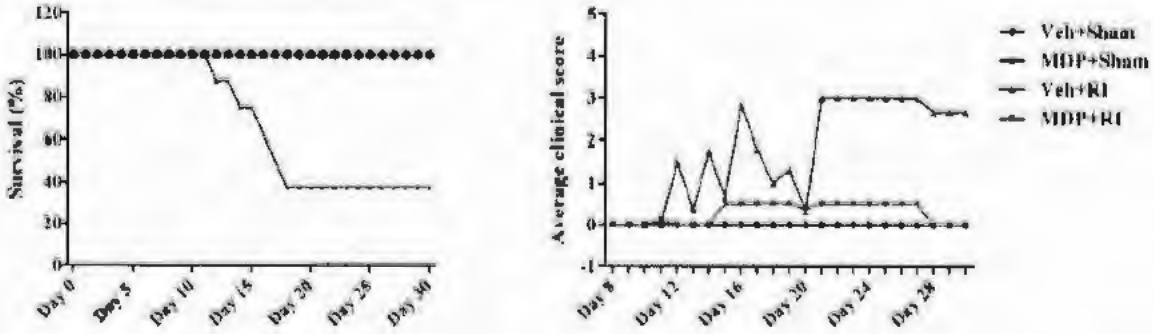

Figure 1. MDP complex confers radio-protection *in vivo*: A) All the mice treated with MDP complex survived a 9.5 Gy dose of irradiation in comparison to a 37.5% survival without MDP treatment and displayed a significantly lower **B)** clinical score.

II.2. Literature Search for Duplication:

II.2.1. Literature Source(s) Searched: PubMed, Defense Technical Information Center (DTIC), and **NIH RePORTER.**

II.2.2. Date of Search: 4/10/2016

II.2.3. Period of Search: 1986-2016

II.2.4. Key Words and Search Strategy: Following key words and their combinations were used to perform the literature search for any duplication. *Deinococcus radiodurans*, radioprotective Manganese complex, radioprotection in mice, gamma irradiation, lethal dose in mice.

II.2.5. Results of Search: In summary no duplication effort was found for the proposed study.

NIH RePORTER: Search for key words D. radiodurans, Manganese complex and radioprotection returned "0" match. Search with key words manganese complex and radiation returned "2" results with studies on manganese superoxide dismutase and its effect on ischemia reperfusion. Search with key words *Deinoccocus* and radiation returned 0 results. Therefore, no duplicating effort was found in the NIH RePORTER system.

PubMed search for manganese complex, radiation injury returned 13 publications which reduced to "0" results when decapeptide word was added to the search terms. Search with the key words *Deinoccocus* and radiation returned more than 500 publication which reduced to 5 articles when radiation was replaced with radiation injury. None of these articles had any duplication of the proposed studies. Search with the key words, radiation injury and treatment returned more than 43000 publications which reduced to 16 articles when manganese peptide was added to the search terms. None of these articles had any duplication of the proposed studies. DTIC search for manganese complex and radiation injury as well as *Deinoccocus* and radiation returned "0" results. Therefore, no duplication effort was found.

III. OBJECTIVE\HYPOTHESIS:

The recent Fukushima nuclear disaster in Japan has brought sharp focus on the urgent need for research on the prevention of acute and chronic radiation effects. Radiological terrorist "dirty bombs" and nuclear explosive devices also are among the most devastating potential threats facing Americans and their allies. *Deinococcus radiodurans*, a bacterial species, has evolved remarkable defenses against, and repair of, damage from radiation, effectively neutralizing all measurable biological damage caused by acute and chronic radiation exposures. The extreme radiation resistance of *D. radiodurans* is dependent on exceptionally efficient forms of protein protection based on intracellular Mn^{2+} complexes. Those Mn^{2+} complexes specifically prevent protein oxidation, and they have been reconstituted *in vitro* by Daly's group [Daly et al 2010].

(b)(6) evaluated the radio-protective potential of MDP complex in B6D2F1/J female mice against a whole-body ^{60}Co γ-radiation exposure at a dose of 9.5 Gy. MDP complex (6.6 mg peptide/mouse) was administered once daily starting from 24h pre-irradiation until day-7 post-irradiation. The MDP treatment resulted in 100% survival (8 mice survived out of 8) in comparison to a 37.5% survival (3 mice survived out of 8) in the absence of treatment. Such remarkable radio-protection on mice conveyed by treatment with MDP supports that the MDP complex of *D. radiodurans* would likely also confer radiation resistance to humans. Notably, MDP treatment in our study also significantly prevented radiation-induced weight loss in mice and depletion of bone marrow cells. Moreover, MDP-treatment prevented splenomegaly in irradiated mice. Based on results from our previous experiment, we will evaluate the radio-protective efficacy of the MDP complex at higher doses of radiation exposure, and to identify the host cellular mechanisms contributing to survival. We will also evaluate the radio-protective efficacy of the MDP complex when administered either only before (prophylactic) or only after (therapeutic) radiation exposure.

(b)(6) hypothesize that a catalytic antioxidant compound such as the MDP complex, which specifically protects proteins from oxidative damage during and after irradiation, can be used in reducing the cell injury/death associated with high radiation exposures. The hypothesis will be tested under the following specific aims.

To test this hypothesis following are the objectives of the study:

1. Evaluate the efficacy of treatment with the MDP complex on survival after RI and evaluate the underlying cellular changes during the process.
2. Evaluate the efficacy of prophylactic and therapeutic treatment with MDP complex on survival after RI.
3. Evaluate the effect of different doses of radiation exposure on the efficacy of radio-protection by MDP complex treatment.

The proposed study has significant military and civilian application as it would characterize (structurally and functionally) the radioprotective Mn^{2+}-peptide complexes of *D. radiodurans*, and would demonstrate if such Mn^{2+}-peptide complexes can protect higher animals from high doses of chronic or acute forms of ionizing radiation (γ-rays).. The major thrust of the proposed study is to exploit the mechanisms of radioprotection conferred by the cytosolic Mn^{2+}-peptide complexes of *D. radiodurans*, which would spur the development and design of novel metallo-organic drugs for prophylaxis and treatment against exposure to ionizing radiation and radiomimetic agents.

IV. MILITARY RELEVANCE:

With the rapidly growing technology today, there is an even greater risk of nuclear sources being misused for destructive purposes by the terrorist groups. There has been a great deal of awareness towards the destructive potential, and the chaos and casualty that can be caused from the use of radiological weaponry from dirty bombs to atomic/nuclear weapons. Any radiation injury scenario during such an event will not only affect military operations but also significantly impact civilian population. Such a possibility presents an area of great concern to the national security and public health. Additionally, the recent incidence of reactor meltdown at Fukushima, Japan and the wide spread suffering caused to the local civilian population, has re-emphasized the requirement for immediate attention.

The proposed study is highly innovative in its approach for C-WMD. One of the main goals of C-WMD is to minimize WMD effects in order to sustain military operations in a "WMD environment". Upon successful completion of the proposed studies, we would have a radio-countermeasure candidate ready to be tested for improved pharmacokinetics and then taken into clinical trials. This would thus be a significant step forward towards developing countermeasures against potential bioterrorist acts causing mass radiation exposure and helping to sustain military operations in "WMD environments" by minimizing the effects of WMD. We anticipate that the information generated by evaluating the hematological and pathological changes as well as protein expression will provide a better understanding of the underlying mechanisms contributing to radioprotection or radiotherapy by MDP complex in the host and have far-reaching scientific implications on how to counter and/or reduce the effects of ionizing radiations.

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures:

V.1.1. Experiment 1:

Evaluate the effect of different routes of MDP complex treatment on the radio-protection efficacy.

We have already seen that MDP complex confers 100% protection against RI at an exposure dose of 9.5 Gy when administered in a combination of oral and subcutaneous (s.c.) injection. However, to identify the best route of MDP treatment, protective efficacy using individual routes of treatment will be evaluated. Mice will be randomly divided into 4 groups (n=10 per group with one iteration) as described in the table below.

Treatment: MDP complex (6.6 mg peptide complex in 200 µl PBS) will be administered either orally or subcutaneously starting 24 hr before irradiation followed by two doses 14-15 hr before and at the time of irradiation. Thereafter, animals will be administered with MDP complex once daily for 7 days. Corresponding vehicle groups will receive PBS instead of MDP treatment.

	Treatment	Route of treatment	N	Iterations /grp	Total animals / grp	Pain category
1.	Vehicle	Oral	10	2	20	E
2.	Vehicle	Subcutaneous	10	2	20	E
3.	MDP	Oral	10	2	20	E
4.	MDP	Subcutaneous	10	2	20	E
		Total			80	

Irradiation: Radiation exposure dose will be 9.5 Gy.

Sample collection and study end point: Water consumption will be monitored for the first 7 days; and total body weights and survival will be monitored for 30 days post irradiation. Blood, spleen, bone marrow, and ileum will be collected from surviving mice on day 30 from all the groups and used for measuring total blood cell counts, bone marrow cell counts, histological evaluation of ileum and sternum etc.

Pain category for the animals (see also section V.4.1.1.1): In this experiment, all animals will receive radiation exposure. Although based on the results from our previous study, we expect that the animals treated with MDP will have significantly higher survival rate and reduced morbidity. However, since they may experience some clinically adverse symptoms initially, all the animals have been placed under category E (n=40 x 2=80). If MDP treated animals consistently show improved clinical score and protection against radiation exposure, it will be reported in the annual report and pain category can be changed to D after consultation with LAM veterinarian and IACUC.

V.1.2 Experiment-2. Evaluate the effect of different doses of radiation exposure on the efficacy of radio-protection by MDP complex treatment.

To test the protective potency of MDP complex treatment against RI, dose reduction factor (DRF) will be determined by studying the survival of MDP complex treated animals against various doses of radiation. Mice will be randomly divided into 8 groups (n=10 per group with one iteration) as described in the table below.

Treatment: MDP treatment will be given as described in experiment-1. Based on the results from Experiment-1, the route of MDP administration resulting in higher protection efficacy will be chosen for this experiment.

Irradiation: Radiation exposure dose of 10.5 Gy generally results in 100% mortality without any treatment. We have already seen that MDP complex confers 100% protection against RI at an exposure dose of 9.5 Gy (resulting in 67.5% mortality without treatment). Thus, under this aim, mice will be exposed to the radiation doses of 10.0 Gy, 10.5 Gy, 11.0 Gy, or 11.5 Gy as described in Table 2.

Table 2: Experimental set-up for Exp-2

	Injury group	Treatment	N	Iterations /grp	Total animals /grp	Pain category
1.	Radiation 10.0Gy	Vehicle	10	2	20	E
2.	Radiation 10.5Gy	Vehicle	10	2	20	E
3.	Radiation 11.0Gy	Vehicle	10	2	20	E
4.	Radiation 11.5Gy	Vehicle	10	2	20	E
5.	Radiation 10.0Gy	MDP	10	2	20	E
6.	Radiation 10.5Gy	MDP	10	2	20	E
7.	Radiation 11.0Gy	MDP	10	2	20	E
8.	Radiation 11.5Gy	MDP	10	2	20	E
		Total			160	

Sample collection and study end point: Water consumption will be monitored for the first 7 days; and gain in total body weights and survival will be monitored for 30 days post irradiation. Blood, spleen, bone marrow, and ileum will be collected from surviving mice on day 30 from all the groups and used for measuring total blood cell counts, bone marrow cell counts, histological evaluation of ileum and sternum etc.

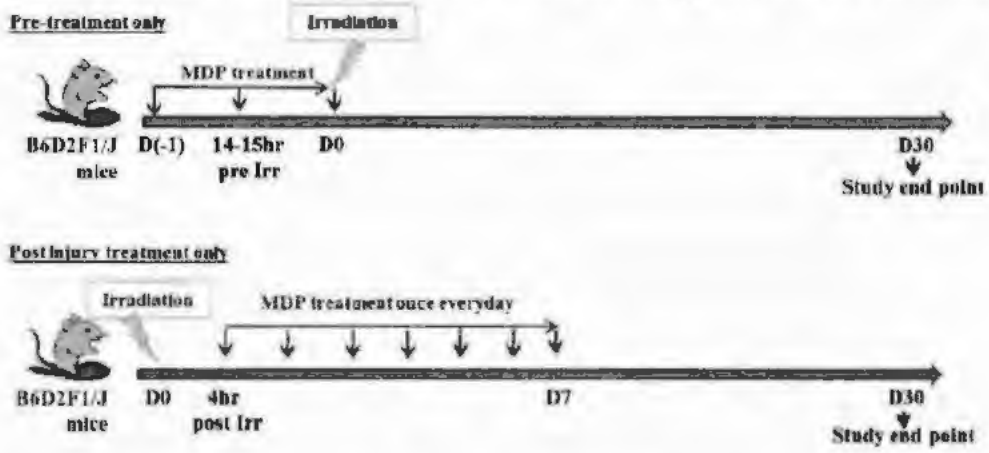
Pain category for the animals (see also section V.4.1.1.1): In this experiment, all animals will receive radiation exposure. Although based on the results from our previous study, we expect that the animals treated with MDP will have significantly higher survival rate and reduced morbidity. However, since the animals will experience some disease symptoms initially and protective effect of MDP against higher doses of radiation exposure is not known, all the animals have been placed under category E (n=160).

V.1.3 Experiment-3. Evaluate the efficacy of prophylactic and therapeutic treatment with MDP complex on survival after RI.

To test the prophylactic and mitigating potentials of MDP complex, this task will evaluate the radio-protection conferred by the MDP complex when given only before and at the time of radiation exposure or only after exposure. Mice will be randomly divided into 8 groups (n=20 per group) as described in Table 3.

Treatment: MDP complex will be administered either three times for the pretreatment only group i.e. 24h and 12h before and at the time of irradiation; or starting 4h post-irradiation until day-7 to the animals in the 4h post-injury group (a total of 7 administrations).

Irradiation: The irradiation dose will be decided based on the results from Exp-2.
Sample collection and study end point: Water consumption will be monitored for the first 7



days; and gain in total body weights, and survival will be monitored for 30 days post-irradiation. Blood, spleen, bone marrow, and ileum will be collected from surviving mice on day 30 from all the groups and used for measuring total blood cell counts, bone marrow cell counts, histological evaluation of ileum and sternum etc.

Table 3: Experimental set-up for Exp-3

	Injury group	Treatment	N	Iterations/ grp	Total animals/ grp	Pain category
1.	Sham	Vehicle (pretreatment only)	5	2	10	C
2.	Sham	MDP complex (pretreatment only)	5	2	10	C
3.	Sham	Vehicle (4h post-injury)	5	2	10	C
4.	Sham	MDP complex (4h post-injury)	5	2	10	C
5.	Radiation	Vehicle (pretreatment only)	10	2	20	E
6.	Radiation	MDP complex (pretreatment only)	10	2	20	E
7.	Radiation	Vehicle (4h post-injury)	10	2	20	E
8.	Radiation	MDP complex (4h post-injury)	10	2	20	E
		Total			**120**	

Pain category for the animals (see also section V.4.1.1.1): In this experiment, the animals receiving radiation exposure have been placed under category E (n=80). Although in previous experiments MDP complex protected animal against radiation exposure, treatment included both pre- and post-exposure treatment. As this experiment tests the prophylactic and therapeutic approach separately effect of which is not known at this time, these animals are placed in pain category E. The animals in the sham groups will not receive any irradiation but will receive PBS or MDP via either oral or subcutaneous route and thus have been placed under category C (n=40).

V.1.4 Experiment-4. Evaluation of effect of radiation exposure on blood cells, bone marrow and ileum after prophylactic and therapeutic treatment with MDP

complex.

To test the effect of prophylactic and mitigating potentials of treatment with MDP complex on blood, bone and marrow cells and various tissues against RI a time-course analysis will be done. Briefly, mice will be randomly divided into 8 groups (n=15 per group) as described in Table 4.

Treatment and irradiation: Radiation exposure doses and MDP treatment regime will be chosen based on the results from experiment-1, 2 and 3.

Sample collection and study end point: Water consumption will be monitored for the first 7 days; and gain in total body weights. Blood, spleen, bone marrow, and ileum will

Table 4: Experimental set-up for Exp-4

	Injury group	Treatment	N (D1, D3 and D7)	Iterations/ grp	Total animals/ grp	Pain category
1.	Sham	Vehicle (pretreatment only)	15	1	15	C
2.	Sham	MDP complex (pretreatment only)	15	1	15	C
3.	Sham	Vehicle (4h post-injury)	15	1	15	C
4.	Sham	MDP complex (4h post-injury)	15	1	15	C
5.	Radiation	Vehicle (pretreatment only)	15	1	15	E
6.	Radiation	MDP complex (pretreatment only)	15	1	15	E
7.	Radiation	Vehicle (4h post-injury)	15	1	15	E
8.	Radiation	MDP complex (4h post-injury)	15	1	15	E
		Total			**120**	

be collected on day 1, 3 and 7 from all the groups (5 mice/group at each time point) and used for measuring total blood cell counts, bone marrow cell counts, serum cytokine levels, histological evaluation of ileum and sternum etc.

Pain category for the animals (see also section V.4.1.1.1): In this experiment, the animals receiving radiation exposure have been placed under category E (n=60). If MDP show protection in animals exposed to irradiation and reduction in clinical score in experiment # 3, then these mice will be moved to category D after consultation with LAM veterinarian and IACUC. The animals in the sham groups will not receive any irradiation but will receive PBS or MDP via either oral or subcutaneous route and thus have been placed under category C (n=60).

V.2. Data Analysis:

Survival in Experiment # 1, 2, and 3 will be described using Kaplan-Meier curves and compared between groups using the logrank test. We anticipate 30% survival in the control group. A sample size of 20 per group (pooled over two iterations) will have 80% power to detect a significant difference in survival between groups if survival in the experimental group is at least 80%. The calculation is based on a 5% two-sided significance level.

In experiment # 4 two-way ANOVA, one-way ANOVA, post-hoc test, chi-square test, and student's will be used for statistical analysis of non-survival outcomes. The required sample size for these outcomes is only 5 per group. This sample size will have 80% power to detect differences of 2 standard deviations between groups based on

Student's t test for independent samples with 5%, two-sided significance level. Note that in experiment 3, only 5 animals per group are requested for sham conditions. 100% of these animals are expected to survive, and the primary comparisons will be for the non-survival outcomes.

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered:

Drug manufacturers use computer modeling – structure function relationship – and screening *in vitro* by cell cultures during the development of candidate drugs. Computer modeling and cell cultures are insufficient to determine whether or not a given regimen (prophylactic or therapeutic) is effective in promoting survival, resisting infection, or enhancing hemopoiesis and biochemical interruption. An integrated, functional, computer model of a mammal has not yet been achieved for the purpose of examining intricate physiological interactions among cells, tissues, and organs that occur after exposure to ionizing radiation. The resiliency of organs, such as the gastrointestinal system or hematopoietic system, to ionizing radiation depends on a complex network of interactive signaling systems to sense the magnitude of tissue damage, and to initiate repair, recovery, and other defense processes. The physiology of these interacting networks is altered by radiation in ways that cannot yet be modeled. In fact, the proposed studies will provide data, which will contribute directly to future models to predict the progress of radiation injury and appropriate medical treatments.

V.3.2. Animal Model and Species Justification:

B6D2F1/J female mice, 12-20 weeks of age, will be housed in a facility accredited by the Association for Assessment and Accreditation of Laboratory Animal Care, International. Animal rooms will be maintained at 22° ± 4°C with 50% ± 20% relative humidity on a 12-hr light/dark cycle. Animals will be randomized prior to each experiment and housed in small shoebox cages (four animals per cage). Commercial rodent ration (Harlan Teklad Rodent Diet 8604) will be freely available as will acidified (pH=2.5 - 3.0) water to control opportunistic infections. All animal-handling procedures will be performed in compliance with guidelines from the National Research Council (1996). The B6D2F1/J female mouse was chosen as the best animal model to use for radiation therapy protocol because:

(1) It is one of the least sentient mammalian species that will permit us to achieve our research objectives.
(2) The cellular proliferative characteristics of gastrointestinal tract and hematopoietic tissues in the mouse are qualitatively similar to those in the human.
(3) Studies in mice have had a direct impact on work with larger animals and humans, as well as clinical treatment.
(4) There are extensive published reports available for comparison, review, and analysis of major biological findings.

V.3.3. Laboratory Animals

	Species#1 (Exp 1, 2, 3 and 4)
Genus & species	Mouse
Strain/stock	B6D2F1/J
Source/ Vendor	(b)(4)
Age	12-20 weeks
Weight	20-30 gm
Sex	Female
Special considerations	BSL-2
Number of animals required	480

V.3.5. Refinement, Reduction, Replacement (3 Rs):

V.3.5.1. Refinement:

The animals will also be humanely euthanized if they become moribund and show signs such as ruffled fur, weakness, lethargy, difficulty breathing, weight loss of more than 20%, or loss of appetite, are cool to the touch, show inappetance, or diarrhea, earlier than the proposed study end points. In our earlier pilot study, MDP complex protected mice from radiation induced death, which was also accompanied by improvement in the clinical score as compared to the sham treated animals. Therefore, MDP complex itself may present as a refinement that protect animals and reduce radiation exposure-induced morbidity and mortality.

V.3.5.2. Reduction:

The number of animals to be used is the minimum number of animals needed to achieve scientifically sound conclusions for the experimental objectives. In order to reduce the number of animals in the study we have kept the number of control animals as low as possible to achieve statistical significance for the data obtained. Experiments are designed in a progressive way so as to reduce the number of groups (e.g. first route of treatment then prophylactic vs therapeutic approach) needed to ascertain the protective effect of MDP complex both on the survival as well as molecular pattern).

V.3.5.3. Replacement:

Extensive *in-vitro* testing of the MDP complex for determining the radiation protection activity. Radiation protection property of the MDP complex was tested on biologically active enzymes and human Jurkat T cells. We have extensively researched for an alternative to the animal model for studying the radiation injury but, no alternative to *in vivo* experiments are available at this time. We are using the lowest animal in the phylogenetic scale that serves well as an animal model to study the radioprotective potential of MDP and its underlying mechanism.

V.4. Technical Methods:

V.4.1. Pain / Distress Assessment:

V.4.1.1. APHIS Form 7023 Information:

V.4.1.1.1. Number of Animals:

	Species #1
V.4.1.1.1.1. Column C:	100
V.4.1.1.1.2. Column D:	
V.4.1.1.1.3. Column E:	380

In experiments 1-4, a total of 380 mice will receive radiation exposure to sub-lethal/lethal doses and thus may become moribund. Some of these animals will receive MDP treatment and others will receive PBS as the vehicle after radiation injury. Although, MDP treatment is expected to alleviate the morbidity caused by radiation injury and enhance the survival, these animals have been placed under category E. A total of 100 mice under exp# 3 and 4 will not be irradiated and will only receive momentary distress due to subcutaneous or oral administrations. These animals will not develop any disease or experience any morbidity. Therefore, they have been placed under category C.

V.4.1.2. Pain Relief / Prevention:

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization:

Anesthesia: Blood collection: At days 1, 3, and 7 for Exp-4 and on day 30 for the rest of the experiments, animals will be anaesthetized appropriately under deep CO_2 inhalation (fill rate of 10-30% of the chamber volume per minute). Blood will be collected via terminal cardiac puncture with 23 G 5/8 - 28G 1/2 needle and will be used for CBC analysis and serum cytokine level evaluation. Tissues will also be collected and frozen at -80°C until use.

Analgesics: No analgesics will be used.

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions:

Animals will be kept at the animal housing facility of LAM for 5-7 days prior to the irradiation procedure and will receive standard care. Post irradiations, animals will be monitored for any distress. Mice will be monitored at least twice a day (i.e., first thing in the morning and then again in the afternoon) during the experiment. If animal is found to be distressed such as ruffled fur, lethargic and weight loss post immunization, animal will be humanely euthanized. For experiment # 1 most morbidity and mortality is expected between days 10-21 post irradiation. For experiment # 2 the period of most morbidity and mortality is expected to occur earlier than is exp#1 as higher doses of radiation will be used. Expected period of most morbidity and mortality is between days 7-15. For experiment #3 the expected range of days when expected morbidity and mortality is high will be based on observation in experiment #2 and is expected to lie

between days 7-15. For Experiment # 4 no such period is expected as animals will be sacrificed by day 7. Observation of animals during this heightened period of morbidity and mortality will be done at least 3 times (early morning, noon, and late afternoon) a day by the investigative staff (twice) and LAM personnel (once). If, during any of the checks, it is suspected that the animals may succumb before the next observation period, the animals will either be checked again before the next scheduled observation period or be euthanized immediately as in section V.4.5.

We will follow the **Rodent Intervention Score Sheet** (see section VIII) to track morbidity and moribund state in injured group of mice. If any single category is above 12 (i.e., the mouse cannot stand or breathe normally, right within 5 seconds when placed gently on side, or respond when the paws are pinched gently), the animal will be euthanized immediately. Mice that score greater than 10 for all categories combined will be considered to be moribund and humanely euthanized. Morbidity signs usually appear much earlier than body weight loss for more than 20%. If there are no above mentioned signs appearing and the body weight loss is an only concern, then mice with body weight loss more than 20% will be euthanized immediately. These mice will be monitored very closely for their appearance, general behavior, respiratory rate, and provoked behavior prior to making a determination of euthanasia. Weights taken 2-24 hours prior to irradiation will be used as a baseline reference.

V.4.1.2.3. Paralytics: NONE

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures:

V.4.1.3.1. Sources Searched: PubMed (National Library of Medicine).

V.4.1.3.2. Date of Search: 4/10/2016

V.4.1.3.3. Period of Search: 1986-2016

V.4.1.3.4. Key Words of Search: Individual and combination of following words was used; pain, analgesic, mice, alternative, procedure, justification, radiation injury.

V.4.1.3.5. Results of Search:

There are no alternative procedures for irradiation because its effects cannot be otherwise duplicated.

Review of several research article for irradiation protocol and post treatment did not reveal any usage of any separate drug specifically for alleviating the pain associated with the irradiation.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification:

All the animals will be treated with local application of antibiotic ointment (over the counter available Neosporin) after the ear punching. Analgesics such as opioids, local anesthetics and non-steroidal anti-inflammatory drugs (NSAIDS) cause alteration in the host inflammation response. Several research articles have been published

looking at the beneficial effect of NSAIDs after radiation exposure and their use has been recommended post irradiation. Since alteration in inflammation hemostasis play a crucial role in radiation injury, administration of these drugs may alter the host response to irradiation and negatively affect determining the radioprotective efficacy of MDP complex. Therefore, these drugs will not be used in the studies (experiment 1-4). We have previously conducted toxicity study for MDP and it was found to be completely safe *in vivo*. Thus, we don't expect any side effects from MDP treatment. Regarding pain, there is no data or indication that it will enhance pain. A logical guess may be that due to its free radical scavenging properties it may reduce the pain via controlling the inflammation, however that is speculative.

However, sufficient care will be given to ensure frequent monitoring of the animals and performing early euthanasia as soon as the disease symptoms (as explained in section V.1.1 and V.4.5) are visible to alleviate unnecessary pain and distress to the animals.

V.4.2. Prolonged Restraint: NONE

V.4.3. Surgery: NONE

V.4.3.1. Pre-surgical Provisions: N/A

V.4.3.2. Procedure: N/A

V.4.3.3. Post-surgical Provisions: N/A

V.4.3.4. Location: N/A

V.4.3.5. Surgeon: N/A

V.4.3.6. Multiple Major Survival Operative Procedures: N/A

V.4.3.6.1. Procedures: N/A

V.4.3.6.2. Scientific Justification: N/A

V.4.4. Animal Manipulations:

V.4.4.1. Injections:

Subcutaneous injections (a total volume of 200µl/ mouse) will be administered on the back of the animals for MDP treatment using 23G 5/8 - 28G 1/2 needles.

V.4.4.2. Biosamples:

For experiment#1, 2 and 3, blood will be collected on day 30 and for experiment#4, blood will be collected on day1, day3 and day7 via cardiac puncture. Animals will be deeply anesthetized with CO_2 (fill rate of 10-30% of the chamber volume per minute),

and thoracic cavity will be opened to gain access to the heart and blood will be drawn using 26 gauge needle on a 1cc syringe from the right ventricle. Spleen, bone marrow, and ileum will be collected from mice for experiment# 1-4.

V.4.4.3. Adjuvants: NONE

V.4.4.4. Monoclonal Antibody (MAbs) Production: NONE

V.4.4.5. Animal Identification: Ear punching will be used to identify the animals within each cage, if needed. Ears will be punched at least 2 days prior to the initiation of the experiments.

V.4.4.6. Behavioral Studies: NONE

V.4.4.7. Other Procedures:

Irradiation procedure:

Animals will be exposed to whole body gamma radiation using the USUHS cesium-137 source (Gammacell 40 or JLS Mark 1 irradiators) at ambient temperature. The irradiators are located inside the USU irradiator facility (b)(6) and access is restricted. Drs. (b)(6) are approved as authorized irradiator operators and authorized for unescorted access into the irradiator facility. They will perform the irradiations. During irradiation mice will be kept in a circular well ventilated covered container which will then be placed in the irradiator on a turn table to ensure uniform whole body irradiation. The amount of time for radiation exposure will be calculated based on the current dose rates of the sources and the final desired dose (as listed in the experiments above). Control animals will be sham-irradiated and will receive the same handling and procedures as the irradiated mice except the radiation exposure. There after animals will be housed back in their original room in a fresh cage containing sterile bedding. Animals will be fed water and food at libitum. We have also consulted with Mr. (b)(6) Assistant RSO, EHS Radiation Safety regarding the irradiation of mice using the Cs^{137} irradiator.

Oral administration of MDP complex: Oral (p.o.) administration of MDP complex will be done using round tipped 20G-1&1/2 disposable animal feeding needles (Fisherbrand, Cat# 01-208-87). 200 ul of MDP complex in saline will be slowly released inside the mouth along the cheek lining and mouse will be allowed to swallow the fluid. Complete oral gavage administering the fluid in mouse stomach is not being done due to issues that the procedure may bruise the esophageal lining resulting in a combined injury (bruising + radiation). Combined injury (wound + radiation) has been shown to reduce the survival in mouse over irradiation alone in B6D2F1/J mice that are proposed in this protocol (Kiang and Fukumoto (2014) Health Phys. 2014 Jun; 106(6): 720–726).

Ear punching: Ear punches will be made 2 days prior to the initiation of the experiments. Scissor style ear punch (Kent Scientific, cat# INS500076) will be used to make ear punch. Animals will be identified in the following manner:

Mouse #1-No holes.
Mouse #2-One hole on the right ear.
Mouse #3-One hole on the left ear.
Mouse #4-One hole on each ear.
Mouse #5-Two holes on the right ear.
Mouse #6-Two holes on the left ear.
Mouse #7-Two holes on the right and one hole on the left.
Mouse #8-Two holes on the left and one hole on the right.
Mouse #9-Two holes on each ear.

Mostly numbering from 1 to 5 five will be required and further identification will be done based on the cage number followed by the animal number. A topical application of Neosporin ointment will be applied over the punch before returning animals to their cage.

V.4.4.8. Tissue Sharing: Tissues and samples collected under study will be stored as appropriate and will be available to share if required and useful in reducing any additional animal work.

V.4.5. Study Endpoint:
For Experiment#1-3 study end point will be day 30 and for experiment#4, study end point will be on day 1, 3 and 7 from the day of irradiation. If an animal is found to exhibit significant adverse clinical symptoms such as ruffled fur, weakness, lethargy, difficulty breathing, weight loss of more than 20%, or loss of appetite, are cool to the touch, show inappetance, or diarrhea, such animals will be identified in consultation with the LAM veterinarian and will be humanely euthanized by LAM staff or PI staff. Experimental mice that are found morbid, but not moribund, based on the scoring criteria listed under section VIII, will be allowed to continue in the experimental protocol in order to obtain an optimal number of specimens for evaluation.

V.4.6. Euthanasia: All animals will be humanely euthanized using deep CO_2 anesthesia (flow rate of 10-30% of the chamber volume per minute) followed by cervical dislocation. Animals will be euthanized at the predetermined end point of each experiment except for the animals that are found moribund as described in section V.4.1.2.2 for which euthanasia will be done as required. In experiments requiring terminal blood collection, blood will be collected via cardiac puncture after deep CO2 anasthesia following which cervical dislocation will be performed as described in V.4.4.2.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs and by LAM personnel for each species in this protocol. Animals will be housed in autoclaved cages and will be provided with acidified water. If the cages are found dirty during inspection by the PI staff, they will also change the bedding as needed. Graduated water bottles will be used

to determine the water consumption per cage per day for 10 days after the irradiation procedure.

V.5.1.1. Study Room: Barrier housing is required for ultra clean condition for immunocompromised animals.. Room will be designated by LAM as per the availability of the room.

Building(s) (b)(6) Room Number(s) TBD

V.5.1.2. Special Husbandry Provisions: Animals will be housed and handled according to LAM SOPs for BSL2 handling.

Food Restriction:	Yes		No	X
Fluid Restriction:	Yes		No	X

V.5.1.3. Exceptions: For experiment # 1-4, mice will be group housed except during the irradiation procedure as described above or in the event that their cage mates have had to be removed from the study; under these circumstances they will be housed individually.

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care: Mice will be checked on daily basis by the LAM veterinarian and PI staff. Routine care such as plentiful chow, water and change of beds will be provided by the DLAM staff. However, LAM staff will be requested (a note will be posted in the room) not to change the water bottles during initial 7 days after irradiation for experiment# 1-4 since water consumption will be monitored by the PI staff.
Mice that show increased distress as determined by the veterinarian and described in section V.4.5 will be removed from the study and will be humanly euthanized by the DLAM or the PI staff as described in the section V.4.6.

V.5.2.2. Emergency Veterinary Medical Care: All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays. Additional two checks will be conducted by the PI staff during the heightened observation period as described in section V.4.1.2.2.). Moribund animals meeting the study endpoint criteria in section V.4.5 will be euthanized as per section V.4.6.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: Except as indicated below, all animals on this protocol will be provided with routine environmental enrichment in accordance with LAM

SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents; balls, toys and food enrichment treats for large animal species.

V.5.3.2. Enrichment Restrictions: None.

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
Subcutaneous injections, oral administration, euthanasia, blood and tissue collection.	(b)(6)	Staff Scientist, > 12 years of experience with the rodent models. SC injections, 12 years; cervical dislocation 12 years; CO_2 anesthesia 12 years; cardiac blood collection, 10 years, oral gavage: 4 years.	Rodent handling training class 2002 and 2006, USUHS Investigator Training Course (2006)
Injection, euthanasia, blood and tissue collection.		Research associate, > 8 years of experience handling animal samples. SC, 7 yrs, CO_2 anesthesia, 7 yrs; and oral gavage: 7 yrs.	
Injection, euthanasia, blood and tissue collection.		Staff Scientist, 8 years of experience handling animal samples. SC injections, 2 years; cervical dislocation 2 years; CO_2 anesthesia 2 years; and cardiac blood collection, 2 years.	Rodent handling training class 2008, USUHS Investigator Training Course 2007,
Injection, euthanasia, blood and tissue collection, and		Post-doctoral fellow, 8 years of experience handling animal samples.	Rodent handling training class 2008, USUHS Investigator Training Course

Irradiation procedure.	(b)(6)	SC injections, 2 years; cervical dislocation 5 years; CO_2 anesthesia 5 years; and cardiac blood collection, 2 years.	2007, Irradiator user training 2012
Injections, euthanasia, blood and tissue collection, and Irradiation procedure.		Post-doctoral fellow, 5 years of experience handling animal samples. SC injections, 2 years; cervical dislocation 2 years; CO_2 anesthesia 2 years, tail vein nick blood collection, 2 years; and tissue collection, 2 years.	Rodent handling training class held on 08/17/2010, USUHS Investigator Training Course 08/17/2010, Irradiator user training 2012

VII. BIOHAZARDS/SAFETY:

Drs (b)(6) listed in the present IACUC protocol have been trained either as radiation users or as general radiation users on a regular basis and will perform the irradiations. Radiation dosimeters will be worn as required during the irradiation procedure and exposure will be minimized in accordance with ALARA principles of radiation safety. Exposure doses will be monitored for each individual as per the USU radiation biosafety program. All investigators and technicians will use appropriate procedures which will include wearing of mask, bonnet, gown, booties, and gloves during observation of mice and terminal sample collections. All PI staff involved in the study with animal contact will undergo annual health survey. All sharps such as needles, surgical blades etc., will be discarded in the red sharps containers. No recapping of needles will be practiced. All formalin requiring procedures such as storing of tissues in formalin for histology will be performed under a chemical hood with specific filters for handling formalin. Formalin waste will be discarded in clearly labeled containers accordance with the USU chemical waste pickup guidelines. All investigators and technicians are current in their safety training and medical surveillance.

VIII. ENCLOSURES:

Rodent Intervention Score Sheet.

Rodent Intervention Score Sheet		
PARAMETER	**DESCRIPTION**	**SCORE**
Appearance	Normal (coats smooth, eyes/nose clear)	**0**
	Reduced grooming OR minor hunching	**1**

	Ocular/nasal discharge AND/OR rough coat and hunching OR facial edema	**3**
	Emaciated, dehydrated, OR soft stools (fecal matter around anus)	**5***
	Presence of bloody diarrhea	**9**
General behavior	Normal	**0**
	Minor changes – writhe or grimace, slightly less active than baseline	**1**
	Moderately less mobile and alert	**2**
	Ataxia, wobbly, appearing weak	**6***
	Unable to stand	**12**
Respiratory Rate	Normal breathing	**0**
	Increased (double) breathing rate, rapid or shallow	**6**
	Abdominal breathing (gasping +/- open mouth breathing)	**12**
Provoked behavior	Normal	**0**
	Subdued or weak, but moves away when stimulated	**1**
	Subdued even when stimulated (moves away slowly).	**3**
	Unresponsive when stimulated, weak, precomatose	**6***
	Does not right when placed gently on side within 5 seconds, or no response when pinch the paws	**12**
***Notify LAM immediately – may need to euthanize**		
<6 – Normal		
6-9 – Morbid, some pain/distress, monitor at least three times a day.		
>10 - Moribund. Either euthanize or notify LAM. If any single category is at 12, euthanize animal immediately.		

Notes: Mice found to have lost greater than 20% of their body weight (relative to weight at start of experiment) will be brought to the attention of LAM staff or euthanized immediately.

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

(b)(6) 4/21/16

Principal Investigator Signature Date

G. Training: The following personnel will attend the next USUHS Investigator/Animal User Training Course:

_____ _____

_____ _____

H. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely, "Responsibility" for implementing animal use alternatives where feasible and conducting humane and lawful research.

(b)(6) 4/21/16

Principal Investigator Signature Date

I. Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

(b)(6) 4/21/16

Principal Investigator Signature Date

X. PROTOCOL ABSTRACT:

A. Animal Protocol Number:

B. Animal Protocol Title: *Deinococcus radiodurans* Mn^{2+} Complexes: A Revolutionary Approach to Radioprotection (in mice).

C. Principal Investigator: (b)(6)

D. Performing Organization: USUHS, Bethesda, MD.

E. Funding: Defense Threat Reduction Agency.

F. Objective and Approach:

The specific objectives of the proposed study are:

1. Evaluate the efficacy of treatment with the MDP complex on survival after RI and evaluate the underlying cellular changes during the process.
2. Evaluate the efficacy of prophylactic and therapeutic treatment with MDP complex on survival after RI.
3. Evaluate the effect of different doses of radiation exposure on the efficacy of radio-protection by MDP complex treatment.

Recently, (b)(6) have shown the protective efficacy of the peptide (b)(4) isolated from the bacteria *Deinococcus radiodurans* against exposure to sub-lethal radiation exposure. Now, we want to further evaluate its radioprotective potential at higher doses of radiation exposure and at different treatment doses. Additionally, we will explore the underlying mechanism of MDP induced radioprotection *in vivo*.

G. Indexing Terms (Descriptors): *Deinococcus radiodurans*, radioprotection, Manganese(Mn^{2+})-Decapeptide-Phosphate complex, radiation injury, protein protection.

July 19, 2013

MEMORANDUM FOR DR. (b)(6) DEPARTMENT OF PEDIATRICS

SUBJECT: IACUC Approval of Protocol – Triennial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on July 19, 2013:

Animal Protocol Title: "Generation and Characterization of Genetically Engineered Mouse Strains Carrying Setbp1 Mutations"

USUHS Protocol Number: (b)(6)

Expiration Date: July 18, 2016

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. NON-TECHNICAL SYNOPSIS: This study is designed to use mice as a model to characterize the function of a new gene called Setbp1 during normal human development. We will generate genetically engineered mice carrying mutations in Setbp1, which will be used to characterize the effects of these mutations on blood generation and neural development. For some studies, immature blood cells from these mutant mice will be transplanted into normal mice to better characterize their regeneration properties. Transplant recipient mice will be irradiated before transplantation to enhance the establishment of the transplant donor cells in their bone marrow. Irradiation at our proposed dosage is lethal to mice if not treated afterwards. However, these recipient mice in our study will be fully rescued by the subsequent transplantation of donor immature blood cells.

II. BACKGROUND:

II.1. Background: Hematopoietic development is a critical process that starts from the hematopoietic stem cells (HSCs) and produces all essential cell types in the blood [1]. HSC is the only cell type in the system capable of extensive self-renewal. The self-renewal of HSCs is essential for sustaining the entire hematopoietic system, and its deregulation has severe consequences. Decreased HSC self-renewal could cause bone marrow failure while increase in self-renewal could lead to leukemia development. However, the critical factors that control HSC self-renewal are still largely unknown. Setbp1 is a novel transcription factor found in our recent mutagenic screens capable of conferring self-renewal capability to hematopoietic progenitor cells that normally lack such capability [2,3], and was also indicated in human leukemia development [4], suggesting that it may play an important role in the (b)(4) and (b)(4). To test this hypothesis, we generated a (b)(4) a (b)(4) and a (b)(4) allele for Setbp1 in mice. (b)(4) (b)(4) Additional studies have been proposed in this protocol to further characterize this (b)(4) due to Setbp1 loss. The (b)(4) reporter transgene driven

by the endogenous (b)(4) promoter and will be used to characterize the normal cell type specific (b)(4) The knowledge that we learned about the function of Setbp1 in the (b)(4) should also help us gain insights into its involvement in leukemia development.

Preliminary studies on (b)(4) embryos also suggest that (b)(4) may cause defects in the (b)(4) (b)(4) knockout versus wild-type embryos. Therefore, studying the function of Setbp1 in (b)(4) may help uncover new molecular mechanisms (b)(4) cells maintenance, which remains poorly understood. However, (b)(4) (b)(4) preventing us from fully assessing their (b)(4) (b)(4) In order to circumvent this problem, we have generated (b)(4) (b)(4) which express a neural specific Cre recombinase resulting (b)(4) (b)(4)

II.2. Literature Search for Duplication:

II.2.1. Literature Source(s) Searched:
BRD, NIH RePORTER, and PubMed

II.2.2. Date of Search: 5/18/2013

II.2.3. Period of Search:
BRD: 1998 – 2013
NIH RePORTER: 1988 – 2013
PubMed: 1950 – 5/30/2013

II.2.4. Key Words and Search Strategy: This study is mainly designed to use knockout mouse models to characterize the function of Setbp1 in (b)(4) (b)(4) Therefore, "Setbp1" in combination with "mouse" was used as the search term.

II.2.5. Results of Search:
Four projects were returned on BRD and they are (b)(6) protocols from 2008 and 2009. (b)(6) project entitled "Role of Setbp1 in leukemic stem cell self-renewal" was the only project returned on NIH RePORTER. However, this project focuses on overexpression of *Setbp1* in leukemia development and does not address the function of (b)(4) Two articles[5,6] were returned on PubMed. However, both of them tried to study effects of Setbp1 overexpression and none addressed the normal function of Setbp1 during development using a (b)(4) (b)(4) mouse model.

III. OBJECTIVE\HYPOTHESIS: The objective of this protocol is to understand the role of Setbp1 during development, especially its function in the self-renewal of hematopoietic stem cells and neural stem cells, through characterizing the phenotypes

of mice carrying different mutations of Setbp1. By carrying out this study, we also hope to gain insights into the mechanism through which overexpression of Setbp1 may cause leukemia development.

IV. MILITARY RELEVANCE:

Military personnel on the battlefield could be exposed to radiation or toxic substances that could induce leukemia development later in life. Understanding the mechanisms underlying leukemia development should help find preventive measures and better treatments for this devastating disease. The focus of this study involves characterizing the molecular mechanisms controlling self-renewal of normal hematopoietic stem cells, however deregulation of the same mechanisms is also likely responsible for the uncontrolled self-renewal by malignant stem cells in leukemias. Therefore, accomplishing this study has the potential to identify novel pathways that could be targeted for treating leukemias.

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures:

V.1.1. Experiment 1:

In our previous studies, we have found that (b)(4) (b)(4) (b)(4) We will test in this study whether this defect can be reversed by expression of exogenous Setbp1in more differentiated hematopoietic progenitors. Fetal liver cells from E18.5 (b)(4) will be used to carry out this study. These cells will be infected with a replication incompetent retroviral vector expressing the Setbp1 cDNA or control empty vector, and subsequently transplanted into irradiated B6-LY5.2/NCr recipient mice (7-12 weeks old) along with supporting bone marrow cells from un-irradiated B6-LY5.2/NCr mice. These recipient mice will be aged for 4 months for the assessment of LT-HSC rescue.

Setbp1and empty virus will be collected from culture medium of cell lines designed to package viral particles in ecotropic envelops. After initial infection these viruses are no longer infectious and are replication deficient. Prior to and during infection, these fetal liver cells may be cultured in the presence of recombinant murine growth factors including interleukin-3 (IL-3), IL-6, and stem cell factor (SCF) to stimulate their proliferation (In-vitro procedures only) B6-LY5.2/NCr mice (7-12 weeks old females purchased from (b)(4) will be used as donors for the competing bone marrow cells as well as transplant recipients. These mice are immune-compatible with our (b)(4) (b)(4) mice and no immune rejection between donor and host cells after transplantation is expected. The hematopoietic cells of B6-LY5.2/NCr mice also carry the LY5.2 marker that is used to distinguish them from the donor (b)(4) cells expressing a different LY5.1 marker. Before transplantation, B6-LY5.2/NCr recipients will be irradiated with1,100 rads of total body irradiation from a ^{137}Cs source located at room (b)(6) which eliminates the endogenous HSCs and enables efficient engraftment of the transplanted cells. The mixture of fetal liver cells and supporting bone marrow cells will

be subsequently introduced into each recipient in 200ul volume in PBS by tail vein injection. The dose of irradiation used is expected to be lethal within 10 days in the absence of bone marrow reconstitution by transplanted cells. Following transfer of the hematopoietic cells mice will be monitored for signs of distress at least twice daily. Since, in our past experience, morbidity due to reconstitution failure usually occurs between 7 and 10 days after irradiation, an additional daily inspection will be carried out during this period to catch distressed animals as soon as possible. Any recipients found morbid will be euthanized immediately. Successful recolonization of the recipient bone marrow in transplanted animals results in restoration of constitutive hematopoiesis over the normal life span of the recipient. Past experience has shown that lethally irradiated mice can suffer from infection. To prevent infection, all recipient mice will receive amoxicillin at a concentration of 500ug/ml in the drinking water from 3 days prior to irradiation to 10 days post irradiation.

Each transplantation experiment consists of 2 experimental groups and requires a total of 11 B6-LY5.2/Cr animals as listed below: 1. ko/ko fetal liver cells transduced by Setbp1 virus(5 recipients); 2. ko/ko fetal liver cells transduced by empty virus (5 recipients). One animal will also be needed to provide supporting bone marrow cells for transplantation along with indicated fetal liver cells. In addition, 3 fetal livers will be needed to provide sufficient donor cells for infection and transplantation into 10 recipients. All recipients should survive for at least 6 months after transplantation. Two of the recipients of each group will be euthanized at 2 month and the rest at 4 month after transplantation. Bone marrow will be collected at euthanization for analysis of reconstitution of long-term hematopoietic stem cell compartment by transduced donor cells by FACS. Above described transplantation experiment will need to be repeated 3 times in order to draw any conclusions. Since this fetal liver cell transduction and transplantation procedure contains several sensitive and error prone steps such as preventing stem cell differentiation during in vitro culturing and ensuring their high transduction efficiency, one additional experiment is requested for personnel training and potential experimental failures due to human errors. Therefore, **the total number of B6-LY5.2/NCr mice required for this study is: [11 animals/experiment (5,5,1) x 4 experiments = 44]. A total of 12 (3 donors/experiment x 4 repeats) E18.5 (b)(4) embryos will be needed as fetal liver cell donors.**

Summary of required animal numbers for Experiment 1:

Strains	Experimental groups		Supporting B.M.	Total
	Setbp1 virus	Empty virus		
B6-LY5.2/NCr	20	20	4	44
(b)(4) (liver cell donor)	12			12

V.1.2. Experiment 2:
We will also determine whether Setbp1 is required for known oncogene (b)(4) to induce leukemia. Fetal liver cells from (b)(4) (b)(4) will be used to carry out this study. These cells will be infected with a replication incompetent retroviral vector expressing the (b)(4) cDNA, and subsequently transplanted into irradiated B6-LY5.2/NCr recipient mice (7-12 weeks old)

along with 5 x 10^5/recipient supporting bone marrow cells from un-irradiated B6-LY5.2/NCr mice. Same infection, irradiation, and transplantation steps as described in Experiment 1 will be followed. Recipient mice will be aged for 4 months for the assessment of leukemia development. Recipients for infected (b)(4) cells are expected to develop leukemia in 3 to 4 weeks and are included as positive controls.

Each transplantation experiment consists of 2 experimental groups and requires a total of 11 B6-LY5.2/Cr animals as listed below: 1 (b)(4) fetal liver cells transduced by (b)(4) virus(5 recipients); 2 (b)(4) fetal liver cells transduced by (b)(4) virus (5 recipients). One animal will also be needed to provide supporting bone marrow cells for transplantation along with fetal liver cells. In addition, 4 fetal livers (2 of each genotype) will be needed to provide sufficient donor cells for infection and transplantation. All recipients should survive for at least 6 months after transplantation. Any transplant recipients showing signs of leukemia development including rough coat, listlessness, decreased body weight, and hunched appearance, will be euthanized immediately and fresh tissues including bone marrow, spleen, thymus, liver, and kidney will be collected and examined by flow cytometry, tissue culturing and pathology. Any remaining mice 4 month after transplantation will be euthanized. Above described transplantation experiment will need to be repeated 3 times in order to draw any conclusions. Since this fetal liver cell transduction and transplantation procedure contains several sensitive and error prone steps such as preventing stem cell differentiation during in vitro culturing and ensuring their high transduction efficiency, one additional experiment is requested for personnel training and potential experimental failures due to human errors. Therefore, **required B6-LY5.2/NCr animals: 11 animals/experiment x 4 experiments = 44 mice. A total of 16 (4 donors/experiment x 4 experiments (b)(4) (b)(4) embryos will be needed as fetal liver cell donors.**

Summary of required animal numbers for Experiment 4:

Strains	Experimental groups (b)(4)		Supporting B.M.	Total
B6-LY5.2/NCr	20	20	4	44
(b)(4) (liver cell donor)	8	8		16

V.1.3. Experiment 3:

We will also determine whether Setbp1 is required for the maintenance of leukemia induced by (b)(4) For this purpose, bone marrow progenitors from (b)(4) mice (2-4 months old) carrying a (b)(4) allele of Setbp1 (b)(4) (b)(4) will be infected with the same (b)(4) virus described in Experiment 2, and subsequently transplanted into irradiated B6-LY5.2/NCr recipient mice (7-12 weeks old) along with 5 x 10^5 supporting bone marrow cells from un-irradiated B6-LY5.2/NCr mice. Once leukemia develops in these mice, they will be euthanized to purify leukemia stem cells ($lin^-Sca\text{-}1^+c\text{-}kit^+$) from their bone marrow. These leukemia stem cells will be subsequently transplanted into irradiated secondary recipient mice (B6-LY5.2/NCr) along with 5 x 10^5 supporting bone marrow cells from un-irradiated B6-LY5.2/NCr mice. At 2 weeks after transplantation, all secondary recipients will be injected with poly I:C, which (b)(4) leukemia

cells and no changes in [(b)(4)] leukemia cells, and subsequently aged for assessment of leukemia development. All retroviral infection, irradiation, transplantation, and monitoring steps will be carried out as described in Experiment 1. Any remaining mice 4 months after transplantation will be euthanized.

In order to achieve statistical significance, 3 primary leukemias of each genotype [(b)(4)] will be tested. To generate these leukemias, 20 [(b)(4)] [(b)(4)] donor mice (10 each genotype) will be needed to extract sufficient bone marrow for infection. 2 additional B6-LY5.2/NCr mice will be needed to provide supporting bone marrow cells. **Therefore, a total of 8 B6-LY5.2/NCr mice (6 as recipients and 2 as supporting marrow donors) and 20 [(b)(4)] mice are needed for leukemia generation.** For secondary transplantations to assess leukemia maintenance, each leukemia will be transplanted into 5 secondary recipients and 6 additional B6-LY5.2/NCr will be needed to provide supporting bone marrow cells. Therefore, **a total of 36 B6-LY5.2/NCr mice (5 recipients/leukemia x 6 leukemias + 6 supporting marrow donors) are required for secondary transplantations.**

Summary of required animal numbers for Experiment 3:

Strains	Experimental groups [(b)(4)]		Supporting B.M.	Total
B6-LY5.2/NCr	18	18	8	44
[(b)(4)] (BM donor)	10	10		20

V.1.4. Experiment 4:

Our previous studies suggest that [(b)(4)] [(b)(4)] To test this idea, [(b)(4)] will be challenged with 5-FU treatments in a competitive reconstitution assay in comparison to wild-type HSCs. The 5-FU treatments deplete the number of more mature progenitor cells in the bone marrow and induce proliferative stress on HSCs. Reduced reconstitution capability of Setbp1 null cells after the treatments will suggest that Setbp1 help protect HSCs under stressful conditions. For this purpose, 5 x 10^5 bone marrow cells from [(b)(4)] mice (2-4 months old) carrying an polyinosinic:polycytidylic acid (poly I:C) inducible [(b)(4)] will be mixed with 5 x 10^5 competing wild-type bone marrow cells from B6-LY5.2/NCr and then transplanted into lethally-irradiated B6-LY5.2/NCr recipient mice. [(b)(4)] will be induced in the transplanted [(b)(4)] cells by poly I:C injections of recipient mice one month after transplantation. Two weeks after poly I:C injections, all recipients will receive two intraperitoneal injections of 5-fluorouracil (5-FU) at a dosage of 150 mg/kg with a 2-week interval. This dosage of 5-FU is not expected to cause animal morbidity and illness[15]. Reconstitution by the donor cells will be determined at one week post poly I:C injections and at 1, 2, and 4 months after the last 5-FU injection by retro-orbital bleeding and FACS. All animals will be euthanized after the last retro-orbital bleeding, and hematopoietic tissues including bone marrow, thymus, and spleen will be collected after euthanasia and analyzed by FACS. Same calculation of animal numbers as in Experiment 1 applies here. 11 B6-LY5.2/NCr mice will be required for each

transplantation experiment containing 2 experimental groups (one group for each of the 2 genotypes, 5 animals per group, 1 competing marrow donor) and 3 experiments in total will be conducted. **The minimum number of B6-LY5.2/NCr mice required for this study is: [11 animals/experiment (5,5,1) x 3 experiments = 33]. A total of 6 (b)(4) mice (1 donor/ transplanted group x 2 groups x 3 repeats) will be needed as bone marrow cell donors.**

Summary of required animal numbers for Experiment 4:

Strains	Experimental groups (b)(4)		Competing B.M.	Total
B6-LY5.2/NCr	15	15	3	33
(b)(4) (BM donor)	3	3		6

V.1.5. Experiment 5:

In order to understand the mechanisms through which Setbp1 (b)(4) (b)(4) we will carry out expression profiling studies to identify targets of (b)(4) Since Setbp1 deletion in (b)(4) mice induced by poly I:C is not specific to the hematopoietic system, to exclude potential effects from Setbp1 deletion in the microenvironment, we will first transplant their bone marrow cells into irradiated B6-LY5.2/NCr recipient mice (5 x 10^6 cell/recipient) and then (b)(4) (b)(4) by injecting the recipient mice with poly I:C. at 4 weeks after transplantation. Irradiation, transplantation, and monitoring of recipients will be carried out as described in Experiment 1. The (b)(4) will be purified from the recipient mice at 2 weeks after the last poly I:C injection by FACS and used for RNA extraction for microarray-based expression profiling experiments. Due to extreme scarcity of (b)(4) in the bone marrow (0.01-0.02%), **10 recipient mice for each genotype (b)(4) will be needed** to obtain sufficient cells for expression profiling in one experiment. As such, **2 (b)(4) mice of each genotype will be needed to provide sufficient donor cells** for transplantation in each experiment. In order to achieve statistical significance, such experiment will be repeated 3 times. **Total required B6-LY5.2/NCr animals: 20 animals/experiment x 3 experiments = 60 mice. A total of 12 (2 donors/genotype x 2 genotypes x 3 experiments) (b)(4) mice will be needed as bone marrow donors.**

Summary of required animal numbers for Experiment 5:

Strains	Experimental groups (b)(4)		Total
B6-LY5.2/NCr	30	30	60
(b)(4) (BM donor)	6	6	12

V.1.6. Experiment 6:

Preliminary studies on Setbp1 null E18.5 embryos suggest that Setbp1 loss may cause (b)(4) (b)(4) are significantly reduced in size in

knockout versus wild-type embryos. Therefore, studying the function of Setbp1 in [redacted] may help uncover new molecular mechanisms controlling [redacted] which remains poorly understood.

For this experiment, age- and sex-matched littermates of [redacted] mice consisting of two genotypes: [redacted] will be euthanized at approximately 2 months of age and their brains will be used to characterize neural stem cell function in the absence of Setbp1. [redacted] will be collected from these animals after euthanasia and subjected to 4 different types of experiments including neural stem cell isolation for neurosphere assay, RNA and protein extraction from neurogenic regions, immunohistochemistry analysis for different neural markers, and also histological examinations. Each type of experiment will need to be repeated on 5 animals per genotype to reach any conclusions. So the minimum animal number for each genotype is: 4 experiment types x 5 animals/genotype = 20. In addition, 3 animals for each genotype are also requested as a preventive measure for potential experimental failures due to unpredictable factors such as human error and equipment breakdowns, and also for technique development/personnel training. Therefore, **for these studies, the requested animal number is: (5 animals/genotype x 2 genotypes x 4 experimental evaluations) + 3 extra mice x 2 genotypes = 46 mice.** In addition, 15 animals of each genotype will also be aged for 12 months to study long-term effect of Setbp1 deletion in the neural system. **The total requested animal number is: 46 mice + (15 animals/genotype x 2 genotypes) = 76 mice.**

Summary of required animal numbers for Experiment 6:

Strains	Experimental groups [redacted]		Total
[redacted]	38	38	76

V.1.7. Experiment 7:

Seb-LacZ mice of 2 genotypes [redacted] will be used to determine the normal expression pattern of Setbp1 [redacted] Hematopoietic tissues including bone marrow, spleen, and thymus will be collected from these animals after euthanasia and analyzed by FACS and also histological examinations. Each type of experiment will need to be repeated on 5 animals per genotype to reach any conclusions. So the minimum animal number for each genotype is: 2 experiment types x 5 animals/genotype = 10. In addition, 3 animals for each genotype are also requested as a preventive measure for potential experimental failures due to unpredictable factors such as human error and equipment breakdowns, and also for technique development/personnel training. **The total requested animal number is: [5 animals/genotype x 2 genotypes x 2 experimental evaluations + 3 extra mice x 2 genotypes = 26 mice].**

Summary of required animal numbers for Experiment 7:

Strains	Experimental groups [redacted]	Total

Seb-LacZ	13	13	26

V.2. Data Analysis: For all 7 experiments, gene expression, contribution of cell populations, colony/cell counts will be compared across genotypes using analysis of variance (ANOVA), student's t test, or nonparametric tests as appropriate. A sample size of 5 in each group will have 80% power to detect a difference of 2 standard deviations between groups using a 2-group t test with a 5%, two-sided significance level.
For aging studies in Experiment 2-4, log-rank tests will be used to compare time to development of sickness such as leukemia across groups. When the sample size in each group is 15, a 5% two-sided log-rank test for equality of survival curves will have 80% power to detect a difference in proportion surviving of at least 54 percentage points (e.g. 99% vs. 45% surviving)

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered: Tissue culture was considered, however hematopoietic development is a complex process that requires proper interactions among different tissue and cell types within the context of a whole animal, and currently there is no tissue culture system capable of recapitulating this environment [8]. In addition, hematopoietic cell lines used in tissue culture studies are different from normal hematopoietic cells in that they have acquired mutations that allow them to replicate indefinitely in culture, and results from these studies may not apply to normal cells. Computer modeling was considered as well, but the regulation of hematopoietic development is still largely unknown and there is no system available in the hematopoiesis field that can be used to predict gene function and consequences of gene mutations.

V.3.2. Animal Model and Species Justification: I have chosen to use mice for my studies because they are genetically well-characterized mammalian organism that has been shown to have a very similar hematopoietic system to that of humans, and more and more studies have been carried out in mice to understand human hematopoiesis and leukemia development [9-11]. In addition, there are many tools available in mice but not in other mammalian models to genetically alter the germline and study the consequences of the mutation on multiple organ systems simultaneously. I also happen to have extensive experiences working with mouse hematopoietic system as a research fellow in the Mouse Cancer Genetics Program at National Cancer Institute. Lower organisms such as Zebrafish and Drosophila were also considered, however both species are very different from mammals and do not represent good models for studying human hematopoiesis.

V.3.3. Laboratory Animals

Species #1 **Species #2**

V.3.3.1. **Genus & Species:** Mus musculus

V.3.3.2. **Strain/Stock:** Seb-LacZ
Seb-KO
(b)(4)
B6-LY5.2/NCr

V.3.3.3. **Source/Vendor:** In-house (Seb-LacZ, Seb-KO, (b)(4) (b)(4) (B6-LY5.2/NCr)

V.3.3.4. **Age:** B6-LY5.2/NCr (7-12 weeks) (b)(4) (2 months); Seb-KO (E18.5); (b)(4) 1 mice (2-4 months); (b)(4) mice (2-12 months)

V.3.3.5. **Weight:** N/A

V.3.3.6. **Sex:** Male: 84
Female: 309

V.3.3.7. **Special Considerations:** Specific pathogen free

V.3.4. **Number of Animals Required (by Species):** Mice: 393 (B6-LY5.2/NCr, 225; (b)(4) 28; (b)(4) (b)(4) 38; (b)(4) (b)(4) 76; Seb-LacZ, 26)

V.3.5. **Refinement, Reduction, Replacement (3 Rs):**

V.3.5.1. **Refinement:**
All animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels. All animals subjected to irradiation will be treated with amoxicillin 3 days prior to irradiation to 10 days post irradiation to reduce distress caused by potential infection.

Animals observed to be ill or showing signs of pain or distress including 30% reduction in body weight (compared to before transplantation), hunched posture, ruffled fur, and decreased activity will be evaluated by veterinary staff to be treated or be euthanized for relief of suffering.

V.3.5.2. Reduction: In order to reduce the animal numbers for this study, experiments have been designed to include tissue sharing among different experimental procedures including DNA extraction, RNA extraction, and protein extraction. Also, sample size calculations were performed to use least number of animals to achieve statistical significance.

V.3.5.3. Replacement: Tissue culture and computer models were considered but not adopted. Detailed explanations are provided in V.3.1.

V.4. Technical Methods:

V.4.1. Pain / Distress Assessment:

V.4.1.1. APHIS Form 7023 Information:

V.4.1.1.1. Number of Animals:

	Species #1	Species #2
V.4.1.1.1.1. Column C:	187	
V.4.1.1.1.2. Column D:		
V.4.1.1.1.3. Column E:	206	

V.4.1.2. Pain Relief / Prevention:

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization: For retro-orbital bleeding, 3.5-4% Isoflurane will be applied before the procedure through induction chamber of an anesthesia machine at LAM until animals are fully anesthetized (judging by lack of movement and decrease in respiratory rate to about once every 4 seconds and a negative pedal withdrawal reflex).

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions: N/A

V.4.1.2.3. Paralytics: N/A

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures: N/A

V.4.1.3.1. Sources Searched: N/A

V.4.1.3.2. Date of Search: N/A

V.4.1.3.3. Period of Search: N/A

V.4.1.3.4. Key Words of Search: N/A

V.4.1.3.5. Results of Search: N/A

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification: Whole body irradiation of recipient mice is essential for successful mouse bone marrow transplantation as it is the only way to efficiently deplete host bone marrow stem cells and to greatly increase donor cell engraftment in mice.

V.4.3.6.1. Procedures: N/A

V.4.3.6.2. Scientific Justification: N/A

V.4.4. Animal Manipulations:

V.4.4.1. Injections: Transplantation of fetal liver and bone marrow cells will be carried out by one time tail vein injection of cells resuspended in 200ul of PBS using 28 Gauge x ½ inch needles. Since transplanted cells are from mice congenic to the recipients, no immune rejection is expected after transplantation. Injection of hematopoietic cells through the tail vein is not known to cause any toxic effects to mice. All cells for injection will be obtained from mice housed in USU colony. Injection of all biological materials will be in accord with USU IACUC Policy #23 on the use of biological in experimental animals.

Transplant recipient mice in Experiment 3, 4 and 5 will also receive 5 intra-peritoneal injections with 2 day intervals of 200 ul poly I:C (a chemical used to induce Cre gene expression) at a concentration of 2 ug/ul diluted in sterile phosphate buffered saline. 28 Gauge x ½ inch needles will be used for the injections. Injection of poly I:C at this dosage is safe for mice[12].

V.4.4.2. Biosamples: Retro-orbital bleeding is chosen for the protocol based on the blood sample size required for our study and available in-house expertise. Given the relatively large sample size (200 ul of blood from each animal each time) that is needed for our study to perform FACS analysis, 2 other blood collection procedures including from the saphenous vein and jugular vein were considered as suitable alternatives.[13,14] Saphenous bleeding is the only procedure that is less painful than retro-oribal bleeding and does not require anesthesia. However, this procedure requires extensive experience and has not been performed on mice by any LAM technicians previously. In contrast, retro-orbital bleeding has been routinely carried out by staff in my laboratory under previously approved protocols and will be done under isoflurane anesthesia.

In this protocol, 200ul blood will be obtained each time by retro-orbital bleeding at one week after poly I:C injections and at 1, 2 and 4 month after last 5-FU injection as described in Experiment 4. IACUC policy on retro-orbital bleeding (POLICY 001) will be strictly followed when performing this procedure. Mice will be anesthetized with Isoflurane. When the animal is no longer moving voluntarily it is placed on a paper towel. The forefinger of the operator's nondominant hand is used to pull the facial skin taut and cause the eyes to protrude slightly while the skin at the back of the neck is grasped by the thumb and remaining fingers to restrain. Breathing and color are monitored throughout the procedure to ensure that the restraint does not compromise the airway. The tip of a capillary tube is gently inserted below the eye at approximately a 45 degree angle into the space between the globe and the lower eyelid. When the tip of the pipette contacts the boney floor of the orbit it is gently twisted between thumb and forefinger to rupture the capillary sinus. Blood is allowed to flow by capillary action into the pipette. Care is taken not to take any more blood than is needed. At the conclusion of the blood withdrawal tension on the animal is released and a gauze pad is gently pressed over the eye for about 30 seconds until the bleeding has stopped. A drop of tetracaine is added in the eye to reduce any postprocedural discomfort that may occur. Normal color and respiration are reconfirmed and the animal is returned to its cage for recovery. Alternate eyes are used for successive bleeds. A maximum of two bleeds per eye (four bleeds total) will be done. In addition, hematopoietic tissues including bone marrow, spleen, thymus, lymph nodes and control tissue brain, lung, and kidney will be extracted after euthanasia.

V.4.4.3. Adjuvants: N/A

V.4.4.4. Monoclonal Antibody (MAbs) Production: N/A

V.4.4.5. Animal Identification: Cage cards will be used to distinguish different study groups.

V.4.4.6. Behavioral Studies: N/A

V.4.4.7. Other Procedures: Recipient B6-LY5.2/NCr mice will be irradiated on the day of transplantation with1100 rads of total body irradiation from a ^{137}Cs source located at room (b)(6) Mice will be transported and irradiated at room temperature in irradiator disks (purchased from Braintree Scientific) that maintain a filter protected sterile environment and hold up to 20 mice at each time. The entire process will last no more than 30 minutes and during which time no food or water will be provided for the animals.

Hematopoietic cells resuspended in PBS in a volume of 200 ul will be introduced by tail vein injection. Following transfer of the hematopoietic cells mice will be monitored twice daily and three times between days 7-10 after irradiation for signs of distress including rough coat, listlessness, 30% reduction in body weight (compared to before transplantation), or hunched posture. Any recipients displaying any combination of two or more signs of distress above will be euthanized immediately by PI staff. The dose of irradiation used is expected to be lethal within 10 days in the absence of bone marrow reconstitution by transplanted cells. Successful recolonization of the recipient bone marrow in transplanted animals results in restoration of constitutive hematopoiesis over the normal life span of the recipient. Past experience has shown that lethally irradiated mice can suffer from infection. To prevent infection, all recipient mice will receive amoxicillin at a concentration of 0.5mg/ml in the drinking water from 3 days prior to irradiation to 10 days post irradiation, and sterile feed and autoclaved caging will be provided.

V.4.4.8. Tissue Sharing: Tissues may be shared with other investigators upon request.

V.4.5. Study Endpoint:
The study endpoint for mice is between 2 to 16 months of age as specified in the experimental design and general procedures section. Animals could be euthanized earlier due to leukemia development or engraftment failure of transplanted hematopoietic cells after irradiation. To capture and euthanize animals in distress as soon as possible, irradiated mice will be monitored at least twice daily by PI staff. Since morbidity due to bone marrow failure usually occurs between 7 and 10 days after irradiation in our past experience, one additional inspection daily will be added during this period to catch any possible distressed animals. Signs of these conditions include rough coat, listlessness, 30% reduction in body weight (compared to before transplantation), or hunched posture. Any animals displaying any combination of two or more symptoms will be euthanized immediately.

V.4.6. Euthanasia:
Animals under this protocol will be euthanized by research personnel. Mice will be euthanized using cylinderized CO2. These animals will be placed in a cage or chamber that is not crowded and exposed to a mix of CO2 and oxygen. The CO2 flow rate will displace at least 20% of the chamber volume per minute. Flow will continue for at least one minute after visible sign of death. CO2 euthanasia will be followed by cervical dislocation to ensure death. Gestation day 18.5 embryos will be first anesthetized by placing them in a Petri dish that is placed on top of ice for 15 minutes and then euthanized by decapitation using surgical scissors. Both procedures are consistent with the 2013 AVMA Guidelines for the Euthanasia of Animals.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol.

V.5.1.1. **Study Room:**

Building(s) _____ Room Number(s) (b)(6)

V.5.1.2. **Special Husbandry Provisions:**

Sterile micro-isolator cages, feed (9% fat), and bedding will be used.

Food Restriction: Yes _____ No X

Fluid Restriction: Yes _____ No X

V.5.1.3. **Exceptions:** N/A

V.5.2. **Veterinary Medical Care:**

V.5.2.1. **Routine Veterinary Medical Care:**

Animals will be observed at least once daily by Center for LAM personnel. PI group will also observe the colony twice daily except during the period 7-10 days post-irradiation during which they will be monitored three times daily. Animals or pups observed to be ill or showing signs of pain or distress including weight loss, hunched posture, ruffled fur, and decreased activity will be evaluated by veterinary staff to be treated or be euthanized. PI should be contacted for potential tissue collection needs if sick animals are to be euthanized by LAM personnel.

V.5.2.2. **Emergency Veterinary Medical Care:** All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays. Sick or moribund animal will be evaluated by veterinary staff to be treated or be euthanized. PI should be contacted for potential tissue collection needs if euthanasia is necessary. Euthanasia by LAM personnel should proceed if PI can not be reached.

V.5.3. **Environmental Enrichment:**

V.5.3.1. **Enrichment Strategy:** Except as indicated below, all animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents.

V.5.3.2. **Enrichment Restrictions:** N/A

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordinations regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

(b)(6) _____ 5/31/13

Principal Investigator Signature Date

G. Training: The following personnel will attend the next USUHS Investigator/Animal User Training Course:

_____ _____

_____ _____

H. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely, "Responsibility" for implementing animal use alternatives where feasible and conducting humane and lawful research.

(b)(6) _____ 5/31/13

Principal Investigator Signature Date

I. Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL** or **WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

X. PROTOCOL ABSTRACT:

A. **Animal Protocol Number:**

B. **Animal Protocol Title**: Generation and characterization of genetically engineered mouse strains carrying Setbp1 mutations

C. **Principal Investigator:** (b)(6) Department of Pediatrics

D. **Performing Organization**: Uniformed Services University of the Health Sciences

E. **Funding**: Department of Pediatrics

F. **Objective and Approach**: The objective of this protocol is to characterize the function of a novel gene Setbp1 during normal mammalian development, with a focus on hematopoietic development. Different genetically engineered mutant mouse strains for Setbp1 will be generated. Developmental defects in these mutant animals will be characterized comparing to wild-type littermates. The three R's (reduction, replacement, and refinement) of animal usage will be employed.

G. **Indexing Terms (Descriptors)**: Animals, mice, Setbp1, and knockout

MEMORANDUM FOR DR (b)(6) DEPARTMENT OF PEDIATRICS

SUBJECT: IACUC Approval of Protocol – Triennial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on August 5, 2013:

Animal Protocol Title: "Generation and Characterization of Genetically Engineered Mouse Strains Carrying Prdm16 Mutations"

USUHS Protocol Number: (b)(6)

Expiration Date: August 4, 2016

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. **NON-TECHNICAL SYNOPSIS:** This study is designed to use mice as a model to characterize the function of a new gene called Prdm16 during normal human development. We will generate genetically engineered mice carrying mutations in Prdm16, which will be used to characterize the effects of these mutations on blood generation. For some studies, immature blood cells from these mutant mice will be transplanted into normal mice to better characterize their regeneration properties. Transplant recipient mice will be irradiated before transplantation to enhance the establishment of the transplant donor cells in their bone marrow. Irradiation at our proposed dosage is lethal to mice if not treated afterwards. However, these recipient mice in our study will be fully rescued by the subsequent transplantation of donor immature blood cells.

II. BACKGROUND:

II.1. Background: Hematopoietic development is a critical process that starts from the hematopoietic stem cells (HSCs) and produces all essential cell types in the blood [1]. HSC is the only cell type in the system capable of extensive self-renewal. The self-renewal of HSCs is essential for sustaining the entire hematopoietic system, and its deregulation has severe consequences. Decreased HSC self-renewal could cause bone marrow failure while increase in self-renewal could lead to leukemia development. However, the critical factors that control HSC self-renewal are still largely unknown. Prdm16 is a novel transcription factor found in our recent mutagenic screens capable of conferring self-renewal capability to hematopoietic progenitor cells that normally lack such capability [2,3], and was also indicated in human leukemia development [4], suggesting that it may play an important role in the (b)(4) and (b)(4) To test this hypothesis, we generated a (b)(4) (b)(4) for Prdm16 in mice. (b)(4) (b)(4) (b)(4) Additional studies have been proposed in this protocol to further characterize this (b)(4) due to Prdm16 loss. The knowledge that we learned about the function of Prdm16 in the (b)(4)

(b)(4) should also help us gain insights into its involvement in leukemia development.

II.2. Literature Search for Duplication:

II.2.1. Literature Source(s) Searched:
BRD, NIH RePORTER, and PubMed

II.2.2. Date of Search: 5/30/2013

II.2.3. Period of Search:
BRD: 1998 – 2013
NIH RePORTER: 1988 – 2013
PubMed: 1950 – 5/30/2013

II.2.4. Key Words and Search Strategy: This study is mainly designed to use knockout mouse models to characterize the function of Prdm16 in normal hematopoietic stem cells. Therefore, "Prdm16" in combination with "mice" and "hematopoietic" were used as the search term.

II.2.5. Results of Search:
Two projects were returned on BRD and they are (b)(4) protocols from 2008 and 2009. A total of 2 projects were returned on NIH RePORTER, entitled respectively "Hematopoietic stem cells and longevity" and "Mechanism of action of Prdm16 in hematopoietic stem cells". While the first project investigates the difference of different naturally occurring alleles of Prdm16 in affecting HSC function, the second project is the only one studying Prdm16 loss of function in mice. However, the mouse model employed is a germline knockout model which only allows them to study fetal liver hematopoietic stem cells as Prdm16 knockout mice die shortly after birth. (b)(4) (b)(4) (b)(4) A total of 9 articles were returned on PubMed [15-23]. Only two of them studied Prdm16 loss of function in mice[18,19]. However, both used the same Prdm16 germline knockout model and (b)(4) that we created.

III. OBJECTIVE\HYPOTHESIS: The objective of this protocol is to understand the role of Prdm16 during hematopoietic development, especially its function in the self-renewal of hematopoietic stem cells, through characterizing the phenotypes of mice carrying different mutations of Prdm16. By carrying out this study, we also hope to gain insights into the mechanism through which overexpression of Prdm16 may cause leukemia development.

IV. MILITARY RELEVANCE:
Military personnel on the battlefield could be exposed to radiation or toxic substances that could induce leukemia development later in life. Understanding the mechanisms underlying leukemia development should help find preventive measures and better treatments for this devastating disease. The focus of this study involves characterizing the molecular mechanisms controlling self-renewal of normal hematopoietic stem cells,

however deregulation of the same mechanisms is also likely responsible for the uncontrolled self-renewal by malignant stem cells in leukemias. Therefore, accomplishing this study has the potential to identify novel pathways that could be targeted for treating leukemias.

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures:

V.1.1. Experiment 1:

In our previous studies, we have found that (b)(4) (b)(4) (b)(4) We will test in this study whether this defect can be reversed by expression of exogenous Prdm16in more differentiated hematopoietic progenitors. Fetal liver cells from E18.5 (b)(4) will be used to carry out this study. These cells will be infected with a replication incompetent retroviral vector expressing the Prdm16 cDNA or control empty vector, and subsequently transplanted into irradiated B6-LY5.2/NCr recipient mice (7-12 weeks old) along with supporting bone marrow cells from un-irradiated B6-LY5.2/NCr mice. These recipient mice will be aged for 4 months for the assessment of LT-HSC rescue.

Prdm16and empty virus will be collected from culture medium of cell lines designed to package viral particles in ecotropic envelops. After initial infection these viruses are no longer infectious and are replication deficient. Prior to and during infection, these fetal liver cells may be cultured in the presence of recombinant murine growth factors including interleukin-3 (IL-3), IL-6, and stem cell factor (SCF) to stimulate their proliferation (In-vitro procedures only) B6-LY5.2/NCr mice (7-12 weeks old females purchased from (b)(4) will be used as donors for the competing bone marrow cells as well as transplant recipients. These mice are immune-compatible with our (b)(4) (b)(4) mice and no immune rejection between donor and host cells after transplantation is expected. The hematopoietic cells of B6-LY5.2/NCr mice also carry the LY5.2 marker that is used to distinguish them from the donor (b)(4) cells expressing a different LY5.1 marker. Before transplantation, B6-LY5.2/NCr recipients will be irradiated with1,100 rads of total body irradiation from a ^{137}Cs source located at room (b)(6) which eliminates the endogenous HSCs and enables efficient engraftment of the transplanted cells. Supporting bone marrow cells will be extracted from un-irradiated B6-LY5.2/NCr mice after their euthanization. The mixture of fetal liver cells and supporting bone marrow cells will be subsequently introduced into each recipient in 200ul volume in PBS by tail vein injection. The dose of irradiation used is expected to be lethal within 10 days in the absence of bone marrow reconstitution by transplanted cells. Following transfer of the hematopoietic cells mice will be monitored for signs of distress at least twice daily. Since, in our past experience, morbidity due to reconstitution failure usually occurs between 7 and 10 days after irradiation, an additional inspection will be carried out during this period to catch distressed animals as soon as possible. Any recipients found morbid will be euthanized immediately. Successful recolonization of the recipient bone marrow in transplanted animals results

in restoration of constitutive hematopoiesis over the normal life span of the recipient. Past experience has shown that lethally irradiated mice can suffer from infection. To prevent infection, all recipient mice will receive amoxicillin at a concentration of 500ug/ml in the drinking water from 3 days prior to irradiation to 10 days post irradiation.

Each transplantation experiment consists of 2 experimental groups and requires a total of 11 B6-LY5.2/Cr animals as listed below: 1. ko/ko fetal liver cells transduced by Prdm16 virus(5 recipients); 2. ko/ko fetal liver cells transduced by empty virus (5 recipients). One animal will also be needed to provide supporting bone marrow cells for transplantation along with indicated fetal liver cells. In addition, 3 fetal livers will be needed to provide sufficient donor cells for infection and transplantation into 10 recipients. All recipients should survive for at least 6 months after transplantation. Two of the recipients of each group will be euthanized at 2 month and the rest at 4 month after transplantation. Bone marrow will be collected at euthanization for analysis of reconstitution of long-term hematopoietic stem cell compartment by transduced donor cells by FACS. Above described transplantation experiment will need to be repeated 3 times in order to draw any conclusions. Since this fetal liver cell transduction and transplantation procedure contains several sensitive and error prone steps such as preventing stem cell differentiation during in vitro culturing and ensuring their high transduction efficiency, one additional experiment is requested for personnel training and potential experimental failures due to human errors. Therefore, **the total number of B6-LY5.2/NCr mice required for this study is: [11 animals/experiment (5,5,1) x 4 experiments = 44]. A total of 12 (3 donors/experiment x 4 repeats) E18.5 (b)(4) fetuses will be needed as fetal liver cell donors.**

Summary of required animal numbers for Experiment 1:

Strains	Experimental groups		Supporting B.M.	Total
	Prdm16 virus	Empty virus		
B6-LY5.2/NCr	20	20	4	44
(b)(4) (liver cell donor)	12			12

V.1.2. Experiment 2:

We will also determine whether Prdm16 is required for known oncogene (b)(4) to induce leukemia. Fetal liver cells from (b)(4) (b)(4) will be used to carry out this study. These cells will be infected with a replication incompetent retroviral vector expressing the (b)(4) cDNA, and subsequently transplanted into irradiated B6-LY5.2/NCr recipient mice (7-12 weeks old) along with 5 x 10^5/recipient supporting bone marrow cells from un-irradiated B6-LY5.2/NCr mice. Same infection, irradiation, and transplantation steps as described in Experiment 1 will be followed. Recipient mice will be aged for 4 months for the assessment of leukemia development. Recipients for infected (b)(4) cells are expected to develop leukemia and are included as positive controls.

Each transplantation experiment consists of 2 experimental groups and requires a total of 11 B6-LY5.2/Cr animals as listed below: 1. (b)(4) fetal liver cells transduced by (b)(4) virus(5 recipients); 2 (b)(4) fetal liver cells transduced by (b)(4) virus (5

recipients). One animal will also be needed to provide supporting bone marrow cells for transplantation along with fetal liver cells. In addition, 4 fetal livers (2 of each genotype) will be needed to provide sufficient donor cells for infection and transplantation. All recipients should survive for at least 6 months after transplantation. Any transplant recipients showing signs of leukemia development including rough coat, listlessness, decreased body weight, and hunched appearance, will be euthanized immediately and fresh tissues including bone marrow, spleen, thymus, liver, and kidney will be collected and examined by flow cytometry, tissue culturing and pathology. Any remaining mice 4 month after transplantation will be euthanized. Above described transplantation experiment will need to be repeated 3 times in order to draw any conclusions. Since this fetal liver cell transduction and transplantation procedure contains several sensitive and error prone steps such as preventing stem cell differentiation during in vitro culturing and ensuring their high transduction efficiency, one additional experiment is requested for personnel training and potential experimental failures due to human errors. Therefore, **required B6-LY5.2/NCr animals: 11 animals/experiment x 4 experiments = 44 mice. A total of 16 (4 donors/experiment x 4 experiments) (b)(4) (b)(4) embryos will be needed as fetal liver cell donors.**

Summary of required animal numbers for Experiment 4:

Strains	Experimental groups (b)(4)		Supporting B.M.	Total
B6-LY5.2/NCr	20	20	4	44
(b)(4) (liver cell donor)	8	8		16

V.1.3. Experiment 3:

We will also determine whether Prdm16 is required for the maintenance of leukemia induced by (b)(4) For this purpose, bone marrow progenitors from (b)(4) mice (2-4 months old) carrying a (b)(4) allele of *Prdm16* (b)(4) (b)(4) will be infected with the same (b)(4) virus described in Experiment 2, and subsequently transplanted into irradiated B6-LY5.2/NCr recipient mice (7-12 weeks old) along with 5 x 10^5 supporting bone marrow cells from un-irradiated B6-LY5.2/NCr mice. Once leukemia develops in these mice, they will be euthanized to purify leukemia stem cells ($lin^-Sca\text{-}1^+c\text{-}kit^+$) from their bone marrow. These leukemia stem cells will be subsequently transplanted into irradiated secondary recipient mice (B6-LY5.2/NCr) along with 5 x 10^5 supporting bone marrow cells from un-irradiated B6-LY5.2/NCr mice. At 2 weeks after transplantation, all secondary recipients will be injected with poly I:C, which (b)(4) leukemia cells and no changes in (b)(4) leukemia cells, and subsequently aged for assessment of leukemia development. All retroviral infection, irradiation, transplantation, and monitoring steps will be carried out as described in Experiment 1. Any remaining mice 4 months after transplantation will be euthanized.

In order to achieve statistical significance, 3 primary leukemias of each genotype (b)(4) will be tested. To generate these leukemias, 20 (b)(4) (b)(4) donor mice (10 each genotype) will be needed to extract sufficient bone marrow for infection. 2 additional B6-LY5.2/NCr mice will be needed to provide

supporting bone marrow cells. **Therefore, a total of 8 B6-LY5.2/NCr mice (6 as recipients and 2 as supporting marrow donors) and 20 (b)(4) mice are needed for leukemia generation**. For secondary transplantations to assess leukemia maintenance, each leukemia will be transplanted into 5 secondary recipients and 6 additional B6-LY5.2/NCr will be needed to provide supporting bone marrow cells. Therefore, **a total of 36 B6-LY5.2/NCr mice (5 recipients/leukemia x 6 leukemias + 6 supporting marrow donors) are required for secondary transplantations.**

Summary of required animal numbers for Experiment 3:

Strains	Experimental groups (b)(4)		Supporting B.M.	Total
B6-LY5.2/NCr	18	18	8	44
(b)(4) (BM donor)	10	10		20

V.1.4. Experiment 4:

Our previous studies suggest that (b)(4) (b)(4) To test this idea (b)(4) will be challenged with 5-FU treatments in a competitive reconstitution assay in comparison to wild-type HSCs. The 5-FU treatments deplete the number of more mature progenitor cells in the bone marrow and induce proliferative stress on HSCs. Reduced reconstitution capability of Prdm16 null cells after the treatments will suggest that Prdm16 help protect HSCs under stressful conditions. For this purpose, 5 x 10^5 bone marrow cells from (b)(4) mice (2-4 months old) carrying an poly I:C inducible (b)(4) (b)(4) will be mixed with 5 x 10^5 competing wild-type bone marrow cells from B6-LY5.2/NCr and then transplanted into lethally-irradiated B6-LY5.2/NCr recipient mice. (b)(4) will be induced in the transplanted (b)(4) cells by poly I:C injections of recipient mice one month after transplantation. Two weeks after poly I:C injections, all recipients will receive two intraperitoneal injections of 5-FU at a dosage of 150 mg/kg with a 2-week interval. This dosage of 5-FU is not expected to cause any animal morbidity and illness. Reconstitution by the donor cells will be determined at 1 week after poly I:C injections and at 1, 2, and 4 months after the last 5-FU injection by retro-orbital bleeding and FACS. All animals will be euthanized after the last retro-orbital bleeding, and hematopoietic tissues including bone marrow, thymus, and spleen will be collected after euthanasia and analyzed by FACS. Same calculation of animal numbers as in Experiment 1 applies here. 11 B6-LY5.2/NCr mice will be required for each transplantation experiment containing 2 experimental groups (one group for each of the 2 genotypes, 5 animals per group, 1 competing marrow donor) and 3 experiments in total will be conducted. **The minimum number of B6-LY5.2/NCr mice required for this study is: [11 animals/experiment (5,5,1) x 3 experiments = 33]. A total of 6 (b)(4) (1 donor/ transplanted group x 2 groups x 3 repeats) will be needed as bone marrow cell donors.**

Summary of required animal numbers for Experiment 4:

Strains	Experimental groups (b)(4)		Competing B.M.	Total
B6-LY5.2/NCr	15	15	3	33
(b)(4) (BM donor)	3	3		6

V.1.5. Experiment 5:
In order to understand the mechanisms through which Prdm16 (b)(4) (b)(4) we will carry out expression profiling studies to identify targets of (b)(4) Since Prdm16 deletion in (b)(4) mice induced by poly I:C is not specific to the hematopoietic system, to exclude potential effects from Prdm16 deletion in the microenvironment, we will first transplant their bone marrow cells into irradiated B6-LY5.2/NCr recipient mice (5 x 10^6 cell/recipient) and then (b)(4) (b)(4) by injecting the recipient mice with poly I:C. at 4 weeks after transplantation. Irradiation, transplantation, and monitoring of recipients will be carried out as described in Experiment 1. The (b)(4) will be purified from the recipient mice at 2 weeks after the last poly I:C injection by FACS and used for RNA extraction for microarray-based expression profiling experiments. Due to extreme scarcity of (b)(4) in the bone marrow (0.01-0.02%), **10 recipient mice for each genotype** (b)(4) **will be needed** to obtain sufficient cells for expression profiling in one experiment. As such, **2** (b)(4) **mice of each genotype will be needed to provide sufficient donor cells** for transplantation in each experiment. In order to achieve statistical significance, such experiment will be repeated 3 times. **Total required B6-LY5.2/NCr animals: 20 animals/experiment x 3 experiments = 60 mice. A total of 12 (2 donors/genotype x 2 genotypes x 3 experiments)** (b)(4) **mice will be needed as bone marrow donors.**

Summary of required animal numbers for Experiment 5:

Strains	Experimental groups (b)(4)		Total
B6-LY5.2/NCr	30	30	60
(b)(4) (BM donor)	6	6	12

V.2. Data Analysis: For all 7 experiments, gene expression, contribution of cell populations, colony/cell counts will be compared across genotypes using analysis of variance (ANOVA), student's t test, or nonparametric tests as appropriate. A sample size of 5 in each group will have 80% power to detect a difference of 2 standard deviations between groups using a 2-group t test with a 5%, two-sided significance level.
For aging studies in Experiment 2 and 6, log-rank tests will be used to compare time to development of sickness such as leukemia across groups. When the sample size in each group is 15, a 5% two-sided log-rank test for equality of survival curves will have

80% power to detect a difference in proportion surviving of at least 54 percentage points (e.g. 99% vs. 45% surviving)

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered: Tissue culture was considered, however hematopoietic development is a complex process that requires proper interactions among different tissue and cell types within the context of a whole animal, and currently there is no tissue culture system capable of recapitulating this environment [8]. In addition, hematopoietic cell lines used in tissue culture studies are different from normal hematopoietic cells in that they have acquired mutations that allow them to replicate indefinitely in culture, and results from these studies may not apply to normal cells. Computer modeling was considered as well, but the regulation of hematopoietic development is still largely unknown and there is no system available in the hematopoiesis field that can be used to predict gene function and consequences of gene mutations.

V.3.2. Animal Model and Species Justification: I have chosen to use mice for my studies because they are genetically well-characterized mammalian organism that has been shown to have a very similar hematopoietic system to that of humans, and more and more studies have been carried out in mice to understand human hematopoiesis and leukemia development [9-11]. In addition, there are many tools available in mice but not in other mammalian models to genetically alter the germline and study the consequences of the mutation on multiple organ systems simultaneously. I also happen to have extensive experiences working with mouse hematopoietic system as a research fellow in the Mouse Cancer Genetics Program at National Cancer Institute. Lower organisms such as Zebrafish and Drosophila were also considered, however both species are very different from mammals and do not represent good models for studying human hematopoiesis.

V.3.3. Laboratory Animals

	Species #1	Species #2
V.3.3.1. Genus & Species:	Mus musculus	
V.3.3.2. Strain/Stock:	(b)(4) B6-LY5.2/NCr	
V.3.3.3. Source/Vendor:	In-house (b)(4) (b)(4) (b)(4) (B6-LY5.2/NCr)	
V.3.3.4. Age:	B6-LY5.2/NCr (7-12	

weeks); (b)(4)
(E18.5) (b)(4)
mice (2-4 months)

V.3.3.5. Weight: N/A

V.3.3.6. Sex: Male: 33
Female: 258

V.3.3.7. Special Considerations: Specific pathogen free

V.3.4. Number of Animals Required (by Species): Mice: 291
(B6-LY5.2/NCr, 225; (b)(4) 28; (b)(4) (b)(4) 38)

V.3.5. Refinement, Reduction, Replacement (3 Rs):

V.3.5.1. Refinement:
All animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels. All animals subjected to irradiation will be treated with amoxicillin 3 days prior to irradiation to 10 days post irradiation to reduce distress caused by potential infection. Animals observed to be ill or showing signs of pain or distress including 30% reduction in body weight (compared to before transplantation), hunched posture, ruffled fur, and decreased activity will be evaluated by veterinary staff to be treated or be euthanized for relief of suffering.

V.3.5.2. Reduction: In order to reduce the animal numbers for this study, experiments have been designed to include tissue sharing among different experimental procedures including DNA extraction, RNA extraction, and protein extraction. Also, sample size calculations were performed to use least number of animals to achieve statistical significance.

V.3.5.3. Replacement: Tissue culture and computer models were considered but not adopted. Detailed explanations are provided in V.3.1.

V.4. Technical Methods:

V.4.1. Pain / Distress Assessment:

V.4.1.1. APHIS Form 7023 Information:

V.4.1.1.1. Number of Animals:

	Species #1	Species #2
V.4.1.1.1.1. Column C:	85	
V.4.1.1.1.2. Column D:		
V.4.1.1.1.3. Column E:	206	

V.4.1.2. Pain Relief / Prevention:

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization: For retro-orbital bleeding, 3.5-4% Isoflurane will be applied before the procedure through induction chamber of an anesthesia machine at LAM until animals are fully anesthetized (judging by lack of movement and decrease in respiratory rate to about once every 4 seconds and a negative pedal withdrawal reflex).

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions: N/A

V.4.1.2.3. Paralytics: N/A

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures: N/A

V.4.1.3.1. Sources Searched: N/A

V.4.1.3.2. Date of Search: N/A

V.4.1.3.3. Period of Search: N/A

V.4.1.3.4. Key Words of Search: N/A

V.4.1.3.5. Results of Search: N/A

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification: N/A

V.4.2. Prolonged Restraint: N/A

V.4.3. Surgery:

V.4.3.1. Pre-surgical Provisions: N/A

V.4.3.2. Procedure: N/A

V.4.3.3. Post-surgical Provisions: N/A

V.4.3.4. Location: N/A

V.4.3.5. Surgeon: N/A

V.4.3.6. Multiple Major Survival Operative Procedures: N/A

V.4.3.6.1. Procedures: N/A

V.4.3.6.2. Scientific Justification: N/A

V.4.4. Animal Manipulations:

V.4.4.1. Injections: Transplantation of fetal liver and bone marrow cells will be carried out by one time tail vein injection of cells resuspended in 200ul of PBS using 28 Gauge x ½ inch needles. Since transplanted cells are from mice congenic to the recipients, no immune rejection is expected after transplantation. Injection of hematopoietic cells through the tail vein is not known to cause any toxic effects to mice. All cells for injection will be obtained from mice housed in USU colony. Injection of all biological materials will be in accord with USU IACUC Policy #23 on the use of biological in experimental animals.

Transplant recipient mice in Experiment 3, 4 and 5 will also receive 5 intra-peritoneal injections with 2 day intervals of 200 ul poly I:C (a chemical used to induce Cre gene expression) at a concentration of 2 ug/ul diluted in sterile phosphate buffered saline. 28 Gauge x ½ inch needles will be used for the injections. Injection of poly I:C at this dosage is safe for mice[12].

V.4.4.2. Biosamples: Retro-orbital bleeding is chosen for the protocol based on the blood sample size required for our study and available in-house expertise. Given the relatively large sample size (200 ul of blood from each animal each time) that is needed for our study to perform FACS analysis, 2 other blood collection procedures including from the saphenous vein and jugular vein were considered as suitable alternatives.[13,14] Saphenous bleeding is the only procedure that is less painful than retro-oribal bleeding and does not require anesthesia. However, this procedure requires extensive experience and has not been performed on mice by any LAM technicians previously. In contrast, retro-orbital bleeding has been routinely carried out by staff in my laboratory under previously approved protocols and will be done under isoflurane anesthesia.

In this protocol, 200ul blood will be obtained each time by retro-orbital bleeding at one week after poly I:C injections at 1, 2 and 4 month after last 5-FU injection as described in Experiment 4. IACUC policy on retro-orbital bleeding (POLICY 001) will be strictly followed when performing this procedure. Mice will be anesthetized with Isoflurane. When the animal is no longer moving voluntarily it is placed on a paper towel. The forefinger of the operator's nondominant hand is used to pull the facial skin taut and cause the eyes to protrude slightly while the skin at the back of the neck is grasped by the thumb and remaining fingers to restrain. Breathing and color are monitored throughout the procedure to ensure that the restraint does not compromise the airway. The tip of a capillary tube is gently inserted below the eye at approximately a 45 degree angle into the space between the globe and the lower eyelid. When the tip of the pipette contacts the boney floor of the orbit it is gently twisted between thumb and forefinger to rupture the capillary sinus. Blood is allowed to flow by capillary action into the pipette. Care is taken not to take any more blood than is needed. At the conclusion of the blood withdrawal tension on the animal is released and a gauze pad is gently pressed over the eye for about 30 seconds until the bleeding has stopped. A drop of

tetracaine is added in the eye to reduce any postprocedural discomfort that may occur. Normal color and respiration are reconfirmed and the animal is returned to its cage for recovery. Alternate eyes are used for successive bleeds. A maximum of two bleeds per eye (four bleeds total) will be done.

In addition, hematopoietic tissues including bone marrow, spleen, thymus, lymph nodes and control tissue brain, lung, and kidney will be extracted only after euthanasia.

V.4.4.3. Adjuvants: N/A

V.4.4.4. Monoclonal Antibody (MAbs) Production: N/A

V.4.4.5. Animal Identification: Cage cards will be used to distinguish different study groups.

V.4.4.6. Behavioral Studies: N/A

V.4.4.7. Other Procedures: Recipient B6-LY5.2/NCr mice will be irradiated on the day of transplantation with1100 rads of total body irradiation from a ^{137}Cs source located at room (b)(6) Mice will be transported and irradiated at room temperature in irradiator disks (purchased from Braintree Scientific) that maintain a filter protected sterile environment and hold up to 20 mice at each time. The entire process will last no more than 30 minutes and during which time no food or water will be provided for the animals. Hematopoietic cells resuspended in PBS in a volume of 200 ul will be introduced by tail vein injection. Following transfer of the hematopoietic cells mice will be monitored monitored twice daily and three times between days 7-10 after irradiation for signs of distress including rough coat, listlessness, 30% reduction in body weight (compared to before transplantation), or hunched posture. Any recipients displaying any combination of two or more signs of distress above will be euthanized immediately by PI staff. The dose of irradiation used is expected to be lethal within 10 days in the absence of bone marrow reconstitution by transplanted cells. Successful recolonization of the recipient bone marrow in transplanted animals results in restoration of constitutive hematopoiesis over the normal life span of the recipient. Past experience has shown that lethally irradiated mice can suffer from infection. To prevent infection, all recipient mice will receive amoxicillin at a concentration of 0.5mg/ml in the drinking water from 3 days prior to irradiation to 10 days post irradiation, and sterile feed and autoclaved caging will be provided.

V.4.4.8. Tissue Sharing: Tissues may be shared with other investigators upon request.

V.4.5. Study Endpoint:
The study endpoint for mice is between 2 to 16 months of age as specified in the experimental design and general procedures section. Animals could be euthanized earlier due to leukemia development or engraftment failure of transplanted hematopoietic cells after irradiation. To capture and euthanize animals in distress as soon as possible, irradiated mice will be monitored at least twice daily by PI staff. Since morbidity due to bone marrow failure usually occurs between 7 and 10 days after

irradiation in our past experience, one additional inspection daily will be added during this period to catch any possible distressed animals. Signs of these conditions include rough coat, listlessness, 30% reduction in body weight (compared to before transplantation), or hunched posture. Any animals displaying any combination of two or more symptoms will be euthanized immediately.

V.4.6. Euthanasia:
Animals under this protocol will be euthanized by research personnel. Mice will be euthanized using cylinderized CO2. These animals will be placed in a cage or chamber that is not crowded and exposed to a mix of CO2 and oxygen. The CO2 flow rate will displace at least 20% of the chamber volume per minute. Flow will continue for at least one minute after visible sign of death. CO2 euthanasia will be followed by cervical dislocation to ensure death. Gestation day 18.5 fetuses will be first anesthetized by placing them in a Petri dish that is placed on top of ice for 15 minutes and then euthanized by decapitation using surgical scissors. Both procedures are consistent with the 2013 AVMA Guidelines for the Euthanasia of Animals.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol.

V.5.1.1. Study Room:
Building(s) _____ Room Number(s) (b)(6)

V.5.1.2. Special Husbandry Provisions:
Sterile micro-isolator cages, feed (9% fat), and bedding will be used.

Food Restriction:	Yes	_____	No	X
Fluid Restriction:	Yes		No	X

V.5.1.3. Exceptions: N/A _____ _____

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care:
Animals will be observed at least once daily by Center for LAM personnel. PI group will also observe the colony twice daily except during the period 7-10 days post-irradiation during which they will be monitored three times daily. Animals or pups observed to be ill or showing signs of pain or distress including weight loss, hunched posture, ruffled fur, and decreased activity will be evaluated by veterinary staff to be treated or be euthanized. PI should be contacted for potential tissue collection needs if sick animals are to be eutharized by LAM personnel.
V.5.2.2. Emergency Veterinary Medical Care: All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health

rounds are conducted by LAM personnel once daily during weekend and holidays. Sick or moribund animal will be evaluated by veterinary staff to be treated or be euthanized. PI should be contacted for potential tissue collection needs if euthanasia is necessary. Euthanasia by LAM personnel should proceed if PI can not be reached.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: Except as indicated below, all animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents.

V.5.3.2. Enrichment Restrictions: N/A

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
Animal monitoring, euthanasia, tissue extraction, intra-peritoneal injection	(b)(6)	PI, 12 years of experience	Animal Care and Use Introductory Training Course at NCI, 2001; Animal Care and Use Training Course at NCI, 2007; Investigator training course at USUHS, 2007.

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordinations regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

(b)(6) _____ 5/31/13

Principal Investigator Signature Date

G. Training: The following personnel will attend the next USUHS Investigator/Animal User Training Course:

_____ _____

_____ _____

H. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely, "Responsibility" for implementing animal use alternatives where feasible and conducting humane and lawful research.

(b)(6) _____ 5/31/13

Principal Investigator Signature Date

I. **Painful Procedure(s):**

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress (WILL) **or WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

X. PROTOCOL ABSTRACT:

A. Animal Protocol Number:

B. Animal Protocol Title: Generation and characterization of genetically engineered mouse strains carrying Prdm16 mutations

C. Principal Investigator: (6)(6) Department of Pediatrics

D. Performing Organization: Uniformed Services University of the Health Sciences

E. Funding: Department of Pediatrics

F. Objective and Approach: The objective of this protocol is to characterize the function of a novel gene Prdm16 during normal mammalian development, with a focus on hematopoietic development. Different genetically engineered mutant mouse strains for Prdm16 will be generated. Developmental defects in these mutant animals will be characterized comparing to wild-type littermates. The three R's (reduction, replacement, and refinement) of animal usage will be employed.

G. Indexing Terms (Descriptors): Animals, mice, Prdm16, and knockout

February 19, 2014

MEMORANDUM FOR DR. (b)(6) DEPARTMENT OF PEDIATRICS

SUBJECT: IACUC Approval of Protocol – Triennial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Full Committee Review on February 19, 2014:

Animal Protocol Title: "Characterizing the Role of (b)(4) During Human Leukemia Development Using a Knock-In Mouse Model"

USUHS Protocol Number: (b)(6)

Expiration Date: February 18, 2017

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. NON-TECHNICAL SYNOPSIS: High levels of (b)(4) expression has been considered an important factor that contributes to the induction of leukemia development in humans. This study is designed to use mouse models to study the molecular mechanism through which (b)(4) overexpression induces human leukemia development. We will use genetically engineered mice carrying increased levels of (b)(4) to characterize the mechanisms responsible for positive effects of (b)(4) overexpression on the growth of blood cells, and to identify cooperating mutations for leukemia development. For some studies, genetically modified immature mouse blood cells will be transplanted into normal mice to better characterize their potential to induce leukemia development. Transplant recipient mice will be irradiated before transplantation to enhance the establishment of the transplant donor cells in their bone marrow. Irradiation at our proposed dosage is lethal to mice if not treated afterwards. However, these recipient mice in our study will be fully rescued by the subsequent transplantation of donor immature blood cells.

II. BACKGROUND:

II.1. Background: (b)(4) is a zinc finger transcription factor involved in chromosome translocations in human myeloid leukemias[1]. However, the mechanisms that (b)(4) overexpression causes leukemia development remain unclear. We have shown that (b)(4) alone is able to immortalize myeloid progenitor cells that normally lack the capability of self-renewal, suggesting that (b)(4) may be responsible for the self-renewal capability of leukemic stem cells[2]. In order to investigate further the mechanism that (b)(4) induces leukemia, we have generated a (b)(4) (b)(4) In this model (b)(4) (b)(4) (b)(4) Once bred with mice carrying hematopoietic-specific or inducible Cre recombinase, (b)(4) be induced tissue specifically or temporally in hematopoietic cells of the compound offspring. We plan to use this model to study the molecular mechanisms responsible for (b)(4) (b)(4) Also, in previous studies, we have found that induction of (b)(4) is not sufficient for leukemia induction in these animals, suggesting that additional

mutations may be required. Therefore, we also plan to apply retroviral insertional mutagenesis to this model to identify such cooperating mutations for (b)(4) in inducing leukemia development

II.2. Literature Search for Duplication:

II.2.1. Literature Source(s) Searched: BRD, NIH RePORTER, and PubMed

II.2.2. Date of Search: 12/4/2013 for BRD and NIH RePORTER, 1/28/2014 for PubMed

II.2.3. Period of Search:
BRD: 1998 – 2009
NIH RePORTER: 1990 – 2013
PubMed:1950-1/28/2014

II.2.4. Key Words and Search Strategy: This study is mainly designed to use an inducible knock-in mouse model and retroviral insertional mutagenesis to identify cooperating partner of (b)(4) for leukemia development. Therefore, the following combination of search terms was used: (b)(4) [text] in combination with "knock-in"[text] and "retroviral insertional mutagenesis" [text].

II.2.5. Results of Search: No projects were returned on BRD. One project entitled "Collaborative pathways that lead to leukemia" was returned on NIH RePORTER. However, this project is focused on a different oncogene CALM-AF10 and (b)(4) activation was identified as one of its cooperating mutations by retroviral insertional mutagenesis. (b)(4) is likely to have many more cooperating partners remained to be identified, which will be addressed by our proposed study. A total of 21 publications [8-28] were returned on PubMed. Vast majority of the articles concentrate either on findings that retroviral vectors or replication competent retrovirus can cause insertional activation of (b)(4) or on designing new retroviral vectors to reduce insertional mutagenesis for gene therapy purpose.[8,10,12-19,21-28] One article describes the functional regulation of (b)(4) by acetylation.[9] Only two articles describe finding of two cooperating partners for (b)(4) in leukemia development, CALM-AF10 and Trib1.[11,20] As discussed earlier, (b)(4) is likely to have more cooperating partners and our proposed insertional mutagenesis study using our unique (b)(4) knock-in mice could be the best approach for identifying them.

III. OBJECTIVE\HYPOTHESIS: The objective of this study is to understand the mechanisms that cooperate with (b)(4) to induce leukemia development using an inducible (b)(4) knock-in mouse model.

IV. MILITARY RELEVANCE: Leukemia represents a significant challenge for DoD medical care. Leukemia occurrence in the general population of U.S. is about 12 every 100,000 people according to statistical studies by National Cancer Institute. About half of these patients will die due to limited treatment options for this devastating disease. There are estimated over 5 million military personnel and their family members under DoD based on a 2004 study reported by Military Family Research Institute at Purdue

University. Therefore, more than 600 new leukemia cases and over 300 deaths due to leukemia are estimated to occur every year in the DoD health care system. These numbers could be even higher as the occurrence of leukemia could potentially further increase among military personnel due to possible exposure to toxic substances or radiation on the battlefield. Finding better treatments for leukemia patients represent an important need for the DoD health care system. Our proposed study will help gain insights into the mechanisms underlying leukemia initiation and progression, and mechanistic understanding of leukemia development should help find preventive measures and better treatments for this devastating disease.

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures:

V.1.1. Experiment 1: To test whether leukemia development can be accelerated by retroviral insertional mutagenesis in bone marrow progenitors of (b)(4) mice and to identify cooperating mutations for (b)(4)

Our preliminary studies using (b)(4) mice have suggested that overexpression of (b)(4) is not sufficient to induce leukemia development and additional mutations may be required. To test this idea, we would like to examine whether leukemia transformation of bone marrow progenitors of (b)(4) mice can be accelerated by random mutations caused by retroviral infection and integration using a bone marrow transduction and transplantation system. (b)(4) mice of 2 genotypes (generated under breeding protocol (b)(6) : (eki/eki, tg/+) and (eki/eki, +/+), will be used as bone marrow transplantation donors for this study. While both mice are homozygous for the inducible (b)(4) allele, only (eki/eki, tg/+) mice express a Tamoxifen-inducible Cre recommbinase transgene and can be induced to overexpress (b)(4) (eki/eki, +/+) mice are included as controls. These mice (between 6-12 weeks old) will be first treated with 5-fluorouracil (5-FU). The 5-FU treatment helps deplete the number of more mature progenitor cells in the bone marrow and induce the cycling of hematopoietic stem cells which facilitate their transduction by retrovirus. Mice will be treated once with 0.2ml of 5-FU in phosphate buffered saline (PBS) via intra-peritoneal injection to achieve a dose of 150 mg/kg body weight 4 days before bone marrow harvesting. The treated mice will be euthanized by CO2 asphyxiation and bone marrow cells will be harvested from their femurs under sterile conditions. The dose of 5-FU used in these experiment is not expected to cause animal morbidity or illness. The harvested bone marrow cells will be infected with a replication incompetent retroviral vector pMYs expressing marker GFP only, and treated with Tamoxifen, and subsequently transplanted along with supporting bone marrow cells from un-irradiated B6-LY5.2/NCr mice into 2 groups of irradiated 7-12 weeks old B6-LY5.2/NCr recipient mice [one group each for the infected (eki/eki, tg/+) and (eki/eki, +/+) donor cells]. The recipient mice of both groups will be subsequently aged for 6 months for leukemia development. Any remaining transplant recipient mice 6 months after transplantation will be euthanized.

pMYs virus used for the transduction of bone marrow progenitors will be generated from sterile culture medium of PLAT-E cells, a human cell line designed to package retroviral particles in ecotropic envelops and free of other known viruses[4]. This virus is replication deficient, and therefore is no longer infectious after initial infection. Prior to and during infection, these bone marrow cells may be cultured in the presence of

recombinant murine growth factors to stimulate their proliferation (In-vitro procedures only).

Recipient B6-LY5.2/Cr mice will be irradiated on the day of transfer of hematopoietic cells with 1100 rads of total body irradiation from a ^{137}Cs source located at room (b)(6) The Infected bone marrow cells (1 x 10^6 cells/mouse) along with 5 x 10^5 supporting bone marrow cells from un-irradiated B6-LY5.2/NCr mice will be resuspended in 200ul PBS and introduced into each recipient by one time tail vein injections. Past experience has shown that lethally irradiated mice can suffer from infection during engraftment of the transplanted cells. To prevent infection, all recipient mice will receive amoxicillin at a concentration of 1mg/ml in the drinking water from 5 days prior to irradiation to 10 days post irradiation. Although occurring rarely, engraftment failure of the transplanted cells will also lead to recipient death between 7 and 10 days after injection. Therefore, to prevent any potential suffering during this critical period of time, recipient mice will be monitored twice daily by PI staff between 7 and 10 days after transplantation for signs of distress including rough coat, listlessness, or hunched posture. Any transplant recipients showing such signs will be euthanized immediately. Leukemia development and progression is a slow process; therefore, for the time periods before day 7 and after day 10 post transplantation, transplant recipient mice will be monitored once daily by PI staff during week days and by LAM personnel during weekends and holidays for signs of leukemia development, which are similar to the above-described signs of engraftment failure. Any transplant recipients showing such signs will be euthanized immediately and fresh tissues including bone marrow, spleen, thymus, liver, and kidney will be collected and examined by flow cytometry, tissue culturing and pathology. We have not observed development of any other cancers besides leukemia in B6-LY5.2/NCr mice irradiated with the same dosage (1100 rads) in our past experience.

In order to statistically establish that retroviral insertional mutagenesis can accelerate leukemia transformation of (b)(4) expressing cells, a group of 15 irradiated B6-LY5.2/NCr recipient mice will need to be transplanted with transduced bone marrow progenitors from (eki/eki, tg/+) mice and another 15 mice will receive similarly infected cells from (eki/eki, +/+) mice as the control group.

Insertional mutagenesis by retroviral vectors is a valuable tool for identifying cooperating mutations in leukemia development [3]. Taking advantage of leukemias generated in this study, we would also like to identify at least (b)(4) (b)(4) We were able to identify 2 cooperating mutations for another oncogene Sox4 from 15 leukemias using a similar insertional mutagenesis approach[3]. Therefore, in order to identify at least (b)(4) we would also like to generate a total of 30 accelerated leukemias that will be used for cloning viral insertions for the purpose of identifying cooperating partner genes for (b)(4) in leukemia induction. We estimate that 60% of the mice that receive pMYs virus transduced cells will develop leukemia within 6 months. Therefore, a total of 50 recipient mice will need to be transplanted with cells transduced by pMYs virus in order to generate 30 leukemias (50 recipients x 60% leukemia penetrance). Therefore, we will transplant 50 instead of 15 recipient mice with cells from (eki/eki, tg/+) mice and 15 recipients with cells from (eki/eki, +/+) mice.

Since 1 x10^6 infected bone marrow cells will be transplanted into each recipient mouse, a minimum of 1 x 10^6 cells x 50 recipients = 5 x 10^7 bone marrow cells will be needed from (eki/eki, tg/+) mice and another 1 x 10^6 cells x 15 recipients= 1.5 x10^7 cells from (eki/eki, +/+) mice. When mice have been treated with 5-FU, harvest of

bone marrow from one mouse is expected to yield 1 x 10^6 cells. When these cells are cultured in the presence of growth factors and in contact with retrovirus, only 50% of the cells can be recovered from culture, yielding 5 x10^5 cells. As such, each transplant recipient will require 2 mice to provide sufficient donor cells. Therefore, for 50 transplant recipients for (eki/eki, tg/+) mice as discussed above, a total of **5 x 10^7 donor cells / (5 x 10^5cells/donor) = 100 donor (eki/eki, tg/+) mice will be needed.** Similarly, for 15 transplant recipients for (eki/eki, +/+) mice, a total of **1.5 x 10^7 donor cells / (5 x 10^5cells/donor) = 30 donor (eki/eki, +/+) mice will be needed.**

We will try to accomplish this study in 8 experiments; therefore, 8 additional B6-LY5.2/NCr will be needed to provide supporting bone marrow cells. **Required B6-LY5.2/NCr recipient animals: 50 animals for (eki/eki, tg/+) + 15 animals for (eki/eki, +/+) + 8 supporting marrow donors = 73 mice.**

Summary of required animal numbers for Experiment 1:

Strains	Experimental groups		Supporting B.M.	Total
	eki/eki, tg/+	eki/eki, +/+		
B6-LY5.2/NCr	50	15	8	**73**
(b)(4) (BM donor)	100	30		**130**

Study endpoint for transplant recipient B6-LY5.2/NCr mice:
6 months after transplantation.

V.1.2. Experiment 2: To test whether (b)(4) -induced self-renewal is mediated by Wnt/β-catenin signaling.

We have found that Wnt/β-catenin pathway is activated in myeloid progenitor cells overexpressing (b)(4) suggesting that the self-renewal function of (b)(4) may be mediated by the Wnt/β-catenin pathway. To test this idea, we will test whether β-catenin deficient myeloid progenitors can be immortalized by retroviral vectors expressing (b)(4) We will breed β-catenin conditional knockout Ctnnb1-CKO mice with Cre-ERT2 mice carrying an inducible Cre transgene as described in Experiment 1 to generate Ctnnb1-ERT2 (cko/cko, tg/+) and control (cko/cko, +/+) mice (The generation of these mice is supported by the breeding protocol (b)(6) Bone marrow cells harvested from these mice will be tested for immortalization in culture by Evi1 expression after treatment with Tamoxifen which will induce deletion of β-catenin only in cells from (cko/cko, tg/+) mice but not in cells from control (cko/cko, +/+) mice.

In order to achieve statistical significance, bone marrow cells from 5 mice of each genotype will be tested. Therefore, **a total of: 5 animals/genotype x 2 genotypes = 10 mice.**

Summary of required animal numbers for Experiment 2:

Strains	Experimental groups		Total
	cko/cko, tg/+	cko/cko, +/+	
Ctnnb1-ERT2	5	5	**10**

V.2. **Data Analysis**: For Experiment 1, log-rank tests will be used to compare time to development of leukemia across groups. When the sample size in each group is 15, a 5% two-sided log-rank test for equality of survival curves will have 80% power to detect a difference in proportion surviving of at least 54 percentage points (e.g. 99% vs. 45% surviving). A sample size of 5 animals in each group (as in Experiment 2), when using t-test, will have 80% power to detect a difference of 2 standard deviations between groups.

V.3. **Laboratory Animals Required and Justification**:

V.3.1. **Non-animal Alternatives Considered**: Cell line studies was considered, however it does not allow identifying (b)(4) targets involved in immortalization as cell lines are already immortal. Also, *In vivo* study is extremely important in leukemia research as the evolvement of leukemic cells is not an isolated event and involves constant interaction with the host environment which has yet to be replicated in tissue culture settings. Computer modeling was considered as well, but the mechanisms underlying leukemia development is still largely unknown and there is no system available in the leukemia field that can be used to predict target genes involved in the immortalization of hematopoietic cells.

V.3.2. **Animal Model and Species Justification**: I have chosen to use mice for my studies because they are genetically well-characterized mammalian organism that has been shown to have a very similar hematopoietic system to that of humans, and more and more studies have been carried out in mice to understand human leukemia development and normal hematopoiesis[5-7]. In addition, there are many tools available in mice but not in other mammalian models to genetically alter the germline and study the consequences of the mutation in normal cells. I also happen to have extensive experiences (for the past 9 years) working with mouse hematopoietic system. Lower organisms such as Zebrafish and Drosophila were also considered, however both species are very different from mammals and do not represent good models for studying human hematopoiesis.

V.3.3. **Laboratory Animals**

	Species #1	Species #2
V.3.3.1. **Genus & Species**:	Mus. Musculus	
V.3.3.2. **Strain/Stock**:	B6-LY5.2/NCr (b)(4) Ctnnb1-ERT2	
V.3.3.3. **Source/Vendor**:	(b)(4) B6-LY5.2/NCr) In-house (b)(4)	

(b)(4) Ctnnb1-ERT2)

V.3.3.4. Age: 6-12 weeks

V.3.3.5. Weight: 20-25g

V.3.3.6. Sex: Male: 65 (b)(4) (b)(4) 65)
Female: 148 (b)(4) (b)(4) 65; B6-LY5.2/NCr, 73; Ctnnb1-ERT2, 10)

V.3.3.7. Special Considerations: N/A

V.3.4. Number of Animals Required (by Species): 213 mice (b)(4) (b)(4) 130; B6-LY5.2/NCr, 73; Ctnnb1-ERT2, 10)

V.3.5. Refinement, Reduction, Replacement (3 Rs):

V.3.5.1. Refinement: All animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels. Animals observed to be ill or showing signs of pain or distress including weight loss, hunched posture, ruffled fur, and decreased activity will be evaluated by veterinary staff to be treated or be euthanized immediately for relief of suffering.

V.3.5.2. Reduction: The estimated numbers of animals for proposed studies have been computed by power analysis to ensure that the smallest numbers of animals required to evaluate the hypotheses are being used.

V.3.5.3. Replacement: Tissue culture and computer models were considered but not adopted. Detailed explanations are provided in V.3.1.

V.4. Technical Methods:

V.4.1. Pain / Distress Assessment:

V.4.1.1. APHIS Form 7023 Information:

V.4.1.1.1. Number of Animals:

	Species #1	Species #2
V.4.1.1.1.1. Column C:	148	
V.4.1.1.1.2. Column D:		
V.4.1.1.1.3. Column E:	65 (B6-LY5.2/NCr mice for receiving irradiation)	

V.4.1.2. Pain Relief / Prevention:

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization: N/A

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions: N/A

V.4.1.2.3. Paralytics: N/A

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures:

V.4.1.3.1. Sources Searched: AWIC and Altweb

V.4.1.3.2. Date of Search: 12/9/2013

V.4.1.3.3. Period of Search: N/A

V.4.1.3.4. Key Words of Search: "Irradiation" in combination with "mouse bone marrow transplantation" was used as key words.

V.4.1.3.5. Results of Search: No relevant matches were returned in both databases.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification: Whole body irradiation of recipient mice is essential for successful mouse bone marrow transplantation as it is the only way to efficiently deplete host bone marrow stem cells and to greatly increase donor cell engraftment in mice.

V.4.2. Prolonged Restraint: N/A

V.4.3. Surgery:

V.4.3.1. Pre-surgical Provisions: N/A

V.4.3.2. Procedure: N/A

V.4.3.3. Post-surgical Provisions: N/A

V.4.3.4. Location: N/A

V.4.3.5. Surgeon: N/A

V.4.3.6. **Multiple Major Survival Operative Procedures**: N/A

V.4.3.6.1. **Procedures**: N/A

V.4.3.6.2. **Scientific Justification**: N/A

V.4.4. **Animal Manipulations**:

V.4.4.1. **Injections**: 28 Gauge x ½ inch needles will be used for all injections. Some mice as specified in Experiment 1 of the experimental design and general procedures section will receive one time intra-peritoneal injection of 5-FU resuspended in phosphate buffered saline (PBS) at a dosage of 150 mg/kg body weight in 200ul volume as described in Experiment section. 5-FU treatment of mice at this dosage is toxic to proliferating cells in the hematopoietic system representing more mature progenitors, but is not expected to cause animal suffering and death.

Transplantat on of bone marrow cells will be carried out by one time tail vein njections of cells resuspended in 200ul of PBS. Recipient mice will be restrained for the injection using a Tailveiner restrainer from Braintree Scientific. Since transplanted cells are from mice congenic to the recipients, no immune rejection is expected a'ter transplantation. Injection of hematopoietic cells through the tail vein is not known to cause any toxic effects to mice All cells for injection will be obtained from mice housed in USU colony. In,ection of all biological materials will be n accord with USU IACUC Policy #23 on the use of biological in experimental animals.

V.4.4.2. **Biosamples**: Hematopoietic tissues including bone marrow, thymus, spleen, and lymph nodes will be collected at euthanasia.

V.4.4.3. **Adjuvants**: N/A

V.4.4.4. **Monoclonal Antibody (MAbs) Production**: N/A

V.4.4.5. **Animal Identification**: Cage cards will be used to distinguish different study groups.

V.4.4.6. **Behavioral Studies**: N/A

V.4.4.7. **Other Procedures**: Recipient B6-LY5.2/NCr mice will be irradiated on the day of transplantation with1100 rads of total body irradiation from a ^{137}Cs source located at room (b)(6) Mice will be transported and irradiated at room temperature in irradiator disks (purchased from Braintree Scientific) that maintain a filter protected sterile environment and hold up to 20 mice at each time. The entire process will last no more than 30 minutes and during which time no food or water will be provided for the animals. Hematopoietic cells resuspended in PBS in a volume of 200 ul will be introduced by tail vein injection. Following transfer of the hematopoietic cells mice will be monitored daily for signs of distress including rough coat listlessness, decreased body weight, or hunched posture. Any recipients displaying any combination of two or more signs of distress above will be euthanized immediately by PI staff. The dose of

irradiation used is expected to be lethal within 10 days in the absence of bone marrow reconstitution by transplanted cells. Successful recolonization of the recipient bone marrow in transplanted animals results in restoration of constitutive hematopoiesis over the normal life span of the recipient. Past experience has shown that lethally irradiated mice can suffer from infection. To prevent infection, all recipient mice will receive amoxicillin at a concentration of 1mg/ml in the drinking water from 5 days prior to irradiation to 10 days post irradiation.

V.4.4.8. Tissue Sharing: N/A

V.4.5. Study Endpoint: The study endpoint for irradiated B6-LY5.2/NCr recipient mice is 6 months after transplantation as specified in the experimental design and general procedures section. Animals could be euthanized earlier due to leukemia development or engraftment failure of transplanted hematopoietic cells after irradiation. Signs of these conditions include rough coat, listlessness, decreased body weight, or hunched posture. Any animals displaying any combination of two or more symptoms will be euthanized immediately.

V.4.6. Euthanasia: Animals under this protocol will be euthanized by PI staff or LAM personnel at study end point or when moribund due to bone marrow engraftment failure or leukemia development as described under V.1.1 Experiment 1. Mice will be euthanized using cylinderized CO2. These animals will be placed in a cage or chamber that is not crowded and exposed to a mix of CO2 and oxygen. The CO2 flow rate will displace at least 20% of the chamber volume per minute. Flow will continue for at least one minute after visible sign of death. CO2 euthanasia will be followed by cervical dislocation to ensure death. This procedure is 2013 AVMA Guidelines for the Euthanasia of Animals.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol.

V.5.1.1. Study Room:
Building(s) _____ Room Number(s) (b)(6)

V.5.1.2. Special Husbandry Provisions: To prevent infection after bone marrow transplantation, all recipient mice will be provided with sterile feed and autoclaved caging will be provided.

Food Restriction:	Yes _____	No X
Fluid Restriction:	Yes _____	No X

V.5.1.3. Exceptions: N/A

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care: Animals will be observed at least once daily by Center for LAM personnel. PI group will also observe the colony once daily during week days except during the period 7-10 days post-irradiation during which they will be monitored twice daily. Animals observed to be ill or showing signs of pain or distress including weight loss, hunched posture, ruffled fur, and decreased activity will be evaluated by veterinary staff to be treated or be euthanized. PI should be contacted for potential tissue collection needs if sick animals are to be euthanized by LAM personnel.

V.5.2.2. Emergency Veterinary Medical Care: All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays. Sick or moribund animal will be evaluated by veterinary staff to be treated or be euthanized. PI should be contacted for potential tissue collection needs if euthanasia is necessary. Euthanasia by LAM personnel should proceed if PI can not be reached.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: All animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents; balls, toys and food enrichment treats for large animal species.

V.5.3.2. Enrichment Restrictions: N/A

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
Animal monitoring, euthanasia, tissue extraction, intra-peritoneal injection	(b)(6)	PI, 12 years of experience	Animal Care and Use Introductory Training Course at NCI, 2001; Animal Care and Use Training Course at NCI, 2007; Investigator training course at USUHS, 2007.

			by PI, 2007
Euthanasia, tissue extraction	(b)(6)	Technician, 5 years of experience	Investigator training course at USUHS, 2007; Rodent Handling course at USUHS, 2007

VII. **BIOHAZARDS/SAFETY**: Replication defective ecotropic retroviral vectors will be used to infect mouse bone marrow cells before transplantation of the infected cells into recipient mice. These viruses will be collected from culture medium of cell lines designed to package viral particles in ecotropic envelops. After initial infection these vectors are no longer infectious and are replication deficient. There is no evidence in the literature that humans can be infected by ecotropic retroviruses. Any person handling these retroviral vectors will be required to wear lab coat and gloves as precaution. Registration for the use of these viral vectors has been submitted to IBC. 5-FU and tamoxifen are harmful if ingested, injected or through skin contact. Therefore, lab coat, gloves, and safety glasses are also required when preparing the solution and carrying out animal injection using these substances.

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course

(b)(6) _____ 12/11/13

Principal Investigator Signature Date

G. Training: The following personnel will attend the next USUHS Investigator/Animal User Training Course:

_____ _____

_____ _____

H. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely, "Responsibility" for implementing animal use alternatives where feasible and conducting humane and lawful research.

(b)(6) _____ 12/11/13

Principal Investigator Signature Date

I. Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL or WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

X. PROTOCOL ABSTRACT:

A. Animal Protocol Number:

B. Animal Protocol Title: Characterizing the role of (b)(4) during human leukemia development using a knock-in mouse model

C. Principal Investigator: (b)(6) Department of Pediatrics

D. Performing Organization: Uniformed Services University of the Health Sciences

E. Funding: Department of Pediatrics

F. Objective and Approach: The objective of this study is to understand the mechanisms that (b)(4) induces human leukemia development. Genetically engineered mouse strain overexpressing (b)(4) will be generated and used for studying leukemia induction. The three R's (reduction, replacement, and refinement) of animal usage will be employed.

G. Indexing Terms (Descriptors): Animals, mice, and knock-in

MEMORANDUM FOR DR. (b)(6) DEPARTMENT OF PEDIATRICS

SUBJECT: IACUC Approval of Protocol - Triennial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on March 26, 2015:

Animal Protocol Title: "Characterization of ptpn-11 Gain of Function Mutations Using Transgenic Mouse Models"

USUHS Protocol Number: (b)(6)

Expiration Date: March 25, 2018

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. NON-TECHNICAL SYNOPSIS: Our laboratory is interested in studying how cancers develop so that we can ultimately help find better treatments. More specifically, we are studying how Juvenile Myelomonocytic Leukemia (JMML), an aggressive form of childhood leukemia, develops and will try to understand the different steps that are required for the development of this aggressive disease. While the cure rates for childhood leukemia has increased to above 80%, the cure rate for JMML is less than 50%, and we do not understand why JMML is a more aggressive disease or why chemotherapy is ineffective against JMML. Despite difficulty in improving the treatments, much has been learned about the genetic lesions which cause JMML. Over the past few years, mutations in ptpn-11 as well as cbl were found in patients with JMML. In fact, 90% of patients with JMML will harbor mutations in ptpn-11, k-ras, n-ras, Cbl, or Nf-1 mutations. Interestingly all of these genes are known to be involved in a common biochemical pathway called the "ras pathway" defining JMML as a disease caused by hyperactive RAS signaling.

Over the past three years, we have developed transgenic mice which carry mutant ptpn-11 transgenes as well the mutant cbl transgenes. Upon aging the ptpn-11 mutant mice, some of the mice develop a myeloproliferative disorder with an enlarged spleen. However, they do not go on to develop fulminant JMML which is likely due to several factors such as requiring additional genetic lesions as well as the fact that our transgenic mice have lower level of expression than the endogenous gene. It also is likely that the level of the normal endogenous gene affects the phenotype of these mice. Our future goals are to further characterize the Cbl transgenic mice to see if they develop JMML as well as explore the other genetic lesions which cooperate with ptpn-11 and Cbl in leading to the development of JMML.

II. BACKGROUND:

II.1. Background: Juvenile Myelomonocytic Leukemia (JMML) is a devastating childhood cancer which is rapidly fatal with infiltration of myeloid cells into multiple organs [1]. Despite remarkable advances in the cure rates of childhood leukemia, we

have made little progress with JMML with stem cell transplant providing the only hope for cure [2]. The discovery that the *ptpn-11* gene is mutated in up to 35% of JMML patient samples has provided an important clue in understanding the pathogenesis of this disease. It is now accepted that perturbations in the RAS pathway are essential in the development of JMML. Moreover, about 25% of JMML samples contain an oncogenic *ras* mutation [3, 4]. Now, with the addition of *c-cbl* mutations which is seen in about 15% of JMML patient samples, it appears that ~90% of the initiating mutations are accounted for and all of them involve genes in the RAS pathway [5, 6].

The *ptpn-11* gene encodes for SHP-2 which is a non-receptor protein tyrosine phosphatase. In order to better understand how *ptpn-11* mutations predisposed these patients to develop myeloid malignancies, we first over-expressed leukemia-associated SHP-2 protein and found that they enhanced the proliferation of murine hematopoietic cells as well as making them hypersensitive to granulocyte-macrophage colony-stimulating factor (GM-CSF). It was also found that these effects are dependent on the increased phosphatase activity of the SHP-2 protein and that these leukemia associated *ptpn-11* mutations were more potent than the Noonan syndrome mutations [7, 8]. Others have also reported similar effects of *ptpn-11* mutations on activating the RAS pathway and are summarized in the review by Mohi [9, 10].

During the past few years, new mouse models with mutant Shp-2 have been published. Chan et. al. reported the development of a knock in mouse model expressing the *ptpn-11*^{D61Y} mutation which is the second most common mutation after *ptpn-11* ^{E76K} mutation. These mice develop a fatal myeloproliferative disorder with a median survival of 45 weeks. These mice also show enhanced phosphorylation of Erk and Stat5 which is similar to *kras*^{G12D} knock in mouse model [11, 12]. Recently, Xu et. al. reported the phenotype of knock in mice which have the *ptpn-11* ^{E76K} mutation and found that these mice develop a myeloproliferative disorder as well as myeloid leukemias and lymphoid leukemias [13]. We have also generated transgenic mice carrying the *ptpn-11* ^{E76K} mutation but these mice develop only mild myeloproliferative disease with splenomegaly when aged but do not die from this disease. This is most likely due to levels of the mutant gene being expressed compared to the knock in mice which have only 50% of the wild type protein being expressed whereas the transgenic mice have normal levels of the wild type protein.

The *c-cbl* gene encodes a multifunctional adaptor protein which contains an N-terminal tyrosine-kinase binding (TKB) domain, a ring finger motif which contain E3 ligase activity, and a C-terminal ubiquitin-associated domain. It is thought that the TKB domain is involved in adaptor functions of the protein whereas the ubiquitin ligase domain results in monoubiquitylation of receptors which promotes lysosomal mediated degradation of activated receptors (reviewed in[14]). Previous mutations in myeloid malignancies have been described where mutations occur in the ring finger domain or the linker domain [15, 16]. It seems that amino acid residue 371, which resides in the linker domain and separates the TKB domain to the Ring domain, is critical in the transformation potential of *cbl* as deletion of Y371 both abolishes the E3 ligase activity and is oncogenic whereas mutation which only abolish E3 ligase activity is not oncogenic [17]. Interestingly, there was a hotspot for mutations at residue 371 in patients with JMML where 1/3 of mutations found in *c-cbl* were found to be a tyrosine to

histidine mutation, *cbl*^{Y371H} [5]. We have generated transgenic mice carrying the *cbl*^{Y371H} mutation. Because Cbl mutations require homozygosity in patients to develop disease, it is likely that we will need to inactivate the normal copy of mouse Cbl in order for the mutant over-expression to result in a disease phenotype. Our initial attempt at generating this model resulted in embryonic lethality due to the deleterious effect of having only mutant Cbl during development. We are now trying to develop a conditional deletion model so that we can bypass the embryonic lethality.

Animal models can be very useful in preclinical testing of novel therapies and especially important for rare diseases such as JMML. Genetically engineered mouse models are now being generated which accurately recapitulate human diseases [18]. Because the RAS pathway is clearly involved in the development of JMML, new drugs which target the downstream effectors of the RAS pathway are attractive candidates. For a rare disease such as JMML, clinical trials would be very time-consuming due to the lack of patient numbers and would not allow analysis of variety of agents which are now becoming available. Thus, transgenic mouse models engineered to phenocopy the biology found in JMML patients would be an attractive platform to test new therapeutic strategies with the statistical power to make an informed choice in taking new therapies to clinical trials.

Finally, In order to investigate cooperating mutations required for the development of ptpn-11 induced cancers, we plan on performing crosses with previously generated mouse models from other oncogenes and tumor suppressor genes. In this way, we will be able to test the interaction of *ptpn-11* mutations with other known oncogenic pathways.

II.2. Literature Search for Duplication:

II.2.1. Literature Source(s) Searched: BRD, NIH RePORTER, PUBMED

II.2.2. Date of Search: Feb 4, 2015

II.2.3. Period of Search:
BRD: 1996-2014
NIH RePorter: 2010-2012
PUBMED: 1960-2014

II.2.4. Key Words and Search Strategy: Mouse models of JMML, Shp-2, ptpn-11, Cbl

II.2.5. Results of Search: There are no reported studies using the ptpn-11 BAC. There is a published mouse model of Noonan syndrome using the "knock in" approach where one specific mutation was tested. There is now a knock in mutation of the ptpn-

11^{E76K} mutation but it was not published when this work was started. There are no mouse models of Cbl^{Y371H} mutation. There is a mutant Cbl ringer finger knock in mice carrying the Cbl^{C379A} which is equivalent to the Cbl^{C381A} which are found in myeloid diseases.

III. OBJECTIVE\HYPOTHESIS: The objective of this protocol is to gain insight into how mutations in *ptpn-11* gene and Cbl results in the development of an aggressive form of childhood leukemia called Juvenile Myelomonocytic Leukemia. By using an animal model of JMML, we will be able to analyze the specific pathways which are perturbed by ptpn-11 mutations as well as investigating the cooperating mutations which are necessary for the development of this cancer. Finally, since the mice carry the exact mutations found in human cancers, we hope to eventually test new therapeutic strategies using this animal model to help develop better therapies for this aggressive disease.

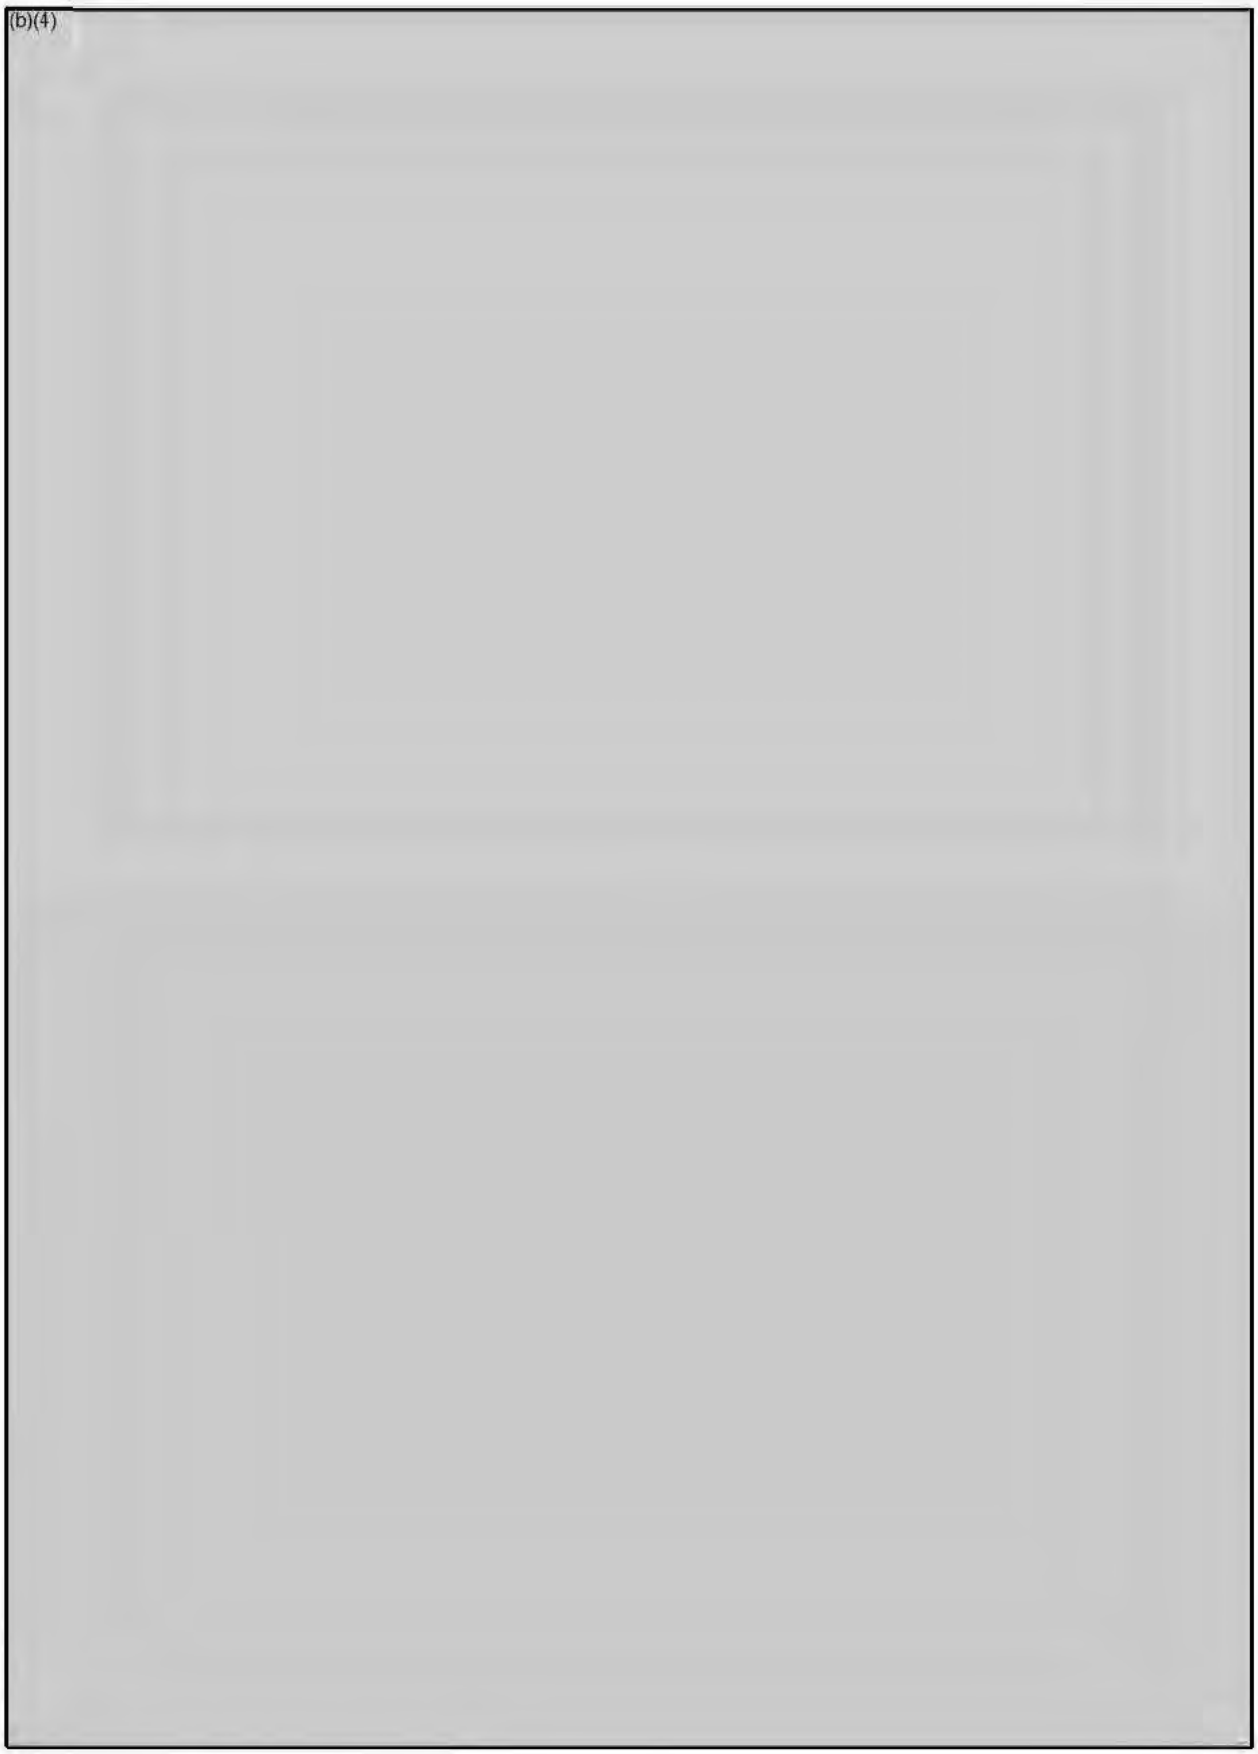
IV. MILITARY RELEVANCE: Military personnel on the battlefield may be exposed to radiation or toxic substances that could induce leukemia development later in life. Understanding the mechanisms underlying leukemia development should help find better treatments for this devastating disease. Although the focus of this study is studying the mechanisms involved in a specific form of childhood leukemia, all cancers share many similarities in pathogenesis such as activation of oncogenes and inactivation of tumor suppressor genes. Therefore, accomplishing this study has the potential to identify novel pathways that could be targeted for treating other cancers.

V. MATERIALS AND METHODS:

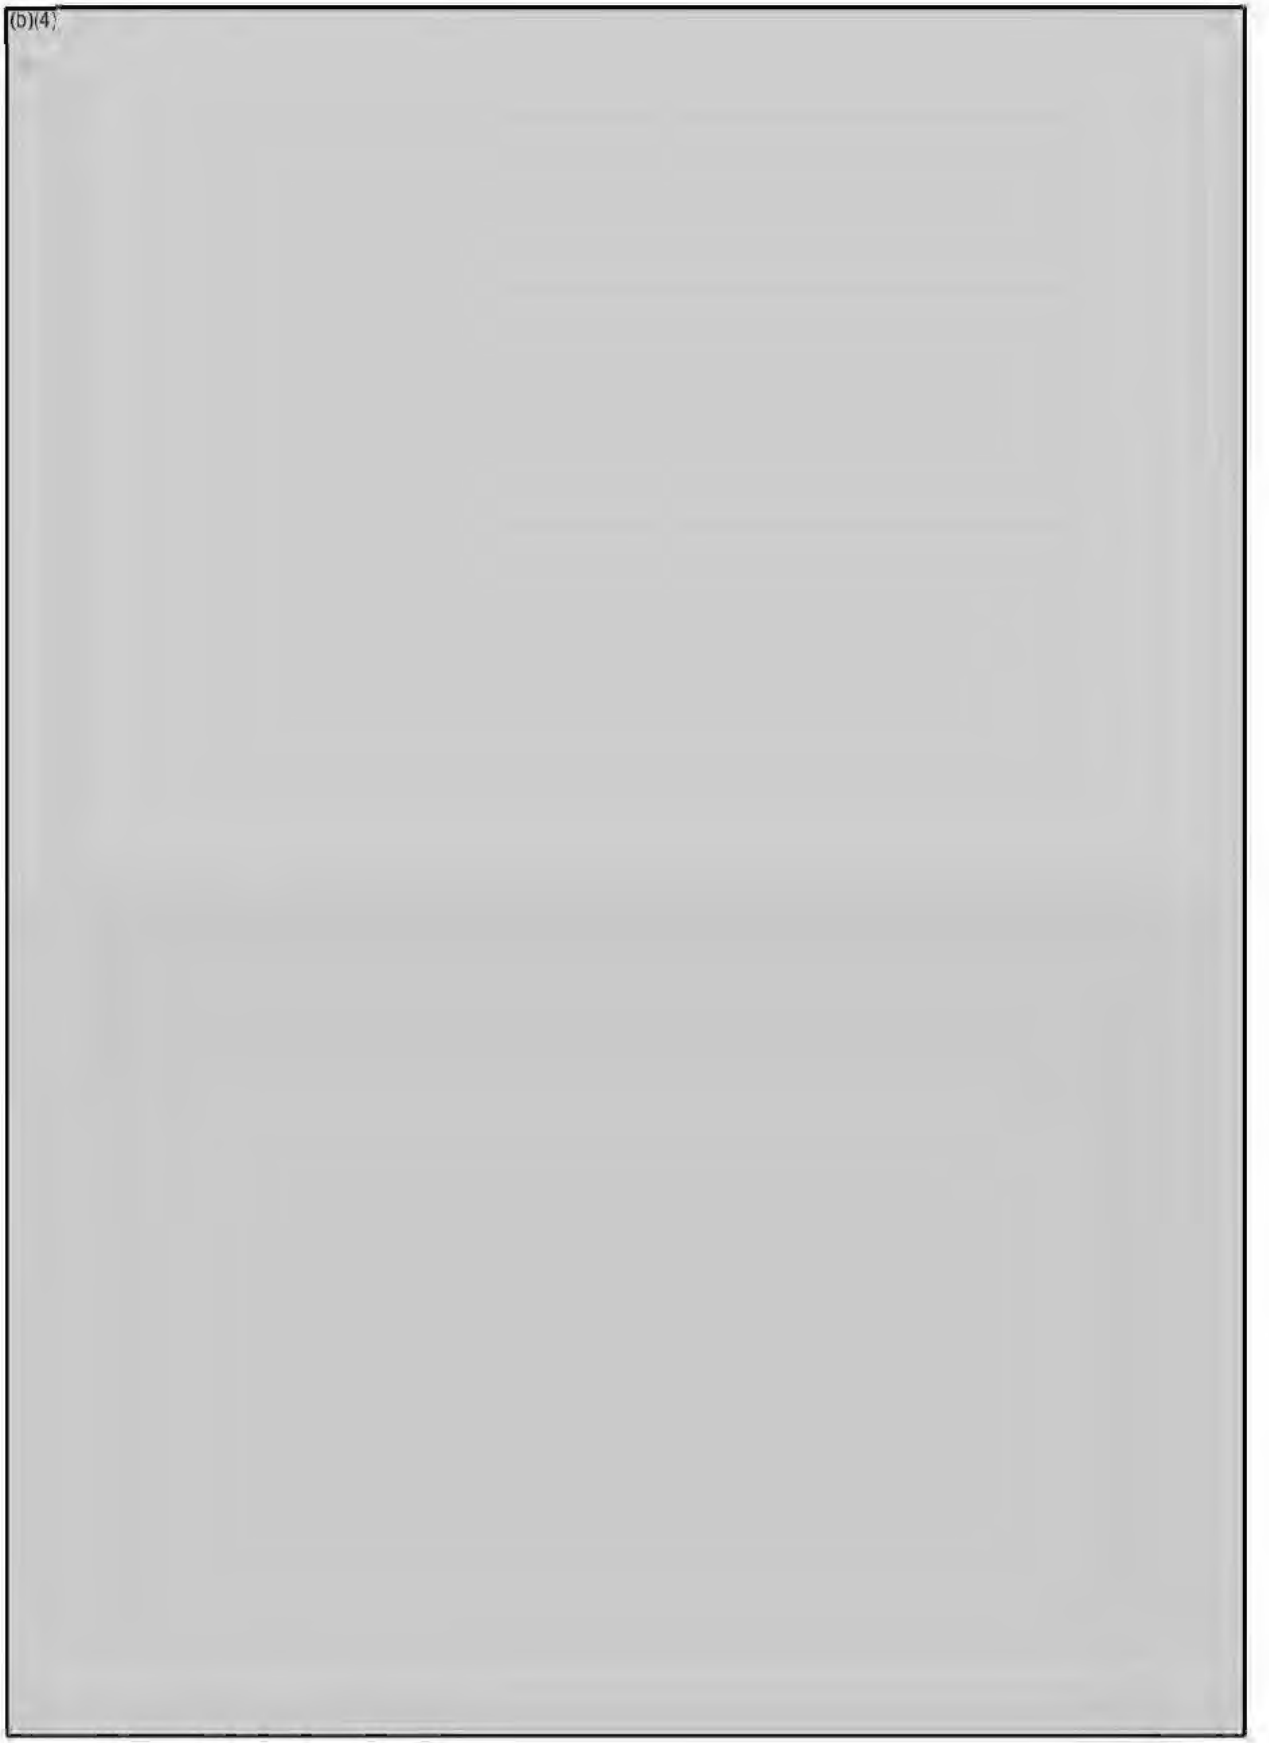
V.1. Experimental Design and General Procedures:

(b)(4)

(b)(4)



(b)(4)



(b)(4)

V.1.4. **Experiment 4: To determine the leukemia initiating population from mutant Cbl mice through bone marrow transplantation.**

Once we have mice that develop MPD and or leukemia, we will further characterize the disease phenotype by examination of the cell surface markers by flow cytometry to determine the type of leukemia. In order to determine whether the myeloproliferative disorder and or leukemia cells from the JMML mouse model is which is a hallmark of leukemia cells and its leukemia initiating cells, we will perform bone marrow transplantation experiments. Leukemic cells or pre-leukemic cells will be collected from donor transgenic mice and then transplanted into lethally radiated normal non transgenic mice. Lethally irradiated hosts will be given normal supporting cells to allow the mice to recover counts with transplanted cells and then followed for the development of disease.

In addition, in order to identify the leukemia initiating cells, different populations will be sorted by flow cytometry and then tested by bone marrow transplantation. Bone marrow will be extracted from mice at 6 to 12 weeks of age after euthanasia, and Hematopoietic Stem Cells (HSC), common myeloid progenitors (CMPs) and granulocyte macrophage progenitor (GMPs) will be purified from transgenic mice and will be transplanted into lethally irradiated B6-LY5.2/Cr mice (8-12 weeks old females, purchased from (b)(4) . The recipient mice will then be aged for up to 12 months after transplantation by monthly blood counts (see section V.4.1.2.1 for anesthesia procedures and section v.4.4.2 for biosample collection) and monitored for the development of disease in order to determine the identity of the leukemia initiating population. In addition, RNA, DNA, and protein will also be extracted from bone marrow cells for gene expression analyses such as microarray analysis and RT-PCR, and western blot analysis.

CMPs and GMPs represent very small percentage of total bone marrow cells. Around 3 mice of each genotype are required to obtain sufficient CMPs (about $3x\ 10^4$ cells) and GMPs (about 6×10^4 cells) for our proposed molecular studies in each experiment. Therefore, for 2 independent experiments, 2 x 6 animals/experiment x 5000

cells = 60000 CMP cells which can be obtained from 6 total animals with the correct genotype. In addition, purification of CMPs and GMPs is a very labor intensive procedure considering the large number of femurs that have to be processed in each setting and requires at least 2 people proficient in this procedure to work together. This procedure also contains several sensitive steps that tend to be error-prone such as 2 separate immuno-staining procedures with different cocktail of antibodies and one final 5-color cell sorting step. Therefore, animals generated in breeding protocol which don't have the correct genotype will be used for training and practice in preparation for these experiments after euthanasia. We will estimate that 20 mice are needed to learn the skills.

Recipient B6-LY5.2/Cr mice will be irradiated on the day of transfer of hematopoietic cells with 850 to 1050 rads of total body irradiation from a ^{137}Cs source located at room (b)(6) Hematopoietic cells resuspended in PBS in a volume of 200 ul will be introduced by tail vein injection. Following transfer of the hematopoietic cells, mice will be monitored for signs of distress daily such as ruffled fur, hunched back, and decreased activity. Past experience has shown that lethally irradiated mice can suffer from infection during engraftment of the transplanted cells. To prevent infection, all recipient mice will receive amoxicillin at a concentration of 1mg/ml in the drinking water from 5 days prior to irradiation to 10 days post irradiation. Although occurring rarely, engraftment failure of the transplanted cells will also lead to recipient death between 7 and 10 days after injection. Therefore, to prevent any potential suffering during this critical period of time, recipient mice will be monitored at least twice daily by PI staff between 7 and 10 days after transplantation for signs of distress including rough coat, listlessness, or hunched posture. Any transplant recipients showing such signs will be euthanized immediately. The dose of irradiation used is expected to be lethal within 10 to 14 days in the absence of bone marrow reconstitution by transplanted cells. Successful recolonization of the recipient bone marrow in transplanted animals results in restoration of constitutive hematopoiesis over the normal life span of the recipient.

Each transplantation experiment consists of 3-6 recipients and 5 experimental groups and requires a total of 25 B6-LY5.2/Cr animals as listed below: 1. PBS injection as positive control for irradiation (3 animals); 2. Supporting bone marrow (5×10^5 bone marrow cells from non-irradiated B6-LY5.2/Cr mice) as positive control for engraftment (3 animals); 3. CMPs (6 animals); 4. GMPs (6 animals); 5.HSCs (6 animals). For each transplant recipient in groups 3-5, 5×10^3 of specified myeloid progenitors will be injected via tail vein along with 5×10^5 bone marrow cells from non-irradiated B6-LY5.2/Cr mice for radioprotection. Therefore, in addition to the total of 24 recipients, one B6-LY5.2/Cr mouse is needed to provide non-irradiated bone marrow cells for each experiment. Group 1 recipients should die within 2 weeks after transplantation and will be euthanized as soon as they show sign of stress. Recipients in groups 2-5 should all survive after transplantation. While group 2 recipients will be euthanized at 4 months after transplantation, some of the recipients in group 3-5 will be euthanized at various times (2, 4, and 6 months) after transplantation for analysis of reconstitution. Bone marrow and spleen after euthanasia will be collected for FACS analysis. This experiment will be repeated 2 times to reach any conclusions.

So the minimum number of B6-LY5.2/Cr mice required for this study is: 25

animals/experiment x 2 experiments = 50.

Requested animal numbers:
Transgenic mouse donors: Need 3 per experiment X 2 experiments X 50 = 300
B6-LY5.2/Cr: 50

Total Requested; 370 (300 donor animals and 48 irradiated recipients and 2 unirradiated mice and 20 practice mice)

V.2. Data Analysis:

For all the experiments, gene expression and serial blood counts will be compared across genotypes using analysis of variance (ANOVA), student's t test, or nonparametric tests as appropriate. A sample size of 5 in each group will have 80% power to detect a difference of 2 standard deviations between groups using a 2-group t test with a 5%, two-sided significance level. This applies to experiment 4 where we are using 6 mice in order to ensure that we meet the minimum 5 needed as sometimes a mouse is lost unpredictably.

For aging studies, log-rank tests will be used to compare time to development of sickness such as cancer across genotype. When the sample size in each group is 20, a 5% two-sided log-rank test for equality of survival curves will have 80% power to detect a difference in proportion surviving to 18 months of at least 40 percentage points (e.g. 99% vs. 59% surviving). This applies to experiment 3.

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered: Tissue culture was considered, however cancer is a complex disease that requires proper interactions among different tissue and cell types within the context of a whole animal, and currently there is no tissue culture system capable of recapitulating this environment. In addition, cell lines used in tissue culture studies are different from normal hematopoietic cells in that they have acquired mutations that allow them to replicate indefinitely in culture, and results from these studies may not apply to normal cells. For example, leukemia associated ptpn-11 mutations introduced into 3T3 fibroblast cell line could not detect any phenotype (KL, unpublished data) while the introduction of Noonan syndrome associated mutation cleared had multiple phenotypes when introduced into the mouse germline (Araki et al, 2004).

Computer modeling was considered as well, but the regulation of hematopoietic development is still largely unknown and there is no system available in the hematopoiesis field that can be used to predict gene function and consequences of gene mutations.

V.3.2. Animal Model and Species Justification: We have chosen to use mice for our studies because they are genetically well-characterized mammalian organism that has been shown to have a very similar hematopoietic system to that of humans. In addition, there are many tools available in mice but not in other mammalian models to genetically alter the germline and study the consequences of the mutation on multiple organ systems simultaneously. We are using "knock out" mice which carry a null *ptpn-11* allele or null cbl allele as well as other transgenic mice such as the vav-icre mice to help characterize the phenotype of ptpn-11 mutant mice and Cbl mutant mice. Other organisms such as Zebrafish and Drosophila were also considered, but both species do not represent the best model for studying human hematopoiesis.

V.3.3. Laboratory Animals

	Species #1	Species #2
V.3.3.1. Genus & Species:	*Mus musculus*	*Mus musculus*
V.3.3.2. Strain/Stock:	(b)(4)	
V.3.3.3. Source/Vendor:	In house	In house
V.3.3.4. Age:	6 weeks to 16 weeks	6 weeks to 12 weeks
V.3.3.5. Weight:	N/A	N/A
V.3.3.6. Sex:	~20 female	~10 females and 10 males
V.3.3.7. Special Considerations:	SPF	SPF
V.3.4. Number of Animals Required (by Species):	Mice 20	Mice 20
	Species #3	Species #4
V.3.3.1. Genus & Species:	*Mus musculus*	*Mus musculus*
V.3.3.2. Strain/Stock:	(b)(4)	
V.3.3.3. Source/Vendor:	In house	In house
V.3.3.4. Age: Age range is acceptable.	6 weeks to 12 weeks	6 weeks to 12 weeks

V.3.3.5. Weight: Weight range is acceptable.	N/A	N/A
V.3.3.6. Sex:	~10 females and 10 males	30 males and 30 females
V.3.3.7. Special Considerations:	SPF	SPF
V.3.4. Number of Animals Required (by Species):	Mice 20	Mice 60
	Species #5	Species #6
V.3.3.1. Genus & Species:	*Mus musculus*	*Mus musculus*
V.3.3.2. Strain/Stock:	C57Bl6/Ly 5.2	(b)(4)
V.3.3.3. Source/Vendor:	(b)(4)	In House
V.3.3.4. Age: Age range is acceptable.	6 weeks to 12 weeks	6 weeks to 6 months
V.3.3.5. Weight: Weight range is acceptable.	N/A	N/A
V.3.3.6. Sex:	35 males and 35 females	~30 males and 30 females
V.3.3.7. Special Considerations:	SPF	SPF
V.3.4. Number of Animals Required (by Species):	Mice 70	Mice 60
	Species #7	Species #8
V.3.3.1. Genus & Species:	*Mus musculus*	*Mus musculus*
V.3.3.2. Strain/Stock:	Cbl^{Y371H};$Cbl^{flox/flox}$	Cbl^{Y371H};$Cbl^{flox/flox}$;vav-icre
V.3.3.3. Source/Vendor:	In house	In house
V.3.3.4. Age: Age range is acceptable.	6 weeks to 12 weeks	6 weeks to 12 weeks

V.3.3.5. Weight: Weight range is acceptable.	N/A	N/A
V.3.3.6. Sex:	~30 females and 30 males	150 males and 150 females
V.3.3.7. Special Considerations:	SPF	SPF
V.3.4. Number of Animals Required (by Species):	Mice 60	Mice 300

V.3.5. Refinement, Reduction, Replacement (3 Rs):

V.3.5.1. Refinement: All animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels. Animals observed to be ill or showing signs of pain or distress such as hunched posture, ruffled fur, and decreased activity will be evaluated by veterinary staff to be treated or be euthanized for relief of suffering.

V.3.5.2. Reduction: In order to reduce the animal numbers for this study, experiments have been designed to include tissue sharing among different experimental procedures including DNA extraction, RNA extraction, and protein extraction.

V.3.5.3. Replacement: Tissue culture and computer models were considered but not adopted. Detailed explanations are provided in V.3.1.

V.4. Technical Methods:

V.4.1. Pain / Distress Assessment: Animals observed to be ill or showing signs of pain or distress such as hunched posture, ruffled fur, and decreased activity will be evaluated by veterinary staff to be treated or be euthanized for relief of suffering.

V.4.1.1. APHIS Form 7023 Information:

V.4.1.1.1. Number of Animals:

	(b)(4)	
V.4.1.1.1.1. Column C:	20	20
V.4.1.1.1.2. Column D:		
V.4.1.1.1.3. Column E:		
	Ptpn-11$^{WT/fl}$; phox2b-cre	(b)(4)
V.4.1.1.1.1. Column C:	20	60

V.4.1.1.1.2. Column D:		
V.4.1.1.1.3. Column E:		
	C57Bl6/Ly 5.2	(b)(4)
V.4.1.1.1.1. Column C:	22	60
V.4.1.1.1.2. Column D:		
V.4.1.1.1.3. Column E:	48	
	(b)(4)	
V.4.1.1.1.1. Column C:	60	300
V.4.1.1.1.2. Column D:		
V.4.1.1.1.3. Column E:		

V.4.1.2. Pain Relief / Prevention: Because we are trying to generate a mouse model of leukemia, some mice will become ill. Animals observed to be ill or showing signs of pain or distress such as hunched posture, ruffled fur, and decreased activity will be evaluated by veterinary staff to be treated or be euthanized for relief of suffering. All procedures except blood draw will be after euthanization. To prevent infection after irradiation, all animals will be given prophylactic antibiotics for 14 days.

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization:

Local anesthesia for blood draw: For superficial temporal vein sampling, we will not use local anesthesia. For lateral tain vein or ventral artery sampling, we will use lidocaine cream or ethyl chloride spray for local anesthesia. For other types of sampling, we will use either isoflurane chamber or injectable anesthesia. Isoflurane chamber is available in LAM for use by investigators and for injectable anesthesia, intraperitoneal injection with 0.1 cc of ketamine/xylazine mixture (10:1 mixture of 100mg/ml solution) will be used if needed.

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions: To prevent infection in irradiated mice, all recipient mice will receive amoxicillin at a concentration of 100ug/ml in the drinking water from 3 days prior to irradiation to 14 days post irradiation.

V.4.1.2.3. Paralytics: N/A

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures:

V.4.1.3.1. Sources Searched: Pubmed

V.4.1.3.2. Date of Search: 2/20/15

V.4.1.3.3. Period of Search: 1990-2014
V.4.1.3.4. Key Words of Search: animal models, animal irradiation procedure and alternatives
V.4.1.3.5. Results of Search:
Based on the search results, replacement of proposed procedure regarding irradiation of mice for bone marrow transplantation was considered but there is no viable replacement for irradiation.
V.4.1.4. Unalleviated Painful or Distressful Procedure Justification: Irradiation is used to prepare the recipient mice for accepted donor bone marrow. Irradiation itself is not painful but results in side effects which can be painful but is needed for transplant procedures. Chemotherapy can be used but results in the same side effects or worse. There are colony formation assays which can be correlated with ability to reconstitute the hematopoietic system. However, there is no substitute for testing in an animal model. We will use the minimum amount of mice necessary for transplant studies and euthanize animals as soon as signs of distress appear.

V.4.2. Prolonged Restraint: N/A

V.4.3. Surgery: N/A

V.4.3.1. Pre-surgical Provisions: N/A

V.4.3.2. Procedure: intravenous injection as described in V4.4.1 below and phlebotomy as described in V4.4.2 below.

V.4.3.3. Post-surgical Provisions: N/A

V.4.3.4. Location: N/A

V.4.3.5. Surgeon: N/A

V.4.3.6. Multiple Major Survival Operative Procedures:

V.4.3.6.1. Procedures: N/A

V.4.3.6.2. Scientific Justification: N/A

V.4.4. Animal Manipulations:

V.4.4.1. Injections: Intravenous injections will be required for infusing whole bone marrow cells, sorted stem cells, and/or leukemia cells for transplant experiments. A 27 gauge needle will be used for tail vein injections with cells in phosphate buffered saline at a maximum of 10% blood volume to be delivered. For inhalation anesthesia, we will use the isoflurane chamber available in LAM or for injectable anesthesia, intraperitoneal injection with 0.1 cc of ketamine/xylazine mixture (10:1 mixture of 100mg/ml solution) will be used if needed.

V.4.4.2. Biosamples: Hematopoietic tissues including bone marrow, thymus, spleen, and lymph nodes will be collected at euthanasia. In addition, animals that are being aged will receive periodic blood counts (not more than monthly) done via tail vein phlebotomy or other IACUC accepted methods such as sub-mandibular phlebotomy. For tail vein phlebotomy, a lancet is used to make an incision at the tail vein and drops of blood are collected using a capillary collection tube. For submandibular phlebotomy, anesthesia is used for the procedure followed by an incision using a lancet and collection using capillary collection tube. Only about 50 to 100 microliter of blood will be collected and used for blood counts which are less than 5% of blood volume.

V.4.4.3. Adjuvants: N/A

V.4.4.4. Monoclonal Antibody (MAbs) Production: N/A

V.4.4.5. Animal Identification: The identification system adopted consists of two parts, a specific animal number assigned to each mouse in the colony and a specific ear punch pattern generated to distinguish individual mouse inside of a cage of 5 animals. Specifically, one animal will not be ear-punched while 4 other animals will be punched in either the top or bottom part of the left or right ear. These ear punch patterns will be assigned with specific codes: 00 for no punches, 01 for top right ear, 03 for bottom right ear, 10 for top left ear, and 30 for bottom left ear. These ear punch codes will be recorded along with the individual animal number assigned to each mouse and the genotypes on the cage card. Ear punches will be performed by me or my future staff.

V.4.4.6. Behavioral Studies: N/A

V.4.4.7. Other Procedures: Irradiation for bone marrow reconstitution experiments: Recipient B6-LY5.2/Cr mice will be irradiated on the day of transfer of hematopoietic cells with 850 to 1050 rads of total body irradiation from a ^{137}Cs source located at room (b)(6) Hematopoietic cells resuspended in PBS in a volume of 200 ul will be introduced by tail vein injection. Following transfer of the hematopoietic cells, mice will be monitored for signs of distress daily such as ruffled fur, hunched back, and decreased activity. All irradiated mice will be monitored by the PI or research staff daily for 14 days. Any recipients found morbid will be euthanized immediately.

V.4.4.8. Tissue Sharing: Tissues may be shared with other investigators upon request.

V.4.5. Study Endpoint: The study endpoint for aged animals is up to 18 months of age or when euthanized earlier due to symptoms of leukemia such as bleeding, listlessness, and cachexia or other diseases. The criteria for early removal of aged animals will be if animals appear to be ill or in discomfort based on the evaluation by the veterinary or research staff and will be treated or euthanized as appropriate.

V.4.6. Euthanasia: Animals under this protocol will be euthanized by research personnel. In general, mice will be euthanized using cylinderized CO2. These animals will be placed in a cage or chamber that is not crowded and exposed to a mix of CO2

and oxygen. The CO2 flow rate will displace at least 20% of the chamber volume per minute. Flow will continue for at least one minute after visible sign of death. CO2 euthanasia will be followed by cervical dislocation to ensure death.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol.

V.5.1.1. Study Room:

Building(s) (b)(6) Room Number(s) (b)(6)

V.5.1.2. Special Husbandry Provisions:

Food Restriction:	Yes _____	No X
Fluid Restriction:	Yes	No X

V.5.1.3. Exceptions: None _____ _____

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care: Animals will be observed at least once daily by Center for LAM personnel. PI will observe the colony at least once a week unless the animals have been irradiated in which case they will be observed daily for 14 days post-irradiation. Animals or pups observed to be ill or showing signs of pain or distress such as hunched posture, ruffled fur, and decreased activity will be evaluated by veterinary staff to be treated or be euthanized. PI should be contacted for potential tissue collection needs if sick animals are to be euthanized by LAM personnel.

V.5.2.2. Emergency Veterinary Medical Care: All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: Except as indicated below, all animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents

V.5.3.2. Enrichment Restrictions: N/A

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
IP injections, tail vein injections, tail vein blood collection, and CO2 euthanasia punching	(b)(6)	14 years of experience	Animal Care and Use Introductory Training Course at Lawerence Berkeley Laboratory, 1989, at Northwestern University, 1992, at UCSF 2005, USUHS 2009) Experimental gen etics of laboratory mouse, course at Jackson laboratory, 1992.
Co2 euthanasia		5 years of experience	Animal Care and Use Introductory Training Course at USUHS April, 2009.

VII. BIOHAZARDS/SAFETY:

Personal protective equipment will be used such as gloves, lab coat and mask when handling mice and its tissues. Anesthetic agents and drugs will be handled wearing gloves with active scavenging system such as a hood or suction device to eliminate potential exposure when using inhalation anesthesia.

VIII. ENCLOSURES:

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

(b)(6)

Principal Investigator Signature Date

G. Training: The following personnel will attend the next USUHS Investigator/Animal User Training Course:

_____

H. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely, "Responsibility" for implementing animal use alternatives where feasible and conducting humane and lawful research.

(b)(6)

Principal Investigator Signature Date

I. Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL or WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

(b)(6)

X. PROTOCOL ABSTRACT:

A. Animal Protocol Number: (b)(6)

B. Animal Protocol Title: Characterization of ptpn-11 and Cbl Gain of Function Mutations using Transgenic mouse models

C. Principal Investigator: (b)(6) MD, PhD, Pediatrics

D. Performing Organization: Uniformed Services University of the Health Sciences

E. Funding: Department of Pediatrics

F. Objective and Approach: Juvenile Myelomonocytic Leukemia (JMML) is an aggressive disease of childhood with a very poor prognosis. Despite improvements in cure rates of childhood leukemia approaching 90%, most patients with JMML ultimately succumb to their disease. The discovery that JMML samples contained a mutated form of the *PTPN11* and Cbl gene has given us new insights into the biological differences between JMML and other leukemias. It has highlighted the importance of gain of function mutations which activate the ras pathway in the pathogenesis of JMML.

Our laboratory is interested in studying how mutations in genes involved in the ras pathway cause the development of JMML and investigating the cooperating events that make this leukemia different. Using known leukemia associated mutations identified from human JMML samples, we have generated mouse models of this disease using a bacterial artificial chromosome (BAC) containing the *PTPN11* locus. In addition, we have also incorporated the Cbl mutations to be expressed using the conditional *PTPN11* BAC as the vector to drive tissue specific expression.

We have been expressing the transgene in specific tissues by crossing the transgenic mice with different Cre expressing strains and are evaluating the mice by serial blood counts. We are planning to further investigate the cooperative events required for the development of JMML by utilizing genetic crosses to investigate the effect of two different oncogenic mutations. We hope to develop novel therapeutic strategies targeting the ras pathway using these mice as a therapeutic platform in the future.

The objective of this protocol is to characterize the role of mutant *ptpn-11* gene and Cbl during normal mammalian development, with a focus on hematopoietic development and leukemogenesis. Different genetically engineered mutant mouse strains for ptpn-11 and Cbl will be generated and characterized. Developmental defects in these mutant animals will be characterized comparing to wild-type littermates. In addition, mutant ptpn-11 mice and Cbl mice will be bred with other transgenic mice to further characterize the mutant phenotype and to study the function of ptpn-11 and Cbl. The three R's (reduction, replacement, and refinement) of animal usage will be employed.

G. Indexing Terms (Descriptors): Transgenic mice, ptpn-11, shp-2, Cbl, JMML

MEMORANDUM FOR DR (b)(6) DEPARTMENT OF PEDIATRICS

SUBJECT: IACUC Approval of Protocol - Triennial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on April 29, 2016:

Animal Protocol Title: "Role of Setbp1 in Leukemic Stem Cell Self-Renewal in Mice"

USUHS Protocol Number: (b)(6)

Expiration Date: April 28, 2019

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a post approval meeting with LAM (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. NON-TECHNICAL SYNOPSIS: This study is designed to use mice as a model to investigate the role of a gene called Setbp1 in the development of leukemia, a deadly disease affecting many people, and also to identify better therapeutic strategies for Setbp1-induced leukemia. Mice carrying bone marrow cells that contain extra copies of the Setbp1 gene or Setbp1 mutations identified in leukemia patients will be generated in some studies by bone marrow transplantation and examined to understand the mechanisms for leukemia development. Bone marrow donor mice will be treated with a drug called 5-fluorouracil to facilitate the introduction of normal or mutant Setbp1 gene copies into their bone marrow cells. 5-fluorouracil treatment at our proposed dosage will not cause adverse symptoms in mice. Bone marrow recipient mice will be irradiated before transplantation to enhance the establishment of the transplanted cells in their bone marrow. Irradiation at our proposed dosage is lethal to mice if not treated afterwards. However, these recipient mice in our study will be fully rescued by the subsequent transplantation of donor bone marrow cells. Some recipient mice that developed leukemia will also be treated with a drug called (b)(4) to test its potential therapeutic effects against Setbp1-induced leukemia. (b)(4) treatment at our proposed dosage will not cause adverse symptoms in mice. The accomplishment of this study will help develop more effective therapies for leukemia patients in the future.

II. BACKGROUND:

II.1. Background: Targeting the unlimited self-renewal capability of leukemia-initiating cells (LICs) represents a new promising strategy for leukemia therapy [1,2]. However, only a small number of genes/mutations have been identified to confer this feature to LICs, which has significantly hampered our understanding of the underlying mechanism(s) for LIC self-renewal and our ability to design effective inhibitory strategies. We have previously found that overexpression of *Set binding protein 1*

(*Setbp1*), which encodes an AT-hook transcription factor, could confer unlimited self-renewal capability to normal mouse bone marrow progenitor cells and cause their immortalization in culture, suggesting that it could be a LIC self-renewal regulator [3]. The relevance of *SETBP1* overexpression to human leukemia development is also indicated by a previous study showing its overexpression in a significant fraction (up to 27%) of human acute myeloid leukemia cells [4]. More recently, in our collaboration with Dr. (b)(4) highly recurrent point mutations of *SETBP1* were identified in 15% of chronic myelomonocytic leukemia and 17% secondary acute myeloid leukemia patients in a sequencing screen of over 700 myelodysplastic syndrome (MDS) and myeloid leukemia patients [5]. These point mutations are missense mutations concentrated in a stretch of 15 amino acids of SETBP1 protein with D868N and I871T being two of the most prevalent changes. Given the high prevalence of these mutations in human patients, it is essential to understand the mechanisms through which they may contribute to leukemogenesis. Under previously approved protocol (b)(6) we have discovered that both *Setbp1* and *Setbp1* mutations are potent oncogenes capable of inducing myeloid leukemia development in mice. However, the molecular mechanisms responsible for their oncogenicity remain unclear. In the proposed studies, we will examine the potential complex formation and cooperation of Setbp1 and Setbp1 mutations with proteins including (b)(4) (b)(4) in inducing leukemia development.

II.2. Literature Search for Duplication:

II.2.1. Literature Source(s) Searched: DTIC, NIH RePORTER and PubMed

II.2.2. Date of Search: April 4, 2016

II.2.3. Period of Search:
DTIC: 1985 – 2016
NIH RePORTER: 1988 – 2016
PubMed: 1950 – 4/4/2016

II.2.4. Key Words and Search Strategy: This study is mainly designed to use the mouse bone marrow transduction and transplantation model to characterize the function of Setbp1 in leukemia development. Therefore, "Setbp1" together with "leukemia" and "mice" were used as the search term.

II.2.5. Results of Search: Four projects were returned on DTIC. Two of them are my animal study protocols from 2008, and the other two are projects focused on prostate cancer. Three projects were returned on NIH RePORTER. One of them is my project funded by NCI. Two other projects returned are focused on cooperation of SETBP1 mutations with CSF3R mutations in chronic neutrophilic leukemia and atypical chronic myeloid leukemia. There is no overlap of these studies with my current study, which investigates cooperation between Setbp1 and (b)(4) in development of acute

myeloid leukemia. Six articles were returned on PubMed as listed below. Article #1, #5, and #6 were published from my laboratory. Article #2 studied the engraftment of human leukemia cells with a SETBP1 mutation in immune-deficient mice. Article #3 is a review article on chronic neutrophilic leukemia. Article #4 studied potential cooperation between SETBP1 and AXSL mutations, which is different from the focus of this proposal. Thus, all six articles have no overlap with my proposed studies.

III. **OBJECTIVE\HYPOTHESIS**: The objectives of this study are to gain novel insights into the cellular and molecular mechanisms by which Setbp1 overexpression and missense mutations induce leukemia development, and also to test new therapeutic

strategies for *SETBP1*-induced leukemias based on these insights through the use of mouse models.

IV. MILITARY RELEVANCE: Leukemia represents a significant challenge for DoD medical care. Leukemia occurrence in the general population of U.S. is about 12 every 100,000 people according to statistical studies by National Cancer Institute. About half of these patients will die due to limited treatment options for this devastating disease. There are estimated over 5 million military personnel and their family members under DoD based on a 2004 study reported by Military Family Research Institute at Purdue University. Therefore, more than 600 new leukemia cases and over 300 deaths due to leukemia are estimated to occur every year in the DoD health care system. These numbers could be even higher as the occurrence of leukemia could potentially further increase among military personnel due to their possible exposure to toxic substances or radiation on the battlefield. Finding better treatments for leukemia patients represents an important need for the DoD health care system. Our proposed study will help gain insights into the mechanisms underlying leukemia initiation and progression, and mechanistic understanding of leukemia development should help find preventive measures and better treatments for this devastating disease.

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures:

V.1.1. Experiment 1: To determine the therapeutic effects of (b)(4) (b)(4) on *Setbp1*-induced myeloid leukemias.

Based on our finding of (b)(4) we have found that treatment with (b)(4) caused apoptosis and differentiation of Setbp1-immortalized myeloid progenitors in culture, suggesting that (b)(4) inhibitors could be used for treatment of human myeloid leukemias with SETBP1 overexpression or SETBP1 activation mutations. To further test this hypothesis, we would like to test the (b)(4) (b)(4) purity= 99.79%), an orally bioavailable (b)(4) in treating murine myeloid leukemias induced by overexpression of wild-type Setbp1 (Setbp1-WT) or Setbp1 activation mutation D868N (Setbp1-DN) *in vivo*. The use of (b)(4) is in accordance with IACUC policy 27 of guidelines for the use of non-pharmaceutical grade compounds in laboratory animals as there is no equivalent veterinary or human drug to (b)(4) that is available for experimental use.

Specifically, bone marrow or spleen cells (viably frozen) from previous Setbp1-induced leukemic mice (generated previously in B6-LY5.2/Cr mice by bone marrow transplantation under (b)(5) will be transplanted into irradiated 7-12 weeks old B6-LY5.2/Cr mice. These B6-LY5.2/Cr recipients will be irradiated on the day of transplantation with1,100 rads of total body irradiation from a ^{137}Cs source located at room (b)(6) The leukemia cells (1×10^6 cells/mouse) along with 5×10^5 supporting bone marrow cells from un-irradiated B6-LY5.2/Cr mice resuspended in PBS in a volume of 200 ul will be introduced into each recipient by tail vein injection.

Following transfer of the hematopoietic cells mice will be monitored for signs of distress daily. Any recipients found morbid will be euthanized immediately. The dose of irradiation used is expected to be lethal within 10 days in the absence of bone marrow reconstitution by transplanted cells. Successful recolonization of the recipient bone marrow in transplanted animals results in restoration of constitutive hematopoiesis over the normal life span of the recipient. Past experience has shown that lethally irradiated mice can suffer from infection. To prevent infection, all recipient mice will receive amoxicillin at a concentration of 1 mg/ml in the drinking water from 5 days prior to irradiation to 10 days post irradiation. Although occurring rarely, engraftment failure of the transplanted cells will also lead to recipient death between 7 and 10 days after injection. Therefore, to prevent any potential suffering during this critical period of time, recipient mice will be monitored twice daily by PI staff between 7 and 10 days after transplantation for signs of distress including rough coat, listlessness, or hunched posture. Any transplant recipients showing such signs will be euthanized immediately.

At one week after transplantation, the recipient mice will be divided into 2 groups, one receiving (b)(4) at 20 mg/kg of body weight (in 200ul 50%PEG400/50%ddH2O) through oral gavage once every 2 days for 22 days (total 10 doses) and the other 200ul vehicle only. (b)(4) is a new investigational compound and no chemical purity standards have been established; however, (b)(4) treatment at the proposed dosage has been shown to be safe for mice [6]. Treated mice will be monitored for signs of leukemia development including rough coat, listlessness, and hunched posture. Any recipients displaying any combination of two or more signs of distress above will be euthanized immediately. It is expected that mice receiving vehicle only will develop leukemia within 2-3 weeks after transplantation. Absence or delayed leukemia development in mice treated with (b)(4) will strongly suggest that (b)(4) can be effective in treating human myeloid leukemia patients with SETBP1 overexpression or activation mutations.

The study end point is 3 months after transplantation when all survived animals will be euthanized. A total of 6 leukemias (3 induced by Setbp1-WT and 3 induced by Setbp1-DN) will be transplanted in order to draw any significant conclusions. For each leukemia, 10 recipient mice will be transplanted (5 for (b)(4) treatment, 5 for vehicle). Therefore, **this experiment requires a total of 60 B6-LY5.2/Cr recipients (6 leukemias x 10 recipients/leukemia). 6 additional B6-LY5.2/Cr mice will be used as donors for supporting bone marrow as each transplantation experiment requires one such donor.**

Required animal numbers for Experiment 1:

Strains	Experimental groups		Supporting B.M.	Total
	(b)(4)	vehicle		
B6-LY5.2/Cr	30 (Category E)	30 (Category E)	6 (Category C)	66

V.1.2. Experiment 2: To determine the cooperation between Setbp1 and (b)(4) (b)(4) gene in leukemia development using mouse bone marrow transduction and transplantation.

We have identified [(b)(4)] as a potential cooperating partner for Setbp1 activation in acute myeloid leukemia development due to its complex formation with [(b)(4)] and Setbp1 and its overexpression in Setbp1-induced leukemia cells. To directly test this idea, we will co-transduce 5-fluorouracil (5-FU) treated mouse bone marrow progenitors with retroviral vectors expressing [(b)(4)] and Setbp1-WT/Setbp1-DN and assess their leukemogenic potential in comparison with singly transduced cells in transplantation recipient mice.

5-FU treated bone marrow progenitors from C57BL/6 mice (8 to 12 weeks old females purchased from [(b)(4)] will be transduced with retrovirus expressing Setbp1-WT/Setbp1-DN alone, [(b)(4)] alone, or the combination, and transplanted into irradiated B6-LY5.2/Cr recipients. The 5-FU treatment helps deplete the number of more mature progenitor cells in the bone marrow and induce the cycling of hematopoietic stem cells which are targets of retroviral transduction in the next step. Mice will be treated once with 0.2ml of 5-FU (pharmaceutical grade) in phosphate buffered saline (PBS) via intra-peritoneal injection to achieve a dose of 150 mg/kg body weight 4 days before bone marrow harvesting. The treated mice will be euthanized by CO2 asphyxiation and bone marrow cells will be harvested from their femurs under sterile conditions. The dose of 5-FU used in these experiment is not expected to cause any animal morbidity or illness.

Bone marrow cells extracted from 5-FU treated mice will be infected with replication incompetent retroviral vectors carrying Setbp1-WT/Setbp1-DN and/or [(b)(4)] (retroviral vector usage has been approved by IBC under project # [(b)(6)] These viruses will be collected from culture medium of cell lines designed to package viral particles in ecotropic envelops. After initial infection these viruses are no longer infectious and are replication deficient. Prior to, during, and post infection, these bone marrow progenitors may be cultured in the presence of recombinant murine growth factors including interleukin-3 (IL-3), interleukin-6 (IL-6), and stem cell factor (SCF) to stimulate their proliferation (In-vitro procedures only). The infected bone marrow progenitor cells (1 x 10^6 cells/mouse) along with 5 x 10^5 supporting bone marrow cells from un-irradiated B6-LY5.2/NCr mice resuspended in PBS in a volume of 200 ul will be introduced into each recipient by tail vein injection. Following transfer of the hematopoietic cells mice will be monitored for possible bone marrow engraftment failure and leukemia development and euthanized if necessary as described in Experiment 1. Any recipients found in distress will be euthanized immediately. At 1, 2, and 4 month after transplantation, 200ul of blood may be collected from each transplant recipient by retro-orbital bleeding to monitor the engraftment of the transduced cells by flow cytometry.

In order to draw any significant conclusions, fifteen recipient mice will be used in each group. Therefore, we will **transplant a total of 45 B6-LY5.2/Cr recipient mice for testing cooperation between Setbp1-WT and** [(b)(4)] (45 recipients for 3 groups of transduced cells). In addition, **5 un-irradiated B6-LY5.2/Cr mice will be required to provide supporting bone marrow cells** as we plan to accomplish above transplantation studies in 5 experiments, each experiment requires one supporting bone marrow donor.

Each transplant recipient will be transplanted with 1 x 10^6 transduced cells, which requires 2 C57BL/6 mice to provide sufficient donor cells. Therefore, for a total of 45 primary transplant recipients as discussed above, **a total of 90 C57BL/6 mice (45 recipients x 2) is required to provide sufficient donor cells for testing cooperation between Setbp1-WT and** (b)(4)

Same transplantation studies will be carried out separately for testing cooperation between Setbp1-DN and (b)(4) **and similarly a total of 50 B6-LY5.2/Cr recipient mice and 90 C57BL/6 mice will be required.**

Required animal numbers for Experiment 2:

For testing Setbp1-WT (b)(4) cooperation:

Strains	Experimental groups			Supporting B.M.	Total
	Setbp1-WT (b)(4)	Setbp1-WT	(b)(4)		
B6-LY5.2/Cr	15 (Category E)	15 (Category E)	15 (Category E)	5 (Category C)	50
C57BL/6 (donors)	90 for 3 groups (Category C)				90

For testing Setbp1-DN (b)(4) cooperation:

Strains	Experimental groups			Supporting B.M.	Total
	Setbp1-DN (b)(4)	Setbp1-DN	(b)(4)		
B6-LY5.2/Cr	15 (Category E)	15 (Category E)	15 (Category E)	5 (Category C)	50
C57BL/6 (donors)	90 for 3 groups (Category C)				90

V.1.3. Experiment 3: To examine the requirement for (b)(4) gene in Setbp1-induced leukemia development.

We also found (b)(4) (b)(4) suggesting that they may cooperate to induce leukemia development. In order to test this hypothesis, we would like to analyze the effects of (b)(4) on the maintenance of leukemia induced by either Setbp1-WT or Setbp1-DN. To achieve this goal, we will obtain (b)(4) mice (b)(4) and breed these mice with Cre-ER mice in which Cre expression can be induced by Tamoxifen treatment. Bone marrow progenitors from the offspring (b)(4) will be used to generate Setbp1 and Setbp1(DN)-induced leukemia cells in which (b)(4) can be deleted by Tamoxifen treatment after transplantation into secondary recipients.

A. Generation of myeloid leukemias using bone marrow progenitors from (b)(4) mice.

Age- and sex-matched littermates at 2 to 3 months of age consisting of 2 genotypes, (cko/cko,tg/+) and (cko/cko,+/+), will be treated with 5-FU as described in Experiment 2.

Bone marrow cells extracted from 5-FU treated mice will be infected with replication incompetent retroviral vectors carrying Setbp1-WT or Setbp1-DN. Since bone marrow progenitors from (b)(4) mice are positive for Ly5.2, transduced cells will be subsequently transplanted into C57BL/6 recipient mice. C57BL/6 recipient mice will be irradiated and treated with Amoxicillin as described for B6-LY5.2/Cr mice in Experiment 2. For both Setbp1-WT and Setbp1-DN, three independent (cko/cko,tg/+) leukemias and three control (cko/cko,+/+) leukemias will need to be generated for studies in B. Due to the scarcity of bone marrow progenitor cells, 2 animals of same genotype are needed for generating one leukemia. **So the minimum animal number required for (b)(4) (b)(4) mice is: 2 donor animals/leukemia x 12 leukemias = 24. In addition, 4 un-irradiated C57BL/6 mice will be required to provide supporting bone marrow cells** as we plan to accomplish above transplantation studies in 4 experiments, each experiment requires one supporting bone marrow donor.

B. Secondary transplantations will be carried out to examine the requirement for (b)(4) for the maintenance of leukemia cells. Six independently generated (cko/cko,tg/+) leukemias will be transplanted into newly irradiated C57BL/6 mice at a dosage of 1 $x10^6$cells/mouse together with 5 $x10^5$ supporting bone marrow cells from non-irradiated C57BL/6 mice. Each leukemia will be transplanted into 10 recipient mice, which will be divided into 2 groups. Starting at 7 days after transplantation, one group will be treated with Tamoxifen at 200mg/kg body weight in 200ul of corn oil while the other with corn oil only by 3 intra-peritoneal injections at 2-day intervals. Treated mice will be monitored for the development of leukemia as described in Experiment 1 for 3 months. Six (cko/cko,+/+) leukemias will also be transplanted and treated similarly to control for effects of Tamoxifen treatment. It is expected that mice receiving (cko/cko,tg/+) leukemia cells and vehicle as well as mice transplanted with (cko/cko,+/+) leukemia cells will develop leukemia within 2-3 weeks after transplantation. Absence or delayed leukemia development in mice receiving (cko/cko,tg/+) leukemia cells and Tamoxifen will strongly suggest that (b)(4) is critical for maintenance of leukemia. Therefore, **this experiment requires a total of 120 C57BL/6 recipients (12 leukemias x 10 recipients/leukemia). 12 additional C57BL/6 mice will be used as donors for supporting bone marrow as each transplantation experiment requires one such donor.**

Required animal numbers for Experiment 3A:

Strains	Experimental groups		Supporting B.M.	Total
	Setbp1-WT	Setbp1-DN		
(b)(4)	12 (Category C)	12 (Category C)		24
C57BL/6	6 (Category E)	6 (Category E)	4 (Category C)	16

Required animal numbers for Experiment 3B:

Strains	Experimental groups		Supporting B.M.	Total
	Tamoxifen	vehicle		

C57BL/6	60 (Category E)	60 (Category E)	12 (Category C)	132

V.1.4. Experiment 4: Conditional knock-in mice will be used to compare the cellular and molecular effects induced by Setbp1-WT and Setbp1-DN.

Our previous studies using mouse bone marrow transduction and transplantation system showed that Setbp1-DN induced leukemia development with much shorter latencies than Setbp1-WT, however the responsible mechanisms are difficult to study in this system due to small number of cells that engraft in the recipient mice. To circumvent this problem, (b)(4) (b)(4) (b)(4) the presence of Cre recombinase. After breeding with Mx1-cre mice in which Cre expression can be induced by poly(I:C) injections, (b)(4) (b)(4) (b)(4) will be used to study leukemia promoting effects induced by Setbp1-WT and -DN after poly(I:C) injections.

A. We will compare early cellular and molecular effects of Setbp1-WT and Setbp1-DN activation. Specifically, age- and sex-matched littermates consisting of 2 genotypes, (ki/+,tg/+) and (ki/+,+/+), will receive 3 intra-peritoneal injections of poly(I:C) at 2-day intervals at 2 to 3 months of age to induce the expression of Setbp1-WT or Setbp1-DN. The injections will be carried out using 28 Gauge x ½ inch needles and 200ul of poly(I:C) at a concentration of 2 ug/ul diluted in sterile phosphate buffered saline will be injected each time. Injection of poly I:C at this dosage is safe for mice. The injected animals will be euthanized at approximately 1 month after the final injection and tissues including hematopoietic tissues such as bone marrow, thymus, and spleen will be used for 2 types of experiments including the preparation of RNA, DNA, and protein for gene expression analysis and fluorescence activated cell sorting (FACS) for analysis of cell number, cell cycle and apoptosis status of hematopoietic stem and progenitor populations. Each type of experiment will need to be successfully repeated 5 times to reach any conclusions. So the minimum animal number for both (b)(4) and (b)(4) mice is: 2 experiment types x 2 genotypes x 5 animals/genotype x 2 strains = 40.

B. Another 30 animals of each strain consisting of 2 genotypes, (ki/+,tg/+) and (ki/+,+/+) will be aged for one year after poly(I:C) injections to test whether leukemias can be eventually induced by activation of Setbp1-WT or Setbp1-DN in these animals. Injected mice will be monitored for signs of leukemia development including rough coat, listlessness, and hunched posture. Any recipients displaying any combination of two or more signs of distress above will be euthanized immediately and fresh tissues including bone marrow, spleen, thymus, liver, and kidney will be collected and examined by flow cytometry, tissue culturing and pathology. Any remaining mice 1 year after poly(I:C) injections will be euthanized

Required animal numbers for Experiment 4A:

Strains	Experimental groups	Total

	ki/+,tg/+	ki/+,+/+	
(b)(4)	10 (Category C)	10 (Category C)	20
(b)(4)	10 (Category C)	10 (Category C)	20

Required animal numbers for Experiment 4B:

Strains	Experimental groups		Total
	ki/+,tg/+	ki/+,+/+	
(b)(4)	15 (Category C)	15 (Category C)	30
(b)(4)	15 (Category C)	15 (Category C)	30

V.2. Data Analysis: For all molecular experiments, engraftment/contribution of cell populations, cell cycle and apoptosis status, and colony/cell counts will be compared across groups using analysis of variance (ANOVA), student's t test, or nonparametric tests as appropriate. A sample size of 5 in each group will have 80% power to detect a difference of 2 standard deviations between groups using a 2-group t test with a 5%, two-sided significance level.
For aging studies, log-rank tests will be used to compare time to development of leukemia across groups. When the sample size in each group is 15, a 5% two-sided log-rank test for equality of survival curves will have 80% power to detect a difference in proportion surviving of at least 54 percentage points (e.g. 99% vs. 45% surviving)

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered: Tissue culture study was considered, however it does not allow identifying and characterizing the effects of mutations within the context of the whole animal. *in vivo* study is extremely important in leukemia research as the evolvement of leukemic cells is not an isolated event and involves constant interaction with the host environment which has yet to be replicated in tissue culture settings. In addition, hematopoietic cell lines used in tissue culture studies are different from normal hematopoietic cells in that they have acquired mutations that allow them to replicate indefinitely in culture, and results from these studies may not apply to normal cells. Computer modeling was considered as well, but the mechanisms underlying leukemia development is still largely unknown and there is no system available in the leukemia field that can be used to predict target genes involved in the transformation of hematopoietic cells.

V.3.2. Animal Model and Species Justification: I have chosen to use mice for my studies because they are a genetically well-characterized mammalian organism that has been shown to have a very similar hematopoietic system to that of humans, and more and more studies have been carried out in mice to understand human leukemia development and normal hematopoiesis [7-9]. In addition, there are many tools available in mice but not in other mammalian models to genetically alter the germline and study

the consequences of the mutation in normal cells. I also happen to have extensive experiences (for the past 13 years) working with mouse hematopoietic system. Lower organisms such as Zebrafish and Drosophila were also considered, however both species are very different from mammals and do not represent good models for studying human hematopoiesis.

V.3.3. Laboratory Animals

ALTERNATIVES CONSIDERATIONS: Does the protocol have any provisions that would qualify it to be identified as one that Refines, Reduces, or Replaces (3R's) the use of animals in relation to other protocols or procedures performed in the past?

V.3.4. **Number of Animals Required (by Species/Strain)**:	50 mice	

V.3.5. **Refinement, Reduction, Replacement (3 Rs)**:

V.3.5.1. Refinement: All animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels. Animals observed to be ill or showing signs of pain or distress including weight loss, hunched posture, ruffled fur, and decreased activity will be evaluated by veterinary staff to be treated or be euthanized immediately for relief of suffering. Anesthesia will be used for retro-orbital bleeding.

V.3.5.2. Reduction: In order to reduce the animal numbers in this study, experiments have been designed to include tissue sharing among different experimental procedures including DNA, RNA, and protein extractions, and also animal sharing for purification of different hematopoietic progenitor populations. The estimated number of animals for proposed studies have been computed by power analysis to ensure that the smallest numbers of animals required to evaluate the hypotheses are being used.

V.3.5.3. Replacement: Tissue culture and computer models were considered but not adopted. Detailed explanations are provided in V.3.1.

V.4.3.6.1. Procedures: N/A

V.4.3.6.2. Scientific Justification: N/A

V.4.4. Animal Manipulations:

V.4.4.1. Injections: 28 Gauge x ½ inch needles will be used for all injections.

Some mice as specified the experimental design and general procedures section will receive one time intra-peritoneal injection of 5-FU (15 mg/ml) resuspended in phosphate buffered saline (PBS) at a dosage of 150 mg/kg body weight in 200ul volume as described in Experiment section. 5-FU treatment of mice at this dosage is toxic to proliferating cells in the hematopoietic system representing more mature progenitors, but is not expected to cause animal suffering and death.

Some mice will receive 3 intra-peritoneal injections of Tamoxifen at 200mg/kg body weight at 2-day intervals dissolved in corn oil or corn oil only at 200ul volume per animal each time. Injection of Tamoxifen at this dosage is safe for mice.

Some mice will receive 3 intra-peritoneal injections of poly(I:C) at 2-day intervals at 2 to 3 months of age to induce the expression of Setbp1-WT or Setbp1-DN. 200ul of poly(I:C) at a concentration of 2 ug/ul diluted in sterile phosphate buffered saline will be injected each time. Injection of poly I:C at this dosage is safe for mice.

Transplantation of bone marrow or spleen cells will be carried out by one time tail vein injections of cells resuspended in 200ul of PBS. Since transplanted cells are from mice congenic to the recipients, no immune rejection is expected after transplantation. Injection of hematopoietic cells through the tail vein is not known to cause any toxic effects to mice. All cells for injection will be obtained from mice housed in USU colony. Injection of all biological materials will be in accord with USU IACUC Policy #23 on the use of biological materials in experimental animals.

V.4.4.2. Biosamples: Retro-orbital bleeding is chosen for the protocol based on the blood sample size required for our study and available in-house expertise. Given the relatively large sample size (200 ul of blood from each animal each time) that is needed for our study to perform FACS analysis, 2 other blood collection procedures including from the saphenous vein and jugular vein were considered as suitable alternatives. Saphenous bleeding is the only procedure that is less painful than retro-orbital bleeding and does not require anesthesia. However, this procedure requires extensive experience and has not been performed on mice by staff in my laboratory. In contrast, retro-orbital bleeding has been routinely carried out by staff in my laboratory under previously approved protocols and will be done under isoflurane anesthesia.
In this protocol, 200ul blood will be obtained each time by retro-orbital bleeding at 1 and 4 month after transplantation for certain animals as described in Experiment 1A. Using the same procedure, same volume of bleeds will also be obtained 3 times after transplantation as described in Experiment 2. IACUC policy on retro-orbital bleeding (POLICY 001) will be strictly followed when performing this procedure. Mice will be anesthetized with Isoflurane. When the animal is no longer moving voluntarily it is placed on a paper towel. The forefinger of the operator's non-dominant hand is used to pull the facial skin taut and cause the eyes to protrude slightly while the skin at the back

of the neck is grasped by the thumb and remaining fingers to restrain. Breathing and color are monitored throughout the procedure to ensure that the restraint does not compromise the airway. The tip of a capillary tube is gently inserted below the eye at approximately a 45 degree angle into the space between the globe and the lower eyelid. When the tip of the pipette contacts the boney floor of the orbit it is gently twisted between thumb and forefinger to rupture the capillary plexus/sinus. Blood is allowed to flow by capillary action into the pipette. Care is taken not to take any more blood than is needed. At the conclusion of the blood withdrawal tension on the animal is released and a gauze pad is gently pressed over the eye for a few seconds until the bleeding has stopped. A drop of tetracaine is added in the eye to reduce any post-procedural discomfort that may occur. Normal color and respiration are reconfirmed and the animal is returned to its cage for recovery. Alternate eyes are used for successive bleeds. A maximum of two bleeds per eye will be done. In addition, hematopoietic tissues including bone marrow, spleen, thymus, lymph nodes and control tissue brain, lung, and kidney will be extracted after euthanasia.

V.4.4.3. Adjuvants: N/A

V.4.4.4. Monoclonal Antibody (MAbs) Production: N/A

V.4.4.5. Animal Identification: Cage cards will be used to distinguish different study groups.

V.4.4.6. Behavioral Studies: N/A

V.4.4.7. Other Procedures:

Oral gavage through 20 Gauge x1.5 inch gavage needles will be used to administer mice with (b)(4) at 20 mg/kg of body weight (in 200ul 50%PEG400/50%ddH2O) once every 2 days for 22 days (total 10 doses). This dosage of (b)(4) when used in mice was shown to be safe and not to cause any significant side effects [6].

Recipient B6-LY5.2/Cr or C57BL/6 mice will be irradiated on the day of transplantation with1100 rads of total body irradiation from a ^{137}Cs source located at room (b)(6) Mice will be transported and irradiated at room temperature in irradiator disks (purchased from Braintree Scientific) that maintain a filter protected sterile environment and hold up to 20 mice at each time. The entire process will last no more than 30 minutes and during which time no food or water will be provided for the animals. Hematopoietic cells resuspended in PBS in a volume of 200 ul will be introduced by tail vein injection. The dose of irradiation used is expected to be lethal within 10 days in the absence of bone marrow reconstitution by transplanted cells. Successful recolonization of the recipient bone marrow in transplanted animals results in restoration of constitutive hematopoiesis over the normal life span of the recipient. Past experience has shown that lethally irradiated mice can suffer from infection. To prevent infection, all recipient mice will receive amoxicillin at a concentration of 1 mg/ml in the drinking water from 5 days prior to irradiation to 10 days post irradiation, and sterile feed and autoclaved caging will be provided. Although occurring rarely, engraftment failure of the transplanted cells will also lead to recipient death between 7 and 10 days after injection.

Therefore, to prevent any potential suffering during this critical period of time, recipient mice will be monitored twice daily by PI staff between 7 and 10 days after transplantation for signs of distress including rough coat, listlessness, or hunched posture. Any transplant recipients showing such signs will be euthanized immediately. Leukemia development and progression is a slow process; therefore, for the time periods before day 7 and after day 10 post transplantation, transplant recipient mice will be monitored once daily by PI staff during week days and by LAM personnel during weekends and holidays for signs of leukemia development, which are similar to the above-described signs of engraftment failure. Any recipients displaying any combination of two or more signs of distress above will be euthanized immediately by PI staff.

V.4.4.8. Tissue Sharing: Tissues may be shared with other investigators upon request.

V.4.5. Study Endpoint: The study endpoint for transplant donor mice is between 6 to 12 weeks of age. The study endpoint for transplant recipient mice is between 4 to 15 months of age as specified in the experimental design and general procedures section. Animals could be euthanized earlier due to engraftment failure of transplanted hematopoietic cells after irradiation or leukemia development. Although occurring rarely, engraftment failure of the transplanted cells will lead to recipient death between 7 and 10 days after injection. Therefore, to prevent any potential suffering during this critical period of time, recipient mice will be monitored twice daily by PI staff between 7 and 10 days after transplantation for signs of distress including rough coat, listlessness, or hunched posture. Any transplant recipients showing any combination of two or more signs of distress above will be euthanized immediately. Leukemia development and progression is a slow process; therefore, for the time periods after day 10 post transplantation, transplant recipient mice will be monitored once daily by PI staff during week days and by LAM personnel during weekends and holidays for signs of leukemia development, which are similar to the above-described signs of engraftment failure. Any recipients displaying any combination of two or more signs of distress above will be euthanized immediately by PI staff.

V.4.6. Euthanasia: Animals under this protocol will be euthanized by research personnel. Mice will be euthanized using cylinderized CO2. These animals will be placed in a cage or chamber that is not crowded and exposed to a mix of CO2 and oxygen. The CO2 flow rate will displace at least 20% of the chamber volume per minute. Flow will continue for at least one minute after visible sign of death. CO2 euthanasia will be followed by cervical dislocation to ensure death. This is consistent with the 2013 AVMA Guidelines for the Euthanasia of Animals.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol.

V.5.1.1. **Study Room**:

Building(s) _____ Room Number(s) (b)(6)

V.5.1.2. **Special Husbandry Provisions**:

Food Restriction: Yes _____ No x

Fluid Restriction: Yes _____ No x

V.5.1.3. **Exceptions**: N/A

V.5.2. **Veterinary Medical Care**:

V.5.2.1. **Routine Veterinary Medical Care**: LAM animal care technicians will observe all animals at least once daily during rounds. The clinical veterinarian will check the rounds sheets daily and evaluate overall animal health IAW LAM. Bone marrow transplant recipient mice will be monitored twice daily by PI staff between 7 and 10 days after transplantation. For the time periods before day 7 and after day 10 post transplantation, transplant recipient mice will be monitored once daily by PI staff during week days.

V.5.2.2. **Emergency Veterinary Medical Care**: All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays.

V.5.3. **Environmental Enrichment**:

V.5.3.1. **Enrichment Strategy**: Except as indicated below, all animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents.

V.5.3.2. **Enrichment Restrictions**: N/A

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Experience of person performing activity (species specific) (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)	Dates of the USU Investigator Training course and required IACUC CITI Training
CO2 euthanasia, intra-peritoneal injection	(b)(6)	PI, 15 years of experience on mouse CO2 euthanasia and intra-peritoneal injection	Rodent Handling Training at NCI, 2001	Investigator training course at USUHS (2007) CITI training (7/22/2014)

Tail vein injection, CO2 euthanasia	(b)(6)	Technician, 8 years of experience on mouse tail vein injection and CO2 euthanasia	Rodent Handling Training by PI, 2007	Investigator training course at USUHS (2007) CITI training (9/30/2014)
CO2 Euthanasia, intra-peritoneal injection		Technician, 8 years of experience on mouse CO2 euthanasia and intra-peritoneal injection	Rodent Handling course at USUHS, 2007	Investigator training course at USUHS (2007) CITI training (6/27/2014)
Oral gavage, Retro-orbital bleeding, CO2 euthanasia		1 year of experience on mouse oral gavage, 5 years experience on retro-orbital bleeding and CO2 euthanasia	Rodent Handling course at USUHS, 2011	Investigator training course at USUHS (2011) CITI training (7/1/2015)
Retro-orbital bleeding, CO2 euthanasia		5 years of experience on mouse retro-orbital bleeding and CO2 euthanasia	Rodent Handling course at USUHS, 2011	Investigator training course at USUHS (2011) CITI training (7/15/2014)
Retro-orbital bleeding, CO2 euthanasia		5 years of experience on mouse retro-orbital bleeding and CO2 euthanasia	Rodent Handling course at USUHS, 2010	Investigator training course at USUHS (2010) CITI training (7/20/2015)
Retro-orbital bleeding, CO2 euthanasia		3 years of experience mouse retro-orbital bleeding and CO2 euthanasia	Rodent Handling course at USUHS, 2012	Investigator training course at USUHS (2012) CITI training (7/2/2014)

VII. BIOHAZARDS/SAFETY:

A. Zoonotic Disease: N/A

B. Safety Hazards: Replication defective ecotropic retroviral vectors will be used to infect mouse bone marrow cells before transplantation of the infected cells into recipient mice. These viruses will be collected from culture medium of cell lines designed to package viral particles in ecotropic envelops. After initial infection these vectors are no longer infectious and are replication deficient. There is no evidence in the literature that humans can be infected by ecotropic retroviruses. Any person handling these retroviral vectors will be required to wear lab coat and gloves as precaution. 5-FU, Tamoxifen, and (b)(4) are inhibitors of Thymidine Synthase, Estrogen Receptor, and (b)(4) respectively. They do not evaporate at room temperature, but are potentially harmful if ingested. Lab coat gloves, and mask are required when preparing the solutions and carrying out animal injection and oral gavage using these substances. Lab coat, gloves, and mask are also required at any time when handling animals to minimize exposure to allergens from animals. For animal irradiation, mice will be transported and irradiated in irradiator disks (purchased from Braintree Scientific) that maintain a filter protected sterile environment. Personnel performing irradiation will be required to wear lab coat and gloves and carry a thermoluminescent dosimeter issued by Radiation Safety Office for monitoring potential radiation exposure during the procedure.

C. Isoflurane: Isoflurane will be used for retro-orbital bleeding.

D. Isoflurane Exposure: To reduce isoflurane exposure, an isoflurane vaporizer with pass-through charcoal canister filter in the exhaust gas line will be used to anesthetize mice for retro-orbital bleeding.

E. Sharp Instruments: Needles will not be re-capped and will be disposed in sharp containers after usage.

F. Infectious Agents that do not cause Zoonoses: N/A

IX. EXTRAMUAL COLLABORATION: N/A

If there are any collaborations with outside entities, please explain here.

X. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

(b)(6) _____ 4/6/2016

Principal Investigator Signature — Date

G. Training: The following personnel will attend the next USUHS Investigator/Animal User Training Course:

_____ _____

_____ _____

H. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely,

"Responsibility" for implementing animal use alternatives where feasible and conducting humane and lawful research.

(b)(6) [redacted]

I. Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL** or **WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

XI. PROTOCOL ABSTRACT:

A. **Animal Protocol Number:**

B. **Animal Protocol Title:** Role of Setbp1 in leukemia-initiating cell self-renewal in mice

C. **Principal Investigator:** (b)(6) Department of Pediatrics

D. **Performing Organization:** Uniformed Services University of the Health Sciences

E. **Funding:** WRNMMC

F. **Objective and Approach:** The objectives of this study are to gain novel insights into the cellular and molecular mechanisms by which Setbp1 overexpression and missense mutations induce leukemia development, and also to test new therapeutic strategies for *SETBP1*-induced leukemias based on these insights through the use of mouse models. The three R's (reduction, replacement, and refinement) of animal usage will be employed.

G. **Indexing Terms (Descriptors):** Animals, mice, Setbp1, and leukemia

APPENDIX A.

PI NAME: (b)(6)
PROTCOL NUMBER:
DRUGS AND CONTROLLED SUBSTANCES

Please list ALL drugs and controlled substances that will be used under this protocol, indicating the DEA Schedule if known. Provide both the Approved Name and the Proprietary Name of each drug if known.

This list, once approved, will be used by the IACUC and the USU Pharmacy to determine which drugs and controlled substances can be supplied to the Principal Investigator. The Pharmacy will not dispense to the PI any drug that is not included in this list.

Drug Name (Please give both approved and Proprietary Names if possible)	DEA Schedule (I, II, III, or IV) (if known)
1.5-fluorouracil (5-FU)	
2. Tamoxifen	
3. (b)(4)

MEMORANDUM FOR DR. (b)(6)

SUBJECT: IACUC Approval of Protocol – Initial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on January 9, 2013:

Animal Protocol Title: "Skin Cancer Biomarkers for Exposure to (b)(4) Ionizing Radiation (Mus Musculus)"

USUHS Protocol Number: (b)(6)

Expiration Date: January 8, 2016

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. NON-TECHNICAL SYNOPSIS:

There is increased risk to US military personnel for unintentional exposure to radiation, either due to a nuclear accident or as the result of terrorist activity. Although significant research has been conducted on the effects of high dose radiation, the true risk of exposure to (b)(4) radiation is not well understood. One theory regarding risk from (b)(4) radiation exposures is the linear no threshold (LNT) model, which states that any level of radiation exposure can result in health risks. Some data indicate that there are significant differences (qualitative and quantitative) between the effects of (b)(4) high dose radiation on specific biomolecular targets including DNA, transcription factors, and molecules involved in initiation of (b)(4) Cellular changes leading to the generation of cancer in response to (b)(4) gamma irradiation have not been well defined, and biomarkers to predict these changes have not been identified. The proposed research will develop a murine model for (b)(4) radiation-induced skin cancer and identify cutaneous biomarker (b)(4)

(b)(4)

II. BACKGROUND:

II.1. Background:

(b)(4)

(b)(4) The biochemical consequences of radiation exposure are pronounced and include: radiation-induced gene expression changes, DNA and protein modifications, and metabolomic, lipidomic, immunomodulatory, cytogenetic and inflammatory mediator changes. (b)(4)

(b)(4)

(b)(4) Examination of transcriptional responses to (b)(4) radiation demonstrated the altered expression of

up to 1,400 genes of which a significant number are correlated with specific cancers. At present, however, much less is known about how (b)(4) radiation effects (b)(4) (b)(4) leading to cancer development.

Findings by several laboratories have provided substantial evidence that some (but not all) changes that occur at high dose radiation (b)(4) For instance, unrepaired DNA damage, as detected by micronuclei, can be reliably observed in murine skin but only following a (b)(4) irradiation. Changes in gene expression can be detected after exposure of (b)(4) but it is unknown whether these early changes in gene expression lead to malignant transformation in response to (b)(4) radiation.

Mitochondrial dysfunction caused by ionizing radiation is thought to be an underlying mechanism driving protein oxidation, where the increased production of reactive oxygen species (ROS) occurs due to a disruption in the electron transport chain. The resulting rise in ROS catalyzes the modification of cellular proteins. Covalent modifications are hallmarks of oxidative stress and are well recognized for their contribution to resulting pathologies. Protein oxidation by oxidative stress and free radical damage, such as that induced by radiation, is a hallmark mechanism underlying the pathology of radiation injury. Protein modification can be utilized as a sensitive system for the detection of radiation-induced cell damage for the following reasons. First, radiation-induced damage of proteins is dose- and time-dependent and thus reflects biologic consequence. Second, data from our laboratory and others indicates that damaged can proteins reflect organ-specific injury. And third, the scientific tools required for analyzing proteins damaged by radiation are generally well established. Importantly, these modifications are chemically stable, protein specific and easily detected using highly sensitive antibody-based procedures.

II.2. Literature Search for Duplication:

II.2.1. Literature Source(s) Searched:
Biomedical Research Database (BRD)NIH RePORTER (replacement database for CRISP) *http://projectreporter.nih.gov/reporter.cfm*
PubMed

II.2.2. Date of Search: November 2, 2012

II.2.3. Period of Search: all dates searched for each database: for BRD, 1998-2012; for RePorter, 1972-2012; for PubMed, 1970-2012.

II.2.4. Key Words and Search Strategy: (b)(4) ionizing radiation, skin, cancer

II.2.5. Results of Search:
Results from NIH RePORTER:
5 grants were found that had the key words.

1. NIH R01 EB008713 by J.P. Desai "Robotic haptic feedback system for BX/RFA of breast tumor under MRI". This grant investigates the use of radiofrequency ablation (RFA) for early stage breast cancer. The grant also proposes the use of MRI instead of CT scans for localizing breast tumors to avoid exposure of patients to ionizing radiation.
2. (b)(4)
3. NIH Z1A CP01033 by M.S. Linet "Studies of populations exposed to occupational sources of radiation". This grant proposes to examine cancer incidence and mortality among US radiologic technologists, in Chornobyl accident survivors and clean-up workers, and in female flight attendants. Skin cancer rates will be examined as results of UV exposures No animal studies are proposed.
4. R21 CA161670 by K.Sheng "A mechanistic model to derive lung tumor motion from the whole surface tracking". This project will investigate technological improvements to the calculations of clinical radiologic instrumentation to allow the delivery of synchronized radiation to tumors, taking into consideration internal tumor motion. The experiments proposed are geared toward tracking lung tumors.

Results from BRD: No matches

Results from PubMed:
There were 271 results from the key words, however, most of these were not related to the induction of cancer by (b)(4) ionizing radiation. Many manuscripts were related to cancer

treatment and not to the induction of cancer in normal cells. A large number of the manuscripts examined UV radiation effects.

III. OBJECTIVE\HYPOTHESIS:

(b)(4)

IV. MILITARY RELEVANCE:

The Department of Defense is prepared to execute military missions within radiation environments, to manage radiation crises associated with terrorist activities, and to manage consequences in the event of nuclear weapons detonation. Recent studies indicate that there is an increasing risk of exposure to ionizing radiation (IR) to military personnel due to increasing terrorist activities, including potential use of stolen nuclear weapons or dispersal of radioactive material in a "dirty bomb" (b)(4) (b)(4) Because of potential exposure of military personnel to radiation, the DoD is committed to protect members of the Armed Services from the adverse health effects of ionizing radiation. (b)(4) IR causes short term, acute injuries including hematopoetic and GI syndromes. However (b)(4) IR (as may result from a radiation dispersal device) can cause cancer including skin cancer.

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures:

The threshold dose of radiation for induction of skin cancers is not known.

V.1.1. Experiment 1: Determination of the threshold doses and time courses of gamma radiation required for the induction of skin cancer in a susceptible murine model.

(b)(4)

Note: female mice will be used for these studies because of reduced aggressive behavior in females during long housing times. Also, homozygous (b)(4) mice will not be used as these mice develop spontaneous tumors in ~2 months.

Non-irradiated (b)(4) mice = (b)(4) mice

(b)(4) animals/group) x (4 radiation doses) x (1 time point) = (b)(4) mice

Control (nonirradiated) (b)(4) mice = (b)(4) mice

(b)(4) animals/group) x (1 radiation doses) x (1 time point) = (b)(4) mice

(b)(4) Endpoint: Animals will be euthanized at months postirradiation. At earlier time points, mice will be euthanized if skin tumors (or any other tumors resulting from radiation exposure) are equal to 20 mm in diameter, or if multiple tumors appear that together equal 20 mm diameter. This is the recommended maximal tumor size for mice according to NCI Frederick ACUC Guidelines Involving Experimental Neoplasia Proposals in Mice and Rats, 2006.

V.1.2. Experiment 2: Identification of skin proteins that undergo carbonylation and the formation of hydroxynonenal (HNE) adducts and the expression of specific markers for (b)(4) gamma radiation in a murine model of radiation-induced skin cancer.

(b)(4)

(b)(4)

Preliminary findings in our laboratory indicate that N = is sufficient for the detection of (b)(4) (b)(4) and signal transduction pathway activation in response to radiation. For these experiments, both male and female mice can be utilized. Also, each animal will provide its own control tissue outside of the field of radiation.

(b)(4) mice

(b)(4) animals/group) x (4 radiation doses) x (5 time points) = (b)(4) mice

(b)(4) mice

(b)(4) animals/group) x (1 radiation doses) x (5 time point) = (b)(4) mice

Study endpoints: Animals will be euthanized at (b)(4) days postirradiation. At earlier time points, mice will be euthanized if skin tumors (or any other tumors resulting from radiation exposure) are equal to 20 mm in diameter, or if multiple tumors appear that together equal 20 mm diameter. This is the recommended maximal tumor size for mice according to NCI Frederick ACUC Guidelines Involving Experimental Neoplasia Proposals in Mice and Rats, 2006.

V.2. Data Analysis:

Mean with standard error, or percentage will be reported if applicable. A significance level is set at 5% for each test. All statistical tests are two-sided. A statistical software, SAS will be used for statistical analyses.

Experiment 1: Log-Rank test will be used for comparison among groups. If significant, Fisher's exact test will be used to detect significant differences across the groups in (b)(4) tumor development rates at months. Kaplan-Meier curves will be displayed. N = (b)(4) mice per group will have 80% power in detecting a significant difference between two groups if any, given type I error of 5% where the treatment group survival rate is at least 68%, compared to a control group survival rate of 20%. Similar statements would apply, if the treatment group survival rates are at least 83%, 78%, or 73%, compared to vehicle group survival rates of 35%, 30%, and 25%, respectively (b)(4)

Experiment 2: Analysis of variance (ANOVA) will be used to detect significant difference among the groups. If significant, then the pair-wise comparison by Tukey-Kramer will be used to identify which group is different from the other. For experiment 2, N = mice per (b)(4) group could have 80% power to detect any significant difference between groups if any, given type I error of 5% and delta/sigma has at least 1.4, where the delta is the estimated mean differences between the two groups and sigma is the pooled standard deviation of the two groups (b)(4)

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered:

For the last 4 years, we have utilized primary cell culture systems to examine radiation effects on cells; however, we must determine whether our culture findings are relevant in whole animals. We will continue to use primary cell culture whenever possible to avoid unnecessary use of animals. We have also considered computer models as alternatives to animals. However, this alternative also lacks the knowledge base and complexity needed to evaluate radiation-induced cancer risks.

V.3.2. Animal Model and Species Justification:

Tissue culture conditions cannot fully substitute for the complexities of whole organisms in response to radiation injury. Such injury involves the interactions between the hematopoietic system and other organ systems. In order to develop viable treatments for humans, we find that our research must be conducted in whole animals.

The mouse as the best species to use for radiation protocols: 1) mice provide the least sentient species available whose response to radiation has been clearly identified, with physiological responses to radiation and cancer development that are similar to human physiology, 2) extensive literature is available on responses of mice to radiation and cancer, 3) more reagents are available to study the relevant cell types and molecules in mice than in any other species except humans, and the availability of transgenic and knockout mice make this model extremely attractive for further research into molecular mechanisms, and 4) our research group have extensive experience with radiation effects in mice, including radiation injury and radioprotection research.

V.3.3. Laboratory Animals

	Species #1	Species #2
V.3.3.1. Genus & Species:	Mus musculus	Mus musculus
V.3.3.2. Strain/Stock:	(b)(4)	
V.3.3.3. Source/Vendor:		
V.3.3.4. Age:	8-12 weeks	8-12 weeks
V.3.3.5. Weight:	Normal adult weight range for this strain: 17-21 g	Normal adult weight range for this strain: 17-21 g
V.3.3.6. Sex:	(b)(4)	
V.3.3.7. Special Considerations:	None	

V.3.4. Number of Animals Required (by Species): mice

V.3.5. Refinement, Reduction, Replacement (3 Rs):

V.3.5.1. Refinement:
Animals demonstrating morbidity due to radiation exposure (b)(4) will be considered to have arrived at the study endpoint and will be immediately euthanized (See sections V.4.5 Study Endpoint and V.4.6 Euthanasia).

Ketamine/xylazine anesthesia will be used during X-ray irradiation to prevent stress from the time the mice are placed in restraint. Under the supervision of AFFRI veterinary staff, we found that in female mice, ~12 weeks old, i.p. injection of 150 mg/kg ketamine plus 18 mg/kg xylazine results in 60-80 min anesthesia with no morbidity or mortality (b)(4) (b)(4) We propose to use this range of concentration of anesthetics, together with a heating pad to keep mice warm during the period of recovery from anesthesia. Standard intraperitoneal injection methods are used for injection of the anesthesia, for which all laboratory personnel have received training.

V.3.5.2. Reduction:

Whenever possible, control groups will be shared between experimental groups for our experiments. Tissues will be collected for multiple assays from the same animals further reducing the total number of animals needed. At every stage of the research, planned experiments will be reevaluated, in an attempt to reduce the numbers of experiments and eliminate repeats of experiments where statistical significance has already been obtained.

V.3.5.3. Replacement:
At this time, it is not feasible to use non-animal systems in place of animal models to address the research questions in this protocol.

V.4. Technical Methods:

V.4.1. Pain / Distress Assessment:

V.4.1.1. APHIS Form 7023 Information:

V.4.1.1.1. Number of Animals: (b)(4)

(b)(4)

V.4.1.1.1.1. Column C:
V.4.1.1.1.2. Column D:
V.4.1.1.1.3. Column E:

V.4.1.2. Pain Relief / Prevention:

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization:
Ketamine/xylazine anesthesia will be used during X-ray irradiation to prevent stress from the time the mice are placed in restraint. Under the supervision of AFFRI veterinary staff, we found that in female mice, ~12 weeks old, i.p. injection of 150 mg/kg ketamine plus 18 mg/kg xylazine results in 60-80 min anesthesia with no morbidity or mortality (b)(4) (b)(4) We propose to use this range of concentration of anesthetics, together with a heating pad to keep mice warm during the period of recovery from anesthesia. Standard intraperitoneal injection methods are used for injection of the anesthesia, for which all laboratory personnel have received training.

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions: Not applicable

V.4.1.2.3. Paralytics: Not applicable

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures:

V.4.1.3.1. Sources Searched:
Sources searched: DoD Bioedical Research Data Base (BRD), CRISP, PubMED

V.4.1.3.2. Date of Search:

V.4.1.3.3. Period of Search:
Search covered published manuscripts from ~1965-present. (BRD search included all available years 1998 -2012).

V.4.1.3.4. Key Words of Search:
Pain, analgesia, anesthesia, mice, radiation, ionizing radiation, humane

V.4.1.3.5. Results of Search:
The literature search revealed that, at present, there are no alternative procedures for irradiation because its effects cannot be otherwise duplicated. In some cases radiation has been demonstrated to reduce pain in laboratory mice (b)(4) and has been in humans reported to alleviate cancer related bone pain (b)(4) (b)(4) A recent report showed that administration of botulinum toxin A was effective for reduction of pain and muscle spasms after clinical radiation for treatment of tumors (b)(4) Application of natural honey 20 min prior to radiation exposure was also shown to reduce mucositis with associated pain in humans following head/neck radiotherapy (b)(4) (b)(4) it has not been determined whether honey acts as a local radioprotectant. Spinal cord stimulation has also been reported in humans to alleviate pain resulting from radiotherapy (b)(4) however, this method would not be practical for use in mice because of the extensive spinal cord manipulation required. Human administration of morphine also relieves pain (b)(4) but again this would not be practical for mice in our experiments because of side effects of the drug. In humans, exposure to total body irradiation may induce vomiting and diarrhea, causing pain and distress. However, mice are not susceptible to vomiting.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification:
Anesthesia will be used before (b)(4) irradiation to avoid stress from restraint. Radiation (b)(4) used for these experiments is not expected to induce pain in any animals, and most time points will be within 30 days postirradiation, prior to the development of cancers. However, animals that are observed to be in pain will be euthanized. Pain will be evaluated using several standard indications including: grimacing, abnormal breathing, hunched or fluffed fur and inactivity, or ataxia. In experiments where tissue collection is needed, animals will be euthanized with pentobarbitol prior to sample collection as described elsewhere. We will utilize the attached score sheets to provide a scale for measurement of criteria for euthanasia. Any animal scoring 12 or more total on the score sheet will be euthanized.

V.4.2. Prolonged Restraint:
(b)(4) irradiation will require restraint in designed jigs for ~20 min to receive X-ray exposure (b)(4) animals will be anesthetized during this period (see Anesthesia above) and tails will be taped to one side with surgical tape. The jigs for use during (b)(4) irradiation were examined and approved by the AFRRI Veterinary staff. An image of the jigs is attached. Under the training protocol at AFRRI in conjunction with the AFRRI veterinary staff, we found that in female CBA mice, ~12 weeks old, i.p. injection of 150 mg/kg ketamine plus 18 mg/kg xylazine results in 60-80 min anesthesia (25 G needle) with no morbidity or mortality (b)(4) The length of time for anesthesia is needed to ensure that animals do not regain

consciousness while being positioned in the lead shield for irradiation. Positioning of the mice must be done carefully to ensure that all animals receive the same exposures. We propose to use this range of concentration of anesthesia, together with a heating pad to keep mice warm during the period of anesthesia. Standard i.p. injection methods are used for injection of the anesthesia.

V.4.3. Surgery:

V.4.3.1. Pre-surgical Provisions: Not applicable

V.4.3.2. Procedure: Not applicable

V.4.3.3. Post-surgical Provisions: Not applicable

V.4.3.4. Location: Not applicable

V.4.3.5. Surgeon: Not applicable

V.4.3.6. Multiple Major Survival Operative Procedures: Not applicable

V.4.3.6.1. Procedures: Not applicable

V.4.3.6.2. Scientific Justification: Not applicable

V.4.4. Animal Manipulations:

V.4.4.1. Injections:
Intra-peritoneal injections of pentobarbital for euthanasia 0.1-0.2 ml/mouse Fatal Plus (39-78 mg pentobarbital/mouse), will be performed with a 25 G needle. I.p. injection of 150 mg/kg ketamine plus 18 mg/kg xylazine will be done using a 25 G needle. This has been extensively examined by the AFRRI Veterinary staff and shown to effectively produce non-lethal anesthesia (b)(4)

V.4.4.2. Biosamples:
Ear punch tissue will be used both for animal identification and for genotyping. Ear punches will be performed without anesthesia.

Sections of skin tissue or skin tumor tissue will be taken in from the backs of euthanized mice. All other tissues will be available to other researchers for tissue sharing.

V.4.4.3. Adjuvants: Not applicable

V.4.4.4. Monoclonal Antibody (MAbs) Production: Not applicable

V.4.4.5. Animal Identification:
All cages will have cage cards identifying the treatment groups for each experiment. For experiments 2 and 3, each animal within a cage will receive ear punches for individual

identification (1 = no cut; 2 = right ear upper corner; 3 = left ear upper corner; 4 = both ears).

V.4.4.6. Behavioral Studies: Not applicable

V.4.4.7. Other Procedures:

Ear punch

The ear punch will be soaked in alcohol to disinfect it before use and between animals. The device will be placed on the pinna of the ear (external ear) in a location where the mouse will be marked for identification. The punch will be pressed firmly to punch a circular hole through the ear, being careful not to rip the delicate membrane of the pinna. The ear will then be gently separated from the device. The ear punch will be cleaned and disinfected in alcohol before use in another mouse.

(b)(4) **irradiation**

The methodology for (b)(4) irradiation of mice including approval of holding jigs and development of anesthesia, was developed in conjunction with the AFRRI Veterinary Staff.

(b)(4) irradiation will be performed using the RS2000 irradiator (b)(6)
Thirty minutes prior to irradiation, the RS2000 irradiator and lead shield will be decontaminated thoroughly with MB10.

Mice will be anesthetized by injection in the USUHS LAM facility. Anesthetized mice will be placed in ventilated Lucite jigs, which restrain the animals to prevent lateral or vertical movement. Tails will be taped to prevent any forward motion of animals. Mice will be irradiated at (b)(4) irradiation. Following radiation exposure, mice will be immediately returned to the LAM and allowed to recover from anesthesia under supervision with heating pads. Immediately upon recovery, animals will be returned to standard cages that house 4 animals per cage. Lucite jigs will be sanitized after each use.

V.4.4.8. Tissue Sharing:

For the proposed studies (b)(4) tissue will be obtained. All other tissues will be available for tissue sharing with other investigators.

V.4.5. Study Endpoint:

(b)(4) The endpoint for Experiment 1 is months. The endpoints for Experiment 2 are (b)(4) (b)(4) days postirradiation. Morbid animals will be monitored at least twice daily, morning and afternoon. The experimental design does not contemplate supportive therapy. Criteria to be used for health evaluation while the animals are on study include: 20% weight loss (mice will be weighed every other day—based on our experience with total body irradiation in which animals can recover from ~25% weight loss (b)(4) ruffled fur, dehydration, decreased activity, and hunched body position, dyspnea, or panting. Animals exhibiting these signs, and scoring above 11 on the pain score sheet may be euthanized, and considered to be at the study endpoint. Also, at earlier time points, mice will be euthanized if skin tumors (or any other tumors

resulting from radiation exposure) are equal to 20 mm in diameter, or if multiple tumors appear that together equal 20 mm diameter. This is the recommended maximal tumor size for mice according to NCI Frederick ACUC Guidelines Involving Experimental Neoplasia Proposals in Mice and Rats, 2006.

V.4.6. Euthanasia:
Animals will be euthanized at the stated endpoints of the experiments by injection of 0.1-0.2 ml/mouse Fatal Plus (39-78 mg pentobarbital/mouse), IP using a 25 G needle. Euthanasia will be confirmed by cervical dislocation. Animals which appear to be experiencing pain or distress as a result of radiation exposure or are found moribund will also be euthanized by pentobarbitol and necropsied. At the end of experiments, unused animals will be transferred to other protocols or euthanized by exposure to 100% CO_2 from a compressed gas cylinder in accordance with the current American Veterinary Medical Association (AVMA) Guidelines for Euthanasia. Exsanguination, cervical dislocation, and/or pneumothorax will be used to ensure euthanasia.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol. Food and water and Rodent Diet will be available ad libitum. The 12:12 hr (lights off at 6 pm) room light cycle is fine for all the studies.

V.5.1.1. Study Room: will be performed in the
Radiation Building (b)(6) Room Number (b)(6)

Euthanasia Building (b)(6) Room number (b)(6)

V.5.1.2. Special Husbandry Provisions:

Food Restriction: Yes _____ No x

Fluid Restriction: Yes _____ No x

V.5.1.3. Exceptions: None
V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care:
Experimental animals will be observed at least twice a day by one of the study investigators or technicians. VSD personnel will also monitor the animals twice a day during their rounds. As described in another section (study endpoint) morbid animals will be monitored at least twice daily, morning and afternoon. The experimental design does not contemplate supportive therapy. The justification for not providing supportive care has been described in the study end point section as well as in the pain category section. Criteria to be used for health evaluation while the animals are on study include: 20% weight loss (mice will be weighed every other day—based on our experience with total body irradiation in which animals can recover from ~25% weight loss (b)(4)

ruffled fur, dehydration, decreased activity, and hunched body position, dyspnea, or panting. Animals exhibiting these signs may be euthanized, and considered to be at the study endpoint.

V.5.2.2. Emergency Veterinary Medical Care:
All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: All animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents; balls, toys and food enrichment treats for large animal species.
V.5.3.2. Enrichment Restrictions: None

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
Ear punch, irradiation, anesthesia, euthanasia	(b)(6)	8+ years	(b)(6)
Ear punch, irradiation, anesthesia, euthanasia		8 years	
		7 years	

VII. BIOHAZARDS/SAFETY: None

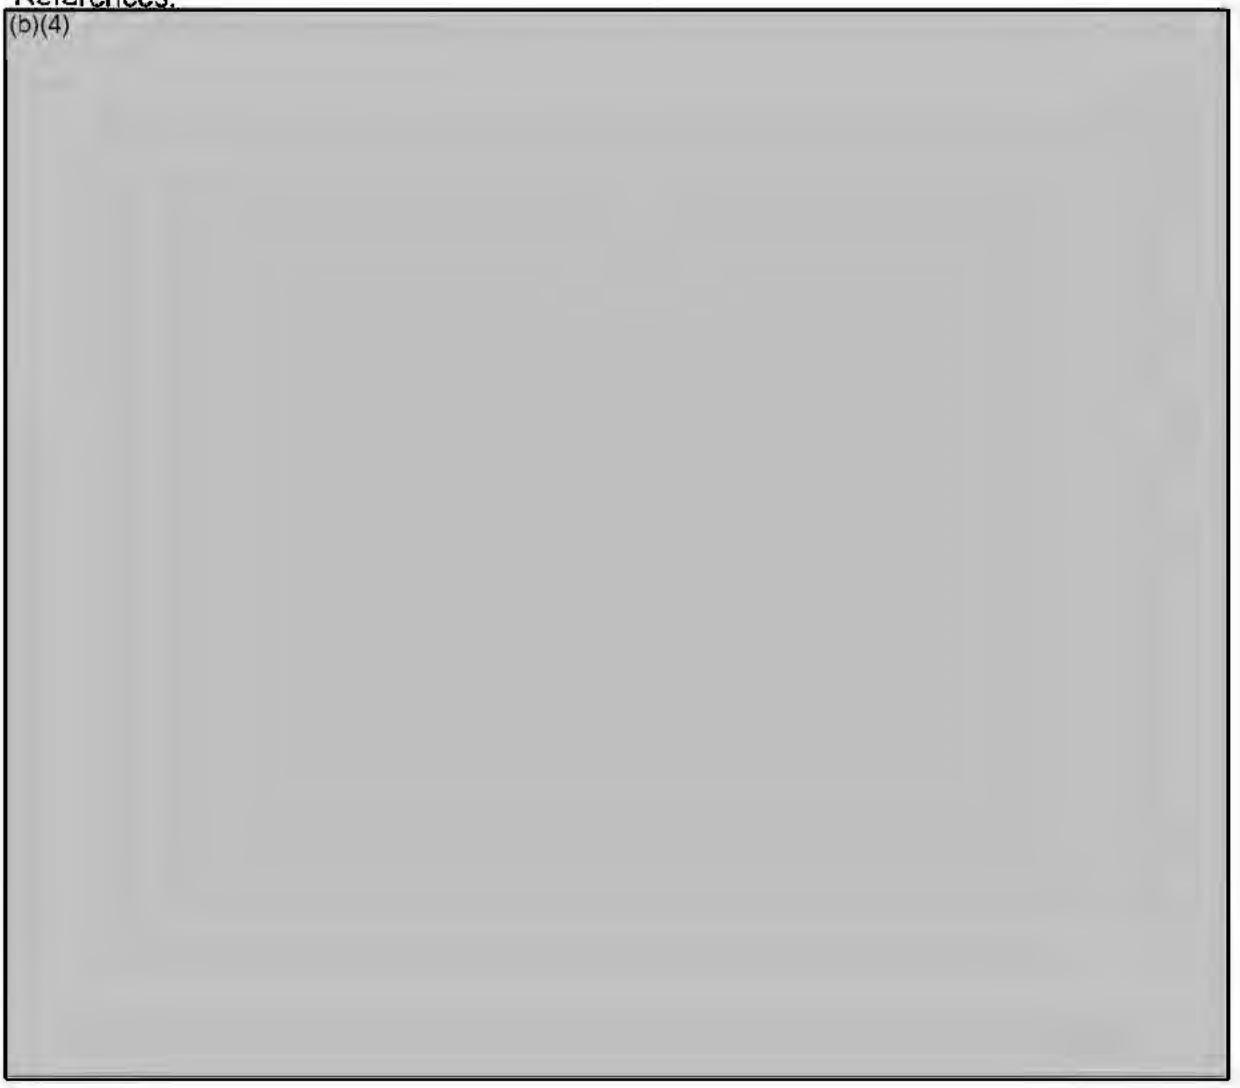
VIII. ENCLOSURES:

1) Images of Lucite jigs for (b)(4) irradiation.

2) Critieria for euthanasia
3) Pain score sheet
4) (b)(4) MSDS

References:

(b)(4)



IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

(b)(6) _____ Nov 12, 2012

Prin ature Date

G. Training: The following personnel will attend the next USUHS Investigator/Animal User Training Course:

_____ _____

_____ _____

H. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely, "Responsibility" for implementing animal use alternatives where feasible and conducting humane and lawful research.

(b)(6) _____ Nov 12, 2012

Princi Date

I. Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL** ~~or **WILL NOT**~~ be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

(b)(6)

X. PROTOCOL ABSTRACT:

There is increased risk to US military personnel for unintentional exposure to radiation, either due to a nuclear accident or as the result of terrorist activity. Although significant research has been conducted on the effects of high dose radiation, the true risk of exposure to (b)(4) radiation is not well understood. One theory regarding risk from (b)(4) radiation exposures is the linear no threshold (LNT) model, which states that any level of radiation exposure can result in health risks. Some data indicate that there are significant differences (qualitative and quantitative) between the effects of (b)(4) high dose radiation on specific biomolecular targets including DNA, transcription factors, and molecules involved in initiation of (b)(4) Cellular changes leading to the generation of cancer in response to (b)(4) gamma irradiation have not been well defined, and biomarkers to predict these changes have not been identified. The proposed research will develop a murine model for (b)(4) radiation-induced skin cancer and identify cutaneous biomarker (b)(4)

January 3, 2013

MEMORANDUM FOR DR. (b)(6)

SUBJECT: IACUC Approval of Protocol – Initial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on January 3, 2013:

Animal Protocol Title: (b)(4)
(b)(4)

USUHS Protocol Number: (b)(6)

Expiration Date: January 2, 2016

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. NON-TECHNICAL SYNOPSIS:

The terrorist attack of September 11, 2001 against the United States has increased the concern that terrorists may acquire and use radioactive sources (e.g. dirty radioactive bombs) to expose military and civilian populations to ionizing radiation. However, despite this concern, there are currently no FDA approved drugs that can be used for the general population to prevent death that is likely to result from exposure to ionizing radiation. (b)(4) irradiation in humans can result in (b)(4) injuries. However, because rodents are more resistant to (b)(4) injuries than humans, there is currently no murine model that has been developed to study both (b)(4) radiation injuries in the same animal.

(b)(4)

II. BACKGROUND:

II.1. Background:

The acute toxic effects of exposure to high doses of ionizing radiation in humans have been shown to occur due to two sequential effects: first the ablation of immune cells, resulting in loss of immune function and increasing likelihood of pathogenic infection (b)(4) and subsequently the loss of epithelial progenitor cells of the gastrointestinal (GI) crypt (b)(4) (b)(4) Both of these events have been shown to be due to the

loss of fast-growing pluripotent and/or progenitor cell types. The time course of the acute injuries correlates with the life span of the mature cell types of the tissue, which are not replaced because of radiation damage to the adult pluripotent cells and adult stem cells. There is currently no FDA approved prophylactic or treatment for prevention of acute radiation injuries following high-dose (b)(4) adiation exposure.

In some cases supportive measures can be used to treat acute radiation syndrome, and survival from (b)(4) adiation exposure is now possible (b)(4) This results in current efforts to mitigate or treat later stage effects of ionizing radiation exposure. (b)(4)

(b)(4)

In humans, death from radiation (b)(4) can occur following survival from (b)(4) Cumulative evidence from a number of laboratories, including our own, shows that there is a threshold dose of radiation of (b)(4) o induce sufficient (b)(4) for the (b)(4) phases to occur in mice; below these doses, no permanent injury manifests, although some short-term effects are observed (b)(4) However, in humans, there is currently no accepted protocol for preventative treatment of radiation-induced (b)(4) and morbidity as high as 50% is associated with each phase (b)(4) (b)(4) injuries from radiation is considered to be a serious problem in the field for the development of agents to prevent these radiation injuries.

(b)(4) **as a radioprotectant:** The biochemical properties of the isoflavones and the investigation of (b)(4) as a protectant against gamma radiation-induced lethality have been investigated by (b)(4), (b)(6) (b)(4) A single i.p. dose of (b)(4) administered hr prior to a lethal dose of (b)(4) (b)(4) radiation resulted in day survival rates of 65%, 91%, and 85% respectively. Mice receiving saline or PEG vehicle alone survived at 8% and 15% respectively. All doses of (b)(4) protected mice significantly ($p < 0.001$) better than vehicle or saline control groups.

The behavioral toxicity was investigated for male mice receiving a single i.p. injection (0.1 ml) of saline, PEG vehicle, or (b)(4) Locomotor activity (total distance traveled), grip strength and motor coordination were evaluated on days (b)(4) post-injection (b)(4) and body weight was measured over days. On day (b)(4) (b)(4) tissues from the testes, liver, adrenal gland, mesenteric lymph node, spleen, and bone marrow of the femur and sternum were collected, fixed in buffered formalin, paraffin embedded, sectioned, and stained by hematoxylin and eosin. The results indicated that there were no significant effects of (b)(4) or vehicle on locomotor activity, grip strength, motor coordination, or body weight, compared to the saline-treated control group. In addition, no gross morphological changes or histopathological alterations were observed (b)(4)

(b)(4) **as a radioprotectant and an antifibrotic agent:** (b)(4) (b)(4) and its proteolytic product (b)(4) are believed to have their primary biological

functions in blood pressure homeostasis. However (b)(4) have been demonstrated to be upregulated in fibrotic tissues. Inhibition of (b)(4) or blockade of the (b)(4) receptors on cells has been shown to ameliorate drug-induced (b)(4) in murine and rat models for (b)(4) (b)(4) receptor antagonists also prevent cardiac remodeling following ischaemia/reperfusion in rat models of cardiac remodeling diseases (b)(4) Several studies have also shown that inhibition of (b)(4) or (b)(4) signaling mitigates radiation-induced injuries, including to the heart and (b)(4) (b)(4) One study shows that the (b)(4) reduces acute damage to the jejunal mucosa in mice following exposure to (b)(4) This work examined only initial tissue injury and did not extend findings past 5 days, and did not examine mortality. A second study found a reduction in (b)(4) in rats exposed to (b)(4) (b)(4) radiation (b)(4)

Preliminary Studies:

III. OBJECTIVE\HYPOTHESIS:

Our objective is to: 1) continue development of a murine model for both the (b)(4) and (b)(4) injuries; and 2) examine protective effects of (b)(4) against these two injuries in the developed model. (b)(4)

(b)(4)

IV. MILITARY RELEVANCE:

The Department of Defense is prepared to execute military missions within radiation environments, to manage radiation crises associated with terrorist activities, and to manage consequences in the event of nuclear weapons detonation. Recent studies indicate that there is an increasing risk of exposure to ionizing radiation (IR) to military personnel due to increasing terrorist activities, including potential use of stolen nuclear weapons or dispersal of radioactive material in a "dirty bomb" (b)(4) Because of potential exposure of military personnel to radiation, the DoD is committed to protect members of the Armed Services from the adverse health effects of ionizing radiation. High dose IR causes short term, acute injuries including hematopoetic and GI syndromes. However, both high and low dose IR (as may result from a radiation dispersal device) can cause (b)(4) as demonstrated by Japanese atomic bomb survivor data as well as accidental exposures to Russian populations (b)(4) (b)(4) While early effects of radiation injury now have treatment/ prophylactic strategies, the delayed effects currently have no treatment. Lack of treatment for late effects of radiation, including (b)(4) will likely lead to delayed morbidity and mortality for personnel exposed to IR.

The Department of Defense (DoD) Chemical and Biological Defense Program 2007 Annual Report to Congress, Chapter 2.7.6 Medical Radiological Defense, addresses the requirements for the development of radioprotectants. This priority is outlined for the development of

protectants for both acute and delayed radiation injuries, with an emphasis on (b)(4) (b)(4) According to this report, the mitigation of (b)(4) is a major research thrust area. (b)(4)

(b)(4)

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures:

(b)(4)

(b)(4) irradiation will be performed using the RS2000 irradiator (b)(6) Thirty minutes prior to irradiation, the RS2000 irradiator and lead shield will be decontaminated thoroughly with MB10. Sham irradiation will be performed by placing the mice in jigs for equal lengths of time with no irradiation. As measurements of (b)(4) from radiation, five criteria will be examined:

(b)(4)

(b)(4)

V.1.1. Experiment 1:

Experiment 1 Determination of field of exposure for (b)(4) irradiation (b)(4)

This pilot experiment will be performed to identify the correct shield cut out size required for exposure of the mouse (b)(4) with minimal exposure to the brain or intestinal tract. Mice will be exposed to (b)(4) with x-ray film in a cassette beneath the shield to determine the correct placement of lead strips to close the size of the opening in the lead shield. Animals will be euthanized once the correct opening size is determined.

V.1.2. Experiment 2:

(b)(4)

PEG-400 (0.1 ml/mouse) vehicle only or (b)(4) will be administered by a single (b)(4) i.p. injection h before radiation exposure. (b)(4) will be provided in the drinking water at (b)(4) to give a dosage of (b)(4) per day for the duration of the experiment starting on day 0. The intake and dosage of drug has been previously studied in our laboratory. Amounts of water with and without (b)(4) were measured daily in sham irradiated and (b)(4) irradiated mice to verify that (b)(4) has no effect on water consumption and the dosage of (b)(4) remains in the effective dose range after radiation (b)(4). Mice will be anesthetized and exposed to (b)(4) x-ray irradiation to give exposures equal to (b)(4) irradiation (b)(4) dose rate. Treatment groups will be: 1) PEG; 2) PEG + (b)(4) 3) (b)(4) 4) (b)(4) (b)(4) water bottles will be prepared by the (b)(6 aboratory, and will be replaced 2X per week. Extra water bottles will be prepared in advance in case they are needed to replace a leaking water bottle. (b)(4) is stable in (b)(4) water for several weeks; bottles will be prepared and available for use over weekends and holidays.

The dose rate of (b)(4) to achieve the total (b)(4) exposure desired will be determined by the Radiation Department, which will perform dosimetry using phantoms in the RS2000 irradiator.

Mice will be monitored monthly using non-invasive, unrestrained (b)(4) to determine (b)(4) For these studies (b)(4) mice are required per radiation dose. The time point for (b)(4) is days, based on data (b)(4) from previous studies by others (b)(4) The time point fo (b)(4) is (b)(4) days, based on previous studies by others (b)(4) The experiment will be repeated

because it is a generally accepted principle of the scientific method that experiments must be repeated to evaluate a hypothesis.

(b)(4) [redacted] mice per group) x (4 treatment groups) x (1 time point) x (3 (b)(4) [redacted] radiation levels) = (b)(4) [redacted]
(b)(4) [redacted] mice/experiment) x (2 experiments) = [redacted] mice

Endpoints: The final endpoint for the experiment is [redacted] days. Mice displaying obvious dyspnea, (b)(4) lethargy, or other markers of morbundity and which appear to be in distress will be euthanized. (b)(4) [redacted] will be histologically examined for (b)(4) [redacted] remodeling. The scale for pain or lethargy is attached. Mice scoring a total of 12 under any measurement will be euthanized.

V.1.3. Experiment 3

Experiment 3: Determination of the mechanism of reduction of (b) [redacted] injury by (b)(4) [redacted]
(b)(4) [redacted]

We have determined that between (b)(4) [redacted] days (b)(4) [redacted] cells exhibit markers of (b)(4) [redacted] and (b)(4) [redacted] following (b)(4) [redacted] irradiation. We will investigate the mechanism of action of (b)(4) [redacted] examining these markers of cell injury.

We will use 4 time points: (b)(4) [redacted] days postirradiation, using (b)(4) [redacted] (b)(4) [redacted] irradiation. Treatment groups will be: 1) PEG; 2) PEG + (b)(4) [redacted] 3) (b)(4) [redacted] 4) (b)(4) [redacted] (b)(4) [redacted] The experiment will be repeated because it is a generally accepted principle of the scientific method that experiments must be repeated to evaluate a hypothesis.

(b)(4) [redacted] mice per group) x (4 treatment groups) x (4 time points) x (3 (b)(4) [redacted] radiation levels) = (b)(4) [redacted]
(b)(4) (b)(4) [redacted] mice/experiment) x (2 experiments) = [redacted] mice
(b)(4) [redacted] sham-irradiated mice will be required as controls.

Endpoint: Endpoints for the experiments will be (b)(4) [redacted] days. Early time points will be taken if any animal exhibits signs or symptoms of morbidity or moribundity. Such animals will be euthanized at the time of observation.

V.2. Data Analysis:

Mean with standard error, or percentage will be reported if applicable. A significance level is set at 5% for each test. All statistical tests are two-sided. A statistical software, SAS will be used for statistical analyses.

Experiments 2 and 3: Analysis of variance (ANOVA) will be used to detect significant difference among the groups. If significant, then the pair-wise comparison by Tukey-Kramer will be used to identify which group is different from the other. For experiment 2, N = [redacted] mice per group could (b)(4) have 80% power to detect any significant difference between groups if any, given type I error of 5% and delta/sigma has at least 1.4, where the delta is the estimated mean differences between the two groups and sigma is the pooled standard deviation of the two groups (b)(4) [redacted] For experiment 3, previous data from this laboratory indicate that the coefficient of variation (CV) of the data is about 0.5, and that differences of between 2- and 30- fold are likely to be
(b)(4) observed. A sample size of [redacted] per group will have 80% power to detect 3-fold increases in biomarkers based on a lognormal t test with a 5% two-sided significance level and a CV of 0.5.

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered:

For the last 8 years, we have utilized primary cell culture systems to examine anti-apoptotic mechanisms; however, we must determine whether our culture findings are relevant in whole animals. We will continue to use primary cell culture whenever possible to avoid unnecessary use of animals. We have also considered computer models as alternatives to animals. However, this alternative also lacks the knowledge base and complexity needed to evaluate radioprotective and radiotherapeutic agents.

V.3.2. Animal Model and Species Justification:

Tissue culture conditions cannot fully substitute for the complexities of whole organisms in response to radiation injury. Such injury involves the interactions between the hematopoietic system and other organ systems. In order to develop viable treatments for humans, we find that our research must be conducted in whole animals.

(b)(4),(b)(6) the mouse as the best species to use for radiation protection and radiotherapy protocols: 1) mice provide the least sentient species available whose response to radiation has been clearly identified, with physiological responses to radiation and radioprotectants that are similar to human physiology, 2) extensive literature is available on responses of mice to radiation and countermeasures, 3) more reagents are available to study the relevant cell types and molecules in mice than in any other species except humans, and the availability of transgenic and knockout mice *make* this model extremely attractive for further research into molecular mechanisms, and 4) (b)(6) (b)(6) have extensive experience with this model in radiation injury and radioprotection research (b)(6)

V.3.3. Laboratory Animals

V.3.3.1. Genus & Species: *Mus musculus*

V.3.3.2. Strain/Stock: CBA

V.3.3.3. Source/Vendor: (b)(4)

V.3.3.4. Age: 10-14 weeks

V.3.3.5. Weight: Normal adult weight range for this strain: 17-21 g.

V.3.3.6. Sex: Female. Only females will be used in this study for the following reasons: 1) we have so far utilized female mice to lay the foundation of our studies for radiation-induced (b)(4) injuries; 2) because of long housing periods, it is advantageous to use female mice that are less aggressive toward each other.

V.3.3.7. Special Considerations: Commercially procured animals must be adventitious disease free. Mice- Pathogen-free, including *Pseudomonas aeruginosa*, and Pasteurella: All mice need to be free of the following agents: Sendai, Pneumonia Virus of Mice (PVM), Reovirus-3 (Reo 3), Mouse Adenovirus (MAD-1, MAD-2), Mouse Cytomegalovirus Virus (MCMV), Ectromelia, K virus, Lymphocytic Choriomeningitis Virus (LCM), Epidemic Diarrhea of Infant Mice (EDIM), Hantaan virus,

Rotavirus, Mouse Parvovirus (MPV), Polyoma Virus, Mouse Minute Virus (MMV), Mouse Thymic Virus (MTV), Theiler's Mouse Encephalomyelitis Virus (TMEV/GDVII), *Encephalitozoon cuniculi*, CAR bacillus; *Helicobacter* spp. *Mycoplasma pulmonis*, and *Clostridium piliforme*. Endoparasite- and ectoparasite-free.

V.3.4. Number of Animals Required (by Species):

V.3.5. Refinement, Reduction, Replacement (3 Rs):

V.3.5.1. Refinement: Animals demonstrating moribundity due to radiation exposure (b)(4) will be considered to have arrived at the study endpoint (b)(4) (b)(4) will likely minimize pain and distress, while (b)(4) has been shown in studies of chemotherapy agents to function as a repair and (b)(4) factor.

Ketamine/xylazine anesthesia will be used during X-ray irradiation to prevent stress from the time the mice are placed in restraint. Under the training protocol at AFRRI inconjunction with the AFFRI veterinary staff, we found that in female C57BL/6J mice, ~12 weeks old, i.p. injection of 150 mg/kg ketamine plus 18 mg/kg xylazine results in 60-80 min anesthesia with no morbidity or mortality (b)(4) We propose to use this range of concentration of anesthetics, together with a heating pad to keep mice warm during the period of recovery from anesthesia. The temperature in room where the mice will be irradiated will be measured, and if necessary a space heater will be used to increase the temperature. Standard intraperitoneal injection methods are used for injection of the anesthesia, as recommended and approved by the AFRRI veterinary staff and for which all laboratory personnel have received training at AFRRI.

V.3.5.2. Reduction: Whenever possible, control groups will be shared between experimental groups for our experiments. Tissues will be collected for multiple assays from the same animals further reducing the total number of animals needed. At every stage of the research, planned experiments will be reevaluated, in an attempt to reduce the numbers of experiments and eliminate repeats of experiments where statistical significance has already been obtained. We also plan to take as many tissues as we can reasonably analyze for experiments examining protein oxidation.

V.3.5.3. Replacement: At this time, it is not feasible to use non-animal systems in place of animal models to address the research questions in this protocol.

V.4. Technical Methods:

V.4.1. Pain / Distress Assessment:

V.4.1.1. APHIS Form 7023 Information:

V.4.1.1.1. Number of Animals: (b)(4)

V.4.1.1.1.1. Column C: (b)(4)

V.4.1.1.1.2. Column D:

V.4.1.1.1.3. Column E: (b)(4)

V.4.1.2. Pain Relief / Prevention:

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization:
We will be unable to use analgesics since they have effects on (b)(4) function that would interfere with the interpretation of our results (b)(4) (b)(4) Some sedatives have been reported to contribute to postoperative (b)(4) which likely reduce some functions of radiation. Additionally, it has been shown that the biometabolism of analgesics can induce protein oxidation, which would interfere with sample analysis (b)(4)

An anesthesia protocol has been developed for use during the X-ray irradiation. Ketamine will be used with xylazine for longer anesthesia in mice to be place in restraints for (b)(4) irradiation. Under the training protocol at AFRRI in conjunction with the AFRRI veterinary staff, we found that in female CBA mice, ~12 weeks old,i.p. injection of 150 mg/kg ketamine plus 18 mg/kg xylazine results in 60-80 min anesthesia (25 G needle) with no morbidity or mortality (b)(4) We propose to use this range of concentration of anesthesia, together with a heating pad to keep mice warm during the period of anesthesia. Standard i.p. injection methods are used for injection of the anesthesia, as recommended and approved by the AFRRI veterinary staff and for which all laboratory personnel have received training at AFRRI.

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions:
Animals will be housed and cared for as described in Section V.5. Veterinary Care both before and after dose administrations and irradiation procedures.

V.4.1.2.3. Paralytics: N/A

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures:

V.4.1.3.1. Sources Searched: DoD Bioedical Research Data Base (BRD), CRISP, PubMED

V.4.1.3.2. Date of Search: 11/7/12

V.4.1.3.3. Period of Search: Search covered published manuscripts from ~1965-present. (BRD search included all available years 1998 -2012).

V.4.1.3.4. Key Words of Search: Pain, analgesia, anesthesia, mice, radiation, ionizing radiation, humane, (b)(4)

V.4.1.3.5. Results of Search:
The literature search revealed that, at present, there are no alternative procedures for irradiation because its effects cannot be otherwise duplicated. In some cases radiation has been demonstrated to reduce pain in laboratory mice (b)(4) and has been in humans reported to alleviate cancer related bone pain (b)(4) (b)(4) A recent report showed that administration of botulinum toxin A was effective for reduction of pain and muscle spasms after clinical radiation for treatment of tumors (b)(4) (b)(4) Application of natural honey 20 min prior to radiation exposure was also shown to reduce mucositis with associated pain in humans following head/neck radiotherapy (b)(4) it has not been determined whether honey acts as a local radioprotectant. Spinal cord stimulation has also been reported in humans to alleviate pain resulting from radiotherapy (b)(4) however, this method would not be

practical for use in mice because of the extensive spinal cord manipulation required. Human administration of morphine also relieves pain (b)(4) but again this would not be practical for mice in our experiments because of side effects of the drug. In humans, exposure to (b)(4) irradiation may induce vomiting and diarrhea, causing pain and distress. However, mice are not susceptible to vomiting. The animals that will be administered (b)(4) will likely receive pain relief as phytoestrogens have been reported to reduce neuropathic pain in rodents (b)(4) preliminary results also indicate that (b)(4) ameliorates acute radiation-induced injuries (b)(4)

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification:
Anesthesia will be used before (b)(4) irradiation to avoid stress from restraint. (b)(4)
(b)(4)
(b)(4) we will be unable to use analgesics after irradiation since they have effects on (b)(4) function that would interfere with the interpretation of our results (b)(4)
(b)(4)
(b)(4) In experiments where tissue collection is needed, animals will be euthanized with pentobarbitol prior to sample collection as described elsewhere.

V.4.2. Prolonged Restraint:
No prolonged restraint is required for (b)(4) irradiation. Whole body (b)(4) is non-invasive and unrestrained. (b)(4) irradiation will require restraint in designed jigs for 20-40 min to receive X-ray exposure (b)(4) animals will be anesthetized during this period (see Anesthesia above) and tails will be taped to one side with surgical tape. The jigs for use during (b)(4) irradiation were examined and approved by the AFRRI Veterinary staff. An image of the jig is now provided (see attached). Under the training protocol at AFRRI in conjunction with the AFRRI veterinary staff, we found that in female CBA mice, ~12 weeks old, i.p. injection of 150 mg/kg ketamine plus 18 mg/kg xylazine results in 60-80 min anesthesia (25 G needle) with no morbidity or mortality (b)(4) We propose to use this range of concentration of anesthesia, together with a heating pad to keep mice warm during the period of anesthesia. Standard i.p. injection methods are used for injection of the anesthesia, as recommended and approved by the AFRRI veterinary staff and for which all laboratory personnel have received training at AFRRI. AFFRI Veterinary staff have provided training and supervision for the placement of anesthetized animals in the approved jigs for irradiation.

V.4.3. Surgery:

V.4.3.1. Pre-surgical Provisions: N/A

V.4.3.2. Procedure: N/A

V.4.3.3. Post-surgical Provisions: N/A

V.4.3.4. Location: N/A

V.4.3.5. Surgeon: N/A

V.4.3.6. Multiple Major Survival Operative Procedures:

V.4.3.6.1. Procedures: N/A

V.4.3.6.2. Scientific Justification: N/A

V.4.4. Animal Manipulations: N/A

V.4.4.1. Injections:
Intra-peritoneal injections of pentobarbital for euthanasia 0.1-0.2 ml/mouse Fatal Plus (39-78 mg pentobarbital/mouse), will be performed with a 25 G needle. I.p. injection of 150 mg/kg ketamine plus 18 mg/kg xylazine will be done using a 25 G needle. This has been extensively examined by the AFRRI Veterinary staff and shown to effectively produce non-lethal anesthesia (b)(4)

V.4.4.1.1. Pharmaceutical Grade Drugs
(b)(4)

V.4.4.1.2. Non-Pharmaceutical Grade Drugs
(b)(4)

Endotoxin in the drugs will be measured by the PI, or information from the company will be provided prior to administration of drugs to the animals.

V.4.4.2. Biosamples:
All biosamples will be taken after euthanasia. (b)(4) (b)(4) or analysis will removed *en bloc*. Intestinal tissue will be taken in smaller amounts (the first segment of the small intestine). All other tissues will be available to other researchers for tissue sharing.

V.4.4.3. Adjuvants: N/A

V.4.4.4. Monoclonal Antibody (MAbs) Production: N/A

V.4.4.5. Animal Identification:
All cages will have cage cards identifying the treatment groups for each experiment. For experiments 2 and 3, each animal within a cage will receive ear punches for individual identification (1 = no cut; 2 = right ear upper corner; 3 = left ear upper corner; 4 = both ears).

V.4.4.6. Behavioral Studies: N/A

V.4.4.7. Other Procedures:

(b)(4) **Irradiation**

The methodology for (b)(4) irradiation of mice including approval of holding jigs and development of anesthesia was developed in conjunction with the AFRRI Veterinary Staff. (b)(4) irradiation will be performed using the RS2000 irradiator (b)(6) Thirty minutes prior to irradiation, the RS2000 irradiator and lead shield will be decontaminated thoroughly with MB10.

Mice will be anesthetized by injection in the USUHS LAM facility. Anesthetized mice will be placed in ventilated Lucite jigs, which restrain the animals to prevent lateral or vertical movement. Tails will be taped to prevent any forward motion of animals. Mice will be irradiated at (b)(4) irradiation. The temperature in room where the mice will be irradiated will be measured, and if necessary a space heater will be used to increase the temperature. Following radiation exposure, mice will be immediately returned to the LAM and allowed to recover from anesthesia under supervision with heating pads. Immediately upon recovery, animals will be returned to standard cages that house 4 animals per cage. Lucite jigs will be sanitized after each use.

(b)(4)

(b)(4) The animals will experience no restraint, no anesthesia, no drugs, or other manipulation during this time. Following the measurement, to be performed in the room in which they are housed, the animals will be returned to their original cages. Chambers will be sanitized after each use.

Ear punch
The ear punch will be soaked in alcohol to disinfect it before use and between animals. The device will be placed on the pinna of the ear (external ear) in a location where the mouse will be marked for identification. The punch will be pressed firmly to punch a circular hole through the ear, being careful not to rip the delicate membrane of the pinna. The ear will then be gently separated from the device. The ear punch will be cleaned and disinfected in alcohol before use in another mouse.

V.4.4.8. Tissue Sharing:

For most studies (b)(4) will be obtained. All other tissues will be available for tissue sharing with other investigators. Our laboratory has made extensive use of shared tissues for training and technique development for tissue. (b)(4)

V.4.5. Study Endpoint:

(b)(4)

(b)(4) Early endpoints will be used in the case of morbidity and morbundity. Specific health assessment criteria including rapid weight loss, ruffled fur, dried lacrimal fluid accumulated in the cul-de-sac of their eyes, are cool to the touch, decreased appetite, diarrhea, difficulty breathing or panting (b)(4) (b)(4) will used to determine early study endpoints for euthanasia. Following (b)(4) irradiation, mice may exhibit injuries from the (b)(4) irradiation during the first week postirradiation. Also, mice are expected to develop (b)(4) injury on days (b)(4) postirradiation. During the critical time periods (the first week postirradiation and (b)(4) days postirradiation), mice will be monitored by the PI or other members of the investigative team at least twice daily, early morning and late afternoon including weekends or holidays. Mice will be considered moribund when, in addition to showing some or all of the signs of morbidity, they exhibit labored

breathing plus either an inability to remain upright or are unmotivated to move. Morbid or moribund mice will be euthanized.

V.4.6. Euthanasia:
Animals will be euthanized at the stated endpoints of the experiments by i.p. injection of ml/mouse Fatal Plus. PHS policy is intraperitoneal injection of at least 200 mg/kg sodium pentobarbital euthanasia solution; Fatal Plus: 390 mg pentobarbitol/1 ml
1 ml/390 ml x 0.02 kg/mouse x 200 mg/1 kg = 0.01-0.02
IP will be performed using a 25 G needle. (Please note that Euthasol cannot be used as additives have effects on lung tissues. We do have Fatal Plus for these experiments.)
Euthanasia will be confirmed by cervical dislocation. Animals which appear to be experiencing pain or distress as a result of radiation exposure or are found moribund will also be euthanized by pentobarbitol and necropsied. At the end of experiments, unused animals will be transferred to other protocols or euthanized by exposure to 100% CO_2 from a compressed gas cylinder in accordance with the current American Veterinary Medical Association (AVMA) Guidelines for Euthanasia. Exsanguination, cervical dislocation, and/or pneumothorax will be used to ensure euthanasia.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol. Food and water and Rodent Diet will be available ad libitum. The 12:12 hr (lights off at 6 pm) room light cycle is fine for all the studies.

V.5.1.1. Study Room: will be performed in the
Radiation Building (b)(6) Room Number (b)(6)

Euthanasia Building (b)(6) Room number (b)(6)

V.5.1.2. Special Husbandry Provisions:

Food Restriction: Yes _____ No x

Fluid Restriction: NOTE: (b)(4) **treated water will be provided.** No x

V.5.1.3. Exceptions: None

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care:
Experimental animals will be observed at least twice a day by one of the study investigators or technicians. VSD personnel will also monitor the animals twice a day during their rounds. As described in another section (study endpoint) morbid animals will be monitored at least twice daily, morning and afternoon. The experimental design does not contemplate supportive therapy. The justification for not providing supportive

care has been described in the study end point section as well as in the pain category section. Criteria to be used for health evaluation while the animals are on study include: 20% weight loss (mice will be weighed every other day—based on (b)(0) with (b)(4) irradiation in which animals can recover from ~25% weight loss (b)(4) (b)(4) ruffled fur, dehydration, decreased activity, and hunched body position, dyspnea, or panting. Animals exhibiting these signs may be euthanized, and considered to be at the study endpoint. Increased monitoring of animals will begin on day (b)(4) through the end of the experiment, based on our previous data that indicated that mortality from (b)(4) irradiation occurs between days (b)(4) postirradiation.

V.5.2.2. Emergency Veterinary Medical Care:
All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: All animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents; balls, toys and food enrichment treats for large animal species.
V.5.3.2. Enrichment Restrictions: none

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

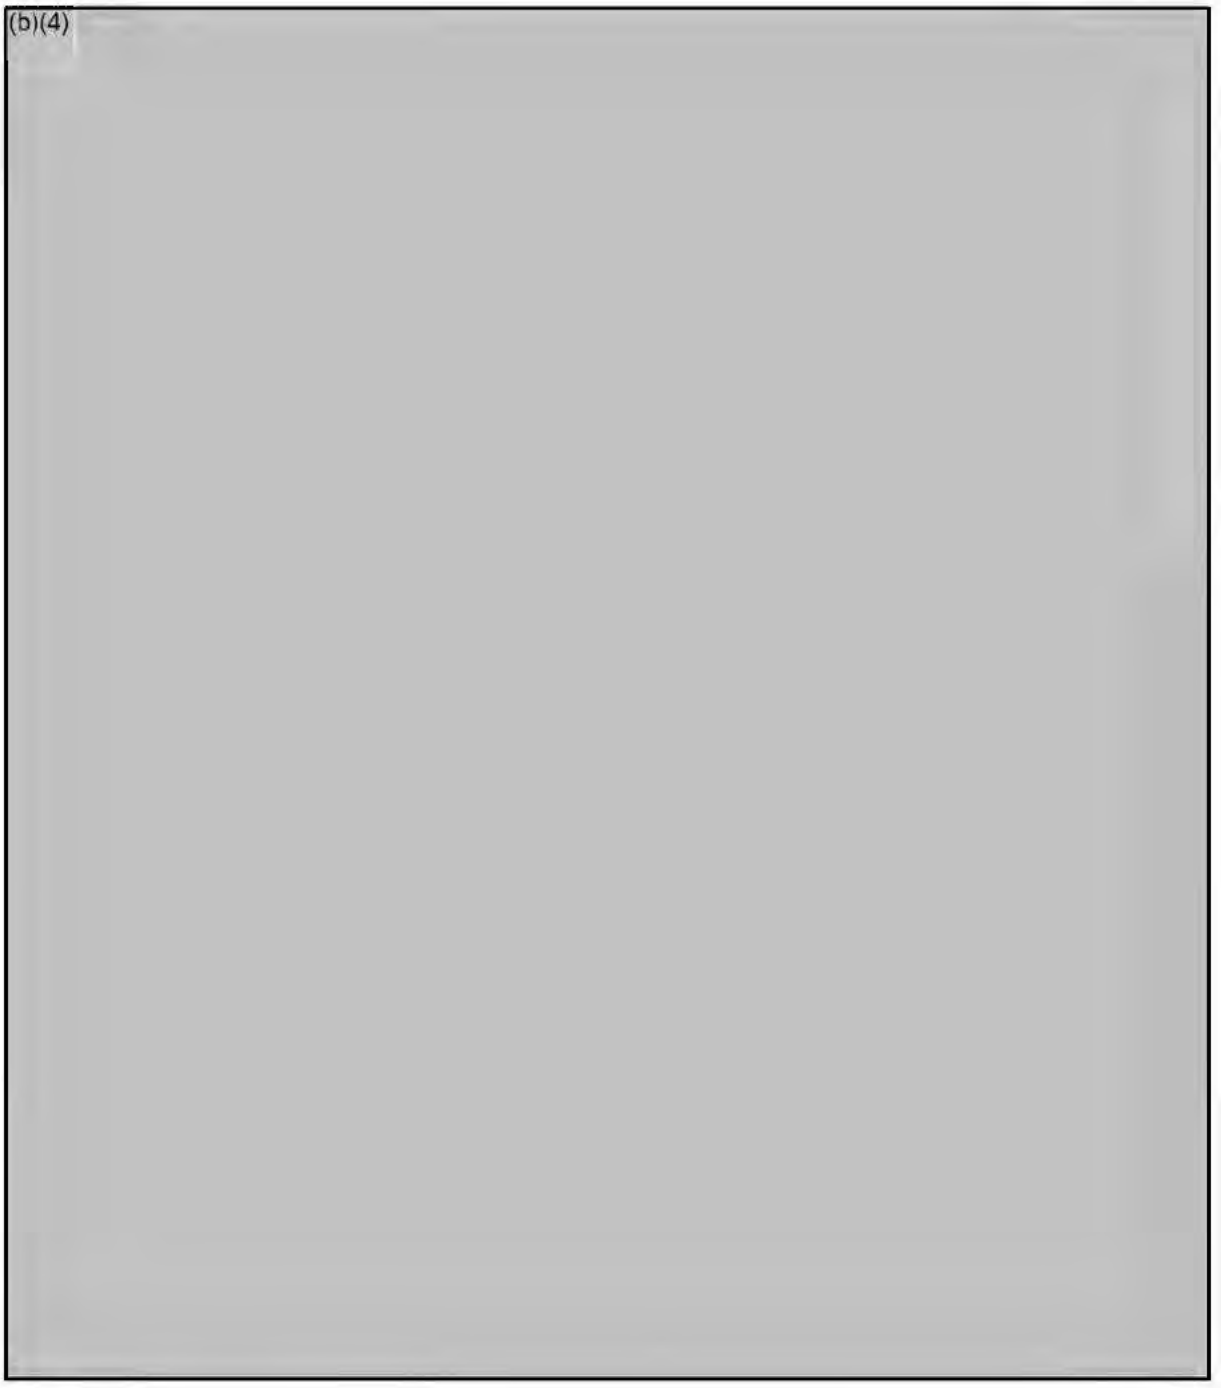
STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
Ear punch, irradiation, anesthesia, euthanasia	(b)(6)	8+ years	(b)(6)
Ear punch, irradiation, anesthesia, euthanasia		6 years	

VII. BIOHAZARDS/SAFETY: None

VIII. ENCLOSURES: Images of jigs, (b)(4) MSDS, manuscripts (b)(4) (b)(4)

References:



(b)(4)

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

H. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely, "Responsibility" for implementing animal use alternatives where feasible and conducting humane and lawful research.

I. Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL or WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

X. PROTOCOL ABSTRACT:

The terrorist attack of September 11, 2001 against the United States has increased the concern that terrorists may acquire and use radioactive sources (e.g. dirty radioactive bombs) to expose military and civilian populations to ionizing radiation. However, despite this concern, there are currently no FDA approved drugs that can be used for the general population to prevent death that is likely to result from exposure to ionizing radiation. (b)(4) irradiation in humans can result in both (b)(4) injuries. However, because rodents are more resistant to (b)(4) injuries than humans, there is currently no murine model that has been developed to study both acute and delayed radiation injuries in the same animal.

MEMORANDUM FOR DR. (b)(6)

SUBJECT: IACUC Approval of Protocol – Initial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on February 25, 2013:

Animal Protocol Title: "Murine Model for (b)(4) Radiation Injuries (Mus Musculus)"

USUHS Protocol Number: (b)(6)

Expiration Date: February 24, 2016

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. NON-TECHNICAL SYNOPSIS:

The terrorist attack of September 11, 2001 against the United States has increased the concern that terrorists may acquire and use radioactive sources (e.g. dirty radioactive bombs) to expose military and civilian populations to ionizing radiation. However, despite this concern, there are currently no FDA approved drugs that can be used for the general population to prevent death that is likely to result from exposure to ionizing radiation. (b)(4) irradiation in humans can result in (b)(4) injuries. However, because rodents are more resistant to (b)(4) injuries than humans, there is currently no murine model that has been developed to study both (b)(4) radiation injuries in the same animal.

(b)(4),(b)(6)

II. BACKGROUND:

II.1. Background:

The acute toxic effects of exposure to high doses of ionizing radiation in humans have been shown to occur due to two sequential effects: first the ablation of immune cells, resulting in loss of immune function and increasing likelihood of pathogenic infection (b)(4) and subsequently the loss of epithelial progenitor cells of the gastrointestinal (GI) crypt (b)(4) (b)(4) Both of these events have been shown to be due to the loss of fast-growing pluripotent and/or progenitor cell types. The time course of the acute injuries correlates with the life span of the mature cell types of the tissue, which are not replaced because of radiation damage to the adult pluripotent cells and adult stem cells. There is currently no FDA approved prophylactic or treatment for prevention of acute radiation injuries following high-dose (b)(4) radiation exposure.

In some cases supportive measures can be used to treat acute radiation syndrome, and survival from (b)(4) radiation exposure is now possible (b)(4) This results in current efforts to mitigate or treat later stage effects of ionizing radiation exposure. (b)(4)

(b)(4)

In humans, death from radiation (b)(4) can occur following survival from (b)(4) Cumulative evidence from a number of laboratories, including our own, shows that there is a threshold dose of radiation of (b)(4) to induce sufficient (b)(4) for the (b)(4) phases to occur in mice; below these doses, no permanent injury manifests, although some short-term effects are observed (b)(4) However, in humans, there is currently no accepted protocol for preventative treatment of radiation-induced (b)(4) and morbiditiy as high as 50% is associated with each phase (b)(4) (b)(4) injuries from radiation is considered to be a serious problem in the field for the development of agents to prevent these radiation injuries.

(b)(4) **as a radioprotectant:** The biochemical properties of the isoflavones and the investigation of (b)(4) as a protectant against gamma radiation-induced lethality have been investigated by (b)(4),(b)(6) (b)(4) A single i.p. dose of (b)(4) administered - hr prior to a lethal dose of (b)(4) (b)(4) radiation resulted in -day survival rates of 65%, 91%, and 85% respectively. Mice receiving saline or PEG vehicle alone survived at 8% and 15% respectively. All doses of (b)(4) protected mice significantly ($p < 0.001$) better than vehicle or saline control groups.

The behavioral toxicity was investigated for male mice receiving a single i.p. injection (0.1 ml) of saline, PEG vehicle, or (b)(4) Locomotor activity (total distance traveled), grip strength and motor coordination were evaluated on days (b)(4) post-injection (b)(4) and body weight was measured over days. On day (b)(4)

(b)(4) tissues from the testes, liver, adrenal gland, mesenteric lymph node, spleen, and bone marrow of the femur and sternum were collected, fixed in buffered formalin, paraffin embedded, sectioned, and stained by hematoxylin and eosin. The results indicated that there were no significant effects of (b)(4) or vehicle on locomotor activity, grip strength, motor coordination, or body weight, compared to the saline-treated control group. In addition, no gross morphological changes or histopathological alterations were observed (b)(4)

(b)(4) **as a radioprotectant and an antifibrotic agent:** (b)(4) (b)(4) and its proteolytic product (b)(4) are believed to have their primary biological functions in blood pressure homeostasis. However, (b)(4) have been demonstrated to be upregulated in fibrotic tissues. Inhibition of (b)(4) or blockade of the (b)(4) receptors on cells has been shown to ameliorate drug-induced (b)(4) in murine and rat models for (b)(4) (b)(4) receptor antagonists also prevent cardiac remodeling following ischaemia/reperfusion in rat models of cardiac remodeling diseases (b)(4) Several studies have also shown that inhibition of (b)(4) (b)(4) signaling mitigates radiation-induced injuries, including to the heart and (b)(4) (b)(4) One study shows that the (b)(4) reduces acute damage to the jejunal mucosa in mice following exposure to (b)(4) This work examined only initial tissue injury and did not extend findings past (b)(4) days, and did not examine mortality. A second study found a reduction in (b)(4) in rats exposed to (b)(4) (b)(4) radiation (b)(4)

Preliminary Studies:

(b)(4)

(b)(4)

Summary of other publications:

(b)(4)

(b)(4)

III. OBJECTIVE\HYPOTHESIS:

Our objective is to: 1) continue development of a murine model for both the (b)(4) (b)(4) injuries; and 2) examine protective effects of (b)(4) against these two injuries in the developed mode (b)(4)

(b)(4)

IV. MILITARY RELEVANCE:

The Department of Defense is prepared to execute military missions within radiation environments, to manage radiation crises associated with terrorist activities, and to manage consequences in the event of nuclear weapons detonation. Recent studies indicate that there is an increasing risk of exposure to ionizing radiation (IR) to military personnel due to increasing terrorist activities, including potential use of stolen nuclear weapons or dispersal of radioactive material in a "dirty bomb" (b)(4) Because of potential exposure of military personnel

to radiation, the DoD is committed to protect members of the Armed Services from the adverse health effects of ionizing radiation. High dose IR causes short term, acute injuries including hematopoetic and GI syndromes. However, both high and low dose IR (as may result from a radiation dispersal device) can cause (b)(4) as demonstrated by Japanese atomic bomb survivor data as well as accidental exposures to Russian populations (b)(4) (b)(4) While early effects of radiation injury now have treatment/ prophylactic strategies, the delayed effects currently have no treatment. Lack of treatment for late effects of radiation, including (b)(4) will likely lead to delayed morbidity and mortality for personnel exposed to IR.

The Department of Defense (DoD) Chemical and Biological Defense Program 2007 Annual Report to Congress, Chapter 2.7.6 Medical Radiological Defense, addresses the requirements for the development of radioprotectants. This priority is outlined for the development of protectants for both acute and delayed radiation injuries, with an emphasis on (b)(4) (b)(4) According to this report, the mitigation of (b)(4) is a major research thrust area. (b)(4)

(b)(4)

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures:

The goal of this project is to investigate the protective effects and mechanisms of (b)(4) (b)(4) treatment for radiation-induced (b)(4) injuries.

(b)(4)

(b)(4) Mice will be exposed to both (b)(4) (b)(4) irradiation to induce the total radiation doses required to induce both

(b)(4) injuries, to simulate the injuries that occur in humans as a result of (b)(4) irradiation.

(b)(4) irradiation will be performed in the (b)(6) using the standard Lucite holders for irradiation. Sham irradiation will be performed by placing the mice in Lucite holders for equal time periods without irradiation. These experiments will involve short end points (less than (b)(4) days) for examination of five criteria. Survival at (b)(4) days will be used to evaluate the (b)(4) **A protocol for (b)(4) irradiation of mice for the proposed experiments in this protocol was approved by the AFRRI IACUC (b)(6) We are awaiting approval for a modification of this protocol to move the mice to USUHS for (b)(4) irradiation and housing thereafter.**

(b)(4) radiation used to induced (b)(4) irradiation will be performed using the RS2000 irradiator (b)(6) Thirty minutes prior to irradiation, the RS2000 irradiator and lead shield will be decontaminated thoroughly with MB10. Sham irradiation will be performed by placing the mice in jigs for equal lengths of time with no irradiation.

V.1.1. Experiment 1:

Experiment 1 Final development of a murine model that incorporates both (b)(4) (b)(4) radiation injuries. (b)(4)

Rationale: (b)(4)

(b)(4)

This experiment, combining (b)(4) doses to achieve (b)(4) dose, will also be used to determine that we do not encounter a significant effect from (b)(4) the dose. To minimize a possible (b)(4) effect, we will keep the interval between radiation exposures as low as possible, (b)(4) min.

To complete our development of the model, we will use five doses of (b)(4) irradiation between (b)(4) Groups will be: 1) (b)(4) irradiation only; and 2) (b)(4) irradiation + (b)(4) irradiation. Time points will be: survival at (b)(4) days postirradiation (b)(4) (b)(4) irradiation will be given to equal a total exposure of (b)(4) (b)(4) Mice will first be exposed to (b)(4) irradiation in the (b)(6) facility (b)(4) then anesthetized and exposed to X-ray irradiation of the (b)(4) in the RS2000 at USU, dose rate (b)(4)

Control mice will be anesthetized and placed in holders to provide a sham for (b)(4) irradiation. The experiment will be repeated because it is a generally accepted principle of the scientific method that experiments must be repeated to evaluate a hypothesis.

(b)(4) Mice needed for experiment: group to reach statistical significance for survival.
(b)(4) mice/group) x (6 conditions) x (1 time point) = animals.
The experiment will be repeated 1 time to confirm findings (total animals). (b)(4)

(b)(4) Endpoint: The endpoint will be days. We will measure survival at both (b)(4) days for the study. Early time points will be taken if any animal exhibits signs or symptoms of morbidity or moribundity (score of >11 as described in the pain score sheet). Specific health assessment criteria including rapid weight loss, ruffled fur, dried lacrimal fluid accumulated in the cul-de-sac of their eyes, are cool to the touch, decreased appetite, diarrhea, difficulty breathing or panting will used to determine early study endpoints for euthanasia (See section V.4.5). Such animals will be euthanized at the time of observation.

Table 1: Schematic for Experiment 1

(b)(4)

V.1.2. Experiment 2

Experiment 2 Determine the effect of (b)(4) on survival following (b)(4) (b)(4) irradiation. (b)(4)

Rationale: Experiment 1 will be used to determine overlapping effects of (b)(4) irradiation on (b)(4) injury by (b)(4) irradiation. This section objective will be to determine the effects and the mechanisms of (b)(4) for the prevention of (b)(4) induced by exposure to (b)(4) irradiation. The approach will be to use murine model of both (b)(4) radiation injuries developed in Experiment 1. We will assess the mechanisms of protection using (b)(4) cellular, histological, molecular, and biochemical markers. The rationale for undertaking this research is that once the mechanisms of (b)(4) prevention of (b)(4) are known, these may help designing therapeutic strategies against radiation-induced (b)(4) injury.

PEG-400 (0.1 ml/mouse) vehicle only or (b)(4) will be administered by a single (b)(4)
(b)(4) (b)(4) i.p. injection h before radiation exposure (b)(4) will be provided in the drinking water at (b)(4) to give a dosage of (b)(4) per day for the duration of the experiment starting on day 0. Our preliminary findings indicate that there are no adverse effects due to long term use of (b)(4) We have used this drug in the water to treat mice for up to days with no findings of (b)(4) adverse effects. Mice will be exposed to (b)(4) using (b)(4) dose rate. Subsequently, mice will be anesthetized and exposed to (b)(4) x-ray irradiation to give exposures equal to (b)(4) irradiation, (b)(4) dose rate. Treatment groups will be: 1) PEG; 2) PEG + (b)(4) 3) (b)(4) and 4) (b)(4) water will be provided for all

mice to reduce opportunistic infections that occur following (b)(4) irradiation. For mice to be treated with (b)(4) will be provided in (b)(4) water. (b)(4) water bottles and (b)(4) water bottles will be prepared by the (b)(6) laboratory, and will be replaced 2X per week in accordance with LAM protocols. Extra water bottles will be prepared in advance and they will be available in the room where the animals are housed in case they are needed to replace a leaking water bottle.

Mice will be monitored monthly using non-invasive, unrestrained (b)(4) to determine (b)(4) For these studies (b)(4) mice are required per radiation dose. The time point for (b)(4) is (b)(4) days, based on data from previous studies by others (b)(4) The time point for (b)(4) is (b)(4) days, based on previous studies by others (b)(4) Although breathing will be monitored, (b)(4) results will not be used as a sole indicator for euthanasia. (See section V.4.6).

The experiment will be repeated because it is a generally accepted principle of the scientific method that experiments must be repeated to evaluate a hypothesis.

(b)(4) (b)(4) mice per group) x (4 treatment groups) x (1 time point) x (3 radiation levels) = (b)(4) (b)(4)
(b)(4) mice/experiment) x (2 experiments) = mice

Endpoints. The final endpoint for the experiment is days. Mice displaying obvious dyspnea, (b)(4) extreme lethargy, or other markers of morbundity as described in the pain score sheet (score of >11), and which appear to be in distress will be euthanized. Specific health assessment criteria including rapid weight loss, ruffled fur, dried lacrimal fluid accumulated in the cul-de-sac of their eyes, are cool to the touch, decreased appetite, diarrhea, difficulty breathing or panting will used to determine early study endpoints for euthanasia (See section V.4.5). (b)(4)
(b)(4)

Table 2. Schematic for Experiments 2 and 3.

(b)(4)

V.2. Data Analysis:

Mean with standard error, or percentage will be reported if applicable. A significance level is set at 5% for each test. All statistical tests are two-sided. A statistical software, SAS will be used for statistical analyses.

Experiments 1 and 2. Log-Rank test will be used for comparison among groups. If significant, Fisher's exact test will be used to detect significant differences across the groups in survival (b)(4) rates at day Kaplan Meier curves will be displayed. N = mice per group will have 80% (b)(4) power in detecting a significant difference between two groups if any, given type I error of 5% where the treatment group survival rate is at least 68%, compared to a control group survival rate of 20%. Similar statements would apply, if the treatment group survival rates are at least 83%, 78%, or 73%, compared to vehicle group survival rates of 35%, 30%, and 25%, respectively (b)(4)

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered:

For the last 8 years, we have utilized primary cell culture systems to examine anti-apoptotic mechanisms; however, we must determine whether our culture findings are relevant in whole animals. We will continue to use primary cell culture whenever possible to avoid unnecessary use of animals. We have also considered computer models as alternatives to animals. However, this alternative also lacks the knowledge base and complexity needed to evaluate radioprotective and radiotherapeutic agents.

V.3.2. Animal Model and Species Justification:

Tissue culture conditions cannot fully substitute for the complexities of whole organisms in response to radiation injury. Such injury involves the interactions between the hematopoietic system and other organ systems. In order to develop viable treatments for humans, we find that our research must be conducted in whole animals.

(b)(4),(b)(6) the mouse as the best species to use for radiation protection and radiotherapy protocols. 1) mice provide the least sentient species available whose response to radiation has been clearly identified, with physiological responses to radiation and radioprotectants that are similar to human physiology, 2) extensive literature is available on responses of mice to radiation and countermeasures, 3) more reagents are available to study the relevant cell types and molecules in mice than in any other species except humans, and the availability of transgenic and knockout mice make this model extremely attractive for further research into molecular mechanisms, and 4) (b)(6) (b)(6) have extensive experience with this model in radiation injury and radioprotection research (b)(6)

V.3.3. Laboratory Animals

V.3.3.1.	**Genus & Species:**	*Mus musculus*
V.3.3.2.	**Strain/Stock:**	CBA
V.3.3.3.	**Source/Vendor:**	(b)(4)
V.3.3.4.	**Age:**	10-14 weeks
V.3.3.5.	**Weight:**	Normal adult weight range for this strain: 17-21 g.
V.3.3.6.	**Sex:**	Female. Only females will be used in this study for the following reasons: 1) we have so far utilized female mice to lay the foundation of our studies for radiation-induced (b)(4) injuries; 2) because of long housing periods, it is advantageous to use female mice that are less aggressive toward each other.
V.3.3.7.	**Special Considerations:**	Commercially procured animals must be adventitious disease free. Mice- Pathogen-free, including *Pseudomonas aeruginosa*, and Pasteurella. All mice need to be free of the following agents: Sendai, Pneumonia Virus of Mice (PVM), Reovirus-3 (Reo 3), Mouse Adenovirus (MAD-1, MAD-2), Mouse Cytomegalovirus Virus (MCMV), Ectromelia, K virus,

Lymphocytic Choriomeningitis Virus (LCM), Epidemic Diarrhea of Infant Mice (EDIM), Hantaan virus, Rotavirus, Mouse Parvovirus (MPV), Polyoma Virus, Mouse Minute Virus (MMV), Mouse Thymic Virus (MTV), Theiler's Mouse Encephalomyelitis Virus (TMEV/GDVII), *Encephalitozoon cuniculi*, CAR bacillus, *Helicobacter* spp. *Mycoplasma pulmonis*, and *Clostridium piliforme*. Endoparasite- and ectoparasite-free

V.3.4. Number of Animals Required (by Species):

V.3.5. Refinement, Reduction, Replacement (3 Rs):

V.3.5.1. Refinement: Animals demonstrating moribundity due to radiation exposure (b)(4) will be considered to have arrived at the study endpoint and will be immediately euthanized (See sections V.4.5 Study Endpoint and V.4.6 Euthanasia) (b)(4) will likely minimize pain and distress, while (b)(4) has been shown in studies of chemotherapy agents to function as a repair and (b)(4) factor.

Ketamine/xylazine anesthesia will be used during X-ray irradiation to prevent stress from the time the mice are placed in restraint. Under the training protocol at AFRRI inconjunction with the AFFRI veterinary staff, we found that in female C57BL/6J mice, ~12 weeks old, i.p. injection of 150 mg/kg ketamine plus 18 mg/kg xylazine results in 60-80 min anesthesia with no morbidity or mortality (b)(4) We propose to use this range of concentration of anesthetics, together with a heating pad to keep mice warm during the period of recovery from anesthesia. The temperature in room where the mice will be irradiated will be measured, and if necessary a space heater will be used to increase the temperature. Standard intraperitoneal injection methods are used for injection of the anesthesia, as recommended and approved by the AFRRI veterinary staff and for which all laboratory personnel have received training at AFRRI.

V.3.5.2. Reduction: Whenever possible, control groups will be shared between experimental groups for our experiments. Tissues will be collected for multiple assays from the same animals further reducing the total number of animals needed. At every stage of the research, planned experiments will be reevaluated, in an attempt to reduce the numbers of experiments and eliminate repeats of experiments where statistical significance has already been obtained. We also plan to take as many tissues as we can reasonably analyze for experiments examining (b)(4)

V.3.5.3. Replacement: At this time, it is not feasible to use non-animal systems in place of animal models to address the research questions in this protocol.

V.4. Technical Methods:

V.4.1. Pain / Distress Assessment:

V.4.1.1. APHIS Form 7023 Information:

V.4.1.1.1. Number of Animals: (b)(4)

V.4.1.1.1.1. Column C: (b)(4)

V.4.1.1.1.2. Column D: (b)(4)

V.4.1.1.1.3. Column E:

V.4.1.2. Pain Relief / Prevention:

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization:
We will be unable to use analgesics since they have effects on (b)(4) function that would interfere with the interpretation of our results (b)(4) (b)(4) Some sedatives have been reported to contribute to postoperative (b)(4) which likely reduce some functions of radiation. Additionally, it has been shown that the biometabolism of analgesics can induce protein oxidation, which would interfere with sample analysis (b)(4)

An anesthesia protocol has been developed for use during the X-ray irradiation. Ketamine will be used with xylazine for longer anesthesia in mice to be place in restraints for (b)(4) irradiation. Under the training protocol at AFRRI in conjunction with the AFRRI veterinary staff, we found that in female CBA mice, ~12 weeks old,i.p. injection of 150 mg/kg ketamine plus 18 mg/kg xylazine results in 60-80 min anesthesia (25 G needle) with no morbidity or mortality (b)(4) We propose to use this range of concentration of anesthesia, together with a heating pad to keep mice warm during the period of anesthesia. Standard i.p. injection methods are used for injection of the anesthesia, as recommended and approved by the AFRRI veterinary staff and for which all laboratory personnel have received training at AFRRI.

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions:
Animals will be housed and cared for as described in Section V.5. Veterinary Care both before and after dose administrations and irradiation procedures.

V.4.1.2.3. Paralytics: N/A

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures:

V.4.1.3.1. Sources Searched: DoD Bioedical Research Data Base (BRD), REPORTER, PubMED

V.4.1.3.2. Date of Search: 1/7/13

V.4.1.3.3. Period of Search: Search covered published manuscripts from ~1965-present. (BRD search included all available years 1998 -2012).

V.4.1.3.4. Key Words of Search: Pain, analgesia, anesthesia, mice, radiation, ionizing radiation, humane, (b)(4)

V.4.1.3.5. Results of Search:
The literature search revealed that, at present, there are no alternative procedures for irradiation because its effects cannot be otherwise duplicated. In some cases radiation has been demonstrated to reduce pain in laboratory mice (b)(4) and has been in humans reported to alleviate cancer related bone pain (b)(4) (b)(4) A recent report showed that administration of botulinum toxin A was effective for reduction of pain and muscle spasms after clinical radiation for treatment of tumors (b)(4) (b)(4) Application of natural honey 20 min prior to radiation exposure was also shown to reduce mucositis with associated pain in humans following head/neck

radiotherapy (b)(4) it has not been determined whether honey acts as a local radioprotectant. Spinal cord stimulation has also been reported in humans to alleviate pain resulting from radiotherapy (b)(4) however, this method would not be practical for use in mice because of the extensive spinal cord manipulation required. Human administration of morphine also relieves pain (b)(4) but again this would not be practical for mice in our experiments because of side effects of the drug. In humans, exposure to (b)(4) irradiation may induce vomiting and diarrhea, causing pain and distress. However, mice are not susceptible to vomiting. The animals that will be administered (b)(4) will likely receive pain relief as phytoestrogens have been reported to reduce neuropathic pain in rodents (b)(4) preliminary results also indicate that (b)(4) ameliorates acute radiation-induced injuries (b)(4)

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification:

Anesthesia will be used before (b)(4) irradiation to avoid stress from restraint. (b)(4) (b)(4) (b)(4) we will be unable to use analgesics after irradiation since they have effects on (b)(4) function that would interfere with the interpretation of our results (b)(4) (b)(4) (b)(4) In experiments where tissue collection is needed, animals will be euthanized with pentobarbitol prior to sample collection as described elsewhere.

V.4.2. Prolonged Restraint:

(b)(4) irradiation will require restraint in designed jigs for 20-40 min to receive X-ray exposure (b)(4) animals will be anesthetized during this period (see Anesthesia above) and tails will be taped to one side with surgical tape. The jigs for use during (b)(4) irradiation were examined and approved by the AFRRI Veterinary staff. An image of the jig is now provided (see attached). Under the training protocol at AFRRI in conjunction with the AFRRI veterinary staff, we found that in female CBA mice, ~12 weeks old, i.p. injection of 150 mg/kg ketamine plus 18 mg/kg xylazine results in 60-80 min anesthesia (25 G needle) with no morbidity or mortality (b)(4) We propose to use this range of concentration of anesthesia, together with a heating pad to keep mice warm during the period of anesthesia. Standard i.p. injection methods are used for injection of the anesthesia, as recommended and approved by the AFRRI veterinary staff and for which all laboratory personnel have received training at AFRRI. AFFRI Veterinary staff have provided training and supervision for the placement of anesthetized animals in the approved jigs for irradiation.

V.4.3. Surgery:

V.4.3.1. Pre-surgical Provisions: N/A

V.4.3.2. Procedure: N/A

V.4.3.3. Post-surgical Provisions: N/A

V.4.3.4. Location: N/A

V.4.3.5. Surgeon: N/A

V.4.3.6. Multiple Major Survival Operative Procedures:

V.4.3.6.1. Procedures: N/A

V.4.3.6.2. Scientific Justification: N/A

V.4.4. Animal Manipulations: N/A

V.4.4.1. Injections:
Intra-peritoneal injections of pentobarbital for euthanasia 0.1-0.2 ml/mouse Fatal Plus (39-78 mg pentobarbital/mouse), will be performed with a 25 G needle. I.p. injection of 150 mg/kg ketamine plus 18 mg/kg xylazine will be done using a 25 G needle. This has been extensively examined by the AFRRI Veterinary staff and shown to effectively produce non-lethal anesthesia (b)(4) PEG-400 (0.1 ml/mouse) vehicle only or (b)(4) will be
(b)(4) administered by a single (b)(4) i.p. injection [redacted] before radiation exposure also with 25 G needles.

V.4.4.1.1. Pharmaceutical Grade Drugs

(b)(4)

V.4.4.1.2. Non-Pharmaceutical Grade Drugs

(b)(4)

Endotoxin in the drugs will be measured by the PI, or information from the company will be provided prior to administration of drugs to the animals. Concentrated PEG 400 has antibacterial activities, and solutions of PEG do not have bacterial contamination. (b)(4) will be handled under sterile conditions.

V.4.4.2. Biosamples:
All biosamples will be taken after euthanasia. (b)(4)
(b)(4) or analysis will removed *en bloc*. Intestinal tissue will be taken in smaller amounts (the first segment of the small intestine). All other tissues will be available to other researchers for tissue sharing.

V.4.4.3. Adjuvants: N/A

V.4.4.4. Monoclonal Antibody (MAbs) Production: N/A

V.4.4.5. Animal Identification:
All cages will have cage cards identifying the treatment groups for each experiment. For experiments 2 and 3, each animal within a cage will receive ear punches for individual identification (1 = no cut; 2 = right ear upper corner; 3 = left ear upper corner; 4 = both ears).

V.4.4.6. Behavioral Studies: N/A

V.4.4.7. Other Procedures:

(b)(4),(b)(6)

(b)(4) irradiation

The methodology for (b)(4) irradiation of mice including approval of holding jigs and development of anesthesia was developed in conjunction with the AFRRI Veterinary Staff. (b)(4) irradiation will be performed using the RS2000 irradiator (b)(6) Thirty minutes prior to irradiation, the RS2000 irradiator and lead shield will be decontaminated thoroughly with MB10.

Mice will be anesthetized by injection in the USUHS LAM facility. Anesthetized mice will be placed in ventilated Lucite jigs, which restrain the animals to prevent lateral or vertical movement. Tails will be taped to prevent any forward motion of animals. Mice will be irradiated at (b)(4) irradiation. The temperature in room where the mice will be irradiated will be measured, and if necessary a space heater will be used to increase the temperature. Following radiation exposure, mice will be immediately returned to the LAM and allowed to recover from anesthesia under supervision with heating pads. Immediately upon recovery, animals will be returned to standard cages that house 4 animals per cage. Lucite jigs will be sanitized after each use.

(b)(4)

(b)(4) The animals will experience no restraint, no anesthesia, no drugs, or other manipulation during this time. Following the measurement, to be performed in the room in which they are housed, the animals will be returned to their original cages. Chambers will be sanitized after each use.

Ear punch

The ear punch will be soaked in alcohol to disinfect it before use and between animals. The device will be placed on the pinna of the ear (external ear) in a location where the mouse will be marked for identification. The punch will be pressed firmly to punch a circular hole through the ear, being careful not to rip the delicate membrane of the pinna. The ear will then be gently separated from the device. The ear punch will be cleaned and disinfected in alcohol before use in another mouse.

V.4.4.8. Tissue Sharing:

For most studies (b)(4) will be obtained. All other tissues will be available for tissue sharing with other investigators. Our laboratory has made extensive use of shared tissues for training and technique development for tissue. (b)(4)

V.4.5. Study Endpoint:

(b)(4)

(b)(4) Early endpoints will be

used in the case of morbidity and morbundity. Specific health assessment criteria including rapid weight loss, ruffled fur, dried lacrimal fluid accumulated in the cul-de-sac of their eyes, are cool to the touch, decreased appetite, diarrhea, difficulty breathing or panting will used to determine early study endpoints for euthanasia. Following (b)(4) irradiation, mice may exhibit radiation injuries during the first week postirradiation. Also, mice are expected to develop (b)(4) postirradiation. During these critical time periods (b)(4) (b)(4) mice will be monitored by the PI or other members of the investigative team at least twice daily, early morning and late afternoon including weekends or holidays. Mice will be considered moribund when, in addition to showing some or all of the signs of morbidity, they exhibit labored breathing plus either an inability to remain upright or are unmotivated to move. Morbid or moribund mice will be euthanized.

V.4.6. Euthanasia:

Animals will be euthanized at the stated endpoints of the experiments by i.p. injection of ml/mouse Fatal Plus. PHS policy is intraperitoneal injection of at least 200 mg/kg sodium pentobarbital euthanasia solution; Fatal Plus: 390 mg pentobarbitol/1 ml

1 ml/390 ml x 0.02 kg/mouse x 200 mg/1 kg = 0.01-0.02

IP will be performed using a 25 G needle. (Please note that Euthasol cannot be used as additives have effects (b)(4) We do have Fatal Plus for these experiments.) Euthanasia will be confirmed by cervical dislocation. Animals which appear to be experiencing pain or distress as a result of radiation exposure or are found moribund will also be euthanized by pentobarbitol and necropsied. At the end of experiments, unused animals will be transferred to other protocols or euthanized by exposure to 100% CO_2 from a compressed gas cylinder in accordance with the current American Veterinary Medical Association (AVMA) Guidelines for Euthanasia. Exsanguination, cervical dislocation, and/or pneumothorax will be used to ensure euthanasia.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: After animals receive (b)(4) irradiation, they will remain at USUHS in a designated quarantine room, as specified by LAM veterinarians. Routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol. Food and acidified water and Rodent Diet will be available ad libitum. The 12:12 hr (lights off at 6 pm) room light cycle is fine for all the studies. Special caging is not needed; standard shoebox cages will be used. Acidified water to reduce infection will be provided for all cages. Autoclaved bedding and food will be used for all cages.

V.5.1.1. Study Room: will be performed in the

Radiation Building (b)(6) Room Number (b)(6)

Euthanasia Building (b)(6) Room number (b)(6)

V.5.1.2. Special Husbandry Provisions:

Food Restriction: Yes _____ No x
Not sterilized

Fluid Restriction: NOTE: (b)(4) No x
water and (b)(4)
(b)(4) treated
water will be
provided.

V.5.1.3. **Exceptions**: None

V.5.2. **Veterinary Medical Care**:

V.5.2.1. **Routine Veterinary Medical Care**:
Experimental animals will be observed at least twice a day by one of the study investigators or technicians. VSD personnel will also monitor the animals twice a day during their rounds. As described in another section (study endpoint) morbid animals will be monitored at least twice daily, morning and afternoon. The experimental design does not contemplate supportive therapy. The justification for not providing supportive care has been described in the study end point section as well as in the pain category section. Criteria to be used for health evaluation while the animals are on study include: 20% weight loss (mice will be weighed every other day—based on our experience with (b)(4) irradiation in which animals can recover from ~25% weight loss (b)(4) (b)(4) ruffled fur, dehydration, decreased activity, and hunched body position, dyspnea, or panting. Animals exhibiting these signs may be euthanized, and considered to be at the study endpoint. Increased monitoring of animals will begin on (b)(4) through the end of the experiment, based on our previous data that indicated that mortality from (b)(4) injury occurs mostly between days (b)(4) postirradiation and from (b)(4) irradiation occurs between days (b)(4) postirradiation.

V.5.2.2. **Emergency Veterinary Medical Care**:
All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays.

V.5.3. **Environmental Enrichment**:

V.5.3.1. **Enrichment Strategy**: All animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents; balls, toys and food enrichment treats for large animal species.
V.5.3.2. **Enrichment Restrictions**: none

VI. **STUDY PERSONNEL QUALIFICATIONS AND TRAINING**:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or	Name of person	Qualifications of person	Specific training in this

procedure (e.g., tail vein injections, euthanasia)	performing activity	performing activity (e.g., research technician, 2 yrs experience)	activity or procedure (e.g., rodent handling class, 1999)

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User

(b)(6) _____ Feb 5 2013
Date

G. Training: The following personnel will attend the next USUHS Investigator/Animal User Training Course:

_____ _____
_____ _____

H. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely, "Responsibility" for implementing animal use alternatives where feasible and conducting humane and lawful research.

(b)(6) _____ Feb 5 2013
Prin Date

I. Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL or WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

X. PROTOCOL ABSTRACT:

The terrorist attack of September 11, 2001 against the United States has increased the concern that terrorists may acquire and use radioactive sources (e.g. dirty radioactive bombs) to expose military and civilian populations to ionizing radiation. However, despite this concern, there are currently no FDA approved drugs that can be used for the general population to prevent death that is likely to result from exposure to ionizing radiation. (b)(4) irradiation in humans can result in (b)(4) injuries. However, because rodents are more resistant to (b)(4) injuries than humans, there is currently no murine model that has been developed to study both (b)(4) radiation injuries in the same animal.

February 21, 2014

MEMORANDUM FOR DR. (b)(6)

SUBJECT: IACUC Approval of Protocol – Initial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on February 21, 2014:

Animal Protocol Title: (b)(4) Protection from Radiation-Induced (b)(4) (b)(4) Injuries in a Murine Model (Mus Musculus)"

USUHS Protocol Number: (b)(6)

Expiration Date: February 20, 2017

Supporting Grant(s) Number: TBD

Name of Principal Investigator: Dr (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

USUHS Form 3206- Animal Study Proposal Form Instructions

USUHS / DOD – SPONSORED ANIMAL RESEARCH PROPOSALS MUST USE THIS STANDARDIZED FORMAT

Reference DOD Directive 3216.1 & USUHS Instruction 3203

****

Specific information requested in the following animal-use protocol template is a result of requirements of the Animal Welfare Act regulations (AWAR), the Guide for the Care and Use of Laboratory Animals, and other applicable Federal regulations and DOD directives.

****

This document is intended to be an aid in the preparation of a USUHS DOD – sponsored animal use proposal. The instructions and written explanations provided for individual paragraphs (ref. animal-use protocol template in AR 40-33 / USUHSINST 3203, Appendix C) are coded as hidden text. To see the instructions and examples for each section, select the "**Show/Hide ¶**" button on your tool bar. To print the hidden text, select "Print" on the drop down file menu. Under the "Options" button, select "Hidden text" under the "Include with document" section. Use of a word processor makes completion of this template a "fill-in-the-blanks" exercise. Please provide all response entries in the following font: Arial, Regular, 12, Black. Please do NOT submit this page of instructions with your animal protocol submission.

With the exception of title headings, each paragraph and subparagraph in the following template must have a response. Portions of the template that are not applicable to your particular protocol, (i.e. no surgery or no prolonged restraint) should be marked "**N/A**". There are no space limitations for the responses.

Pertinent standing operating procedures or similar documents that are readily available to your IACUC may be referenced to assist in the description of specific procedures. It is critical that only animal studies or procedures documented in an IACUC – approved protocol be performed at your facility. Additionally, Principal Investigators, or other delegated research personnel, should keep accurate experimental records and be able to provide an audit trail of animal expenditures and use that correlates to their approved protocol.

GRANT TITLE (if different from above): Enhancing cancer treatment by normal tissue protection

USUHS PROJECT NUMBER: To be determined

CO-INVESTIGATOR(S): Dr. (b)(6)

POSTDOCS, STUDENTS, TECHNICIANS(S): (b)(6)

I. NON-TECHNICAL SYNOPSIS:

Despite advances in precision of targeting tumors with radiation therapy (RT) (eg., intensity-modulated RT and stereotactic radiosurgery), loco-regional recurrence is still a major problem due to the inability to deliver a sufficiently high dose to achieve tumor control without unacceptable late normal tissue and organ toxicity. Tumors in which loco-regional control is problematic include locally advanced breast, lung, head and neck, brain, cervical cancer, and others. Two other situations where radiation protection may be useful are: 1) in children, where RT can impair normal growth and development; and 2) in patients receiving combined RT and chemotherapy, where the acute effects of treatment may be severe, particularly when RT and chemotherapy are given concurrently. One method to improve the therapeutic index is by use of agents that differentially protect normal tissues relative to tumors.

The only FDA-approved radioprotector is amifostine, a pro-drug that is converted to an active thiol-type free-radical scavenger. Amifostine is approved to reduce xerostomia in patients receiving head and neck irradiation, but its use is limited because it must be given intravenously shortly before RT and it has systemic toxicity (b)(4)

(b)(4)

(b)(4) Our aim is to develop an effective, non-toxic radioprotectant/ radiotherapeutic treatment strategy that can be used for protection against radiation injury to normal tissues during clinical radiation for cancer treatment.

II. BACKGROUND:

II.1. Background:

The acute toxic effects of exposure to high doses of ionizing radiation in humans have been shown to occur due to two sequential effects: first the ablation of immune cells, resulting in loss of immune function and increasing likelihood of pathogenic infection (b)(4) ; and subsequently the loss of epithelial progenitor cells of the gastrointestinal (GI) crypt (b)(4)

(b)(4) Both of these events have been shown to be due to the loss of

fast-growing pluripotent and/or progenitor cell types. The time course of the acute injuries correlates with the life span of the mature cell types of the tissue, which are not replaced because of radiation damage to the adult pluripotent cells and adult stem cells. There is currently no FDA approved prophylactic or treatment for prevention of acute radiation injuries following high-dose (b)(4) radiation exposure.

(b)(4)

In humans, severe radiation (b)(4) can result in death (b)(4) (b)(4) Cumulative evidence from a number of laboratories, including our own, shows that there is a threshold dose of radiation of (b)(4) to induce sufficient (b)(4) for the (b)(4) phases to occur in mice; below these doses, no permanent injury manifests, although some short-term effects are observed (b)(4) However, in humans, there is currently no accepted protocol for preventative treatment of radiation-induced (b)(4) and morbiditiy as high as 50% is associated with each phase (b)(4) (b)(4) (b)(4) injuries from radiation is considered to be a serious problem in the field for the development of agents to prevent these radiation injuries.

III. OBJECTIVE\HYPOTHESIS:

(b)(4)

IV. MILITARY RELEVANCE:

Military personnel and their families receive medical treatment for cancer, including clinical radiation. The development of agents for the protection of normal tissues during cancer radiotherapy would allow the use of higher doses of radiation which has been shown to improve the level of tumor control and cancer irradiation. The goals of this research are consistent with improved cancer treatment in military

personnel and their families.

Additionally, the Department of Defense is prepared to execute military missions within radiation environments, to manage radiation crises associated with terrorist activities, and to manage consequences in the event of nuclear weapons detonation. Recent studies indicate that there is an increasing risk of exposure to ionizing radiation (IR) to military personnel due to increasing terrorist activities, including potential use of stolen nuclear weapons or dispersal of radioactive material in a "dirty bomb" (b)(4) Because of potential exposure of military personnel to radiation, the DoD is committed to protect members of the Armed Services from the adverse health effects of ionizing radiation. High dose IR causes short term, acute injuries including hematopoetic and GI syndromes. However, both high and low dose IR (as may result from a radiation dispersal device) can cause (b)(4) as demonstrated by Japanese atomic bomb survivor data as well as accidental exposures to Russian populations (b)(4) (b)(4) While early effects of radiation injury now have treatment/ prophylactic strategies, the delayed effects currently have no treatment. Lack of treatment for late effects of radiation, including (b)(4) (b)(4) will likely lead to delayed morbidity and mortality for personnel exposed to IR.

The Department of Defense (DoD) Chemical and Biological Defense Program 2007 Annual Report to Congress, Chapter 2.7.6 Medical Radiological Defense, addresses the requirements for the development of radioprotectants. This priority is outlined for the development of protectants for both acute and delayed radiation injuries, with an emphasis on (b)(4) According to this report, the mitigation of (b)(4) is a major research thrust area. This project is also designed to investigate mechanism(s) of protection to aid in the development of such agents.

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures:

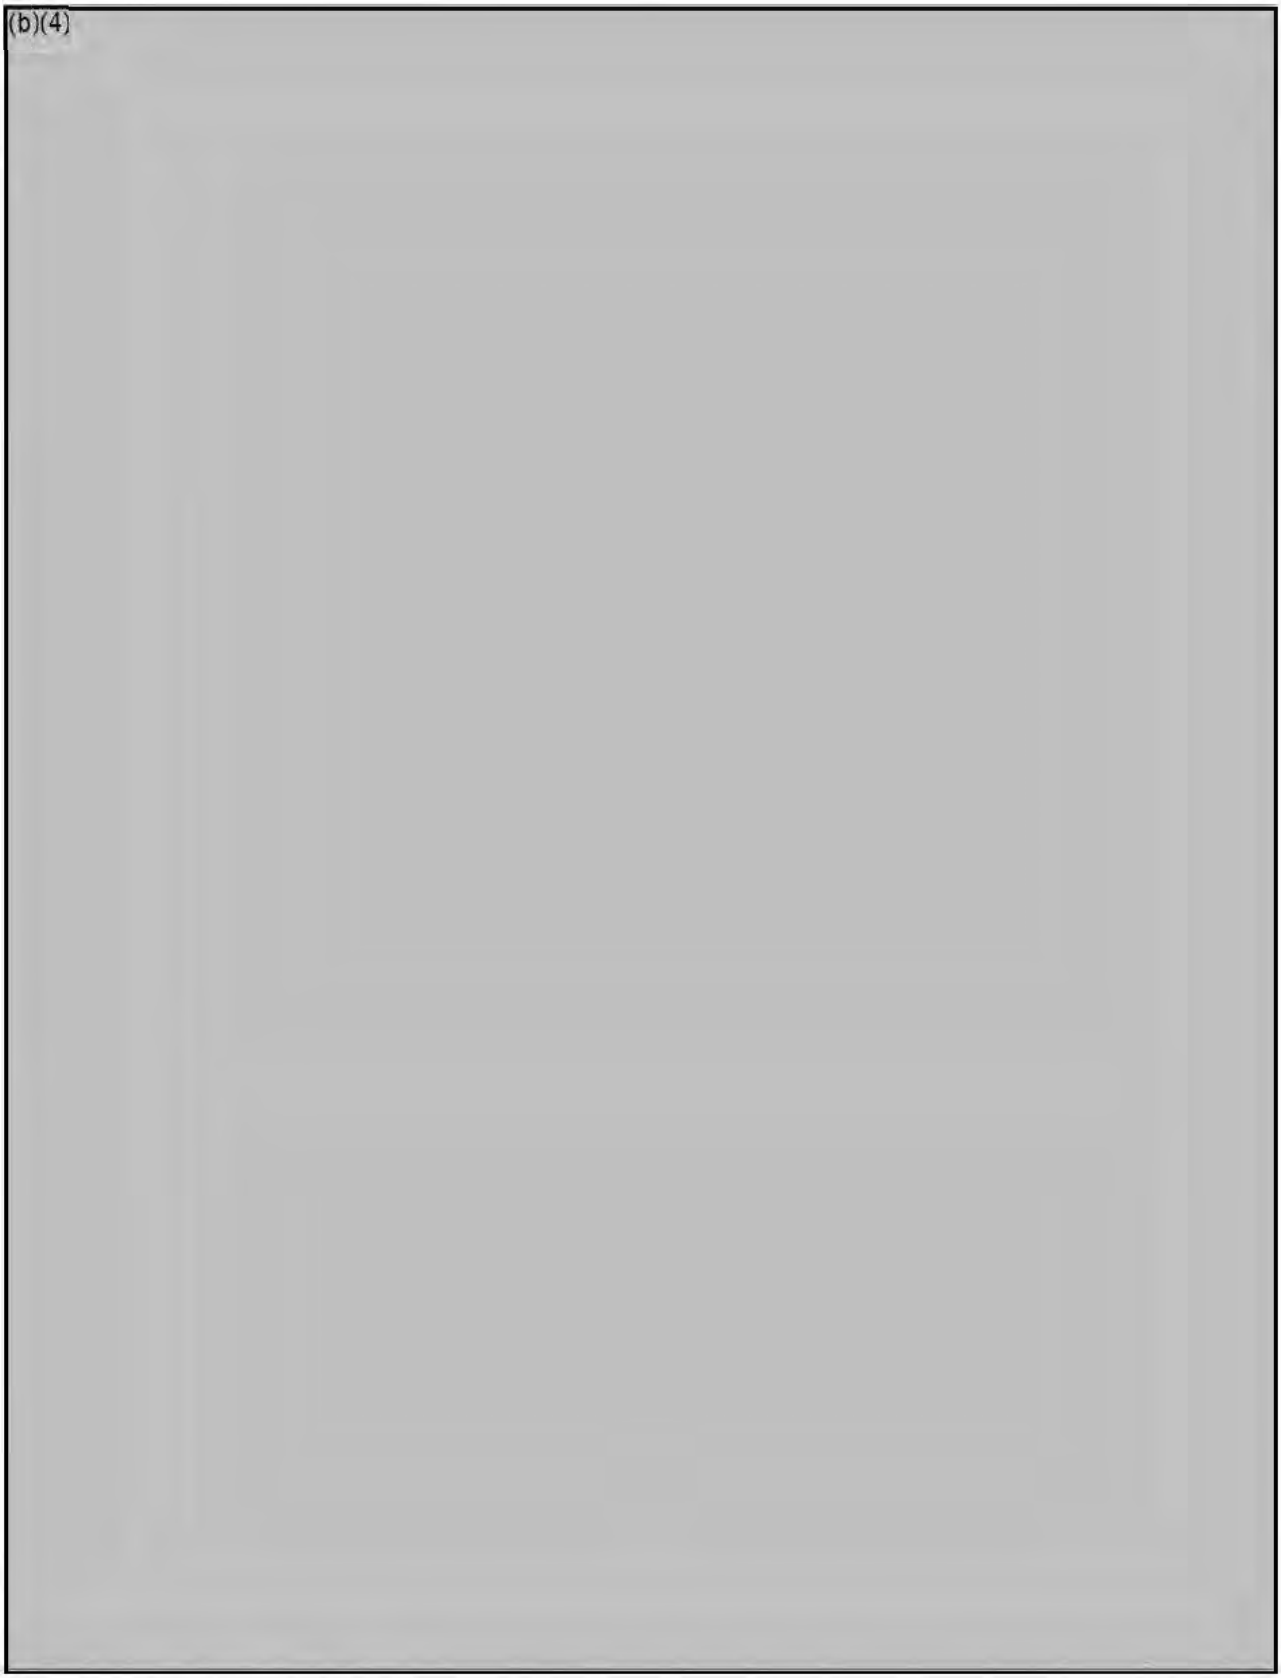
The goal of this project is to investigate the protective effects and mechanisms of (b)(4) for radiation-induced (b)(4) injuries.

(b)(4) Rationale for Doses and Times of Administration:

(b)(4)

Radiation Rationale for Doses and Times of Administration

(b)(4)



(b)(4)

(b)(4)

Experiments 1-5: Effect of (b) on radiation-induced (b)(4) in C57L mice.

V.1.1. Pilot study for (b)(4) protection (b)(4)
This pilot experiment will be performed to survival from (b)(4)
Two groups will be studied: (b)(4)
(b)(4)

(b)(4) mice per group) x (2 treatment groups) x (1 time point) = mice (b)(4)

Endpoint: The final endpoint for the experiment is days. Mice displaying obvious dyspnea, (b)(4)
lethargy, or other markers of morbundity and which appear to be in distress will be euthanized.
(b)(4) The scale for pain or
lethargy is attached. Mice scoring a total of 12 under any measurement will be euthanized.

Note: If the Pilot Study for survival does not support the hypothesis (b)(4)
(b)(4) Experiments 2-4 will not be conducted. We will consult with the USU IACUC for
the possibility of conducting Experiment 5 to determine the mechanism for the lack of protection of the
(b)(4)

V.1.2. Experiment 2: Dose-modifying effect of (b)(4)
(b)(4)
Once we have established the efficacy of (b)(for protecting mice from (b)(4) irradiation at the
(b)(4) we will determine the dose modifying effect using three doses of (b)(4) irradiation (b)(4)
(b)(4)
(b)(4) Two groups
of mice will be studied: 1) IR +vehicle (control) and 2) IR + (experimental). For these studies, (b)(4)
(b)(4) we will require mice per group in the radiation groups. We will include controls with animals (b)(4)
per group: 1) Sham IR + vehicle and 2) Sham IR.

Radiation groups
(b)(4) mice per group) x (2 treatment groups) x (1 time point) x (3 (b)(4) radiation levels) = (b)(4)
(b)(4) (b)(4) mice/experiment) x (2 experiments) = mice

Control groups
(b)(4) mice per group) x (2 treatment groups) x (1 time point) = mice (b)(4)

Endpoint: The final endpoint for the experiment is days. Mice displaying obvious dyspnea, (b)(4)
lethargy, or other markers of morbundity and which appear to be in distress will be euthanized. (b)(4)
(b)(4) The scale for pain or lethargy is
attached. Mice scoring a total of 12 under any measurement will be euthanized.

V.1.3. Experiment 3 Survival from fractionated-dose irradiation (b)(4)
Humans receive radiation for cancer treatment in fractionated doses. Our preliminary studies will
utilize single doses of radiation for the induction of (b)(4) injuries. Once we have established
the efficacy of (b)(4 for the protection of (b)(4 tissue against radiation injury from single high doses of

radiation, we will investigate the use of (b)(4) for protection against fractionated radiation. A schedule
(b)(4) of fractionated radiation, using (b)(4) fractions of (b)(4) given equally spaced (b)(4) over (b)(4) days, has been demonstrated in a murine model to be effective for the induction of radiation (b)(4) injuries (b)(4) We will utilize two treatment groups: 1) IR + vehicle; 2) IR + (b)(4)

(b)(4) (b)(4) mice per group) x (2 treatment groups) x (1 time point) = (b)(4)
(b)(4) (b)(4) mice/experiment) x (2 experiments) = (b)(4) mice

Endpoint: The final endpoint for the experiment is (b)(4) days. Mice displaying obvious dyspnea, (b)(4) lethargy, or other markers of morbundity and which appear to be in distress will be euthanized. (b)(4) (b)(4) The scale for pain or lethargy is attached. Mice scoring a total of 12 under any measurement will be euthanized.

V.1.4. Experiment 4 (b)(4) protection against (b)(4)
(b)(4)
We will investigate the degree of (b)(4) protection against radiation-induced (b)(4) We will determine levels of (b)(4) For
(b)(4) this experiment we will require only (b)(4) mice/group, and we will examine 4 groups: 1) sham + vehicle; 2)
(b)(4) sham + (b)(4) 3) IR + vehicle; 4) IR + (b)(4)

(b)(4) (b)(4) mice per group) x (4 treatment groups) x (1 time point) = (b)(4)
(b)(4) (b)(4) mice/experiment) x (2 experiments) = (b)(4) mice

Endpoint: The final endpoint for the experiment is (b)(4) days. Mice displaying obvious dyspnea, (b)(4) lethargy, or other markers of morbundity and which appear to be in distress will be euthanized. (b)(4) The scale for pain or lethargy is attached. Mice scoring a total of 12 under any measurement will be euthanized.

V.1.5. Experiment 5 (b)(4) protection against (b)(4)
(b)(4)
(b)(4) For this experiment we will require only
(b)(4) (b)(4) mice/group, and we will examine 4 groups: 1) sham + vehicle; 2) sham + (b)(4) 3) IR + vehicle; 4) IR + (b)(4) The experiment will be repeated because it is a generally accepted principle of the scientific method that experiments must be repeated to evaluate a hypothesis.

(b)(4) (b)(4) mice per group) x (4 treatment groups) x (4 time points) = (b)(4)
(b)(4) (b)(4) mice/experiment) x (2 experiments) = (b)(4) mice

Endpoints: Endpoints for the experiments will be (b)(4) days. Early time points will be taken if any animal exhibits signs or symptoms of morbidity or moribundity. Such animals will be euthanized at the time of observation.

Experiments 6-7: Effect of (b)(4) on radiation-induced (b)(4)

V.1.6. Experiment 6 (b)(4) protection against (b)(4)
(b)(4)

irradiation. We will use two groups: 1) IR + vehicle; 2) IR + (b)(4) For this experiment we will use (b)(4) animals per group.

(b)(4) mice per group) x (2 treatment groups) x (2 time points) = (b)(4)
(b)(4) mice/experiment) x (2 experiments) = mice

Endpoints: Endpoints for the experiments will be (b)(4) days. Early time points will be taken if any animal exhibits signs or symptoms of morbidity or moribundity. Such animals will be euthanized at the time of observation.

V.1.7. Experiment 7 (b)(4) protection against (b)(4)

(b)(4)

(b)(4) For this experiment we will require only mice/ (b)(4) group, and we will examine 4 groups: 1) sham + vehicle; 2) sham + (b)(4) 3) IR + vehicle; 4) IR + (b)(4) The experiment will be repeated because it is a generally accepted principle of the scientific method that experiments must be repeated to evaluate a hypothesis.

(b)(4) mice per group) x (4 treatment groups) x (4 time points) = (b)(4)
(b)(4) mice/experiment) x (2 experiments) = mice

Endpoints: Endpoints for the experiments will be (b)(4) days. Early time points will be taken if any animal exhibits signs or symptoms of morbidity or moribundity. Such animals will be euthanized at the time of observation.

V.2. Data Analysis:

Mean with standard error, or percentage will be reported if applicable. A significance level is set at 5% for each test. All statistical tests are two-sided. A statistical software, SAS will be used for statistical analyses.

Experiments 1-3: Analysis of variance (ANOVA) will be used to detect significant difference among the groups. If significant, then the pair-wise comparison by Tukey-Kramer will be used to identify which group is different from the other. For experiment 2, N = mice per group could (b)(4) have 80% power to detect any significant difference between groups if any, given type I error of 5% and delta/sigma has at least 1.4, where the delta is the estimated mean differences between the two groups and sigma is the pooled standard deviation of the two groups (b)(4)

Experiments 4,5,7: Previous data from this laboratory indicate that the coefficient of variation (CV) of the data is about 0.5, and that differences of between 2- and 30- fold are likely to be observed.
(b)(4) A sample size of per group will have 80% power to detect 3-fold increases in biomarkers based on a lognormal t test with a 5% two-sided significance level and a CV of 0.5.

Experiment 6: Previous data from this laboratory indicate that the coefficient of variation (CV) of the data is about 0.5, and that differences of between 2- and 30- fold are likely to be observed. A
(b)(4) sample size of per group will have 80% power to detect 3-fold increases in biomarkers based on a lognormal t test with a 5% two-sided significance level and a CV of 0.5.

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered:

For the last 9 years, we have utilized primary cell culture systems to examine anti-apoptotic mechanisms; however, we must determine whether our culture findings are relevant in whole animals. We will continue to use primary cell culture whenever possible to avoid unnecessary use of animals. We have also considered computer models as alternatives to animals. However, this alternative also lacks the knowledge base and complexity needed to evaluate radioprotective and radiotherapeutic agents.

V.3.2. Animal Model and Species Justification:

Tissue culture conditions cannot fully substitute for the complexities of whole organisms in response to radiation injury. Such injury involves the interactions between the hematopoietic system and other organ systems. In order to develop viable treatments for humans, we find that our research must be conducted in whole animals.

Work by (b)(6) also advocates the mouse as the best species to use for radiation protection and radiotherapy protocols: 1) mice provide the least sentient species available whose response to radiation has been clearly identified, with physiological responses to radiation and radioprotectants that are similar to human physiology, 2) extensive literature is available on responses of mice to radiation and countermeasures, 3) more reagents are available to study the relevant cell types and molecules in mice than in any other species except humans, and the availability of transgenic and knockout mice make this model extremely attractive for further research into molecular mechanisms, and 4) (b)(6) have extensive experience with this model in radiation injury and radioprotection research (b)(6) (b)(6)

The strains of mice to be utilized for each portion of the study are based on the literature and on findings from our own laboratory. Strain C57L mice have been demonstrated to have patterns of radiation-induced (b)(4) injury similar to that observed in humans (b)(4) Our laboratory has found that C57BL/6 mice have radiation-induced (b)(4) damage similar to that reported in the literature for humans.

V.3.3. Laboratory Animals

V.3.3.1.	**Genus & Species:**	*Mus musculus*	*Mus musculus*
V.3.3.2.	**Strain/Stock:**	C57L	C57BL/6
V.3.3.3.	**Source/Vendor:**	(b)(4)	
V.3.3.4.	**Age:**	10-14 weeks	10-14 weeks
V.3.3.5.	**Weight:**	Normal adult weight range for this strain: 17-21 g	Normal adult weight range for this strain: 17-21 g

V.3.3.6. **Sex**:	Female. Only females will be used in this study for the following reasons: 1) we have so far utilized female mice to lay the foundation of our studies for radiation-induced (b)(4) (b)(4) injuries; 2) because of long housing periods, it is advantageous to use female mice that are less aggressive toward each other.	Female. Only females will be used in this study for the following reasons: 1) we have so far utilized female mice to lay the foundation of our studies for radiation-induced (b)(4) (b)(4) injuries; 2) because of long housing periods, it is advantageous to use female mice that are less aggressive toward each other.
V.3.3.7. **Special Considerations**:	Commercially procured animals must be adventitious disease free. Mice- Pathogen-free, including *Pseudomonas aeruginosa*, and Pasteurella: All mice need to be free of the following agents: Sendai Pneumonia Virus of Mice (PVM), Reovirus-3 (Reo 3), Mouse Adenovirus (MAD-1, MAD-2), Mouse Cytomegalovirus Virus (MCMV), Ectromelia, K virus, Lymphocytic Choriomeningitis Virus (LCM), Epidemic Diarrhea of Infant Mice (EDIM), Hantaan virus, Rotavirus, Mouse Parvovirus (MPV), Polyoma Virus, Mouse Minute Virus (MMV), Mouse Thymic Virus (MTV), Theiler's Mouse Encephalomyelitis Virus (TMEV/GDVII), *Encephalitozoon cuniculi*, CAR bacillus; *Helicobacter* spp. *Mycoplasma pulmonis* and *Clostridium piliforme*. Endoparasite- and ectoparasite-free.	

V.3.4. **Number of Animals Required (by Species)**: C57L C57BL/6 (b)(4)

V.3.5. **Refinement, Reduction, Replacement (3 Rs)**:

V.3.5.1. **Refinement**: Animals demonstrating moribundity due to radiation exposure (b)(4) (b)(4) will be considered to have arrived at the study endpoint and will be immediately euthanized (See sections V.4.5 Study Endpoint and V.4.6 Euthanasia).

Ketamine/xylazine anesthesia will be used during X-ray irradiation to prevent stress from the time the mice are placed in restraint. Under the training protocol at AFRRI inconjunction with the AFFRI veterinary staff, we found that in female CBA or C57BL/6J mice, ~12 weeks old, i.p. injection of 150 mg/kg ketamine plus 18 mg/kg xylazine results in a minimum of 40 min anesthesia with no morbidity or mortality (b)(4) We will use a heating pad to keep mice warm during the period of recovery from anesthesia. The temperature in room where the mice will be irradiated will be measured, and if necessary a space heater will be used to increase the temperature. Standard intraperitoneal injection methods are used for injection of the anesthesia, as recommended and approved by the AFRRI veterinary staff and for which all laboratory personnel have received training at AFRRI.

V.3.5.2. **Reduction**:

Whenever possible, control groups will be shared between experimental groups for our experiments. Tissues will be collected for multiple assays from the same animals further reducing the total number of animals needed. At every stage of the research, planned experiments will be reevaluated, in an attempt to reduce the numbers of experiments and eliminate repeats of experiments where statistical significance has already been obtained. For (b)(4) irradiation studies, each animal will be able to provide its own control tissue from the non-irradiated area. Preliminary results from our laboratory demonstrate that tissue from the abdominal region is normal under our experimental conditions.

V.3.5.3. Replacement: At this time, it is not feasible to use non-animal systems in place of animal models to address the research questions in this protocol.

V.4. Technical Methods:

V.4.1. Pain / Distress Assessment:

V.4.1.1. APHIS Form 7023 Information:

V.4.1.1.1. Number of Animals: (b)(4)

V.4.1.1.1.1. Column C: (b)(4)

V.4.1.1.1.2. Column D:

V.4.1.1.1.3. Column E:

V.4.1.2. Pain Relief / Prevention:

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization:
We will be unable to use general analgesics since they have effects on (b)(4) function that would interfere with the interpretation of our results (b)(4) (b)(4) Some sedatives have been reported to contribute to postoperative (b)(4) which likely reduce some functions of radiation. For C57BL/6 mice exposed to (b)(4) irradiation to induce radiation (b)(4) daily on animals displaying radiation injury to alleviate discomfort and to prevent infection. This agent is also used for humans.

An anesthesia protocol has been developed for use during the X-ray irradiation. Ketamine will be used with xylazine for longer anesthesia in mice to be place in restraints for (b)(4) irradiation. Under the training protocol at AFRRI in conjunction with the AFRRI veterinary staff, we found that in female C57BL/6 and CBA mice, ~12 weeks old,i.p. injection of 150 mg/kg ketamine plus 18 mg/kg xylazine results in in a minimum of 40 min anesthesia (25 G needle) with no morbidity or mortality (b)(4) We propose to use this range of concentration of anesthesia, together with a heating pad to keep mice warm during the period of anesthesia. Standard i.p. injection methods are used for injection of the anesthesia, as recommended and approved by the AFRRI veterinary staff and for which all laboratory personnel have received training at AFRRI.

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions:
Animals will be housed and cared for as described in Section V.5. Veterinary Care both before and after dose administrations and irradiation procedures. The PI and research staff will monitor animals after radiation or sham irradiation during anesthesia recovery. The PI and research staff will also monitor animals daily following radiation exposure, and twice daily during critical periods. Otherwise, the animals will receive standard veterinary care in the USU vivarium.

V.4.1.2.3. Paralytics: N/A

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures:

V.4.1.3.1. Sources Searched: DoD Bioedical Research Data Base (BRD), NIH Reporter, PubMED

V.4.1.3.2. Date of Search: 1/30/14

V.4.1.3.3. Period of Search: Search covered published manuscripts from ~1965-present. (BRD search included all available years 1998 -2014).

V.4.1.3.4. Key Words of Search: Pain, analgesia, anesthesia, mice, radiation, ionizing radiation, humane, (b)(4)

V.4.1.3.5. Results of Search:
The literature search revealed that, at present, there are no alternative procedures for irradiation because its effects cannot be otherwise duplicated. In some cases radiation has been demonstrated to reduce pain in laboratory mice (b)(4) and has been in humans reported to alleviate cancer related bone pain (b)(4) (b)(4) A recent report showed that administration of botulinum toxin A was effective for reduction of pain and muscle spasms after clinical radiation for treatment of tumors (b)(4) (b)(4) Application of natural honey 20 min prior to radiation exposure was also shown to reduce mucositis with associated pain in humans following head/neck radiotherapy (b)(4) it has not been determined whether honey acts as a local radioprotectant. Spinal cord stimulation has also been reported in humans to alleviate pain resulting from radiotherapy (b)(4) however, this method would not be practical for use in mice because of the extensive spinal cord manipulation required. Human administration of morphine also relieves pain (b)(4) but again this would not be practical for mice in our experiments because of side effects of the drug. In humans, exposure to (b)(4) irradiation may induce vomiting and diarrhea, causing pain and distress. However, mice are not susceptible to vomiting. There are no reports regarding the effects of on pain in general or (b)(4) radiation-induced pain.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification:
Anesthesia will be used before (b)(4) irradiation to avoid stress from restraint. (b)(4) (b)(4) (b)(4) we will be unable to use analgesics after irradiation since they have effects on (b)(4) function that would interfere with the interpretation of our results (b)(4) (b)(4) (b)(4) Pain will be evaluated using several standard indications including: grimacing, abnormal breathing, hunched or fluffed fur and inactivity, or ataxia. In experiments where tissue collection is needed, animals will be euthanized with pentobarbitol prior to sample collection as described in Section V.4.6. We will utilize the attached score sheets to provide a scale for measurement of criteria for euthanasia. Score sheet will be used daily after irradiation. During critical periods, animals will be monitored twice daily, and during the second monitoring score sheets will be updated if necessary for that day. Any animal scoring 12 or more total on the score sheet will be euthanized. In experiments where tissue collection is needed, animals will be euthanized with pentobarbitol prior to sample collection as described elsewhere.

V.4.2. **Prolonged Restraint**:
(b)(4) irradiation will require restraint in designed jigs for ~20 min to receive X-ray exposure (b)(4) animals will be anesthetized during this period (see Anesthesia above) and tails will be taped to one side with surgical tape. The jigs for use during (b)(4) irradiation were examined and approved by the AFRRI Veterinary staff. An image of the jigs is attached. Under the training protocol at AFRRI in conjunction with the AFRRI veterinary staff, we found that in female CBA and C57BL/6 mice, ~12 weeks old, i.p. injection of 150 mg/kg ketamine plus 18 mg/kg xylazine results in a minimum of 40 min anesthesia (25 G needle) with no morbidity or mortality (b)(4) The length of time for anesthesia is needed to ensure that animals do not regain consciousness while being positioned in the lead shield for irradiation. Positioning of the mice must be done carefully to ensure that all animals receive the same exposures. We propose to use this range of concentration of anesthesia, together with a heating pad to keep mice warm during the period of anesthesia. Standard i.p. injection methods are used for injection of the anesthesia. We propose to use this range of concentration of anesthesia, together with a heating pad to keep mice warm during the period of anesthesia. AFFRI Veterinary staff provided training and supervision for the placement of anesthetized animals in the approved jigs for irradiation.

V.4.3. **Surgery**:
V.4.3.1. **Pre-surgical Provisions**: N/A

V.4.3.2. **Procedure**: N/A

V.4.3.3. **Post-surgical Provisions**: N/A

V.4.3.4. **Location**: N/A

V.4.3.5. **Surgeon**: N/A

V.4.3.6. **Multiple Major Survival Operative Procedures**:
V.4.3.6.1. **Procedures**: N/A

V.4.3.6.2. **Scientific Justification**: N/A

V.4.4. **Animal Manipulations**: N/A

V.4.4.1. **Injections**:
Intra-peritoneal injections of pentobarbital for euthanasia 0.01-0.02 ml/mouse Fatal Plus (39-78 mg pentobarbital/mouse), will be performed with a 25 G needle. I.p. injection of 150 mg/kg ketamine plus 18 mg/kg xylazine will be done using a 25 G needle. This level of anesthesia was first developed for our use in collaboration with the AFRRI Veterinary staff and shown to effectively produce non-lethal anesthesia for in a minimum of 40 min (b)(4)

(b)(4)

V.4.4.1.1. Pharmaceutical Grade Drugs

(b)(4)

V.4.4.1.2. Non-Pharmaceutical Grade Drugs
None.

V.4.4.2. Biosamples:
All biosamples will be taken after euthanasia. (b)(4) will removed *en bloc*. (b)(4) will be removed from the (b)(4) as control tissue. All other tissues will be available to other researchers for tissue sharing.

V.4.4.3. Adjuvants: N/A

V.4.4.4. Monoclonal Antibody (MAbs) Production: N/A

V.4.4.5. Animal Identification:
All cages will have cage cards identifying the treatment groups for each experiment. For experiments 2 and 3, each animal within a cage will receive ear punches for individual identification (1 = no cut; 2 = right ear upper corner; 3 = left ear upper corner; 4 = both ears).

V.4.4.6. Behavioral Studies: N/A

V.4.4.7. Other Procedures:

(b)(4) irradiation
The methodology for (b)(4) irradiation of mice including approval of holding jigs and development of anesthesia was developed in conjunction with the AFRRI Veterinary Staff. (b)(4) irradiation will be performed using the RS2000 irradiator in (b)(6)
Thirty minutes prior to irradiation, the RS2000 irradiator and lead shield will be decontaminated thoroughly with MB10.

Mice will be anesthetized by injection in the USUHS LAM facility. Anesthetized mice will be placed in ventilated Lucite jigs, which restrain the animals to prevent lateral or vertical movement. Tails will be taped to prevent any forward motion of animals. Mice will be irradiated at (b)(4) to deliver (b)(4) irradiation. The temperature in room where the mice will be irradiated will be measured, and if necessary a space heater will be used to increase the temperature. Following radiation exposure, mice will be immediately returned to the LAM and allowed to recover from anesthesia under supervision with heating pads. Immediately upon recovery, animals will be returned to standard cages that house 4 animals per cage. Lucite jigs will be sanitized after each use.

Ear punch
The ear punch will be soaked in alcohol to disinfect it before use and between animals. The device will be placed on the pinna of the ear (external ear) in a location where the mouse will be marked for identification. The punch will be pressed firmly to punch a circular hole through the ear, being careful not to rip the delicate membrane of the pinna. The ear will then be gently separated from the device. The ear punch will be cleaned and disinfected in alcohol before use in another mouse.

V.4.4.8. Tissue Sharing:

For most studies, (b)(4) tissue will be obtained. All other tissues will be available for tissue sharing with other investigators. Our laboratory has made extensive use of shared tissues for training and technique development for (b)(4) tissue.

V.4.5. Study Endpoint:

(b)(4)

(b)(4) Early endpoints will be used in the case of morbidity and morbundity. Specific health assessment criteria including rapid weight loss, ruffled fur, dried lacrimal fluid accumulated in the cul-de-sac of their eyes, are cool to the touch, decreased appetite, dehydration, diarrhea, difficulty breathing or panting (b)(4) (b)(4) or hunched body position will used to determine early study endpoints for euthanasia. The experimental design does not contemplate supportive therapy, and animals exhibiting these signs may be euthanized, and considered to be at the study endpoint.

Following (b)(4) irradiation, mice may exhibit injuries from the (b)(4) irradiation *during* the first week postirradiation. Also, mice are expected to develop (b)(4) injury on days (b)(4) postirradiation. During the critical time periods (b)(4) days postirradiation), mice will be monitored by the PI or other members of the investigative team at least twice daily, early morning and late afternoon including weekends or holidays.

V.4.6. Euthanasia:

Animals will be euthanized at the stated endpoints of the experiments by i.p. injection of ml/mouse Fatal Plus. PHS policy is intraperitoneal injection of at least 200 mg/kg sodium pentobarbital euthanasia solution; Fatal Plus: 390 mg pentobarbitol/1 ml.

1 ml/390 ml x 0.02 kg/mouse x 200 mg/1 kg = 0.01-0.02

IP will be performed using a 25 G needle. (Please note that Euthasol cannot be used as additives have effects on (b)(4) We do have Fatal Plus for these experiments.) Euthanasia will be confirmed by cervical dislocation. Animals which appear to be experiencing pain or distress as a result of radiation exposure or are found moribund will also be euthanized by pentobarbitol and necropsied. At the end of experiments, unused animals will be transferred to other protocols or euthanized by exposure to 100% CO_2 from a compressed gas cylinder in accordance with the current American Veterinary Medical Association (AVMA) Guidelines for Euthanasia. Exsanguination, cervical dislocation, and/or pneumothorax will be used to ensure euthanasia.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol. Mice will be housed 4 per cage. Food and water and Rodent Diet will be available ad libitum. The 12:12 hr (lights off at 6 pm) room light cycle is fine for all the studies.

V.5.1.1. Study Room:

Radiation Building (b)(6) Room Number (b)(6)

Euthanasia Building (b)(6) Room number (b)(6)

V.5.1.2. Special Husbandry Provisions:

Food Restriction:	Yes _____	No	x
Fluid Restriction:	**NOTE: Acidified water will be provided to reduce infections after radiation exposure.**	No	x

Acidified water (pH 2.5 – 3.0) is produced at AFRRI for their vivarium using 2.0 N HCl.

V.5.1.3. Exceptions: None

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care:
Experimental animals will be observed at least twice a day by one of the study investigators or technicians. LAM personnel will also monitor the animals twice a day during their rounds. As described in another section (study endpoint) morbid animals will be monitored at least twice daily, morning and afternoon. The experimental design does not contemplate supportive therapy. The justification for not providing supportive care has been described in the study end point section as well as in the pain category section. Criteria to be used for health evaluation while the animals are on study include: 20% weight loss compared with average weights of sham irradiated animals (mice will be weighed every other day between days (b)(4) —based on our experience with (b)(4) irradiation in which animals can recover from ~25% weight loss (b)(4) ruffled fur, dehydration, decreased activity, and hunched body position, dyspnea, or panting. Animals exhibiting these signs may be euthanized, and considered to be at the study endpoint. Increased monitoring of C57L animals will begin on day (b)(through the end of the experiment, based on our previous data that indicated that mortality from (b)(4) irradiation occurs between days (b)(4) postirradiation. Increased monitoring of C57BL/6 animals exposed to (b)(4) irradiation for (b)(4) will be monitored between days (b)(4) when the most prominent (b)(4) (b)(4) is expected. In the event of debilitating illness the decision to euthanize will be made by the veterinarian and/or PI.

V.5.2.2. Emergency Veterinary Medical Care:
All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays. In the case of an emergency health problem, if the responsible person (e.g. investigator) is not available or if the investigator and veterinary staff cannot reach consensus on treatment, the veterinarian has the authority to treat the animal, remove it from the experiment, institute appropriate measures to relieve severe pain or distress, or perform euthanasia if necessary.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: All animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents; balls, toys and food enrichment treats for large animal species.

V.5.3.2. Enrichment Restrictions: none

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
Ear punch, irradiation, anesthesia, euthanasia	(b)(6)	8+ years	(b)(6)
Ear punch, irradiation, anesthesia, euthanasia		6 years	
Rodent handling		10+ years	
Anesthesia, euthanasia, irradiation		5+ years	

VII. BIOHAZARDS/SAFETY: None

VIII. ENCLOSURES: Image of jigs for (b)(4) irradiation; pain score sheet; criteria for euthanasia

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

(b)(6) _____ Feb 10, 2014

Princi ure Date

G. Training: The following personnel will attend the next USUHS Investigator/Animal User Training Course:

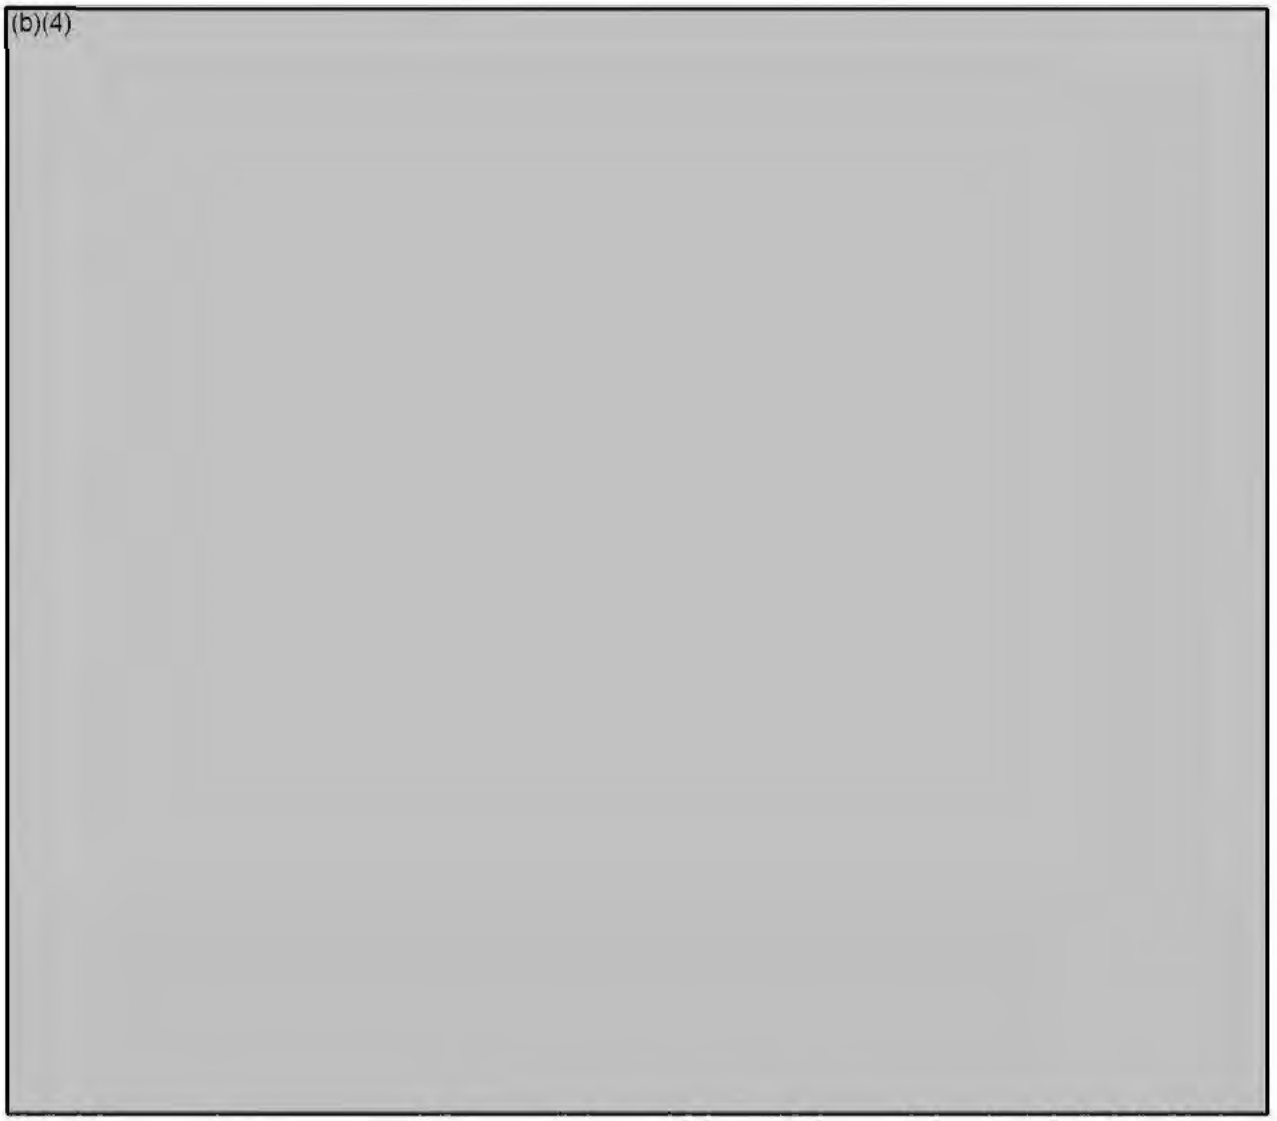
_____ _____

_____ _____

H. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely, "Responsibility" for implementing animal use alternatives where feasible and conducting humane and lawful research.

(b)(6) _____ Feb 10, 2014

Prin gnature Date



(b)(4)

I. Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL or WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

June 2, 2014

MEMORANDUM FOR DR. (b)(6)

SUBJECT: IACUC Approval of Protocol – Initial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on June 2, 2014:

Animal Protocol Title: (b)(4) Inhibition to Mitigate Radiation-Induced (b)(4) in the (b)(4) Mus Musculus)"

USUHS Protocol Number: (b)(6)

Expiration Date: June 1, 2017

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

USUHS Form 3206- Animal Study Proposal Form Instructions

USUHS / DOD – SPONSORED ANIMAL RESEARCH PROPOSALS MUST USE THIS STANDARDIZED FORMAT

Reference DOD Directive 3216.1 & USUHS Instruction 3203

****

Specific information requested in the following animal-use protocol template is a result of requirements of the Animal Welfare Act regulations (AWAR), the Guide for the Care and Use of Laboratory Animals, and other applicable Federal regulations and DOD directives.

****

This document is intended to be an aid in the preparation of a USUHS DOD – sponsored animal use proposal. The instructions and written explanations provided for individual paragraphs (ref. animal-use protocol template in AR 40-33 / USUHSINST 3203, Appendix C) are coded as hidden text. To see the instructions and examples for each section, select the "**Show/Hide ¶**" button on your tool bar. To print the hidden text, select "Print" on the drop down file menu. Under the "Options" button, select "Hidden text" under the "Include with document" section. Use of a word processor makes completion of this template a "fill-in-the-blanks" exercise. Please provide all response entries in the following font: Arial, Regular, 12, Black. Please do NOT submit this page of instructions with your animal protocol submission.

With the exception of title headings, each paragraph and subparagraph in the following template must have a response. Portions of the template that are not applicable to your particular protocol, (i.e. no surgery or no prolonged restraint) should be marked "**N/A**". There are no space limitations for the responses.

Pertinent standing operating procedures or similar documents that are readily available to your IACUC may be referenced to assist in the description of specific procedures. It is critical that only animal studies or procedures documented in an IACUC – approved protocol be performed at your facility. Additionally, Principal Investigators, or other delegated research personnel, should keep accurate experimental records and be able to provide an audit trail of animal expenditures and use that correlates to their approved protocol.

I. NON-TECHNICAL SYNOPSIS:

Exposure to high dose radiation can occur as the result of a nuclear accident or terrorist event. Exposure to ionizing radiation in humans results in severe and usually fatal illnesses due to multi-organ damage. The effects of radiation on the lung are delayed, but result in high mortality. Despite a large amount of research into the effects of high dose radiation exposure, there has been a delay in the development of drugs or treatments to prevent radiation injury in individuals exposed to radiation.

Our long term goal is to develop agents to prevent immediate and delayed effects of ionizing radiation in multiple organs. Our aim is to investigate drugs targeting the (b)(4) (b)(4) for the prevention of radiation-induced cell damage to the (b)(4) Ionizing radiation has detrimental effects on (b)(4) and leading to increased (b)(4) that persists for long periods of time following the initial damage by radiation exposure.

Previous studies from our lab demonstrated that the principle effect of radiation on normal cells is loss of ability of cells to grow normally and instead to become (b)(4) in a process termed (b)(4) Our data further indicate that radiation-induced (b)(4) (b)(4) The activation of (b)(4) in vivo correlates with (b)(4) upregulation in (b)(4) tissue in a murine model of radiation-induce multi-organ injuries. Therefore, we hypothesize that inhibition the (b)(4) prevent (b)(4) (b)(4) resulting in the mitigation of radiation injuries.

Our proposed studies here will examine the effects of (b)(4) inhibition mitigating (b)(4) radiation injuries in murine models for these injuries. We will utilize C57L mice exposed to (b)(4) X-ray irradiation at (b)(4) to determine the efficacy and mechanisms of (b)(4) for the protection of the (b)(4) against radiation injury. We will utilize C57BL/6 mice exposed to (b)(4) radiation in the (b)(4) region to determine the efficacy and mechanisms of protection of the (b)(4) against radiation injury. Our aim is to develop an effective, non-toxic radioprotectant/ radiotherapeutic treatment strategy that can be used for protection against radiation injury to normal tissues during clinical radiation for cancer treatment.

II. BACKGROUND:

II.1. Background:

Ionizing radiation has been demonstrated to ablate normal vascular function, compromising the endothelial barrier, leading to tissue edema and inflammation in cycles that occur long after the initial radiation insult (b)(4) The cellular injuries from radiation occur in several stages. Early damage occurs in minutes to several hours after radiation exposure and is believed to lead to early inflammatory reactions in response to the activation of proteolytic enzymes (b)(4) (b)(4) Subsequent cycles of cell damage (days to months after radiation exposure) are believed to be due to another mechanism, potentially cellular senescence or apoptosis, possibly associated with inflammation.

The acute toxic effects of exposure to high doses of ionizing radiation in humans have been shown to occur due to two sequential effects: first the ablation of immune cells, resulting in loss of immune function and increasing likelihood of pathogenic infection (b)(4) and subsequently the loss of epithelial progenitor cells of the gastrointestinal (GI) crypt (b)(4) (b)(4) Both of these events have been shown to be due to the loss of fast-growing pluripotent and/or progenitor cell types. The time course of the acute injuries correlates with the life span of the mature cell types of the tissue, which are not replaced because of radiation damage to the adult pluripotent cells and adult stem cells. There is currently no FDA approved prophylactic or treatment for prevention of acute radiation injuries following high-dose (b)(4) radiation exposure.

(b)(4)

In humans, severe radiation (b)(4) can result in death (b)(4) (b)(4) Cumulative evidence from a number of laboratories, including our own, shows that there is a threshold dose of radiation of (b)(4) to induce sufficient (b)(4) for the (b)(4) phases to occur in mice; below these doses, no permanent injury manifests, although some short-term effects are observed (b)(4) However, in humans, there is currently no accepted protocol for preventative treatment of radiation-induced (b)(4) and morbidity as high as 50% is associated with each phase (b)(4) (b)(4) injuries from radiation is considered to be a serious problem in the field for the development of agents to prevent these radiation injuries.

(b)(4) **as a radioprotectant:** Inhibitors for (b)(4) signaling have been tested in animal models for cancer and brain injury, and a number of these agents are currently being used in clinical trials.

(b)(4)

(b)(4) inhibitors are oral drugs with accepted safety profiles.

Preliminary Studies:

Model system for radiation-induced (b)(4) We determined that although (b)(4) irradiation at (b)(4) can induce some early alterations of gene expression in the (b)(4) (b)(4) this level of radiation does not induce observable radiation-induced (b)(4) in C57BL/6J mice (b)(4) For this reason, we have decided to perform studies of radiation-induced (b)(4) using higher doses of (b)(4) irradiation. Using X-ray radiation sources at AFRRI and USUHS, we have determined that (b)(4) irradiation is a threshold dose of radiation exposure for the induction of radiation (b)(4) in several strains of mice including CBA and C57BL/6. Published findings indicate that C57L mice respond to radiation in a manner similar to these mice (b)(4)

Model system for radiation-induced (b)(4) We previously determined that (b)(4) irradiation of C57BL/6 mice induces (b)(4) (b)(4) there is some tissue repair—(b)(4) (b)(4) However, histological evaluation revealed continued (b)(4) underlying structural remodeling of the (b)(4) Our studies suggest that (b)(4) is a threshold dose of radiation for unrepaired (b)(4) in these mice. These findings from our laboratory have not yet been published.

(b)(4) **as a radiation countermeasure:** Our preliminary studies indicate that in primary cultures of human (b)(4) are upregulated within several hours of radiation exposure (b)(4) Additionally the (b)(4) (b)(4) receptor is activated rapidly in response to radiation and remains activated for up to h (b)(4) postirradiation (b)(4) We determined that the inhibition of (b)(4) blocked radiation-induced (b)(4) in both human primary cell cultures (b)(4) (b)(4) Cells maintained normal morphology and proliferative capacity. This finding suggested that radiation-induced (b)(4) in primary cells requires the (b)(4) pathway. We have also observed the activation of (b)(4) from irradiated mice in a time course that correlates with the onset of cellular (b)(4) We hypothesize that the inhibition of radiation-induced cellular (b)(4) in vivo may also be blocked by (b)(4) leading to the preservation of normal cellular function after radiation exposure and preventing delayed tissue damage.

II.2. Literature Search for Duplication:

II.2.1. Literature Source(s) Searched:

Biomedical Research Database (BRD), NIH RePORTER (replacement database for CRISP) *http://projectreporter.nih.gov/reporter.cfm*, and PubMed

II.2.2. Date of Search:

Data base searches conducted on 04/02/14.

II.2.3. Period of Search:

Searches conducted for the entire time periods available in each data base. For BRD, 1998-2014; for RePorter, 1972-2013. For PubMed, 1970-2014.

III. OBJECTIVE\HYPOTHESIS:

(b)(4)

IV. MILITARY RELEVANCE:

Military personnel and their families receive medical treatment for cancer, including clinical radiation. The development of agents for the protection of normal tissues during cancer radiotherapy would allow the use of higher doses of radiation which has been shown to improve the level of tumor control and cancer irradiation. The goals of this research are consistent with improved cancer treatment in military personnel and their families.

Additionally, the Department of Defense is prepared to execute military missions within radiation environments, to manage radiation crises associated with terrorist activities, and to manage consequences in the event of nuclear weapons detonation. Recent studies indicate that there is an increasing risk of exposure to ionizing radiation (IR) to military personnel due to increasing terrorist activities, including potential use of stolen nuclear weapons or dispersal of radioactive material in a "dirty bomb" (b)(4) . Because of potential

exposure of military personnel to radiation, the DoD is committed to protect members of the Armed Services from the adverse health effects of ionizing radiation. High dose IR causes short term, acute injuries including hematopoetic and GI syndromes. However, both high and low dose IR (as may result from a radiation dispersal device) can cause (b)(4) as demonstrated by Japanese atomic bomb survivor data as well as accidental exposures to Russian populations (b)(4) (b)(4) While early effects of radiation injury now have treatment/ prophylactic strategies, the delayed effects currently have no treatment. Lack of treatment for late effects of radiation, including (b)(4) will likely lead to delayed morbidity and mortality for personnel exposed to IR.

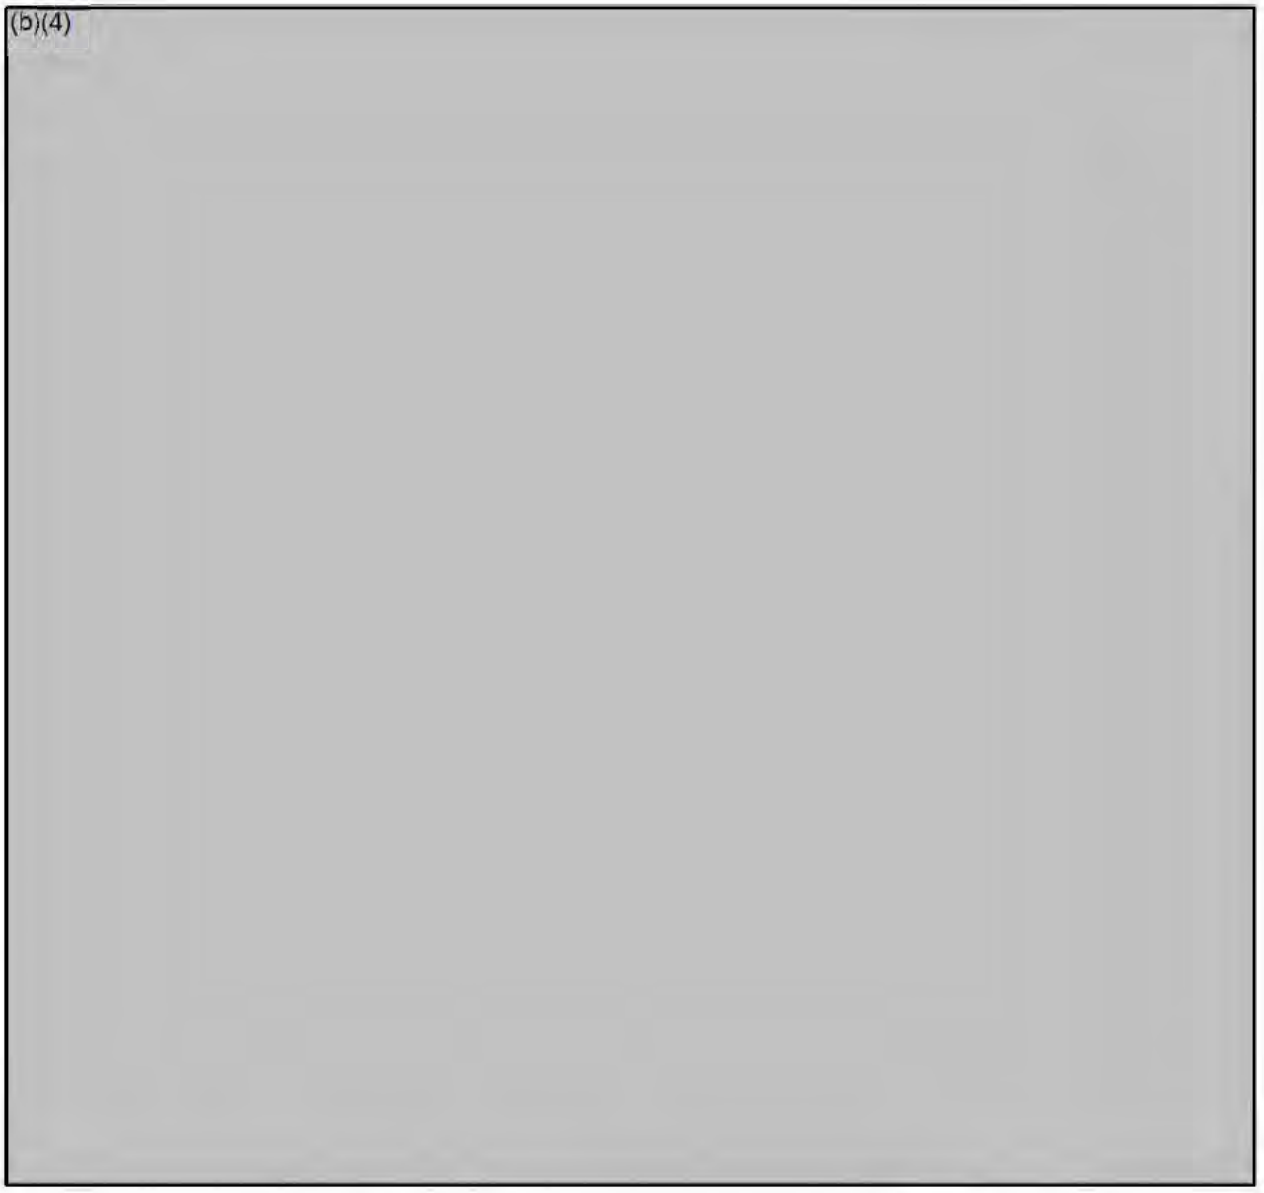
The Department of Defense (DoD) Chemical and Biological Defense Program 2007 Annual Report to Congress, Chapter 2.7.6 Medical Radiological Defense, addresses the requirements for the development of radioprotectants. This priority is outlined for the development of protectants for both acute and delayed radiation injuries, with an emphasis on (b)(4) According to this report, the mitigation of (b)(4) is a major research thrust area. This project is also designed to investigate mechanism(s) of protection to aid in the development of such agents.

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures:

The goal of this project is to investigate the protective effects and mechanisms of (b)(4) treatment for radiation-induced (b)(4)

(b)(4)



Experiments 1-2: Effect of (b)(4) inhibition on radiation-induced (b)(4) injury following (b)(4) ionizing radiation in C57L mice and C57BL/6 mice, respectively.

V.1.1. Effects of (b)(4) administration for (b)(4) injuries (b)(4) (b)(4)

This experiment will determine whether (b)(4) inhibition prevents radiation-induced (b)(4) and improves (b)(4) or vehicle will be administered h postirradiation (b)(4) with administration daily for (b)(4) after radiation exposure (b)(4) Two groups will be studied: (b)(4) + vehicle and (b)(4)

(b)(4) mice per group) x (2 treatment groups) x (1 time point) = mice (b)(4)

Endpoint: The final endpoint for the experiment is days. Mice displaying obvious dyspnea, (b)(4) lethargy, or other markers of morbundity and which appear to be in distress will be euthanized.

(b)(4) The scale for pain or lethargy is attached. Mice scoring a total of 12 under any measurement will be euthanized.

V.1.2. Experiment 2: Effects of (b)(4) inhibition for the mitigation of (b)(4) radiation injury (b)(4)

We will determine the effect of (b)(4) inhibition on radiation (b)(4) The effect of (b)(4) inhibition on (b)(4) will be scored at (b)(4) days postirradiation. (b)(4) or vehicle will be administered (b)(4) h postirradiation, with administration daily for (b)(4) after radiation exposure (b)(4) region irradiation will be used. Groups will be: 1) radiation + no treatment; 2) radiation +vehicle (control); and 3) irradiation + (b)(4) (b)(4) For these studies, we will require (b)(4) mice per group in the radiation groups. We will obtain control tissue outside of the field of radiation, which previous experiments in our laboratory have demonstrated are appropriate as controls.

The experiment will be repeated because it is a generally accepted principle of the scientific method that experiments must be repeated to evaluate a hypothesis.

Radiation groups

(b)(4) (b)(4) mice per group) x (3 treatment groups) x (2 time points) = (b)(4)

(b)(4) (b)(4) mice/experiment) x (2 experiments) = (b)(4) mice

Endpoint: The final endpoint for the experiment is (b)(4) days. Mice displaying obvious lethargy, or other markers of morbundity and which appear to be in distress will be euthanized. The scale for pain or lethargy is attached. Mice scoring a total of 12 under any measurement will be euthanized.

Experiments 3-5: Effect of (b)(4) inhibition for mitigation of radiation-induced cellular (b)(4) These experiments will be performed only if positive results are obtained from experiments 1 or 2.

V.1.3. Experiment 3 Effect of (b)(4) inhibition on (b)(4) (b)(4)

If we find that (b)(4) inhibition results in reduction of radiation-induced (b)(4) injury at (b)(4) days postirradiation, we will further investigate the mechanism of the improvement. We will determine whether (b)(4) reduces (b)(4) and improves cell survival following radiation exposure in the (b)(4) We will use 3 time point groups (b)(4) days postirradiation to examine markers for (b)(4) by western blotting and immunohistochemistry (b)(4) (b)(4) will be assessed by immunohistochemistry and by qRT-PCR for immune cell (b)(4) markers (b)(4) will also be determined using the tissue from Experiment 2, with the time points (b)(4) days postirradiation. Groups will be: 1) radiation + no treatment; 2) radiation + vehicle; 3) radiation + (b)(4) Control tissue will be obtained from outside of the radiation field.

The experiment will be repeated because it is a generally accepted principle of the scientific method that experiments must be repeated to evaluate a hypothesis.

(b)(4) (b)(4) mice per group) x (3 treatment groups) x (3 time points) = (b)(4)

(b)(4) (b)(4) mice/experiment) x (2 experiments) = (b)(4)

Endpoint: The endpoints for the experiment are days (b)(4) postirradiation. Mice displaying obvious dyspnea, lethargy, or other markers of morbundity and which appear to be in distress will be

euthanized. The scale for pain or lethargy is attached. Mice scoring a total of 12 under any measurement will be euthanized.

V.1.4. Experiment 4 (b)(4) **inhibition on** (b)(4)
(b)(4)
We will investigate the effecs of (b)(4) inhibition of (b)(4) We will determine levels of (b)(4) using histological methods at (b)(4) days after (b)(4) irradiation, as well as (b)(4) For this
(b)(4) experiment we will require only mice/group, and we will examine 6 groups: 1) sham; 2) sham + vehicle 3) sham + (b)(4) 4) IR 5) IR + vehicle; 6) IR + (b)(4)

The experiment will be repeated because it is a generally accepted principle of the scientific method that experiments must be repeated to evaluate a hypothesis.

(b)(4) mice per group) x (6 treatment groups) x (1 time point) = (b)(4)
(b)(4) mice/experiment) x (2 experiments) = mice

Endpoint: The final endpoint for the experiment is days. Mice displaying obvious dyspnea, (b)(4) lethargy, or other markers of morbundity and which appear to be in distress will be euthanized. (b)(4) The scale for pain or lethargy is attached. Mice scoring a total of 12 under any measurement will be euthanized.

V.1.5. Experiment 5 (b)(4) **inhibition on** (b)(4)
(b)(4) **following irradiation** (b)(4)
We will investigate the activation of (b)(4) pathway and monitor (b)(4) We will examine these aspects through immunohistochemistry and determine if the (b)(4) treatment was sufficient to inhibit the feed-forward (b)(4) Four time points will be examined, correlating with the times we have observed for (b)(4) (b)(4) following radiation exposure: (b)(4) weeks postirradiation. We will analyze (b)(4) and the expression of (b)(4)
(b)(4) For this experiment we will require only mice/group, and we will examine 6 groups: 1) sham irradiation + no treatment; 2) sham + vehicle 3) sham + (b)(4) 4) IR; 5) IR + vehicle; 6) IR + (b)(4) The experiment will be repeated because it is a generally accepted principle of the scientific method that experiments must be repeated to evaluate a hypothesis.

(b)(4) mice per group) x (6 treatment groups) x (4 time points) = (b)(4)
(b)(4) mice/experiment) x (2 experiments) = mice

Endpoints: Endpoints for the experiments will (b)(4) weeks postirradiation. Early time points will be taken if any animal exhibits signs or symptoms of morbidity or moribundity. Such animals will be euthanized at the time of observation.

V.2. Data Analysis:

Mean with standard error, or percentage will be reported if applicable. A significance level is set at 5% for each test. All statistical tests are two-sided. A statistical software, SAS will be used for statistical analyses.

Experiment 1: Analysis of variance (ANOVA) will be used to detect significant difference among the groups. If significant, then the pair-wise comparison by Tukey-Kramer will be used to identify which group is different from the other. For experiment 1, N = mice per group could have 80%(b)(4) power to detect any significant difference between groups if any, given type I error of 5% and delta/sigma has at least 1.4, where the delta is the estimated mean differences between the two groups and sigma is the pooled standard deviation of the two groups (b)(4)

Experiments 2-5: Previous data from this laboratory indicate that the coefficient of variation (CV) of the data is about 0.5, and that differences of between 2- and 30- fold are likely to be observed. A (b)(4) sample size of [redacted] per group will have 80% power to detect 3-fold increases in biomarkers based on a lognormal t test with a 5% two-sided significance level and a CV of 0.5.

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered:

For the last 10 years, we have utilized primary cell culture systems to examine anti-apoptotic mechanisms; however, we must determine whether our culture findings are relevant in whole animals. We will continue to use primary cell culture whenever possible to avoid unnecessary use of animals. We have also considered computer models as alternatives to animals. However, this alternative also lacks the knowledge base and complexity needed to evaluate radioprotective and radiotherapeutic agents.

V.3.2. Animal Model and Species Justification:

Tissue culture conditions cannot fully substitute for the complexities of whole organisms in response to radiation injury. Such injury involves the interactions between the hematopoietic system and other organ systems. In order to develop viable treatments for humans, we find that our research must be conducted in whole animals.

Work by (b)(6) [redacted] also advocates the mouse as the best species to use for radiation protection and radiotherapy protocols: 1) mice provide the least sentient species available whose response to radiation has been clearly identified, with physiological responses to radiation and radioprotectants that are similar to human physiology, 2) extensive literature is available on responses of mice to radiation and countermeasures, 3) more reagents are available to study the relevant cell types and molecules in mice than in any other species except humans, and the availability of transgenic and knockout mice make this model extremely attractive for further research into molecular mechanisms, and 4) our research group has extensive experience with this model in radiation injury and radioprotection research.

The strains of mice to be utilized for each portion of the study are based on the literature and on findings from our own laboratory. (b)(4) [redacted] (b)(4) [redacted] Our laboratory has found that C57BL/6 mice have radiation-induced (b)(4) damage similar to that reported in the literature for humans.

V.3.3. Laboratory Animals

V.3.3.1. Genus & Species:	*Mus musculus*	*Mus musculus*
V.3.3.2. Strain/Stock:	C57L	C57BL/6
V.3.3.3. Source/Vendor:	(b)(4) [redacted]	
V.3.3.4. Age:	10-14 weeks	10-14 weeks
V.3.3.5. Weight:	Normal adult weight range for this strain: 17-21 g.	Normal adult weight range for this strain: 17-21 g.

V.3.3.6. Sex:	Female. Only females will be used in this study for the following reasons: 1) we have so far utilized female mice to lay the foundation of our studies for radiation-induced (b)(4) (b)(4) injuries; 2) because of long housing periods, it is advantageous to use female mice that are less aggressive toward each other.	Female. Only females will be used in this study for the following reasons: 1) we have so far utilized female mice to lay the foundation of our studies for radiation-induced (b)(4) (b)(4) injuries; 2) because of long housing periods, it is advantageous to use female mice that are less aggressive toward each other.
V.3.3.7. Special Considerations:	Commercially procured animals must be adventitious disease free. Mice- Pathogen-free, including *Pseudomonas aeruginosa*, and Pasteurella. All mice need to be free of the following agents: Sendai, Pneumonia Virus of Mice (PVM), Reovirus-3 (Reo 3), Mouse Adenovirus (MAD-1, MAD-2), Mouse Cytomegalovirus Virus (MCMV), Ectromelia, K virus, Lymphocytic Choriomeningitis Virus (LCM), Epidemic Diarrhea of Infant Mice (EDIM), Hantaan virus, Rotavirus, Mouse Parvovirus (MPV), Polyoma Virus, Mouse Minute Virus (MMV), Mouse Thymic Virus (MTV), Theiler's Mouse Encephalomyelitis Virus (TMEV/GDVII), *Encephalitozoon cuniculi*, CAR bacillus, *Helicobacter* spp. *Mycoplasma pulmonis*, and *Clostridium piliforme*. Endoparasite- and ectoparasite-free.	

V.3.4. Number of Animals Required (by Species): C57L C57BL/6 (b)(4)

V.3.5. Refinement, Reduction, Replacement (3 Rs):

V.3.5.1. Refinement: Animals demonstrating moribundity due to radiation exposure will be considered to have arrived at the study endpoint and will be immediately euthanized (See sections V.4.5 Study Endpoint and V.4.6 Euthanasia).

Ketamine/xylazine anesthesia will be used during X-ray irradiation to prevent stress from the time the mice are placed in restraint. Under the training protocol at AFRRI in conjunction with the AFFRI veterinary staff, we found that in female CBA or C57BL/6J mice, ~12 weeks old, i.p. injection of 150 mg/kg ketamine plus 18 mg/kg xylazine results in a minimum of 40 min anesthesia with no morbidity or mortality (b)(4) We will use a heating pad to keep mice warm during the period of recovery from anesthesia. The temperature in room where the mice will be irradiated will be measured, and if necessary a space heater will be used to increase the temperature. Standard intraperitoneal injection methods are used for injection of the anesthesia, as recommended and approved by the USUHS veterinary staff and for which all laboratory personnel have received training at USUHS.

V.3.5.2. Reduction: Whenever possible, control groups will be shared between experimental groups for our experiments. Tissues will be collected for multiple assays from the same animals

further reducing the total number of animals needed. At every stage of the research, planned experiments will be reevaluated, in an attempt to reduce the numbers of experiments and eliminate repeats of experiments where statistical significance has already been obtained. For (b)(4) irradiation studies, each animal will be able to provide its own control tissue from the non-irradiated area. Preliminary results from our laboratory demonstrate that tissue from the abdominal region is normal under our experimental conditions.

V.3.5.3. Replacement: At this time, it is not feasible to use non-animal systems in place of animal models to address the research questions in this protocol.

V.4. Technical Methods:

V.4.1. Pain / Distress Assessment:

V.4.1.1. APHIS Form 7023 Information:

V.4.1.1.1. Number of Animals:

	C57L	C57BL/6
V.4.1.1.1.1. Column C:	(b)(4)	
V.4.1.1.1.2. Column D:		
V.4.1.1.1.3. Column E:		

V.4.1.2. Pain Relief / Prevention:

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization:
We will be unable to use general analgesics since they have effects on (b)(4) function that would interfere with the interpretation of our results (b)(4) (b)(4) Some sedatives have been reported to contribute to postoperative (b)(4) which likely reduce some functions of radiation. For C57BL/6 mice exposed to (b)(4) irradiation to induce radiation (b)(4) daily on animals displaying radiation injury to alleviate discomfort and to prevent infection. This agent is also used for humans.

An anesthesia protocol has been developed for use during the X-ray irradiation. Ketamine will be used with xylazine for longer anesthesia in mice to be place in restraints for (b)(4) irradiation. Under the training protocol at AFRRI in conjunction with the AFRRI veterinary staff, we found that in female C57BL/6 and CBA mice, ~12 weeks old,i.p. injection of 150 mg/kg ketamine plus 18 mg/kg xylazine results in a minimum of 40 min anesthesia (25 G needle) with no morbidity or mortality (b)(4)

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions:
Animals will be housed and cared for as described in Section V.5. Veterinary Care both before and after dose administrations and irradiation procedures. The PI and research staff will monitor animals after radiation or sham irradiation during anesthesia recovery. The PI and research staff will also monitor animals daily following radiation exposure, and twice daily during critical periods. Otherwise, the animals will receive standard veterinary care in the USU vivarium. Animals displaying radiation-induced (b)(4) will receive (b)(4) (b)(4) is approved for human use.

V.4.1.2.3. Paralytics: N/A

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures:

V.4.1.3.1. Sources Searched: DoD Bioedical Research Data Base (BRD), NIH Reporter, PubMED

V.4.1.3.2. Date of Search: 3/31/14

V.4.1.3.3. Period of Search: Search covered published manuscripts from ~1965-present (BRD search included all available years 1998 -2014).

V.4.1.3.4. Key Words of Search: Pain, analgesia, anesthesia, mice, radiation, ionizing radiation, humane (b)(4)

V.4.1.3.5. Results of Search:
The literature search revealed that, at present, there are no alternative procedures for irradiation because its effects cannot be otherwise duplicated. In some cases radiation has been demonstrated to reduce pain in laboratory mice (b)(4) and has been in humans reported to alleviate cancer related bone pain (b)(4) (b)(4) A recent report showed that administration of botulinum toxin A was effective for reduction of pain and muscle spasms after clinical radiation for treatment of tumors (b)(4) (b)(4) Application of natural honey 20 min prior to radiation exposure was also shown to reduce mucositis with associated pain in humans following head/neck radiotherapy (b)(4) it has not been determined whether honey acts as a local radioprotectant. Human administration of morphine also relieves pain (b)(4) but again this would not be practical for mice in our experiments because of side effects of the drug. In humans, exposure to (b)(4) irradiation may induce vomiting and diarrhea, causing pain and distress. However, mice are not susceptible to vomiting.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification:
Anesthesia will be used before (b)(4) irradiation to avoid stress from restraint (b)(4) (b)(4) (b)(4) we will be unable to use analgesics after irradiation since they have effects on (b)(4) function that would interfere with the interpretation of our results (b)(4) (b)(4) Pain will be evaluated using several standard indications including: grimacing, abnormal breathing, hunched or fluffed fur and inactivity, or ataxia. In experiments where tissue collection is needed, animals will be euthanized with pentobarbitol prior to sample collection as described in Section V.4.6. We will utilize the attached score sheets to provide a scale for measurement of criteria for euthanasia. Score sheet will be used daily after irradiation. During critical periods, animals will be monitored twice daily, and during the second monitoring score sheets will be updated if necessary for that day. Any animal scoring 12 or more total on the score sheet will be euthanized. In experiments where tissue collection is needed, animals will be euthanized with pentobarbitol prior to sample collection as described elsewhere.

V.4.2. Prolonged Restraint:
(b)(4) irradiation will require restraint in designed jigs for ~30 min to receive X-ray exposure (b)(4) (b)(4) animals will be anesthetized during this period (see Anesthesia above) and tails will be taped to one side with surgical tape. The jigs for use during (b)(4) irradiation were examined and approved by the AFRRI Veterinary staff. An image of the jigs is attached. Under the training protocol at AFRRI in conjunction with the AFRRI veterinary staff, we found that in female CBA and C57BL/6 mice, ~12 weeks old, i.p. injection of 150 mg/kg ketamine plus 18 mg/kg xylazine results in a minimum of 40 min anesthesia (25 G needle) with no morbidity or mortality (b)(4) The length of time

for anesthesia is needed to ensure that animals do not regain consciousness while being positioned in the lead shield for irradiation. Positioning of the mice must be done carefully to ensure that all animals receive the same exposures. We propose to use this range of concentration of anesthesia, together with a heating pad to keep mice warm during the period of anesthesia. Standard i.p. injection methods are used for injection of the anesthesia. We propose to use this range of concentration of anesthesia, together with a heating pad to keep mice warm during the period of anesthesia. AFFRI Veterinary staff provided training and supervision for the placement of anesthetized animals in the approved jigs for irradiation.

V.4.3. Surgery:

V.4.3.1. Pre-surgical Provisions: N/A

V.4.3.2. Procedure: N/A

V.4.3.3. Post-surgical Provisions: N/A

V.4.3.4. Location: N/A

V.4.3.5. Surgeon: N/A

V.4.3.6. Multiple Major Survival Operative Procedures:

V.4.3.6.1. Procedures: N/A

V.4.3.6.2. Scientific Justification: N/A

V.4.4. Animal Manipulations: N/A

V.4.4.1. Injections:

Intra-peritoneal injections of pentobarbital for euthanasia 0.01-0.02 ml/mouse Fatal Plus (39-78 mg pentobarbital/mouse), will be performed with a 23 G needle. I.p. injection of 150 mg/kg ketamine plus 18 mg/kg xylazine will be done using a 25 G needle. This level of anesthesia was first developed for our use in collaboration with the AFRRI Veterinary staff and shown to effectively produce non-lethal anesthesia for a minimum of 40 min (b)(4)

(b)(4)

(b)(4) Animals will be monitored using the "Pain Score Sheet".

V.4.4.1.1. Pharmaceutical Grade Drugs

(b)(4)

V.4.4.1.2. Non-Pharmaceutical Grade Drugs

(b)(4)

(b)(4)

V.4.4.2. Biosamples:
All biosamples will be taken after euthanasia. (b)(4) will removed *en bloc*. (b)(4 will be removed from the (b)(4) as experimental tissue and from the (b)(4) as control tissue. All other tissues will be available to other researchers for tissue sharing.

V.4.4.3. Adjuvants: N/A

V.4.4.4. Monoclonal Antibody (MAbs) Production: N/A

V.4.4.5. Animal Identification:
All cages will have cage cards identifying the treatment groups for each experiment.

V.4.4.6. Behavioral Studies: N/A

V.4.4.7. Other Procedures:

(b)(4) **irradiation**
The methodology for (b)(4) irradiation of mice including approval of holding jigs and development of anesthesia was developed in conjunction with the AFRRI Veterinary Staff. (b)(4) irradiation will be performed using the RS2000 irradiator in (b)(6) Thirty minutes prior to irradiation, the RS2000 irradiator and lead shield will be decontaminated thoroughly with MB10.

Mice will be anesthetized by injection in the USUHS LAM facility. Anesthetized mice will be placed in ventilated Lucite jigs, which restrain the animals to prevent lateral or vertical movement. Tails will be taped to prevent any forward motion of animals. Mice will be irradiated at (b)(4) (b)(4) irradiation. The temperature in room where the mice will be irradiated will be measured, and if necessary a space heater will be used to increase the temperature. Following radiation exposure, mice will be immediately returned to the LAM and allowed to recover from anesthesia under supervision with heating pads. Immediately upon recovery, animals will be returned to standard cages that house 4 animals per cage. Lucite jigs will be sanitized after each use.

V.4.4.8. Tissue Sharing:
For most studies (b)(4) will be removed *en bloc* or (b)(4 tissue with substructure tissues will be removed. All other tissues will be available for tissue sharing with other investigators. Our laboratory has made extensive use of shared tissues for training and technique development for (b)(4) tissue.

V.4.5. Study Endpoint:
(b)(4)
(b)(4) Early endpoints will be used in the case of morbidity and morbundity. Specific health assessment criteria including rapid weight loss, ruffled fur, dried lacrimal fluid accumulated in the cul-de-sac of their eyes, are cool to the touch, decreased appetite, dehydration, diarrhea, difficulty breathing or panting (b)(4) (b)(4) or hunched body position will used to determine early study

endpoints for euthanasia. The experimental design does not contemplate supportive therapy, and animals exhibiting these signs may be euthanized, and considered to be at the study endpoint.

Following (b)(4) irradiation, mice may exhibit injuries from the (b)(4) irradiation during the (b)(4) (b)(4) postirradiation. Also, mice are expected to develop (b)(4) postirradiation. During the critical time periods (b)(4) postirradiation), mice will be monitored by the PI or other members of the investigative team at least twice daily, early morning and late afternoon including weekends or holidays.

V.4.6. Euthanasia:

Animals will be euthanized at the stated endpoints of the experiments by i.p. injection of ml/mouse Fatal Plus. PHS policy is intraperitoneal injection of at least 200 mg/kg sodium pentobarbital euthanasia solution; Fatal Plus: 390 mg pentobarbitol/1 ml.

1 ml/390 ml x 0.02 kg/mouse x 200 mg/1 kg = 0.01-0.02

IP injection will be performed using a 23 G needle. (Please note that Euthasol cannot be used as additives have effects on (b)(4) We do have Fatal Plus for these experiments.) Euthanasia will be confirmed by cervical dislocation. Animals which appear to be experiencing pain or distress as a result of radiation exposure or are found moribund will also be euthanized by pentobarbitol and necropsied. At the end of experiments, unused animals will be transferred to other protocols or euthanized by exposure to 100% CO_2 from a compressed gas cylinder in accordance with the current American Veterinary Medical Association (AVMA) Guidelines for Euthanasia. Exsanguination, cervical dislocation, and/or pneumothorax will be used to ensure euthanasia.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol. Mice will be housed 4 per cage. Food and water and Rodent Diet will be available ad libitum. The 12:12 hr (lights off at 6 pm) room light cycle is fine for all the studies.

V.5.1.1. Study Room:

Radiation Building (b)(6) Room Number (b)(6)

Euthanasia Building (b)(6) Room number (b)(6)

V.5.1.2. Special Husbandry Provisions:

Food Restriction:	Yes _____	No	x
Fluid Restriction:	**NOTE: Acidified water will be provided to reduce infections after radiation exposure.**	No	x

Acidified water (pH 2.5 – 3.0) is produced at AFRRI for their vivarium using 2.0 N HCl. The water will be obtained from USUHS LAM. Unused ~~water will~~ be neutralized with sodium bicarbonate and the pH will be verified before disposal.

V.5.1.3. Exceptions: None

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care:
Experimental animals will be observed at least twice a day by one of the study investigators or technicians. LAM personnel will also monitor the animals twice a day during their rounds. As described in another section (study endpoint) morbid animals will be monitored at least twice daily, morning and afternoon. The experimental design does not contemplate supportive therapy. The justification for not providing supportive care has been described in the study end point section as well as in the pain category section. Criteria to be used for health evaluation while the animals are on study include: 20% weight loss compared with average weights of sham irradiated animals (mice will be weighed every other day between days (b)(4) (b)(4) ruffled fur, dehydration, decreased activity, and hunched body position, dyspnea, or panting. Animals exhibiting these signs may be euthanized, and considered to be at the study endpoint. Increased
(b)(4) monitoring of C57L animals will begin on day through the end of the experiment, *based on our* previous data that indicated that mortality from (b)(4) irradiation occurs between days (b)(4) postirradiation in CBA mice. Increased monitoring of C57BL/6 animals exposed to (b)(4) irradiation for (b)(4) will be monitored between days (b)(4) when the most prominent (b)(4) (b)(4) is expected. In the event of debilitating illness the decision to euthanize will be made by the veterinarian and/or PI.

V.5.2.2. Emergency Veterinary Medical Care:
All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays. In the case of an emergency health problem, if the responsible person (e.g. investigator) is not available or if the investigator and veterinary staff cannot reach consensus on treatment, the veterinarian has the authority to treat the animal, remove it from the experiment, institute appropriate measures to relieve severe pain or distress, or perform euthanasia if necessary.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: All animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents; balls, toys and food enrichment treats for large animal species.

V.5.3.2. Enrichment Restrictions: none

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
Ear punch, irradiation, anesthesia, euthanasia	(b)(6)	9+ years	(b)(6)
Irradiation, anesthesia, euthanasia		6 years	
Rodent handling		10+ years	
Anesthesia, euthanasia, irradiation		5+ years	

VII. BIOHAZARDS/SAFETY: Laboratory personnel working with animals will be wearing standard personal protective equipment (PPE), including dust masks, gloves, and lab coats, as required by USUHS LAM. No additional protection is required for handling irradiated animals, since the animals will be exposed to X-ray irradiation and are not themselves radioactive or otherwise infectious. The RS2000 X-ray irradiator utilizes a fully shielded cabinet for animal irradiation that has been tested and approved by the USUHS Radiation Safety Office. Personal dosimeters are worn by laboratory personnel during X-ray irradiation of the animals, as designated by the Radiation Safety Office.

VIII. ENCLOSURES: Image of jigs for (b)(4) irradiation; pain score sheet; criteria for euthanasia

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

(b)(6)

I.

Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL or WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

DATE:	Time:	Animal ID#	Score
Appearance:			
	Normal (smooth coat, clear eyes/nose)		0
	Hunched and/or fluffed		1
	Ocular discharge, and/or edema		3
	Emaciated, dehydrated (skin tent) **		5
	Soft stools (fecal matter around anus)		5
	Bloody diarrhea		9
Respiratory rate:			
	Normal breathing		0
	Increased breathing (double normal rate, rapid, shallow)		6
	Abdominal breathing (gasping +/- open mouth breathing)*		12
General Behavior:			
	Normal (based on baseline observations)		0
	Stretching of hind limbs with abdominal motion (writhe) or grimace (App. B and C)		1
	Decreased mobility		2
	Ataxia, wobbly, weak**		6
	Inability to stand*		12
Provoked Behavior:			
	Normal (moves when cage is disturbed, runs from hand (mice) or investigates (rat))		0
	Subdued; responds to stimulation (moves away briskly)		1
	Subdued even to stimulation (moves away slowly)		3
	Unresponsive to gentle prodding **		6
	Does not right when placed gently on side within 5 seconds*		12
TOTAL			_____

Definitive criteria for morbidity:
Weight Loss up to 10% baseline (if available)**
Pale, white mucous membranes/ skin * *
Fever >104F/40C (if available)**

Definitive criteria for moribundity:
Weight Loss > 20% OR <15g (adult mouse)*
Blue mucous membranes/ skin (cyanosis)*
Cool to the touch or <86F/30C (if available)*

**** Regardless of score, notify appropriate person immediately.**

*** Regardless of score, immediately euthanize (death is imminent)**

Score:
< 6 Normal
6 - 9 Morbid: Monitor at least 3 times per day; notify appropriate personnel immediately
> 10 Moribund: Notify responsible personnel immediately for euthanasia (if no single criteria is 12*)
Any single criteria of 12* euthanize immediately; consider as 'found dead'

(Note: This form does not have to filled out for every individual at every observation, so long as the criteria are used in informing decisions on increased monitoring and/or euthanasia. This form may be used to make a spreadsheet for greater ease of multiple animal observations, as long as the criteria and numbering system are exactly copied.)

BETHESDA, MARYLAND 20814-4799

June 9, 2015

MEMORANDUM FOR DR. (b)(6)

SUBJECT: IACUC Approval of Protocol – Initial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on June 8, 2014:

Animal Protocol Title: "Development of (b)(4) for the Mitigation of Acute Injuries from Ionizing Radiation in Gottingen Minipigs (Sus scrofa domestica)"

USUHS Protocol Number: (b)(6)

Expiration Date: June 7, 2018

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. NON-TECHNICAL SYNOPSIS: The (b)(4) system is sensitive to injury by ionizing radiation. (b)(4) Syndrome, a part of Acute Radiation Syndrome (ARS), occurs in response to exposure of significant portions of the active (b)(4) to ionizing radiation, above (b)(4) A very limited number of large animal models are available for the testing of radiation countermeasures, including non-human primates, dogs and swine. An improved understanding of the natural history of radiation sickness and development of multi-organ failure is still largely incomplete.

Dr (b)(6) has been developing a minipig model of ARS. Dr. (b)(6) has characterized (b)(4) ARS and has tested the efficacy of the radiation countermeasure G-CSF on survival and (b)(4) recovery in the irradiated Gottingen minipig. Signs and symptoms, kinetics of blood cell depletion and recovery, multi-organ dysfunction and histological findings resembled closely what observed in human victims of radiation accidents and in other large animal models (b)(4)

Our laboratory has characterized the use of (b)(4) as a radiation countermeasure for (b)(4) syndrome in mice. We have demonstrated in mice the required time course for administration of (b)(4) and dosages of the drug required for preventing mortality at (b)(4) (b)(4) levels of radiation exposure. Our research has also demonstrated that (b)(4) suppresses radiation-induced (b)(4) in the (b)(4) and other tissues, mitigates radiation-induced hypoxia, and reduces the induction of cytokines induced in response to radiation damage (b)(4)
(b)(4)

Advanced development of a radiation countermeasure requires the testing of the countermeasure in two animal species as well as demonstration of the mechanism of action in order to fulfill the FDA Animal Rule. The purpose of the current study is the testing of (b)(4) as a countermeasure in the minipig model developed by Dr (b)(6) to fulfill the requirement of a second species for radiation testing according to FDA requirements.

II. BACKGROUND:

II.1. Background:

High dose total body irradiation (TBI) in humans can result in both acute and delayed injuries. The Acute Radiation Syndrome (ARS) is characterized by the (b)(4) (b)(4) syndromes. The mechanisms leading to (b)(4) ARS remain largely unknown, but current information indicate that (b)(4) may play a major role in the loss of (b)(4) (b)(4) leading to (b)(4) There are currently no approved countermeasures for radiation-induced (b)(4) injuries, and it is our long range goal to develop effective agents for this condition. The objective of this application is to evaluate the effects of an FDA-approved drug (b)(4) for mitigating (b)(4) radiation injuries. (b)(4) as a mitigator of radiation-induced (b)(4) injury using a murine model for (b)(4) injuries, and (b)(6) have conducted significant experiments to elucidate its mechanism of action in mice and in ex vivo experiments. Radiation countermeasures must be approved for human use under the FDA Animal Rule, which requires demonstration of efficacy in two species. One species may be a rodent, and is fulfilled by our murine model experiments, however the other species must be non-rodent. Our central hypothesis is that (b)(4) administration will have significant combined effects in mitigating radiation (b)(4) radiation injuries in the Gottingen minipig model of (b)(4) ARS. (b)(4) administered daily (b)(4) was demonstrated to mitigate radiation-induced damage to the kidney in swine (b)(4) (b)(4) was also demonstrated in swine to reduce cardiac remodeling after experimentally-induced myocardial infarction (b)(4) With Dr. (b)(6) we will assess in vivo protection and potential mechanisms of action of (b)(4) against radiation-induced (b)(4) injury in the minipig model of (b)(4) ARS. This research supports DoD goals of identifying novel therapeutic strategies to mitigate/treat the health consequences of ionizing radiation exposure that exist as a threat under military operations, humanitarian, and counter terrorism environments.

II.2. Literature Search for Duplication:

II.2.1. Literature Source(s) Searched: BRD, PubMed, NIH RePORTER

II.2.2. Date of Search: 1/06/2015

II.2.3. Period of Search: BRD: 1998-2014; PubMed: 1985-present; NIH RePORTER: 2006-present

II.2.4. Key Words and Search Strategy:
Searches were performed using the following key word combinations:
(b)(4) + minipig + (b)(4) + radiation, or (b)(4) + minipig + radiation, or (b)(4) + minipig + radiation, or swine + radiation

II.2.5. Results of Search:

The NIH RePORTER search of all funded grants since 2006 revealed no related grants. Swine + radiation provided 123 matches, but none related to ARS. Swine + radiation + (b)(4) (b)(4) provided no matches.

The PubMed search of the list of key words minipig + radiation + (b)(4) and swine + radiation + (b)(4) provided 1 result.

1) (b)(4)

The BRD search (1998-2007): no grants were identified for minipig + radiation searches. For swine + radiation there were 4 results:

1) Implantation Techniques and Specific Absorption Rates for Swine (*Sus scrofa*) in Directed Energy Health and Safety Studies
2) Pilot study: Development of Gottingen minipig (*Sus scrofa domestica*) as radiation injury model
3) NIRVANA: Non-Ionizing Radiation Vision for a New Army
4) Extended Electro Magnetic Medical Advisor: A Diagnostic Tool for Casualty Triage by Combat Medics

III. OBJECTIVE\HYPOTHESIS:

Data from our laboratory and the literature indicate that the inhibition of (b)(4) activation is protective against (b)(4) injuries from radiation in the murine model of radiation-induced (b)(4) syndrome. We hypothesize that inhibition of (b)(4) to inhibit (b)(4) activation may mitigate radiation induced (b)(4) injury by reducing the loss of mature blood cells, sparing (b)(4) cells, and enhancing (b)(4) (b)(4) recovery in the Gottingen minipig model of (b)(4) syndrome. We anticipate an improvement in survival of at least 30%.

IV. MILITARY RELEVANCE:

The Department of Defense (DoD) is prepared to execute military missions within radiation environments, to manage radiation crises associated with terrorist activities, and to manage consequences in the event of nuclear weapons detonation. Recent studies indicate that there is an increasing risk of exposure to ionizing radiation to military personnel due to increasing terrorist activities, including potential use of stolen nuclear weapons, the detonation of an improvised nuclear device (IND) or a large radiological dispersal device (RDD) (b)(4) (b)(4) High dose ionizing radiation results in short term, acute injuries including (b)(4) syndromes. However, both high and low dose radiation (as may result from a radiation dispersal device) can cause delayed (b)(4) as demonstrated by previous radiation accidental exposures. For example, individuals accidentally exposed to 8-24 Gy radiation in the Tokai-mura, Japan radiation accident were successfully treated for acute radiation injuries but succumbed to delayed respiratory failure between 82-210 days

postirradiation (b)(4) A radiation accident victim in Belarus also recovered from acute injuries but died from radiation-induced (b)(4) 130 days following a 10 Gy exposure (b)(4)

At present, there are no FDA approved medical countermeasures for mitigation or treatment of acute or delayed radiation injuries. The development of new medical radiological countermeasures will significantly enhance the warfighting mission by sustaining unit effectiveness and are critical for operational preparedness in nuclear/radiological threat environments. These agents are essential for the prevention of radiation casualties and preserving the Warfighter's effectiveness. One of the primary focuses of the DoD medical radiological defense research area is to develop broad-spectrum postirradiation therapeutics effective against acute radiation syndrome (April, 2009).

The DoD is committed to protecting the Warfighter from the adverse health effects of ionizing radiation. Our research is aimed at developing an effective postirradiation countermeasure to: 1) reduce the casualty load at medical treatment facilities, 2) sustain a more effective operational force after a radiation exposure event, 3) allow commanders to conduct operations in radiation field environments without undue risk of decremented performance of personnel due to acute tissue injury, and to 4) reduce the negative psychological impact on personnel tasked to operate in contaminated environments.

The research outlined in this proposal is aimed at developing effective therapeutic strategies for the combined treatment of acute and late radiation-induced injuries for the Warfighter. Results from these studies will additionally have application for civilian use and the medical community at large.

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures:

Male Gottingen minipigs will be obtained from (b)(4) at age of approximately 4 months, and at a weight appropriate for healthy animals of that age range. Minipigs will be housed singly to avoid injuries, and fed (b)(4) according to their weight, following recommendations from the vendor (b)(4) and IAW USUHS-LAM SOP 22-205 Routine Husbandry of Pigs. Animal care and use procedures will only be performed by trained and certified personnel.

Animals will have 1-2 weeks to acclimate to the USUHS LAM (see time line, below). A blood draw will be made from each animal to establish baseline blood cell levels.

(b)(6) Animals will be transported under anesthesia to (b)(6) for (b)(4) irradiation in the (b)(6) facility (see V.4.1.2.2.). Sham irradiated animals will be anesthetized, and placed in transport and moved to (b)(6) but not irradiated. (b)(4) (b)(4) will be freshly injected into a grape or marshmallow for the animal to eat (b)(4)

Health of animals will be monitored twice-daily, and temperatures will be taken for each animal *once* a day in the morning. CBC/differential will be monitored on the days (b)(4) (b)(4) except in emergency cases, where blood for (b)(4) will be taken by LAM request. These experiments will utilize the husbandry, irradiation, and blood draw procedures perfected in the studies performed under previously approved protocols at (b)(6)

Animals will be euthanized on day (b)(4) Tissues and blood samples may be taken at the time of euthanasia and shared with other investigators for biodosimetric and mechanistic studies.

Secondary data-points will be standard hematology measurements in peripheral blood (b)(4) etc.), body temperature, body weight, and occurrence of bloody stools. On day (b)(4) each surviving minipig will be euthanized, blood taken for (b)(4) and tissues collected for histopathology and tissue repository.

Time Line for experiment:

(b)(4)

V.1.1. Experiment 1: Effects of (b)(4) treatment on (b)(4) (b)(4) in Gottingen minipigs.

Our experiments will be conducted with Gottingen minipigs. Animals will be either sham irradiated or receive (b)(4) irradiation in the (b)(6) facility. We will determine the effect of (b)(4) on normal (b)(4) after (b)(4) of treatment: 1) (b)(4) cell analysis; 2) histological analysis of (b)(4) (b)(4) 3) the levels of (b)(4) cytokines in the blood; and 4) extramedulary (b)(4) will be determined by cellular analysis of the spleen and liver. (b)(4) analysis, and spleen and liver analysis can be performed using the same animals.

Treatment groups will be: 1) sham irradiated (b)(4) 2) sham irradiated + (b)(4) 3) (b)(4) irradiation (b)(4) 4) (b)(4) irradiation + (b)(4) (b)(4) Survival will be determined at (b)(4) Samples of blood will be obtained on days - (b)(4) and at the time of euthanasia (Time 0 is the time of (b)(4) irradiation). The (b)(4) and livers will be removed for analysis. We (b)(4) require a total of N = animals per group, and 4 iterations total for this pilot experiment, (b)(4) giving a total of N = per group. The iterations would be performed over a period of (b)(4) (b)(4) will be required to complete the experiments since animals will be singly housed, which means that experiments can only be conducted when there is sufficient space in LAM for the experiment. Also (b)(6) will be shutting down their (b)(6) facility for (b)(6) meaning that there will be significant delays for the experiments to be performed. We want to ensure that we can complete this pilot to obtain clear data to determine whether a larger scale experiment should be performed. This will be sufficient to provide proof of concept for protection by (b)(4) prior to initiation of a larger study.

(b)(4) animals/group x 4 treatment groups = animals
(b)(4) One experimental repeated for 4: total = animals
Groups with no pain (Category C): (b)(4)
Groups with alleviated pain (Category D): (b)(4)
Groups with non-alleviated pain (Category E): (b)(4)

V.2. Data Analysis:

(b)(4) histology will be scored by a blinded veterinary pathologist. Experiments investigating the effects of (b)(4) (b)(4) will be done for each endpoint using ANOVA in 2^2, 2^3, and 2^4 designs. These analyses may also include replication. Other statistical analyses will be used where found appropriate. Based on previous experience in our laboratory an N of s enough to obtain statistical (b)(4) significance for survival in swine and to obtain statistical significance for other (b)(4) (b)(4) data (b)(4) Although space
(b)(4) requirements only allow N = group per iteration, we will obtain sufficient N for (b)(4) analysis after 2 iterations. For survival, a higher N is required. We believe that N = (b)(4) will be sufficient for proof of principle under the current funding.

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered:
For the last 9 years, we have performed extensive experiments in primary cell culture systems to investigate the effects of radiation on normal cells. However, our culture findings have not yet been shown to completely recapitulate the complexity of the whole animal system. We will continue to use primary cell culture whenever possible to avoid unnecessary use of animals. We have also considered computer models as alternatives to animals. However, this alternative also lacks the knowledge base and complexity needed to evaluate fibrosis and preventative agents.

Because we do not know all the cell types and tissues involved in radiation injury, and how these systems interact with one another for repair or for extension of initial radiation damage, there is vital information that can be gained only from the use of a whole animal system. Up until now, we have utilized mice as the least sentient whole animal system for our research of (b)(4) as a radiation countermeasure. However, in order to advance our research to FDA requirements under the Animal Rule, we must investigate the efficacy of (b)(4) in another, non-rodent species.

V.3.2. Animal Model and Species Justification:
Tissue culture conditions cannot fully substitute for the complexities of whole organisms in response to radiation injuries. Such injury involves the interactions between the (b)(4) system and other organ systems. In order to develop viable treatments for humans, we find that our research must be conducted in whole animals.

Dr. (b)(6) have investigated the Gottingen minipig as an additional large animal model for the study of (b)(4) radiation injury and

for the development of radiation countermeasures (b)(4) (b)(4) Large, long-lived, non-rodent animal models are required for drug studies submitted to the FDA for licensure applications. Our previous studies have utilized mice for the investigation of (b)(4) timing of administration, and mechanism(s) of action as a radiation countermeasure.

V.3.3. Laboratory Animals

		Strain #1	Strain #2
V.3.3.1.	**Genus & Species:**	*Sus scrofa domestica*	
V.3.3.2.	**Strain/Stock:**	Gottingen	
V.3.3.3.	**Source/Vendor:**	(b)(4)	
V.3.3.4.	**Age:**	4-6 months	
V.3.3.5.	**Weight:**	Standard (7-13 kg)	
V.3.3.6.	**Sex:**	Male	
V.3.3.7.	**Special Considerations:**	None	

V.3.4. Number of Animals Required (by Strain): *Sus scrofa domestica*
Gottingen = (b)(4)

V.3.5. Refinement, Reduction, Replacement (3 Rs):

V.3.5.1. Refinement:
The study data-points currently mandated by the FDA for approval of radiation countermeasures under the Animal Efficacy Rule is mortality. Hence the primary study data-point in our development of Gottingen minipigs as a model for ARS is survival. Moribundity will be used as a surrogate for mortality, and euthanasia will be used in order to minimize pain and distress, using an extensive set of criteria (see animal endpoints, paragraph V.4.5 – Lethargy, weight loss, temperature, respiratory distress, food intake, bleeding etc). Animal care and use procedures will only be performed by trained personnel. Extensive human interaction every weekday will reduce stress in the animals. Use of slings and anesthesia will minimize distress during (b)(4) collections and the animals will be gradually acclimated to the slings for these procedures.

V.3.5.2. Reduction:
Blood samples obtained from minipigs before irradiation will serve as controls, thus reducing the number of animals required for this study. Use of historical controls will reduce the number of animals needed for this study.

V.3.5.3. Replacement:

Our laboratory has made extensive use of primary cell culture systems for all preceding experiments. Every effort will be made to continue to use primary cell culture whenever possible in place of animals.

V.4. Technical Methods:

V.4.1. Pain / Distress Assessment:

V.4.1.1. APHIS Form 7023 Information:

V.4.1.1.1. Number of Animals:

	Strain #1	Strain #2
V.4.1.1.1.1. Column C:	(b)(4)	
V.4.1.1.1.2. Column D:		
V.4.1.1.1.3. Column E:		

V.4.1.2. Pain Relief / Prevention:

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization:

BLOOD DRAWS
For blood draws, animals will be placed in a sling and anesthetized with inhaled isoflorane via a nose cone delivered from a precision vaporizer. If necessary, animals will be injected with Telazol (1-2 mg/kg i.m.), acepromazine (1.1-2.2mg/kg im,iv,sc), or midazolam (0.1-0.5mg/kg im or sc) in order to place the mask on the animals . (b)(4) (b)(4) after disinfection of the area. Isoflorane will be administered using a mask (1-4%), and passive scavenging will be done by F/air charcoal canister.

IRRADIATION
Prior to transportation to (b)(6) for irradiation, animals will be anesthetized at (b)(6) with Telazol® 4.4 mg/kg i.min combination with xylazine 2mg/kg im. Alternatively, ketamine (5-20 mg/kg i.m.)/xylazine (1-2 mg/kg i.m.) can also be used for anesthesia. Atropine (0.05 mg/kg s.c., i.m. or i.v.; atropine sulfate, Butler, Columbus, OH) or glycopyrrolate (0.01 mg/kg) i.m. or i.v. may be given to reduce mucosal secretions.

BONE MARROW ASPIRATION
A bone marrow aspiration will be performed immediately prior to euthanasia. Samples will be collected prior to death to obtain the best quality sample. Animals will be anesthetized with Telazol® (4.4 mg/kg i.m) or Ketamine (5-20mg/kg i.m.) in combination with xylazine 2mg/kg im.

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions:

Body weights will be determined at least once prior to treatment, on the first day of treatment, and on days of blood collection.

TRANSPORTATION OF ANIMALS TO (b)(6) FOR IRRADIATON

Pre-Irradiation at USUHS and Transport to (b)(6) Animals will be fasted overnight (approximately 16 – 18 h). Animals will be anesthetized with injectable drugs, placed in a large animal kennel on a wheeled cart and taken to the LAM van. The anesthetized animals will be driven to (b)(6) and monitored en route. Animals will be provided with additional anesthesia if needed prior to irradiation. The kennel containing the swine will be handed over to the (b)(6) staff.

IRRADIATION

Pre-Irradiation at (b)(6) Anesthetized at USUHS as described above. Upon arrival to (b)(6) animals will be under the care of the (b)(6) veterinary staff. At (b)(6) minipigs will be transported to the (b)(6) in an approved, covered transport cage. Heart rate and temperature will be measured prior to irradiation. At least one vet tech or one veterinarian will be present at the time of irradiation. Immediately before irradiation, the vet or vet tech will determine whether or not to administer additional sedative to keep the animal anesthetized during irradiation.

Irradiation procedure: Animals will be strapped in place into slings in polyvinylchloride PVC frames for irradiation. Effect of anesthesia will be monitored in real time through video cameras positioned in the (b)(6) waiting area. Minipigs will be removed from the slings once irradiation is completed. Temperature and heart rate will be taken before returning the minipigs to their home cages.

Post-Irradiation: After irradiation, animals will be transported back to USUHS. Animals will be returned to their cages, where they will be allowed to recover from anesthesia under the careful surveillance of LAM and/or research staff who will monitor vital signs and provide thermal support (e.g. Bair Hugger blanket) if necessary (b)(4)

Preparation of the animals: Animals will be fasted overnight prior to blood draws. Blood draws will be performed by trained research and veterinary staff. For blood draws, animals will be placed in slings and sedated using inhaled isoflorane via a mask. If necessary, Telazol (1-2 mg/kg i.m.), acepromazine (1.1-2.2mg/kg im,iv.sc), or midazolam (0.1-0.5mg/kg im or sc).will be injected prior to isoflorane. 2-6 ml of blood will be withdrawn from the cephalic, saphenous, ear vein or other peripheral vein after the area has been disinfected. Blood draws will occur on days (b)(4) (see time line for experiment).

After blood draw, animals will be returned to their cages and checked to ensure that the needle puncture wound is closed and the blood has clotted.

BONE MARROW ASPIRATION

A bone marrow aspiration will be performed immediately prior to euthanasia. Samples will be collected prior to death to obtain the best quality sample. Animals will be anesthetized with Telazol® (4.4 mg/kg i.m) or Ketamine (5-20mg/ kg im) in combination with xylazine (2mg/kg im). Bone marrow espiration will be performed with a standard bone marrow aspiration needle (Jamshidi). The skin will be disinfected using isopropyl alcohol. Samples will be collected from the medial aspect of the proximal tibia, approximately at the level of the tibial crest. Alternatively, bone marrow may be aspirated from the dorsal aspect of the tuber coxae or midsternum.

V.4.1.2.3. Paralytics: Not applicable

V.4.1.3. **Literature Search for Alternatives to Painful or Distressful Procedures:**

V.4.1.3.1. **Sources Searched:** Agricola, Pubmed

V.4.1.3.2. **Date of Search:** January 8, 2015

V.4.1.3.3. **Period of Search:** All available

V.4.1.3.4. **Key Words of Search:**
The aspects of the study relevant to alternatives to painful or distressful procedures are the sequelae to exposure to [redacted] at doses causing ARS. We used the following key words in the search for alternatives: swine, radiation/ionizing radiation/gamma radiation, ARS/hematology, sequelae, pain, distress, alternatives.

(b)(4)

V.4.1.3.5. **Results of Search:**
PubMed search: There were a number of reports for the searches that were relevant for UV radiation, but these were not included in our analysis.

Swine + ionizing radiation + pain: 2 reports

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification:

Due to the nature of ionizing radiation and the intended treatment given, animals are expected to die from a compromised immune system, opportunistic infections and acute radiation syndrome. The remaining surviving animals are dependent on the countermeasure given. Administering systemic anesthetic agents to animals after irradiation are known to interact with the immune system (see references in (b)(4) (b)(4) (b)(4) As a result, this will skew our results and would not be productive. Alternatively, we are providing supportive care in terms of fluids/

nutritional support to increase survival. Use of supportive care is expected to mitigate the pain associated to the sequelae of irradiation. Although we have utilized mice for most of our studies as the least sentient animals to provide preclinical information about countermeasures against the toxic effects of radiation, in order to develop (b)(4) as a countermeasure for future use for humans, efficacy of the drug must be demonstrated in an additional non-rodent species, in compliance with the Food and Drug Administration (FDA) Animal Rule. We have selected swine as a species currently acceptable by the FDA for acute radiation syndrome drug testing.

V.4.2. Prolonged Restraint:

Only short periods of restraint in the panepinto sling (<30 minutes) will be necessary for blood collections and the irradiation procedure. To minimize discomfort, a new type of sling that uses softer, elastic material to support the animal, and utilizes a more efficient restraint design that maintains the animal in place while reducing manipulation by technicians and consequently stress to the animals.

After the acclimation period, animals are acclimated to the sling for 5-10 minutes, 2-3 times before initiating blood draws. Acclimation to the sling is very rapid and non-stressful; animals are petted and gently spoken to while restrained. It has been the experience of Dr. (b)(6) group that resting on the sling does not agitate the animal at all.

Animals are anesthetized at USUHS, transported to (b)(6) (b)(6) holding area before being put into slings for irradiation (<20 minutes). Animals will be kept under continuous observation while in the sling. Slings will be cleaned with a towel after each use, and washed weekly and sanitized.

V.4.3. Surgery:

V.4.3.1. Pre-surgical Provisions: Not applicable

V.4.3.2. Procedure: Not applicable

V.4.3.3. Post-surgical Provisions: Not applicable

V.4.3.4. Location: Not applicable

V.4.3.5. Surgeon: Not applicable

V.4.3.6. Multiple Major Survival Operative Procedures:

V.4.3.6.1. Procedures: Not applicable

V.4.3.6.2. Scientific Justification: Not applicable

V.4.4. Animal Manipulations:

V.4.4.1. Injections:
All injections will be administered i.m., i.v., i.c., or s.c. using sterile needles (23 – 21 gauge) and syringes. Specific drugs for injection are defined below:

Drugs for injection:
Atropine/Atropine sulfate 0.04 mg/kg. s.c., i.v., or i.m.
Euthasol® (sodium pentobarbital, 1 ml/4.5 kg i.v. or i.c.
Glycopyrrolate 0.01 mg/kg i.m. or i.v.
Ketamine/xylazine 5 - 20 mg/kg i.m. /xylazine 1 -2 mg/kg i.m.
Telazol/xylazine 4.4 mg/kg i.m./2 mg/kg i.m
Telazol 1-2mg/kg i.m.
Acepromazine 1.1-2.2mg/kg im,iv.sc
Midazolam 0.1-0.5mg/kg im or sc

V.4.4.2. Biosamples:
Blood samples will be collected from the cephalic, saphenous, ear vein, or other peripheral vein. Animals will be anesthetized with inhaled isoflorane with injected Telazol (1-2 mg/kg i.m.), Acepromazine (1.1-2.2mg/kg im,iv.sc), or Midazolam (0.1-0.5mg/kg im or sc), if necessary prior to isoflurane delivery. Blood will be drawn after disinfection of the area with 70% ethanol using a 21-25 gauge needle. Blood draws will be made on days (b)(4) (b)(4) see experimental time line); day 0 is the day of irradiation. This will be performed as it is done routinely in the previous minipig protocols by Dr (b)(6) Each sample will be a maximum of 6 ml in volume or less than 1% total blood volume (whichever is less) and will be collected from the ear vein, saphenous vein, or leg vein.

Tissue and histological samples:
Tissue samples, to include organs, (b)(4) and hairs, may be taken at the time of euthanasia for slide preparation as well as for frozen tissue repository, and may be shared with other investigators.

V.4.4.3. Adjuvants: None

V.4.4.4. Monoclonal Antibody (MAbs) Production: None

V.4.4.5. Animal Identification: Tattoos or ear tags and cage cards/tags will be used.

V.4.4.6. Behavioral Studies: None

V.4.4.7. Other Procedures:

Treatment with (b)(4)
(b)(4) will
(b)(4) given twice daily orally, mg/kg. The (b)(4) will be made up in sterile saline and injected into a grape or a marshmallow and given to the animals to be eaten immediately after injection. Animals will be observed for a few minutes after the food item is given to ensure that the entire item is eaten. This measurement is based on published reports of efficacy of (b)(4) for mitigation of radiation injuries to the (b)(4) (b)(4)

V.4.4.8. Tissue Sharing:
All tissues are available for tissue sharing since our research will utilize small quantities of tissues only.

V.4.5. Study Endpoint:

The data-point currently mandated by the FDA for approval of radiation countermeasures under the Animal Efficacy Rule is moribundity or mortality. Moribundity will be used as a surrogate for mortality, and euthanasia will be used in order to minimize pain and distress. Euthanasia will be carried out when any one or combination of the following signs of moribundity are observed and in consultation with USUHS veterinarians.

Absolute

1. Non responsive, assuming the animal has recovered from anesthesia.
2. Dyspnea
3. Loss of 20% of expected weight (based on Marshall Bio-resources growth chart –weight vs age- and day 0 baseline percentile).

Non-absolute

1. Hyper/hypothermia
2. Anorexia (skip 3 consecutive BID meals)
3. Anemia/pallor, CRT >2 seconds. CRT will be performed behind the ears.
4. Petechiae/ecchymosis
5. Vomiting/diarrhea
6. Lethargy
7. Seizures or vestibular signs (falling, circling or head tilt)
8. Uncontrollable hemorrhage

V.4.6. Euthanasia:

Animals will be euthanized according to current American Veterinary Medical Association (AVMA) guidelines. Animals will be anesthetized with Telazol® (4.4 mg/kg i.m.) or ketamine (5-20 mg/kg i.m.)/xylazine (2 mg/kg i.m.). A bone marrow aspiration will be performed after the animal is anesthetized. Animals will then be euthanized with Euthasol® (sodium pentobarbital, (1 ml/4.5 kg i.v. or i.c.) or another commercial euthanasia solution. Death will be confirmed by USUHS veterinarian or veterinary technician via auscultation of the heart, with cessation of sounds for at least 2 minutes or longer as per current SOP. See item V.4.5 for euthanasia criteria before the end of the study.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations:

Animals will be singly housed. This is necessary since irradiated animals will have reduced immune function and can develop infections from biting or wounds from rough play which can be common in these animals. Rooms will be maintained on a 12:12 h light (0600 to 1800) dark cycle with the temperature set to 27 to 29°C and 30% to 70% relative humidity. Commercial diet (Mini-Swine Diet 8753, Harlan Teklad Diets, Madison, WI) will be provided. Water will be provided ad libitum. Animals will be fed twice a day to control weight gain. Animals will also need to be fasted (b)(4) h prior to anesthetizing for blood draws and for transport for irradiation at (b)(6)

V.5.1.1. Study Room:

Euthanasia will be performed in LAM.

Building(s) (b)(6) Room Number(s) (b)(6)

V.5.1.2. Special Husbandry Provisions:

Food Restriction: Yes X No _____

Fluid Restriction: Yes _____ No X

V.5.1.3. Exceptions:
None

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care: Animals will be monitored for health, humane treatment, and husbandry considerations, twice daily by LAM personnel during routine weekday rounds and at least once daily on weekends/holidays. This is in addition to, and not in place of, the monitoring that is done by the PI and their staff. In the event of a debilitating illness or adverse reaction, the decision to treat or euthanize an animal will be made by either the veterinarian and/or PI.

V.5.2.2. Emergency Veterinary Medical Care:
All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy:
All animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Standard enrichment for swine will be included.

V.5.3.2. Enrichment Restrictions: None. Animals will be singly housed. This is necessary since irradiated animals will have reduced immune function and can develop serious infections from biting or wounds from rough play which can be common in these animals.

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
Euthanasia	(b)(6)	3 yrs as researcher 6 yrs as PI 8+yrs as researcher	(b)(6)

			(b)(6)

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

(b)(6) _____ March 23 2015

Prin ure Date

G. Training: The following personnel will attend the next USUHS Investigator/Animal User Training Course:

_____ _____

_____ _____

H. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely, "Responsibility" for implementing animal use alternatives where feasible and conducting humane and lawful research.

(b)(6) _____ March 23 2015

Prin e Date

I. Painful Procedure(s):

I am **NOT** conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

X. PROTOCOL ABSTRACT:

High dose total body irradiation (TBI) in humans can result in both acute and delayed injuries. The Acute Radiation Syndrome (ARS) is characterized by the (b)(4) (b)(4) syndromes. The mechanisms leading to (b)(4) ARS remain largely unknown, but current information indicate that (b)(4) may play a major role in (b)(4) There are currently no approved countermeasures for radiation-induced (b)(4) injuries, and it is our long range goal to develop effective agents for this condition. The objective of this application is to evaluate the effects of an Food and Drug Administration (FDA)-approved drug, (b)(4) for mitigating (b)(4) radiation injuries. (b)(4) (b)(4) as a mitigator of radiation-induced (b)(4) injury using a murine model for (b)(4) injuries, and we have conducted significant experiments to elucidate its mechanism of action in mice and in ex vivo experiments. Radiation countermeasures must be approved for human use under the FDA Animal Rule, which requires demonstration of efficacy in two species. One species may be a rodent, and is fulfilled by our murine model experiments, however the other species must be non-rodent. Our central hypothesis is that (b)(4) administration will have significant combined effects in mitigating radiation (b)(4) radiation injuries in the Gottingen minipig model of (b)(4) ARS. With Dr. (b)(6) we will assess in vivo protection and potential mechanisms of action of (b)(4) against radiation-induced (b)(4) injury in the minipig model of (b)(4) ARS. This research supports DoD goals of identifying novel therapeutic strategies to mitigate/treat the health consequences of ionizing radiation exposure that exist as a threat under military operations, humanitarian, and counter terrorism environments. We anticipate an improvement in survival of at least 30%.

A. **Animal Protocol Number**: To be assigned

B. **Animal Protocol Title**: Development of (b)(4) for the mitigation of acute injuries from ionizing radiation in Gottingen minipigs (*Sus scrofa domestica*)

C. **Principal Investigator**: (b)(6) Ph.D.

D. **Performing Organization**: USUHS/AFRRI

E. **Funding**: DMRDP

Objective and Approach

We will assess in vivo protection and potential mechanisms of action of (b)(4) against radiation-induced (b)(4) injury in the minipig model of (b)(4) acute radiation syndrome. We will administer (b)(4) orally to Gottingen minipigs following (b)(4) (b)(4) irradiation (b)(4) recovery and survival will be monitored as well as indicators of radiation-induced (b)(4)

Indexing Terms (Descriptors): radiation, acute (b)(4) injury, radiation countermeasure, swine, minipig (b)(4) irradiation

MEMORANDUM FOR DR. (b)(6)

SUBJECT: IACUC Approval of Protocol – Initial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on February 1, 2016:

Animal Protocol Title: "Development of (b)(4) for the Mitigation of (b)(4) Injuries from Ionizing Radiation in Mice (Mus Musculus)"

USUHS Protocol Number: (b)(6)

Expiration Date: January 31, 2019

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MA (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. **NON-TECHNICAL SYNOPSIS:** The terrorist attack of September 11, 2001 against the United States has increased the concern that terrorists may acquire and use radioactive sources (e.g. dirty radioactive bombs) to expose military and civilian populations to ionizing radiation. However, despite this concern, there are currently no FDA approved drugs that can be used for the general population to prevent death that is likely to result from exposure to ionizing radiation. (b)(4) irradiation in humans can result in both (b)(4) (b)(4) injuries. However, because rodents are more resistant to pulmonary injuries than humans, there is currently no murine model that has been developed to study (b)(4) (b)(4) radiation injuries in the same animal.

(b)(4)

(b)(4) In fact, we have recently found that (b)(4) can be administered h postirradiation up to h postirradiation (b)(4) to provide statistically similar levels of mitigation. Our proposed studies here will expand our understanding of the mechanism for the effects of (b)(4) for protection against (b)(4) (b)(4) radiation injuries in animal models for each of these injuries.

Our overall aim is to develop an effective, non-toxic radioprotectant/ radiotherapeutic treatment strategy that can be used for protection against both (b)(4) effects of radiation exposure in a murine model for both types of radiation injury. Our laboratory has characterized the use of (b)(4) as a radiation countermeasure for (b)(4) syndrome in mice. We have demonstrated in mice the required time course for administration of (b)(4) and dosages of the drug required for preventing mortality at the 50% lethal dose at (b)(4) (b)(4) levels of radiation exposure. Our research has also demonstrated that (b)(4) suppresses radiation-induced (b)(4) and other tissues, mitigates radiation-induced (b)(4) and reduces the induction of (b)(4) induced in response to radiation damage (b)(4)

(b)(4) We have also found that (b)(4) reduces radiation-induced (b)(4) (b)(4) when administered from h postirradiation through days (b)(4) postirradiation. We wish to determine whether a shorter time course of (b)(4) administration would have similar effects.

II. BACKGROUND:

II.1. Background:

The acute toxic effects of exposure to high doses of ionizing radiation in humans have been shown to occur due to two sequential effects: first the ablation of immune cells, resulting in loss of immune function and increasing likelihood of pathogenic infection [1]; and subsequently the loss of epithelial progenitor cells of the gastrointestinal (GI) crypt [2, 3]. Both of these events have been shown to be due to the loss of fast-growing pluripotent and/or progenitor cell types. The time course of the acute injuries correlates with the life span of the mature cell types of the tissue, which are not replaced because of radiation damage to the adult pluripotent cells and adult stem cells. There is currently no FDA approved prophylactic or treatment for prevention of acute radiation injuries following high-dose (b)(4) radiation exposure.

In some cases supportive measures can be used to treat acute radiation syndrome, and survival from (b)(4) radiation exposure is now possible [4, 5]. This results in current efforts to mitigate or treat later stage effects of ionizing radiation exposure (b)(4)

(b)(4)

In humans, death from (b)(4) can occur following survival from (b)(4) syndrome (b)(4) Cumulative evidence from a number of laboratories, including our own, shows that there is a threshold dose of radiation of (b)(4) to induce sufficient (b)(4) for the (b)(4) and (b)(4) phases to occur in mice; below these doses, no permanent injury manifests, although some short-term effects are observed (b)(4) However, in humans, there is currently no accepted protocol for preventative treatment of radiation-induced (b)(4) and morbiditiy as high as 50% is associated with each phase [6] (b)(4) (b)(4) injuries from radiation is considered to be a serious problem in the field for the development of agents to prevent these radiation injuries.

(b)(4) **as a radioprotectant and an antifibrotic agent:** (b)(4) (b)(4) and its proteolytic product (b)(4) are believed to have their primary biological functions in blood pressure homeostasis. However (b)(4) have been demonstrated to be upregulated in fibrotic tissues. Inhibition of (b)(4) or blockade of the (b)(4) receptors on cells has been shown to ameliorate drug-induced (b)(4) in murine and rat models for (b)(4) (b)(4) receptor antagonists also prevent (b)(4) following ischaemia/reperfusion in rat models of (b)(4) diseases (b)(4) Several studies have also shown that inhibition of (b)(4) signaling mitigates radiation-induced injuries, including to the (b)(4) One study shows that the (b)(4) reduces acute damage to the (b)(4) in mice following exposure to (b)(4) This work examined only initial tissue injury and

(b)(4) did not extend findings past [redacted] days, and did not examine mortality. A second study found a reduction in (b)(4) in rats exposed to (b)(4) radiation (b)(4)

Summary of other publications

(b)(4)

III. OBJECTIVE\HYPOTHESIS:

Our objective is to: 1) examine the effects of (b)(4) administration on radiation-induced (b)(4) using the (b)(6) designed for the irradiation of small animals that we have utilized for the past 4 years for studying (b)(4) ; 2) to examine the effects of (b)(4) administration and (b)(4) of administration on radiation-induced (b)(4) using the (b)(6) and 3) examine the mechanism of delayed and limited time course of administration of (b)(4) for prevention of (b)(4)

IV. MILITARY RELEVANCE:

The Department of Defense (DoD) is prepared to execute military missions within radiation environments, to manage radiation crises associated with terrorist activities, and to manage consequences in the event of nuclear weapons detonation. Recent studies indicate that there is an increasing risk of exposure to ionizing radiation to military personnel due to increasing terrorist activities, including potential use of stolen nuclear weapons, the detonation of an improvised nuclear device (IND) or a large radiological dispersal device (RDD) (b)(4) (b)(4) High dose ionizing radiation results in short term, acute injuries including hematopoietic and GI syndromes. However, both high and low dose radiation (as may result from a radiation dispersal device) can cause (b)(4) as demonstrated by previous radiation accidental exposures. For example, individuals accidentally exposed to (b)(4) radiation in the Tokai-mura, Japan radiation accident were successfully treated for acute radiation injuries but succumbed to (b)(4) between 82-210 days postirradiation (b)(4) A radiation accident victim in

Belarus also recovered from acute injuries but died from radiation-induced (b)(4) 130 days following a (b)(4) exposure (b)(4)

At present, there are no FDA approved medical countermeasures for mitigation or treatment of acute or delayed radiation injuries. The development of new medical radiological countermeasures will significantly enhance the warfighting mission by sustaining unit effectiveness and are critical for operational preparedness in nuclear/radiological threat environments. These agents are essential for the prevention of radiation casualties and preserving the Warfighter's effectiveness. One of the primary focuses of the DoD medical radiological defense research area is to develop broad-spectrum postirradiation therapeutics effective against acute radiation syndrome (b)(4) (b)(4)

The DoD is committed to protecting the Warfighter from the adverse health effects of ionizing radiation. Our research is aimed at developing an effective postirradiation countermeasure to: 1) reduce the casualty load at medical treatment facilities, 2) sustain a more effective operational force after a radiation exposure event, 3) allow commanders to conduct operations in radiation field environments without undue risk of decremented performance of personnel due to acute tissue injury, and to 4) reduce the negative psychological impact on personnel tasked to operate in contaminated environments.

The research outlined in this proposal is aimed at developing effective therapeutic strategies for the combined treatment of acute and late radiation-induced injuries for the Warfighter. Results from these studies will additionally have application for civilian use and the medical community at large.

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures:

(b)(4) radiation used to induced (b)(4) irradiation will be performed using the (b)(6) irradiator in (b)(6) Thirty minutes prior to irradiation, the (b)(6) irradiator and lead shield will be decontaminated thoroughly with MB10. Sham irradiation, where indicated, will be performed by placing the mice in jigs for equal lengths of time with no irradiation.

V.1.1. Experiment 1 Determine the effect of delayed administration of (b)(4) on survival following (b)(4) irradiation. mice: in category E)

(b)(4) (b)(4)

Rationale: Experiment 1 will be used to determine whether (b)(4) can be administered in a delayed time course following radiation exposure, and to determine the shortest time course of administration. Our experiment will be based on findings by (b)(4) showing that another (b)(4) can mitigate radiation-induced (b)(4) when administered starting days postirradiation continued through days postirradiation. Our laboratory also found that (b)(4) could mitigate radiation-induce (b)(4) injuries when initiated h postirradiation through weeks postirradiation; survival was not statistically different from administration of (b)(4) from h postirradiation through weeks postirradiation.

(b)(4) (b)(4) (b)(4) (b)(4)

(b)(4) will be provided in the drinking water at (b)(4) to give a dosage of (b)(4) per day for the duration of the experiment starting on day 0. Our preliminary findings indicate that there are no adverse effects due to long term use of (b)(4) We have used this drug in the water to treat mice for up to days with no findings of adverse effects. Mice will be exposed to (b)(4) (b)(4) x-ray irradiation (b)(4) dose rate, in the (b)(6)

(b)(4)

Acidified water will be provided for all mice to reduce opportunistic infections that occur following (b)(4) irradiation. For mice to be treated with (b)(4) will be provided in acidified water. Acidified water bottles and (b)(4) water bottles will be prepared by the (b)(4) and will be replaced 2× per week in accordance with LAM protocols. Extra water bottles will be prepared in advance and they will be available in the room where the animals are housed in case they are needed to replace a leaking water bottle.

Mice will be monitored monthly using non-invasive, unrestrained (b)(4) to determine (b)(4) For these studies (b)(4) mice are required per radiation dose to provide statistical significance; the experiment will not need to be repeated with this number of animals per group. The time point for (b)(4) is (b)(4) days, based on data from previous studies by others (b)(4) The time point for (b)(4) is (b)(4) days, based on previous studies by others (b)(4) Although breathing will be monitored, (b)(4) results will not be used as a sole indicator for euthanasia. (See section V.4.6).

Experiment 1a: To determine the optimal time of initiation of (b)(4) Treatment groups will be: 1) no treatment; 2) (b)(4) days postirradiation; 3) (b)(4) days postirradiation (b)(4) days postirradiation; 4) (b)(4) days postirradiation (b)(4) days postirradiation; 5) (b)(4) days postirradiation (b)(4) days postirradiation.

(b)(4) mice/group × 5 groups = mice, all category E

Experiment 1b: To determine the optimal time for ending (b)(4) administration for mitigation of (b)(4) The optimal time point for initiation of (b)(4) administration will be obtained in experiment 1a. In this experiment (b)(4) will be initiated at that optimal time point and continued for (b)(4) days. There will also be a no treatment group control,that will receive acidified water with (b)(4)

(b)(4) mice/group × 5 groups = mice, all category E

Endpoint: Endpoint for the experiment will be survival at days. Animals surviving to (b)(4) (b)(4) days will be euthanized and tissue will be obtained. Early time points will be taken if any animal exhibits signs or symptoms of morbidity or moribundity. Such animals will be euthanized at the time of observation.

V.1.2. Experiment 2 Determine the optimal dose of (b)(4) for improved survival following (b)(4) irradiation. (b)(4) mice: (b)(4) in category E)

Rationale: Experiment 2 will be used to determine whether (b)(4) dosage can be reduced for mitigation of delayed radiation-induced (b)(4) injuries. Our data from (b)(4) irradiation and the use of (b)(4) for protection against (b)(4) injury indicated that (b)(4) can be reduced to as little as (b)(4) in mice to obtain survival equivalent to (b)(4) We will use the optimal time course for (b)(4) administration, as identified in Experiments 1a and 1b (b)(4) will be administered at (b)(4) in acidified water). Control group will have acidified water with no drug administered. For these studies (b)(4) mice are required per radiation dose to provide statistical significance; the experiment will not need to be repeated with this number of animals per group.

(b)(4) mice/group × 3 groups = mice, all category E

V.1.2. Experiment 3 Determine the mechanism of action of (b)(4) for mitigation of (b)(4) injuries. [redacted] mice [redacted] in category E, [redacted] category C)

Rationale: Experiment 3 will be used to examine the mechanism of protection for (b)(4) against (b)(4) injuries using the newly identified optimized times of administration of (b)(4) from Experiments 1 and 2. Our data from our previous experiments indicates that (b)(4) reduces (b)(4) that can be detected at [redacted] days postirradiation. We will examine the optimal time course and optimal dosage of (b)(4) compared with our previous findings (b)(4) postirradiation). A control group will receive acidified water but no (b)(4) For this experiment, a sham irradiated group will also be required. Only [redacted] animals per group are needed. Tissues will be obtained from animals at the [redacted] days postirradiation (b)(4) tissue will be obtained for (b)(4) (b)(4) analysis. This experiment will need to be repeated once.

[redacted] mice/group x 4 groups = [redacted] mice, [redacted] category E, [redacted] category C
1 repeat, total animals (b)(4) category E, [redacted] category C

V.2. Data Analysis:

Experiments 1 and 2: Survival: Log-Rank test will be used for comparison among groups. If significant, Fisher's exact test will be used to detect significant differences across the groups in survival rates at day [redacted] Kaplan Meier curves will be displayed. N = [redacted] mice per group will have 80% power in detecting a significant difference between two groups if any, given type I error of 5% where the treatment group survival rate is at least 68%, compared to a control group survival rate of 20%. Similar statements would apply, if the treatment group survival rates are at least 83%, 78%, or 73%, compared to vehicle group survival rates of 35%, 30%, and 25%, respectively (b)(4)

Experiment 3: Analysis of variance (ANOVA) will be used to detect significant difference among the groups. If significant, then the pair-wise comparison by Tukey-Kramer will be used to identify which group is different from the other. Based on our current data from other radiation experiments for the induction of apoptotic and senescence markers and specific inflammatory cytokines, N = [redacted] mice per group could have 80% power to detect any significant difference between groups if any, given type I error of 5% and delta/sigma has at least 1.4, where the delta is the estimated mean differences between the two groups and sigma is the pooled standard deviation of the two groups (b)(4)

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered:

For the last 9 years, we have performed extensive experiments in primary cell culture systems to investigate the effects of radiation on normal cells. However, our culture findings have not yet been shown to completely recapitulate the complexity of the whole animal system. We will continue to use primary cell culture whenever possible to avoid unnecessary use of animals. We have also considered computer models as alternatives to animals. However, this alternative also lacks the knowledge base and complexity needed to evaluate (b)(4) and preventative agents. Because we do not know all the cell types and tissues involved in radiation injury, and how these systems

interact with one another for repair or for extension of initial radiation damage, there is vital information that can be gained only from the use of a whole animal system.

V.3.2. Animal Model and Species Justification:

Tissue culture conditions cannot fully substitute for the complexities of whole organisms in response to radiation injury. Such injury involves the interactions between the hematopoietic system and other organ systems. In order to develop viable treatments for humans, we find that our research must be conducted in whole animals.

Research in the field of radiation countermeasures also advocates the mouse as the best species to use for radiation protection and radiotherapy protocols: 1) mice provide the least sentient species available whose response to radiation has been clearly identified, with physiological responses to radiation and radioprotectants that are similar to human physiology, 2) extensive literature is available on responses of mice to radiation and countermeasures, 3) more reagents are available to study the relevant cell types and molecules in mice than in any other species except humans, and the availability of transgenic and knockout mice make this model extremely attractive for further research into molecular mechanisms, and 4) our research group have extensive experience with this model in radiation injury and radioprotection research.

		Strain #1	Strain #2
V.3.3.1.	**Genus & Species:**	*Mus musculus*	
V.3.3.2.	**Strain/Stock:**	CBA, female. CBA mice have previously been demonstrated to be sensitive to radiation-induced (b)(4) (b)(4) in a shorter time course than C57BL/6 mice, and in a pattern that more closely resembles (b)(4) in humans (b)(4)	
V.3.3.3.	**Source/Vendor:**	(b)(4)	
V.3.3.4.	**Age:**	6-10 weeks	
V.3.3.5.	**Weight:**	Standard (17-21 g)	
V.3.3.6.	**Sex:**	Female Only females will be used in this study for the following reasons: 1) we have so far utilized female mice to lay the foundation of our studies for radiation-induced	

(b)(4)
lung injuries; 2) because of long housing periods, it is advantageous to use female mice that are less aggressive toward each other

V.3.3.7. Special Considerations: None

V.3.4. Number of Animals Required (by Strain): *Mus musculus* =(b)(4)

V.3.5. Refinement, Reduction, Replacement (3 Rs):

V.3.5.1. Refinement:
Animals demonstrating moribundity due to radiation exposure (b)(4) (b)(4) will be considered to have arrived at the study endpoint and will be immediately euthanized (See sections V.4.5 Study Endpoint and V.4.6 Euthanasia). The literature search revealed that, at present, there are no alternative procedures for irradiation because its effects cannot be otherwise duplicated. In some cases radiation has been demonstrated to reduce pain in laboratory mice (b)(4) and has been in humans reported to alleviate cancer related bone pain (b)(4) (b)(4) A recent report showed that administration of botulinum toxin A was effective for reduction of pain and muscle spasms after clinical radiation for treatment of tumors (b)(4) Application of natural honey 20 min prior to radiation exposure was also shown to reduce mucositis with associated pain in humans following head/neck radiotherapy (b)(4) (b)(4) it has not been determined whether honey acts as a local radioprotectant. Spinal cord stimulation has also been reported in humans to alleviate pain resulting from radiotherapy (b)(4) however, this method would not be practical for use in mice because of the extensive spinal cord manipulation required. Human administration of morphine also relieves pain (b)(4) but again this would not be practical for mice in our experiments because of side effects of the drug. In humans, exposure to total body irradiation may induce vomiting and diarrhea, causing pain and distress. However, mice are not susceptible to vomiting.

V.3.5.2. Reduction:
Whenever possible our laboratory used shared control groups between experiments. Tissues will be collected for multiple assays from the same animals further reducing the total number of animals needed. At every stage of the research, planned experiments will be reevaluated, in an attempt to reduce the numbers of experiments and eliminate repeats of experiments where statistical significance has already been obtained. We also plan to take as many tissues as we can reasonably analyze for experiments.

V.3.5.3. Replacement:
Our laboratory has made extensive use of tissue culture techniques to study the effects of (b)(4) and radiation on cells. While these studies have provided valuable

data, it is not feasible to use non-animal systems in place of animal models to address the research questions in this protocol.

V.4. Technical Methods:

V.4.1. Pain / Distress Assessment:

V.4.1.1. APHIS Form 7023 Information:

V.4.1.1.1. Number of Animals:

	Strain #1
V.4.1.1.1.1. Column C:	(b)(4)
V.4.1.1.1.2. Column D:	
V.4.1.1.1.3. Column E:	

V.4.1.2. Pain Relief / Prevention:

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization:

We will be unable to use analgesics since they have effects on (b)(4) function that would interfere with the interpretation of our results (b)(4) (b)(4) Some sedatives have been reported to contribute to postoperative (b)(4) which likely reduce some functions of radiation. Additionally, it has been shown that the biometabolism of analgesics can induce protein oxidation, which would interfere with sample analysis (b)(4)

An anesthesia protocol has been developed for use during the X-ray irradiation. Ketamine will be used with xylazine for longer anesthesia in mice to be place in restraints for (b)(4) irradiation. Under the training protocol at AFRRI in conjunction with the AFRRI veterinary staff, we found that in female CBA mice, ~12 weeks old, i.p. injection of 150 mg/kg ketamine plus 18 mg/kg xylazine results in 60-80 min anesthesia (25 G needle) with no morbidity or mortality (b)(4) We propose to use this concentration of anesthesia, together with a heating pad to keep mice warm during the period of anesthesia. Standard i.p. injection methods are used for injection of the anesthesia

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions:

Animals will be housed and cared for as described in Section V.5. Veterinary Care both before and after dose administrations and irradiation procedures.

V.4.1.2.3. Paralytics: Not applicable

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures:

V.4.1.3.1. Sources Searched: DoD Bioedical Research Data Base (BRD), REPORTER, PubMED

V.4.1.3.2. Date of Search: November 19, 2015

V.4.1.3.3. Period of Search: All available

V.4.1.3.4. Key Words of Search:
Pain, analgesia, anesthesia, mice, radiation, ionizing radiation, humane, (b)(4)

V.4.1.3.5. Results of Search:
The literature search revealed that, at present, there are no alternative procedures for irradiation because its effects cannot be otherwise duplicated. In some cases radiation has been demonstrated to reduce pain in laboratory mice (b)(4) and has been in humans reported to alleviate cancer related bone pain (b)(4) (b)(4) A recent report showed that administration of botulinum toxin A was effective for reduction of pain and muscle spasms after clinical radiation for treatment of tumors (b)(4) Application of natural honey 20 min prior to radiation exposure was also shown to reduce mucositis with associated pain in humans following head/neck radiotherapy (b)(4) (b)(4) it has not been determined whether honey acts as a local radioprotectant. Spinal cord stimulation has also been reported in humans to alleviate pain resulting from radiotherapy (b)(4) however, this method would not be practical for use in mice because of the extensive spinal cord manipulation required. Human administration of morphine also relieves pain (b)(4) but again this would not be practical for mice in our experiments because of side effects of the drug. In humans, exposure to total body irradiation may induce vomiting and diarrhea, causing pain and distress. However, mice are not susceptible to vomiting.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification:
Anesthesia will be used before (b)(4) irradiation to avoid stress from restraint. We will be unable to use analgesics after irradiation since they have effects on (b)(4) function that would interfere with the interpretation of our results (b)(4) (b)(4) (b)(4) In experiments where tissue collection is needed, animals will be euthanized with pentobarbitol prior to sample collection as described elsewhere.

V.4.2. Prolonged Restraint:

(b)(4) irradiation will require restraint in designed jigs for ~30 min to receive X-ray exposure (b)(4) animals will be anesthetized during this period (see Anesthesia above) and tails will be taped to one side with surgical tape. The jigs for use during (b)(4) irradiation were examined and approved by the Veterinary staff. An image of the jig is now provided (see attached). We found that in female CBA mice, ~12 weeks old, i.p. injection of 150 mg/kg ketamine plus 18 mg/kg xylazine results in 60-80 min anesthesia (25 G needle) with no morbidity or mortality (b)(4) (b)(4) We propose to use this range of concentration of anesthesia, together with a heating pad to keep mice warm during the period of anesthesia. Standard i.p. injection methods are used for injection of the anesthesia, as recommended.

V.4.3. Surgery:

V.4.3.1. Pre-surgical Provisions: Not applicable

V.4.3.2. Procedure: Not applicable

V.4.3.3. Post-surgical Provisions: Not applicable

V.4.3.4. Location: Not applicable

V.4.3.5. Surgeon: Not applicable

V.4.3.6. Multiple Major Survival Operative Procedures:

V.4.3.6.1. Procedures: Not applicable

V.4.3.6.2. Scientific Justification: Not applicable

V.4.4. Animal Manipulations:

V.4.4.1. Injections:

Intra-peritoneal injections of pentobarbital for euthanasia 0.1-0.2 ml/mouse Fatal Plus (39-78 mg pentobarbital/mouse), will be performed with a 25 G needle. A single I.p. injection of 150 mg/kg ketamine plus 18 mg/kg xylazine will be done using a 25 G needle. This has been extensively used by our laboratory and shown to effectively produce non-lethal anesthesia. (b)(4) (b)(4) vehicle only or (b)(4) will be administered by a single (b)(4) i.p. injection h before radiation exposure also with 25 G needles.

(b)(4)

V.4.4.2. Biosamples:

All biosamples will be taken after euthanasia. (b)(4) will removed *en bloc*. All other tissues will be available to other researchers for tissue sharing.

V.4.4.3. Adjuvants: None

V.4.4.4. Monoclonal Antibody (MAbs) Production: None

V.4.4.5. Animal Identification: Ear punch and cage cards/tags will be used.

V.4.4.6. Behavioral Studies: None

V.4.4.7. Other Procedures:

Treatment with (b)(4) (b)(4) Our preliminary findings indicate that there are no adverse effects due to long term use of (b)(4) We have used this drug in the water to treat mice for up to days with no findings of adverse effects.

(b)(4)

Thoracic irradiation

The methodology for (b)(4) irradiation of mice including approval of holding jigs and development of anesthesia was developed in conjunction with the AFRRI Veterinary Staff. (b)(4) irradiation will be performed using the (b)(6) irradiator in (b)(6) inner room. Thirty minutes prior to irradiation, the (b)(6) irradiator and lead shield will be decontaminated thoroughly with MB10.

Mice will be anesthetized by IP injection in the USUHS LAM facility. Anesthetized mice will be placed in ventilated Lucite jigs, which restrain the animals to prevent lateral or vertical movement. Tails will be taped to prevent any forward motion of animals. Mice will be irradiated at (b)(4) irradiationFollowing radiation exposure, mice will be immediately returned to the LAM and allowed to recover from anesthesia under supervision with heating pads. Immediately upon recovery, animals will be returned to standard cages that house 4 animals per cage. Lucite jigs will be sanitized with soap and water after each use.

Whole body, non-invasive plethysmography
Non-anesthetized, unrestrained (b)(4) will require individual animals to be placed in a clean plexiglass chamber (~ 12 cm in diameter, ~15 cm high) for 45-60 min. Animals will not have food or water during this time, but they will have a continuous flow of fresh room air. Their (b)(4) is measured based on warming and humidifying of the air in the chamber. The animals will experience no restraint, no anesthesia, no drugs, or other manipulation during this time. Following the measurement, to be performed in the room in which they are housed, the animals will be returned to their original cages. Chambers will be sanitized after each use.

V.4.4.8. Tissue Sharing:
All tissues are available for tissue sharing since our research will utilize small quantities of tissues only.

V.4.5. Study Endpoint:
For experiments 1 and 2, survival will be the endpoint. For experiment 3, an early time point will
(b)(4) be taken, [redacted] days postirradiation. Moribundity will be used as a surrogate for mortality, and euthanasia will be used in order to minimize pain and distress. Mice will be monitored following signs of moribundity. Specific health assessment criteria including rapid weight loss (10–15%), ruffled fur, dried lacrimal fluid accumulated in the cul-de-sac of their eyes, are cool to the touch, decreased appetite, diarrhea, difficulty breathing or panting (b)(4) (b)(4) Mice exhibiting these signs will be considered morbid and will be monitored by the PI or other members of the investigative team at least twice daily, early morning and late afternoon. Mice will be considered moribund when, in addition to showing some or all of the signs of morbidity, they exhibit labored breathing plus either an inability to remain upright or are unmotivated to move.

V.4.6. Euthanasia:
Animals will be euthanized according to current American Veterinary Medical Association (AVMA) guidelines. Animals will be anesthetized with Telazol® (4.4 mg/kg i.m.) or ketamine (5-20 mg/kg i.m.)/xylazine (2 mg/kg i.m.). Animals will then be euthanized with Euthasol® (sodium pentobarbital, (1 ml/4.5 kg i.p) or another commercial euthanasia solution. A physical method of euthanasia (cervical dislocation of bilateral thoracotomy) will be used to ensure that no animals recover. See item V.4.5 for euthanasia criteria before the end of the study.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations:

Animals will be group housed. No food or liquid restrictions are required. Water containing (b)(4) will be provided and will be labeled and present in the room in case water bottles need to be refilled. Laboratory staff will be responsible for refilling water bottles.

V.5.1.1. Study Room:
Euthanasia will be performed in (b)(6)
Building(s) (b)(6) Room Number(s) (b)(6)

V.5.1.2. Special Husbandry Provisions:

Food Restriction: Yes _____ No X

Fluid Restriction: Yes _____ No X

V.5.1.3.Exceptions:
(b)(4) water with or without (b)(4) will be provided for all animals by the PI, but no restriction in fluid will be needed.

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care: Animals will be monitored for health, humane treatment, and husbandry considerations, twice daily by (b)(6) personnel during routine weekday rounds and at least once daily on weekends/holidays. This is in addition to, and not in place of, the monitoring that is done by the PI and their staff. In the event of a debilitating illness or adverse reaction, the decision to treat or euthanize an animal will be made by either the veterinarian and/or PI.

V.5.2.2. Emergency Veterinary Medical Care:
All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by (b)(6) personnel once daily during weekend and holidays.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy:
All animals on this protocol will be provided with routine environmental enrichment in accordance with (b)(6) SOPs and IACUC Policies. Standard enrichment for mice will be included, such as nestlets.

V.5.3.2. Enrichment Restrictions: No restrictions

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
Euthanasia	(b)(6)	9 yrs experience for euthanasia	(b)(6)
Euthanasia		10 yrs for euthanasia	
Euthanasia		12 yrs for euthanasia	
Thoracic irradiation		4 yrs experience for thoracic irradiation	
Thoracic irradiation		4 yrs experience for thoracic irradiation	
Thoracic irradiation		4 yrs experience for thoracic irradiation	

VII. BIOHAZARDS/SAFETY: PPE will be used to minimize allergens produced by mice. Standard PPE include dust mask, gloves, shoe covers, and lab coats.

VIII. ENCLOSURES: (b)(4) data sheets

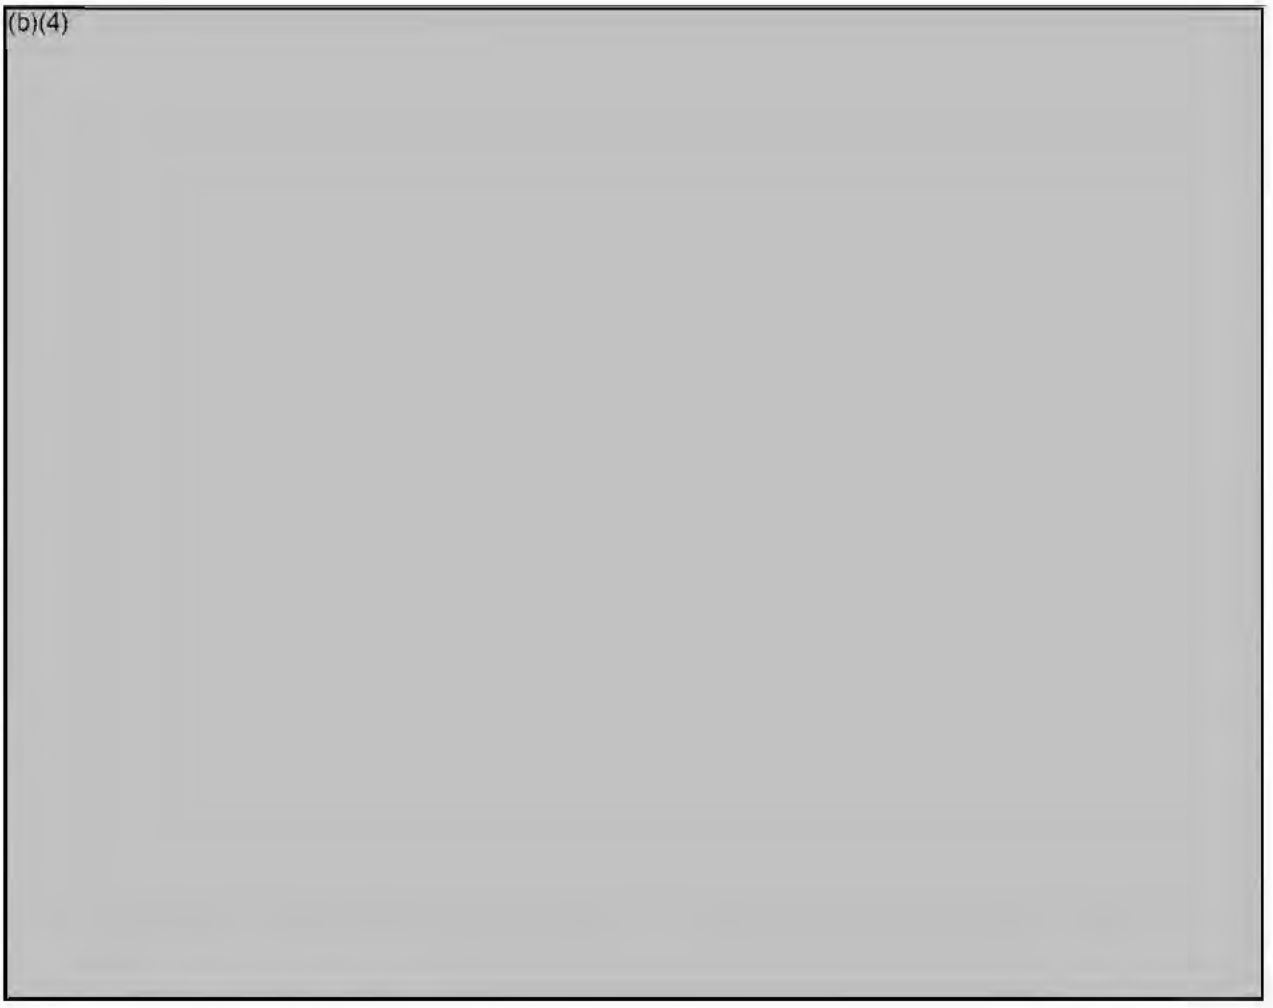
(b)(4)

(b)(4)



IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation

I. Painful Procedure(s):

I am **NOT** conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

(b)(6) [redacted]

X. PROTOCOL ABSTRACT:

The terrorist attack of September 11, 2001 against the United States has increased the concern that terrorists may acquire and use radioactive sources (e.g. dirty radioactive bombs) to expose military and civilian populations to ionizing radiation. However, despite this concern, there are currently no FDA approved drugs that can be used for the general population to prevent death that is likely to result from exposure to ionizing radiation. (b)(4) irradiation in humans can result in both (b)(4) injuries. However, because rodents are more resistant to (b)(4) injuries than humans, there is currently no murine model that has been developed to study both (b)(4) radiation injuries in the same animal.

Our studies have shown that administration of the (b)(4) (b)(4) can protect laboratory mice from the acute lethal effects of ionizing irradiation. We have tested (b)(4) in a high-dose (b)(4) only irradiation model for the generation of (b)(4) in mice. Our preliminary data indicate that (b)(4) protects (b)(4) from radiation-induced and increases the mean survival time from (b)(4) irradiation by ~50-75%. Our proposed studies here will examine the optimal time course for (b)(4) administration and the optimal dosage of (b)(4) in mice. Our aim is to develop an effective, non-toxic radioprotectant/ radiotherapeutic treatment strategy that can be used for protection against both (b)(4) effects of radiation exposure in a murine model for both types of radiation injury.

A. Animal Protocol Number: To be assigned

B. Animal Protocol Title: Development of (b)(4) for the mitigation of (b)(4) (b)(4) injuries from ionizing radiation in mice (*Mus musculus*)

C. Principal Investigator: (b)(6) Ph.D.

D. Performing Organization: USUHS

E. Funding: DMRDP

Objective and Approach

We will assess *in vivo* protection of the (b)(4) from radiation injuries using (b)(4) administration and short time courses of administration of (b)(4) in mice.

Indexing Terms (Descriptors): radiation, (b)(4) injury, radiation countermeasure, mouse, (b)(4) irradiation

UNIFORMED SERVICES UNIVERSITY OF THE HEALTH SCIENCES

BETHESDA, MARYLAND 20814-4799

May 16, 2016

MEMORANDUM FOR DR. (b)(6) DEPARTMENT OF PHARMACOLOGY

SUBJECT: IACUC Approval of Protocol – Initial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on May 16, 2016:

Animal Protocol Title: "Kappa Receptor Antagonists as Rapid Acting Antidepressants in Mice (mus musculus)"

USUHS Protocol Number: (b)(6)

Expiration Date: May 15, 2019

Supporting Grant(s) Number: USU TBD

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the RATS system and LAM resources are available to meet your needs.

I. NON-TECHNICAL SYNOPSIS:

The purpose of studies in this protocol is to use mouse models to determine whether kappa opioid receptor antagonists are likely to be effective for the clinical treatment of depression and anxiety disorders and should be advanced to the next stage of investigation. Current antidepressant medications have a slow onset of action and many patients (20-40%) fail to respond to multiple trials and are treatment resistant. Recently, ketamine has been shown to produce rapid antidepressant effects that are sustained for about a week in treatment-resistant human patients and in animal models, but hallucinogenic and amnesic effects limit its widespread application. This proposal will compare the effects of ketamine with two novel kappa opioid antagonists (LY2456302 and LY2444296) because preliminary data showed that other kappa opioid antagonists can produce rapid and sustained antidepressant and anxiolytic effects in animal models. The results of this project will establish whether these two novel kappa opioid receptor antagonists have the ability to produce rapid antidepressant and anxiolytic responses in mice that are similar to those of ketamine and to determine whether they share a common molecular mechanism of action.

II. BACKGROUND:

II.1. Background:

There is a clear medical need for new drugs that would expand options for treating comorbid depression and anxiety, especially for treatment-resistant patients. This is especially true recently since an increasing number of patients (30-40%) are refractory to current antidepressant medications. In the past few years, low dose ketamine has been shown to produce antidepressant effects in treatment-resistant patients, showing that novel antidepressants can be developed. The effects of ketamine are a medical breakthrough because they occur immediately and last for about a week, unlike most antidepressants that require a month or longer before they even begin to work. The overall goal of this research program is to use established rodent models for antidepressant and anxiolytic drug effects to provide evidence that kappa opioid

receptor (KOR) antagonists have the potential to be developed as rapid and sustained antidepressants.

KOR antagonists are another unique class of drugs that may have rapid antidepressant effects. KORs and their endogenous ligand dynorphin are established to underlie dysphoria and depression accompanying exposure to stress. Some experimental KOR antagonists have been shown to produce antidepressant and anxiolytic effects in animal models, but pharmacological characteristics (irreversible blockade) of these compounds have made them unsuitable for clinical development in humans.

The proposed studies will evaluate the effects of two novel KOR antagonists, LY2456302 and LY2444295, as potential antidepressant and anxiolytic drugs using animal behavior tests. These are new compounds that can be developed in humans. Studies will determine whether the KOR antagonists produce their behavioral effects in mice more rapidly than established antidepressants and are sustained with a similar time course to ketamine. The behavioral tests used will be: the forced swim test and novelty-induced hypophagia, tests that are sensitive to traditional antidepressant drugs. The experiments focus on comparing the time of onset or duration of activity for ketamine, LY2456302 and LY2444295 with the known delayed action for SSRI antidepressants. Other experiments will establish the mechanism of action of the KOR antagonists using mice with constitutive deletion of kappa and mu opioid receptors or after treatment with a glutamate antagonist. The most rigorous rodent studies will show reversal of the effects of chronic mild stress on the production of anhedonia and anxiety, effects similar to those shown by human depressed patients. Taken together, these experiments will form a basic foundation for proposing the development of novel KOR antagonists as rapid acting antidepressants for eventual testing in patients with treatment-resistant depression.

II.2. Literature Search for Duplication:

II.2.1. Literature Source(s) Searched: Pubmed, PsychInfo, DTIC, FEDRIP or NIH RePORT

II.2.2. Date of Search: April 29, 2016

II.2.3. Period of Search: entirety of each database

II.2.4. Key Words and Search Strategy:
#1 - Kappa antagonist AND Depression AND Forced swim test AND Mice
#2 - Kappa antagonist AND Depression AND Novelty-induced hypophagia test AND Mice
#3 - Kappa antagonist AND Depression AND Chronic mild stress AND Mice

II.2.5. Results of Search:

There latest search on April 29, 2016 found 8 hits for LY2456302. Four of the studies demonstrated LY2456302 penetrated the brain and occupied kappa opioid receptors. One studied pupil diameter in rats and humans. One study involved only humans. One hit mentioned LY2456302 in a review article. The Rorick-Kehn

reference [(b)(4)] measured the effects of LY2444295 in the forced swim test of NIH Swiss mice shortly after drug administration using a different strain of mouse than used in our laboratory. The duration of effect for LY2456302 in the forced swim test or any other behavioral test, the point of these studies, was not measured. There were 3 hits for LY24444296. One of the hits involved acute effects of LY2444295 on alcohol drinking. Two hits involved the acute effects of LY2444295 in the forced swim test or the NIH test. However, there was no information at longer time intervals, as proposed to be studied in these experiments. In addition, no studies with either drug involved measuring drug effects in the UCMS procedure or with genetic mutants as proposed in these experiments.

III. OBJECTIVE\HYPOTHESIS:

Our overall goal is to evaluate the potential of two novel kappa opioid receptor antagonists to produce behavioral effects that are similar to established antidepressant drugs (fluoxetine) and to ketamine under three different rodent behavioral tests and models of antidepressant effects. The hypothesis is that the kappa opioid antagonists LY2456302 and LY2444295 will show a pattern of antidepressant-like behavioral responses.

IV. MILITARY RELEVANCE:

Major Depressive Disorder (MDD) is one of the most common psychiatric disorders, with a lifetime prevalence of 17% in the United States [(b)(4)] [(b)(4)] MDD is considered one of the most disabling medical conditions and is predicted to be a leading contributor to the worldwide burden of disease [(b)(4)] [(b)(4)] Depression and suicide are acknowledged to be important problems in military personnel, with rates of depression and suicide that are even higher in non-deployed Army soldiers than in the general population. Conventional antidepressants are only effective with 50-60% of patients. Our goal is to use data from animal behavior tests to help develop kappa opioid receptor (KOR) antagonists as a novel antidepressant medication for patients with treatment-resistant depression and suicidal ideation.

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures:

The effects of ketamine and the novel KOR antagonists, LY2444296 and LY2456302, will be studied in models of depression and anxiety in mice. Experiment 1 will examine the effects of the drugs in the mouse forced swim test. It is also necessary to examine the effects of the drugs on locomotor activity to know whether the effects in the forced swim test are specific. Experiment 2 will evaluate the effects of the drugs on the novelty-induced hypophagia test. Experiment 3 will evaluate the effects of the KOR antagonists at blocking analgesia. Experiment 4 evaluate the effects of the drugs in mice without mu and kappa opioid receptors. Experiment 5 is the ability of AMPA antagonists to block the effects of ketamine and the KOR antagonists. Experiments 6

and 7 will evaluate the effects of the drugs in the Unpredictable Chronic unpredictable mild stress (UCMS) model.

V.1.1. Experiment 1: Forced swim test (FST) and locomotor activity.

Ketamine produces acute and protracted behavioral effects on antidepressant tests in rodents such as the FST. Acute effects occur during the first hour whereas protracted effects persist for days after a single injection. This experiment will examine whether the KOR antagonists also produce both acute and protracted behavioral effects in a rodent model of antidepressant activity. The experiment will first determine a dose-response curve (0.3, 1.0, and 3.0 mg/kg i.p.) for the acute effects of the selective KOR antagonists LY2456302, LY2444296 and ketamine at reducing immobility in the mouse FST 1 hour after injection. From these results, a dose will be selected for further testing of each drug over time. The time course of behavioral activity will be determined over days (at 24 hours, 48 hours or longer) after injection to determine whether these drugs produce protracted behavioral effects.

NUMBER OF ANIMALS REQUIRED: 360 males, 80 females; Category E

N = 10 animals/group. Different animals are required to be tested at different times because prior experience with the FST can change performance. The experiment tests how long each drug produces its effects on this behavior.

Female mice: NIH requires that female mice will be included in the research program. A group of female mice (N=80 mice) will be tested with each drug using a dose shown to be effective in male mice.

JUSTIFICATION:

Time after injection

Ketamine	1 hour	24 hours	48 hours
Saline	10	10	10
0.3	10	10	10
1	10	10	10
3	10	10	10

0.3	10	10	10
1	10	10	10
3	10	10	10

Locomotor activity

It is important for characterizing antidepressant effects in the FST that drugs do not show increases in locomotor activity. To evaluate locomotor activity for these drugs, the mice will be tested for changes in locomotor activity using the same doses and time parameters as were active in the FST. To conserve animals, the tests will be done with the same mice used in the FST one week later.

NUMBER OF ANIMALS REQUIRED: 360 males, 80 females

N = 10 animals/group

For justification, see table above.

V.1.2. **Experiment 2**: NIH test.

This experiment will determine a dose-response curve and time course for the acute effects of ketamine and selective KOR antagonists in the NIH test. Mice are first trained to eat Reese's peanut butter chips from a petri dish in daily feeding sessions lasting 15 min in individual cages. Training sessions continue until the mice approach the food in less than 30 seconds for three consecutive days.

After accomplishing the training described above, mice are presented the food in a novel cage session, with bright overhead lights and a lemon scent. Approach latency and food consumed are measured during the 30 min session. Mice will be injected with drugs 1 hour prior to testing. A complete dose-response curve for the effects of LY2456302, LY2444296 and ketamine will be obtained at: 0.3, 1.0, and 3.0 mg/kg i.p. given 1 hour prior to testing, in comparison with saline-treated control groups tested simultaneously. After selecting a dose for further testing of each drug, the time course of behavioral activity will be determined over days (at 24 hours and 48 hours) after injection to determine whether these drug treatments produce protracted behavioral effects in the NIH test.

NUMBER OF ANIMALS REQUIRED: 360 males, 80 females; Category C

N = 10 animals/group

For justification, see numbers in table above. Different animals are required to be tested at different times because the novel test cage is no longer novel after prior exposure. The experiment tests how long each drug produces its effects on this behavior.

V.1.3. **Experiment 3**: Analgesia study.

This experiment will use analgesia produced by either the MOR agonist morphine or the KOR agonist U50,488 to measure the occupation of the two KOR antagonists and ketamine at MOR and KOR during behavioral testing . Analgesia will be measured using the response of mice to lick their paw or jump off the surface of a hot plate set at 55 degrees C. If animals do not make either the licking or jumping response within 30 sec, they will be removed from the hot plate to protect them from tissue damage. The occupation of opioid receptors by the antagonists will be estimated from studies that measure the doses and time course for blockade of analgesia produced by the KOR

agonist U50,488 (10 mg/kg) or the MOR agonist morphine (20 mg/kg) at 1 hour post-injection. Sustained opioid receptor occupation over time will be determined by retesting the same animals at 24 and 48 hours post-injection. The experiments will determine: 1) whether the KOR antagonists are selective for kappa vs mu opioid receptors; and 2) whether the KOR antagonists produce acute or protracted behavioral effects using analgesia as a behavioral model that is directly related to their occupation of KORs.
NUMBER OF ANIMALS REQUIRED: 360 mice; Category D.
N = 10 animals/group

JUSTIFICATION:
LY2456302 tested at 1 hour post-injection

Dose	Saline	U50,488	Morphine
Saline	10	10	10
0.3	10	10	10

V.1.4. Experiment 4: Studies of drug effects in opioid knockout mice.
The purpose of this experiment is to determine whether the absence of KORs in genetic mutants block the behavioral effects of the KOR antagonists and ketamine in the FST and NIH tests. Mice with genetic deletion of KORs (Oprk1$^{-/-}$ mice) will be treated with the KOR antagonists LY2456302, LY2444296 or ketamine, all at 3 mg/kg. Their effects will be evaluated at either 1 h or 48 h after injection in order to assess the role of KORs in producing the acute and protracted behavioral effects in the FST and NIH tests.
NUMBER OF ANIMALS REQUIRED: 480 mice will be used in the experiments. 240 mice will be tested in the FST; Category E. 240 mice will be tested in the NIH test; Category C.
N = 10 animals/group

JUSTIFICATION:

	WT	Oprm1$^{-/-}$	Oprk1$^{-/-}$
FST			
Saline	20	20	20
Ketamine	20	20	20
LY2456302	20	20	20
LY2444296	20	20	20
NIH test			
Saline	20	20	20
Ketamine	20	20	20
LY2456302	20	20	20
LY2444296	20	20	20

V.1.5. Experiment 5: Role of AMPA receptors in the behavioral effects of ketamine LY2456302 and LY2444296.

The protracted effects of ketamine are thought to involve the following neurochemical events: 1) activation of AMPA receptors from glutamate release, 2) activation of TrkB receptor from the release of BDNF, and the activation of mTor. The purpose of this study is to determine whether the protracted behavioral effects of the KOR antagonists involve a similar signaling cascade involving AMPA receptors.

Studies will be conducted with both the FST and the NIH tests. The AMPA receptor antagonist NBQX will be given prior to testing the effects of ketamine or the KOR antagonists LY2456302 and LY2444296 at 1 h or 48 h post-injection. The first time point evaluates the acute effects and the second time point evaluates the protracted effects of ketamine and the KOR antagonists.

NUMBER OF ANIMALS REQUIRED: 240 mice in total. 120 mice will be tested in the FST; Category E. 120 mice will be tested in the NIH test; Category C.
N = 10 animals/group

JUSTIFICATION:

	Time after injection of ketamine (3 mg/kg)	
Treatment	1 hour	48 hours
Saline	10	10
NBQX	10	10

	Time after injection of LY2456302 (3 mg/kg)	
Treatment	1 hour	48 hours

NBQX	10	10

Time after injection of

	LY2444295 (3 mg/kg)	
Treatment	1 hour	48 hours
Saline	10	10
NBQX	10	10

V.1.6. Experiment 6: Effects of acute drug treatments after exposure to UCMS.

The goal of this experiment is to determine how exposure of mice to the UCMS procedure changes expression of the protracted behavioral effects of acute single doses of ketamine (3 mg/kg) and the KOR antagonists LY2456302 (3 mg/kg) and LY2444296 (3 mg/kg). Drug effects will be measured for 3 consecutive days starting 24 hours after injection. Anhedonia will be measured using the sucrose preference test. Anxiety will be measured using the light-dark emergence test. Stress coping will be measured using the forced swim test. The behavioral effects in mice after UCMS will be compared with non-stressed controls.

NUMBER OF ANIMALS REQUIRED: 270 males, 180 females. Category E.

Note on animal numbers. In UCMS studies, mice that do not demonstrate sucrose preference greater than 65% at baseline prior to any experimental manipulation will not be entered into the study. In the past, 25% of mice fail to make this criterion. Therefore, we have estimated an additional 30 mice in the UCMS groups will be needed for this experiment. Females will only be tested with ketamine and LY2456302.

N = 20-25 animals/group

JUSTIFICATION:

UCMS		Non-stressed Controls	
Saline	25	Saline	20
Ketamine	25	Ketamine	20
UCMS		Non-stressed Controls	
Saline	25	Saline	20
LY2456302	25	LY2456302	20
UCMS		Non-stressed Controls	
Saline	25	Saline	20
LY2444296	25	LY2444296	20

V.1.7. Experiment 7: Effects of chronic drug treatments after exposure to UCMS.

Reversal of the behavioral effects of UCMS exposure usually require chronic administration of antidepressants for 4 weeks. The present experiment will determine whether the effects of ketamine and the KOR antagonists act more rapidly the SSRI

fluoxetine when given chronically. In the present study, the effects of chronic administration of the KOR antagonists LY2456302 and LY2444296 will be compared with the SSRI fluoxetine and saline controls after their chronic administration for 28 days in a UCMS paradigm. The behavioral effects in mice after UCMS on sucrose preference, the light-dark test and the FST will be compared with non-stressed controls.

NUMBER OF ANIMALS REQUIRED: 360 males, 180 females. Category E.

Note on animal numbers. In UCMS studies, mice that do not demonstrate sucrose preference greater than 65% at baseline prior to any experimental manipulation will not be entered into the study. In the past, 25% of mice fail to make this criterion. Therefore, we have estimated an additional 40 mice in the UCMS groups will be needed for this experiment. Females will only be tested with ketamine and LY2456302.

N = 20-25 animals/group

JUSTIFICATION:

UCMS		Non-stressed Controls	
Saline	25	Saline	20
Ketamine	25	Ketamine	20
UCMS		Non-stressed Controls	
Saline	25	Saline	20
LY2456302	25	LY2456302	20
UCMS		Non-stressed Controls	
Saline	25	Saline	20
LY2444296	25	LY2444296	20
UCMS		Non-stressed Controls	
Saline	25	Saline	20
Fluoxetine	25	Fluoxetine	20

V.2. Data Analysis: Sample size estimates are guided by the results of prior published research and preliminary data generated in our laboratory using these techniques [redacted]. Estimates of the effect size expected from different experimental groups are: FST, NIH approach latency, hot plate analgesia, locomotor activity. The effect sizes from prior studies agree with the calculated expected number of animals necessary to achieve statistically significant results with a power of 0.800. For the UCMS study, data for the dependent measures (sucrose preference, preference and approach latency for the dark side in the dark/light emergence test, FST immobility) will be analyzed by a 2-way ANOVA, with stress and

drug treatment independent factors. Significant interactions will be followed by Neuman-Keuls test.

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered: The effects of ketamine and the kappa opioid antagonists, LY2444296 and LY2456302, will be studied in models of depression and anxiety in mice. The overall goal is to provide sufficient evidence for potential efficacy in treating depression to justify and stimulate the performance of clinical trials with patients. Behavioral studies of antidepressant drugs in mice using the validated procedures described in this protocol are believed to provide information pertinent toward understanding the effects of these drugs on depression and stress in humans and their underlying neurochemical mechanisms. These complex interactions governing mood and behavior cannot be adequately studied with in vitro systems or lower organisms such as invertebrates.

V.3.2. Animal Model and Species Justification: The studies are proposed in mice as a model organism that measures the behavioral effects of antidepressant drugs and environmental stress in a manner similar to those shown by other mammals, including humans. There are no lower species that provide the same information. Because of the extensive literature using these rodent models, positive results with these tests will stimulate the field to plan corresponding clinical trials in humans.

V.3.3. Laboratory Animals

	Strain #1	Strain #2	Strain#3
V.3.3.1. Genus & Species:	*Mus musculus*	*Mus musculus*	*Mus musculus*
V.3.3.2. Strain/Stock:	C57BL/6	Oprm1$^{-/-}$	Oprk1$^{-/-}$
V.3.3.3. Source/Vendor:	(b)(4)	In-house	In-house
V.3.3.4. Age:	6-8 weeks	6-8 weeks	6-8 weeks
V.3.3.5. Weight:	Appropriate for age	Appropriate for age	
V.3.3.6. Sex:	Male and female	Male	Male
V.3.3.7. Special Considerations:	Pathogen free		

V.3.4. Number of Animals Required (by Species): 2,950

V.3.5. **Refinement, Reduction, Replacement (3 Rs)**:

V.3.5.1. **Refinement**: 1) Mice are handled daily and acclimatized to the testing room on the days prior to conducting a behaviorel procedure. 2) An observer watches all mice in the forced swimming test for signs of distress. They will prevent any animal from drowning by removing them from the cylinder. 3) Mice will be anesthetized prior to decapitation to immobilize the animal.

V.3.5.2. **Reduction**: The same groups of male mice used to measure the forced swim test will be used to assess the effects of drugs on locomotor activity. Power calculations have been used to estimate the minimum number of mice required to reach statistical significance.

V.3.5.3. **Replacement**: There is no alternative to live animal use to study the effects of environmental stress on behavior. If an alternative to live animal use for the study of environmental stress becomes available, this alternative will be used.

V.4. **Technical Methods**:

V.4.1. **Pain / Distress Assessment**:

Analgesia: Mice are allowed to remain on the hot plate for a maximum of 60 seconds to prevent the development of tissue damage.

Forced swim test: Mice are ordinarily good swimmers and swim through the 6-min test without difficulty. An observer watches all mice in the forced swimming test for signs of distress, such as failing to swim on the surface of the water. The observer will intervene and remove any animal from the cylinder on the rare occasion that they show signs of distress.

UCMS procedure: Mice are weighed and observed daily. Any mouse showing intractable weight loss or signs of distress will be removed from the experiment in consultation with LAM.

V.4.1.1. **APHIS Form 7023 Information**:

V.4.1.1.1. **Number of Animals**:

	Strain #1	Strain #2	Strain#3
V.4.1.1.1.1. **Column C**:	800		
V.4.1.1.1.2. **Column D**:	360		
V.4.1.1.1.3. **Column E**:	1790		

V.4.1.2. **Pain Relief / Prevention**:

V.4.1.2.1. **Anesthesia/Analgesia/Tranquilization**: N/A

V.4.1.2.2. **Pre- and Post-procedural (not surgery) Provisions**: N/A

V.4.1.2.3. **Paralytics**: None.

V.4.1.3. **Literature Search for Alternatives to Painful or Distressful Procedures**:

V.4.1.3.1. **Sources Searched**: PubMed, PsychInfo

V.4.1.3.2. **Date of Search**: February 14, 2016

V.4.1.3.3. **Period of Search**: PubMed 1995 through present; PsychInfo 1965 through present.

V.4.1.3.4. **Key Words of Search**: (alternative or refine), distress, mice and forced swim test; alternative, distress and NIH test; alternative, distress and chronic mild stress.

V.4.1.3.5. **Results of Search**: The search procedure examined alternatives to the forced swim test (by searching for (alternative or refine) and chronic mild stress procedure or the NIH test (by searching for (alternative or refine) and distress and NIH test or novelty-induced hypophagia). Two databases were searched, Pubmed and Psychinfo. There were no alternative procedures located through this search. There were no hits for the keyword combinations in either PubMed or PsychInfo.

V.4.1.4. **Unalleviated Painful or Distressful Procedure Justification**: Mice tested with the forced swim test were placed in Category E. This test measures the behavioral coping responses evoked in mice when they are placed in cylinder of water for 6 min. Mice either will react passively to the stress and develop behavioral immobility or they will react actively with increased swimming and reduced behavioral immobility. Antidepressant drugs cause mice to favor an active response to the unmitigated swim stress. Mice must be tested without alleviation of the stress in order to determine how the effects of stress or drug treatments have affected their response. The mice are tested only for a limited period of time because the test is timed at 6 min

V.4.2. **Prolonged Restraint**: N/A

V.4.3. **Surgery**: N/A

V.4.3.1. **Pre-surgical Provisions**: N/A

V.4.3.2. **Procedure**: N/A

V.4.3.3. **Post-surgical Provisions**: N/A

V.4.3.4. **Location**: N/A

V.4.3.5. **Surgeon**: N/A

V.4.3.6. Multiple Major Survival Operative Procedures: N/A

V.4.3.6.1. Procedures: N/A

V.4.3.6.2. Scientific Justification: N/A

V.4.4. Animal Manipulations:

V.4.4.1. Injections: Injections will be performed with a 1 cc syringe, 26 g, ½ inch needle, and 10 cc / kg approx. volume for i.p. injections. For the FST and NIH studies, the drugs that will be used are: ketamine (3 mg/kg, i.p.) and the KOR antagonists LY2444296, and LY2456302 at a dose range of 1-3 mg/kg, i.p. Drugs will be given either 1 hour or 24 hours prior to behavioral testing. In the analgesia studies, mice will be injected with morphine or U50,488 at 10 mg/kg i.p. 30 min prior to testing. For studies with the AMPA receptor blocker NBQX, the dose of 1 mg/kg i.p. NBQX will be given 10 min prior to ketamine or the KOR antagonists. In the UCMS procedure, mice will be injected with saline, ketamine, LY2456302, LY2444296, or fluoxetine (5 mg/kg, i.p.) once daily in the UCMS procedure.

V.4.4.2. Biosamples: Brain tissue samples (cortex, hippocampus, amygdala and striatum) will be taken from all mice participating in the UCMS studies.

V.4.4.3. Adjuvants: None.

V.4.4.4. Monoclonal Antibody (MAbs) Production: None.

V.4.4.5. Animal Identification:

Ear tag in mice.

Cage card also will be labeled with animal number

A log book containing the animal number, gender / sex; dates of behavioral testing, dates of euthanasia; dates of injections, will be maintained for each mouse.

V.4.4.6. Behavioral Studies:

Hot plate analgesia. The nociceptive threshold for analgesia will be examined with a hotplate analgesia meter (Columbus Instruments, Columbus, Ohio). The hot plate provides a constant 55 degree (C) surface, a temperature low enough to avoid harming the mice, but high enough to be uncomfortable for a wild-type saline-treated animal. A small plastic cage around the hot plate prevents the animal from leaving the plate surface. Animals will be placed on the hot plate and the latency (s) to lick their hind-paw or jump will be recorded. After displaying either of these behaviors, or upon reaching the predetermined cut-off time (60 s), the animals will be removed from the hot plate. For drug studies, mice will be injected with drug 30 min prior to behavioral testing. Behavior is expressed either as the latency to lick or jump or the percentage analgesia. Percentage analgesia is calculated by taking the mean latency for saline treated mice

(s) minus the latency of the test animal (s) divided by 60 s (maximum time animals can spend on the plate) minus the mean latency for saline-treated mice (s).

Forced swim test (FST). This test is a recognized model of depressive behavior induced by inescapable stress. Because the studies model the way that antidepressant drugs alleviate stress in clinical depression, the stress cannot be alleviated by sedatives or analgesics. All experimental sessions will be conducted between 1200 and 1800 hours. Swim test sessions are conducted by placing mice in individual glass cylinders (46 cm tall, 21 cm in diameter) filled with water (23-25°C water) to a depth of 15 cm. Only one test is given with the mouse for a standard 6-min test duration. The water in the cylinder is changed after every test. Antidepressant drugs are administered only once, either 1 hour, 24 hours or 48 hours prior to testing, and the post-injection interval will be manipulated as a variable in the present experiments. A digital recorder positioned directly above the cylinders records the swim sessions. Digital video files are analyzed for immobility by a trained observer blind to the experimental treatment condition. Immobility is defined as the absence of movement on the water surface, except that necessary to keep afloat. The swimming test will be conducted only once for each animal. Injection of mice with standard antidepressant drugs produces a significant reduction of immobility by delaying the time required for mice to adopt a passive immobility behavior during the FST (b)(4) Digital files will be stored on a secured lab server.

Locomotor activity. Locomotor activity will be measured in cages resembling the home cage environment (28.9 x 17.8 x 12 cm). The cages are placed inside an infrared-sensitive motion detection system (30 x 24 x 8 cm) with an 8-beam photocell array strip (Med Associates Inc, St. Albans, VT). Total ambulatory activity, crossing the longitudinal axis and rearing is measured by counting the number of beam breaks. The test will be performed only once for each animal.

Novelty-induced hypophagia (NIH) test. Mice are exposed to 8 training sessions in a familiar feeding cage prior to testing in a novel environment. The training consists of daily sessions (15 min) in which mice are given access to a highly palatable food (peanut butter chips; Nestle, Glendale, CA) delivered in a clear plastic petri dish in a familiar feeding cage. The latency to approach and initiate ingestion and the amount of food consumption is measured regularly and mice come to approach the food within 30 sec. The novel cage environment consists of an empty clear polycarbonate cage without bedding located under bright overhead illumination located in a room different than training. The novel cage test session duration is 15 min and is videotaped. The latency to ingestion and the amount of food consumed during the novel cage session are the endpoints measured. The test is given only once for each animal in the novel cage. Drugs will be administered either 1 hour or 24 hours prior to testing. Antidepressant treatments reduce the latency to approach food in the novel environment without effects in the home cage (b)(4)

Sucrose preference test. During an 8 h session, mice are given a free choice between two bottles, one with water and one with a 1% sucrose solution. To avoid side preference, bottles are switched halfway through the test. Bottles are weighed before

and after the test. Preference is calculated as the percentage of consumed sucrose from the total amount of liquid drunk (sucrose and water).

Dark-light emergence test. The dark/light emergence test is conducted in an apparatus consisting of a two-chambered box (17 × 20 cm for each side) made of plexiglas with an opening (5 x 5 cm) connecting both chambers. One side is colored black (room light entry is limited) and the other side is white. Room illumination is 600 lux. Mice are placed into the dark side and then allowed to freely explore either the light or dark side for 5 min. Anxiety-like behavior is measured as the time required to emerge from the dark side and the time spent on the white side during the 5 min session. The apparatus is cleaned with 70% EtOH between animals.

Unpredictable Chronic unpredictable mild stress (UCMS). Mice will be exposed to a variable sequence of mild, unpredictable stressors for a duration of 21 days called the UCMS procedure. Mice are exposed to three physical or psychosocial stressors per day for a period of one hour for a duration of up to five weeks. The stressors used are: cage rotation, lights on overnight, cage on gentle shaker for 30 min, cage tilt (45 degrees), isolation for 10 hours, exposure to cold, introduction of a new partner, restraint for 30 min, exposure to rat odor, lights off (during the day), stroboscopic lighting (in the dark) and wet bedding. The stressors will be presented in a procedure room or specialty room (walk-in refrigerator) and last up to 30 min, except for stressors presented overnight. After the stressor is presented in the procedure room, the mice are returned to the animal colony. Mice are weighed every day. Mice that lose more than 10% of their body weight will be eliminated from the study. The schedule of stressor exposure in the UCMS procedure is presented below in the Table.

After exposure to the UCMS procedure for 14 days, the effects of the experimental antidepressants will be evaluated. In Experiment 6, the effects of a single acute exposure to ketamine and the KOR antagonists will be evaluated. Experiment 7 will evaluate the effects of drugs given chronically for for 7 days prior to the start of behavioral testing (see timeline below). After 7 days of treatment, mice are given three behavioral tests: sucrose preference, dark-light emergence and the forced swim test. The UCMS procedure causes reduced sucrose preference (anhedonia), increased emergence time from the dark (anxiety) and increased immobility in the forced swim test (decreased stress resilience). Non-stressed controls are weighed every day and injected with the same drugs, but not subjected to any of the stressors. Antidepressant drug treatments reverse these effects of stress without producing any effect in non-stressed controls.

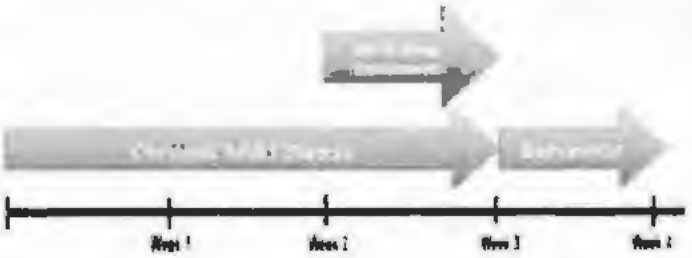
Table 1S

Schedule of Stressor Presentations in the UCMS Procedure

Day	Morning	Afternoon	Overnight
0	Rotate		Lights on
1	Cage on shaker	Rat odor	Cage tilt
2	Restraint	Cold	Stroboscopic light

3	Swim	Lights off	Isolation
4	Rat odor	Restraint + lights off	Wet bedding
5	Cage on shaker	New partner	Lights on + white noise
6	Cold	Lights off + cage tilt	Wet bedding
7	Cold swim	Restraint on shaker	Cage tilt
8	Rat odor + white noise	Cold + isolation	Lights on
9	Lights off, cage tilt, wet bedding	Home cage switch	Stroboscopic light
10	Rat odor + shaker	Restraint + lights off	Isolation
11	Swim	Cage on shaker	Wet bedding + white noise
12	Cage tilt	New partners	Lights on + white noise
13	Restraint	Lights off	Stroboscopic light
14	Home cage switch	Rat odor	No stress (Sucrose habituation)
15	Cage on shaker	Cage tilt	Wet bedding
16	Restraint	Cold	Stroboscopic light
17	Swim	Lights off	Isolation
18	Rat odor	Restraint + lights off	Wet bedding
19	Cage on shaker	New partner	Lights on + white noise
20	Cold	Lights off + cage tilt	Wet bedding
21	Cold swim	Restraint on shaker	Cage tilt

Timeline for UCMS Procedure and Drug Administration



V.4.4.7. Other Procedures: None.

V.4.4.8. Tissue Sharing: No tissue sharing is planned at this time. However, we welcome investigators to utilize tissue from these animals following completion of the study protocol. We will do whatever we can, in coordination with the IACUC, to accommodate requests for tissue.

V.4.5. Study Endpoint: Mice will be euthanized after the completion of the behavioral tests described in Experiments 1-7. PI will consult with CLAM veterinarians to evaluate animals in the UCMS procedure. Animals deemed to be in distress will be euthanized by CLAM personnel, the PI or his staff.

V.4.6. Euthanasia: Mice deemed in distress will be anesthetized with isofluorane and decapitated in Rm (b)(6) by PI or his staff or euthanized by CLAM personnel with CO_2 followed by cervical dislocation or bilateral thoracotomy.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol.

V.5.1.1. Study Room: Space for Dr (b)(6) laboratory has not yet been assigned.

Building(s) _____ Room Number(s) _____

V.5.1.2. Special Husbandry Provisions: None.

Food Restriction:	Yes _____	No X
Fluid Restriction:	Yes _____	No X

V.5.1.3. Exceptions: N/A

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care: No special veterinary medical care is anticipated for these experiments. Animals deemed to be in distress will be treated or euthanized by CLAM personnel or the PI. PI will anesthetize with isoflurane followed by decapitation. If CLAM personnel observe a mouse in distress, PI should be contacted before euthanasia for possible experimental use of the mouse. PI will provide work and home contact information to CLAM.

V.5.2.2. Emergency Veterinary Medical Care: All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: Except as indicated below, all animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents.

V.5.3.2. Enrichment Restrictions: Enrichment will be withheld from mice subjected to UCMS because enrichment could alter experimental outcomes. Since all mice in control and experimental groups need to be treated identically to enable a valid comparison, enrichment will be withheld from all mice in the UCMS protocol.

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
Behavioral testing, IP injections, Isoflurane Administration, Decapitation	(b)(6)	PI, 35 yr experience with mouse research, including behavioral testing, including the FST, light-dark box, NIH test and sucrose drinking, and decapitation.	Completed iInvestigator training at U Penn, 2000.
Behavioral testing, IP injections, Isoflurane Administration, Decapitation		Co-PI, 12 yr experience with mouse research, including behavioral testing, including the FST, light-dark box, NIH test and	Completed iInvestigator training at U Penn, 2013.

		sucrose drinking, and decapitation.	
Behavioral testing, IP injections, Isoflurane Administration, Decapitation	To be hired	Research technician. Will be trained by PI or Co-PI as needed.	

VII. **BIOHAZARDS/SAFETY**: PPE, including gowns, masks and gloves, will be worn by all personnel to reduce allergen exposure. No special precautions are necessary for working with the drugs used in these studies.

VIII. **ENCLOSURES**: none.

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

Principal Investigator Signature _____ Date _____

G. Training: The following personnel will attend the next USUHS Investigator/Animal User Training Course:

(b)(6) _____ _____

H. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely, "Responsibility" for implementing animal use alternatives where feasible and conducting humane and lawful research.

I. Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress WILL or **WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

X. PROTOCOL ABSTRACT:

A. Animal Protocol Number:

B. Animal Protocol Title: Kappa Receptor Antagonists as Rapid Acting Antidepressants

C. Principal Investigator: (b)(6)

D. Performing Organization: USU

E. Funding: NIMH

F. Objective and Approach: There is an unmet medical need for new drugs that could treat comorbid depression and anxiety, especially for treatment-resistant patients. Depression is one of the most common psychiatric illnesses, especially in military personnel. An increasing number of patients (30-40%) are unresponsive to current antidepressant medications. In the past few years, low dose ketamine has been shown to produce antidepressant effects in treatment-resistant patients, showing that novel antidepressants can be developed. The effects of ketamine are a medical breakthrough because they occur immediately and last for about a week, unlike most antidepressants that require a month or longer before they even begin to work. However, the widespread use of ketamine has been limited because it is a drug of abuse and causes unwanted side effects.

The proposed studies will evaluate the effects of two novel kappa opioid receptor antagonists, LY2456302 and LY2444295, using animal behavior tests for their potential to be developed into antidepressant and anxiolytic drugs that could be used in humans. Studies will determine whether the kappa opioid receptor antagonists produce behavioral effects in mice similar to those of established antidepressants but only more rapidly and sustained over days. Their effects will be compared with low dose ketamine as a standard. The behavioral tests used will be: the forced swim test and novelty-induced hypophagia, tests that are sensitive to traditional antidepressant drugs. The experiments focus on comparing the time of onset or duration of activity for ketamine, LY2456302 and LY2444295 with the known delayed action for SSRI antidepressants. Other experiments will establish the mechanism of action of the kappa opioid receptor antagonists using mice with constitutive deletion of kappa and mu opioid receptors or after treatment with a glutamate receptor antagonist. The most rigorous evidence for antidepressant potential will come from rodent studies that will show reversal of the effects of chronic mild stress on the production of anhedonia and anxiety, symptoms similar to those shown by human depressed patients. Taken together, these experiments will form a basic foundation for evaluating the development of novel kappa opioid receptor antagonists as rapid acting antidepressants and for eventual testing in patients with treatment-resistant depression.

G. Indexing Terms (Descriptors): animals, mice, depression, anxiety, antidepressants, ketamine, kappa opioid receptors, stress,

MEMORANDUM FOR DR. (b)(6) DEPARTMENT OF PSYCHIATRY

SUBJECT: IACUC Approval of Protocol – Triennial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on May 11, 2012:

Animal Protocol Title: "Stress and Drug Seeking In Rats: Role of the Endocannabinoid System and Caffeine"

USUHS Protocol Number: (b)(6)

Expiration Date: May 10, 2015

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. NON-TECHNICAL SYNOPSIS: Posttraumatic stress disorder (PTSD) is a debilitating anxiety disorder affecting military service members and civilians in the U.S. Among the individuals with PTSD, the rate of nicotine dependence is quite high. Approximately 28.5% of the population is current smokers and 47.1% have smoked at some time in their life in the U.S. (Lasser, Boyd et al. 2000). Of those with a history of PTSD, 63.3% had smoked daily at some point in their lifetime and 45.3% were current smokers – rates considerably higher than those with no history of PTSD (47.1% lifetime and 28.5% current). Also, PTSD patients are more likely to be heavy smokers and relapse to smoking tobacco (Fu, McFall et al. 2007). These suggest that nicotine dependence is a serious problem in the individuals with PTSD. Among the potential biological mechanisms, the endocannabinoid system (ECS) has been implicated in both anxiety disorder (Picciotto and Corrigall 2002) and nicotine dependence (Cohen, Kodas et al. 2005). Thus, developing drugs targeting the ECS may have therapeutic potential on treating PTSD and nicotine dependence. Using well-established rat models of stress and nicotine self-administration, we'll investigate the effects of three stress models on anxiety and depression behavior as well as relapse to nicotine seeking. We will further investigate the effects of the cannabinoid receptor 1 agonist and caffeine during stress exposure on subsequent anxiety/depression behavior and relapse to nicotine seeking in rats. The outcome of these studies will enhance our understanding of the biological mechanisms by which the ECS regulates mood, anxiety and drug seeking, and provide a novel treatment strategy for comorbid PTSD and nicotine dependence.

II. BACKGROUND:

II.1. Background:

Post-Traumatic Stress Disorder (PTSD) and substance abuse

PTSD is a debilitating anxiety disorder that can develop in response to traumatic stress exposure such as combat or other physical and/or psychological stress. The estimated lifetime prevalence of trauma exposure is 60.7% for men and 51.2% for women with men more likely to report physical attacks, combat experience, being threatened with a weapon, while women likely to report sexual assault, childhood neglect and childhood

physical abuse (Kessler, Sonnega et al. 1995). It is well established that the exposure to traumatic stressors predisposes persons to an increased probability of use of psychoactive and addictive drugs (Brown and Wolfe 1994). The use of psychoactive drugs such as nicotine, marijuana and caffeine continues to be one of the more damaging squeal to deployment-associated PTSD in military personnel. However, biological mechanisms underlying the substance use disorder displayed in PTSD subjects are not well understood, and therapeutic interventions to reduce subsequent drug abuse in traumatized personnel are empirical and of uncertain efficacy.

PTSD and the endocannabinoid system (ECS)

The endocannabinoid system (ECS) has recently emerged as a possible target for the treatment of mood and anxiety disorders including PTSD (Chhatwal and Ressler 2007; Hill and Gorzalka 2009; Moreira and Wotjak 2010; Alger and Kim 2011). For example, a cannabinoid receptor 1 (CB1R) agonist prevented the development of behavioral and endocrine alterations in a rat model of intense stress (Ganon-Elazar and Akirav 2012). Rats were treated with the CB1R agonist WIN55,212-2 (WIN) immediately after intense stress exposure and were tested 1 week later for anxiety and hypothalamic-pituitary-adrenal (HPA) axis function. Exposure to stress enhanced anxiety behavior and HPA axis function and treatment with WIN after stress exposure prevented anxiety and HPA axis function. These effects were blocked by administration of the CB1R antagonist AM251, suggesting the involvement of the CB1R. This study suggested that the preventive effects induced by WIN are mediated by an activation of CB1 receptors in the brain and that cannabinoids could serve as a pharmacological treatment of PTSD.

PTSD and nicotine dependence

Nicotine use is associated with exposure to traumatic events and PTSD (Feldner, Babson et al. 2007). Individuals with PTSD show higher rates of smoking and worse smoking cessation outcome. For instance, almost 94% of individuals with PTSD relapsed in the first week after quitting in a community sample of daily smokers (Zvolensky, Gibson et al. 2008). Other studies have shown that smokers exposed to a traumatic event who develop PTSD tend to smoke more than those exposed to trauma that do not develop PTSD, a relationship consistent across age and trauma type (Shalev, Bleich et al. 1990; Lipschitz, Rasmusson et al. 2003; Hapke, Schumann et al. 2005). Smoking among trauma-exposed adults has been found to range between 32% (Weinbaum, Stratton et al. 2001) and 58% (Weaver and Etzel 2003). Compared to the non-smokers, smokers were more likely to develop posttraumatic stress symptoms (Ganz 2000), which is in line with the findings that traumatic event exposure facilitates smoking behavior (Feldner, Babson et al. 2007).

Growing evidence suggests a relationship between trauma exposure and subsequent smoking behavior in a military population. Beckham et al (1997) found that the number of Vietnam combat veterans who smoked was not significantly different between those with PTSD (53%) and those without PTSD (45%) (Beckham, Kirby et al. 1997). However, they found that veterans with PTSD were more likely to be heavy smokers (48% smoked $\geq$ 25 cigarettes daily vs. 28% in veterans without PTSD). Also, Vietnam veterans with PTSD who smoked reported more PTSD symptoms than non-smokers with PTSD (Beckham, Roodman et al. 1995). Among treatment-seeking veterans with PTSD (N=826) who were referred to a VA clinic for comprehensive health assessment, 73% smoked $\geq$ 20 cigarettes per day (Buckley, Mozley et al. 2004),

indicating a high prevalence of nicotine dependence in the military personnel after the trauma exposure.

The ECS and nicotine dependence

The ECS appears to play a critical role in mediating the reinforcing effects of nicotine and relapse to nicotine-seeking behavior in abstinent subjects. However, the results from the previous studies have been inconsistent. A study, using a CB1R agonist WIN 55,212-2, on nicotine self-administration with a progressive-ratio (PR) schedule of reinforcement and a reinstatement paradigm, showed that CB1R stimulation facilitates motivation for nicotine and nicotine seeking in rats (Gamaleddin, Wertheim et al. 2012). These effects were reversed by the CB1R antagonist rimonabant, but not by the CB2R antagonist AM630 indicating CB1R specific effects. Another study reported that the CB1R antagonist SR141716 reduced nicotine self-administration by antagonizing dopamine release in the mesolimbic system (Cohen, Perrault et al. 2002). These studies indicate that the CB1Rs in the brain play an important role in nicotine self-administration. However, studies using indirect agonists for the ECS reported conflicting results. For instance, the endocannabinoid reuptake inhibor VDM11 attenuated relapse to nicotine-seeking in rats (Gamaleddin, Guranda et al. 2011). Another means of elevating the endocannabinoid levels is by inhibiting activity of the hydrolase fatty acid amide hydrolase (FAAH), an enzyme responsible for breakdown of the endocannabinoids. It has been shown that a FAAH inhibitor URB597 attenuated nicotine withdrawal symptoms in rats (Cippitelli, Astarita et al. 2011). These results suggest that direct stimulation the CB1Rs facilitate nicotine self-administration while indirectly increasing the levels of the endocannabinoids attenuate nicotine self-administration in rats. Thus, drugs targeting the CB1Rs may have therapeutic potential for the treatment of nicotine dependence.

PTSD and caffeine

Caffeine is the most widely used licit drug with psychoactive effects, used by 80% of the world's population (James 1997). Although the effects of caffeine on learning and memory have been well understood (Abreu, Silva-Oliveira et al. 2011; Leite, Wilhelm et al. 2011; Nebes, Pollock et al. 2011; Panlilio, Ferre et al. 2011), the effects of caffeine on trauma-related memory and subsequent drug-seeking behavior remain largely unknown. There has been a recent increase in the availability and the use of "Energy Drinks" containing higher levels of caffeine (Reissig, Strain et al. 2009). For example, energy drink consumption of 1 or more times a day by the U.S, Army service members are 17.78% and energy drink consumption with alcohol of 1 or more times a week are 13.5% within a 30 day period (unpublished data). An animal study reported that caffeine exerts anxiogenic effects in rats tested on an unstable elevated exposed plus maze (Jones, Duxon et al. 2002). Interestingly, co-administration of caffeine and THC (an active ingredient of marijuana) worsened memory deficits induced by THC alone (Panlilio, Ferre et al. 2011). The authors demonstrated that this effect was due to A1 receptor, but not A2 receptor, blockade in the brain. However, little is known on the effects of caffeine during trauma exposure and subsequent anxiety/depression and drug seeking behavior. We hypothesize that caffeine use during trauma exposure may strengthen fear memory and subsequent stress responses. We will investigate the effects of caffeine on stress responses and drug seeking using rat models. Understanding the biological mechanism by which caffeine modulates fear memory and

drug seeking may contribute to the development of novel treatments for a comorbid PTSD and nicotine dependence.

We found no previous studies reporting the experiments that we proposed in this protocol.

III. OBJECTIVE\HYPOTHESIS: The driving hypothesis for this project is that exposure to aversive stress affects the endocannabinoid system in brain regions associated with reward pathways in ways that tend to increase drug seeking and drug taking behaviors in stressed individuals. We will compare the effects of three stress models on subsequent anxiety/depression behavior and relapse to drug seeking in rats. Different stress models will be compared to study changes in genes and proteins in the brain and drug seeking that are related to stress in general, not to one specific stress paradigm. One model is the "*traumatic stress*" which includes restraint and tail shock over three days developed by Dr. (b)(6) It has been shown that this paradigm produces physiological and behavioral abnormalities, such as elevations in basal plasma corticosterone levels, exaggerated acoustic startle responses and reduced body weight (Servatius, Ottenweller et al. 1995). A second stress model is the "*warrior stress*" paradigm developed by the (b)(6) lab. This model combines predator odor stress with unpredictable environmental stimuli. Unpredictable stress has face validity in relation to human stress and has been shown to reliably produce elevations in stress hormones including CORT and CRH (Weinstock,

Matlina et al. 1992) and behavior (Gonzalez Jatuff, Berastegui et al. 1999) in rodent studies. A third model is classical fear learning. This model has been used extensively in studying consolidation and retrieval of fear memory in rats (LeDoux 2003). We will test whether retrieval of fear memory triggers relapse to nicotine seeking in rats.

Recent studies have shown that CB1R agonist WIN55,212-2 attenuates stress and anxiety symptoms (Ganon-Elazar and Akirav 2012) while facilitating relapse to nicotine seeking (Gamaleddin, Wertheim et al. 2012) in rats. However, these studies failed to investigate the effects of CB1 agonist on stress-induced nicotine seeking. Since nicotine self-administration has been shown to reduce certain anxiety and stress symptoms in humans (Ziedonis, Hitsman et al. 2008), this may explain why CB1R stimulation facilitates nicotine self-administration and reduces stress responses simultaneously. Interestingly, co-administration of caffeine and THC (an active ingredient of marijuana) worsened memory deficits induced by THC alone (Panlilio, Ferre et al. 2011). However, little is known on the effects of caffeine on trauma-related memory and subsequent drug seeking behavior. Thus, we will investigate the effects of the cannabinoids and caffeine on stress-induced anxiety and relapse to nicotine seeking in rats.

Using intravenous drug self-administration in rats, we will investigate

Specific Aim 1: the effects of three stress models (traumatic stress, warrior stress and fear learning) on depression, anxiety and relapse to nicotine seeking in rats.

Specific Aim 2: the effects of CB1R agonist during stress exposure on depression, anxiety and relapse to nicotine seeking in rats.

Specific Aim 3: the effects of caffeine during stress exposure on depression, anxiety and relapse to nicotine seeking in rats.

IV. MILITARY RELEVANCE: There is a high comorbidity of PTSD and substance use disorders in the military population (Beckham, Wiley et al. 2008; Boden, Kimerling et al. 2011; Booth, Mengeling et al. 2011). A substantial number of military veterans and active duty service members relies on licit and illicit substances such as caffeine, nicotine, alcohol and marijuana to alleviate stress and anxiety symptoms as an active coping strategy (Boden, Kimerling et al. 2011). Thus, the outcome from this study will contribute to the development of more effective therapeutic interventions aimed at preventing or treating a comorbid PTSD and substance use disorders in the military population.

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures: To determine the biological mechanisms of different stressors on nicotine seeking, and the role of CB1R agonist and caffeine, it is necessary to use well-established animal models of stress and an intravenous nicotine self-administration paradigm.

Anxiety and depression measures

Open field locomotor activity will be measured using an Accuscan Electronics Digiscan infrared photocell system. Animals are placed singly in a 20 x 20 x 30 cm clear Plexiglas

arena and a Plexiglas lid with multiple ventilation holes placed on top of the arena. Data are automatically gathered and transmitted to a computer operating the Fusion 3.4 software system for data collection and analyses. The interfaced software measures two dozen activity variables, including total distance and horizontal and vertical activity. Chambers are cleaned between subjects with Clidox-S base, water, and activator in a 1:18:1 preparation. The duration of locomotor activity testing is a maximum of 60 min per session. Sixteen open field activity boxes from the Dr (b)(6) Lab will be used.

Open field center time: Center time is measured using the Accuscan open field activity system during the open field activity session. Anxiety is considered to be inversely related to amount of time spent in the center zone of the open field chamber.

Rearing: Vertical activity is measured in the Accuscan open field activity system to provide an index of depression. Rearing (or vertical activity) is considered to be inversely related to major depressive symptoms.

Intravenous nicotine self-administration

Apparatus

Eight operant chambers (Med Associates Inc., St. Albans, VT, USA) for nicotine self-administration are contextually different from the animals' home cage, and located in a different room (b)(6) Each chamber is equipped with an infusion pump assembly consisting of a Razel Model A pump (Stamford, CT, USA) and 10 ml syringe connected to a fluid swivel (Instech, Plymouth Meeting, PA, USA) by Teflon tubing. Tygon® tubing enclosed by a metal spring connected the swivel to the animal's catheter exit port and was secured to Teflon threads on the catheter assembly. Each operant chamber contains two levers, and either one (Fixed Ratio 1) or five (Fixed Ratio 5) 20 g lever press responses on the active lever delivered an i.v. injection of sterile nicotine solution (Sigma/Aldrich, MO, USA) dissolved in 0.9% saline. During each injection, a cue light above the active lever is illuminated, and the house light is extinguished. Each injection is followed by an additional "time-out" (TO) period in which the cue light is extinguished; lever press responses during the entire injection-TO period are recorded but had no programmed consequences. Responses on the inactive lever are recorded but had no scheduled consequence. A detailed procedure on intravenous drug self-administration in rats has been described previously (b)(6),(b)(4) (b)(6),(b)

Lever press training

Animals are initially trained to press a lever for sucrose pellets in ventilated operant chambers under restricted diet conditions for three days. This procedure will facilitate initial nicotine self-administration training. This procedure requires an initial 16–20 hrs of food restriction followed by ad lib feeding for a few hrs after each test session. This procedure allows transient weight gain overnight, but animals return to 90% initial body weight prior to the next test session on the following day.

Intravenous (IV) catheter surgery

Please see section V.4.3 below (page 18).

Intravenous nicotine self-administration and reinstatement

After a minimum 6 day recovery from IV catheter surgery, animals are placed in operant test chambers and allowed to acquire nicotine self-administration (0.03 mg/kg/0.1 ml in a 1 s injection) on one lever press/injection (Fixed Ratio 1: Time Out 20 sec) reinforcement schedule in a daily 2-h self-administration test sessions for 5 days per week. Animals are weighed before each nicotine self-administration session to adjust nicotine dose (0.03 mg/kg). After 2-3 weeks of nicotine self-administration, animals will be tested on extinction and reinstatement paradigm. Reinstatement test will measure the ability of specific experimenter delivered stimuli to induce relapse to drug seeking behavior as described previously (Sutton, Schmidt et al. 2003). Prior to reinstatement testing, nicotine self-administration behavior will be extinguished through extinction training when lever press responses are no longer reinforced by drug injections. When lever press responding is extinguished, reinstatement testing commences with experimenter delivered injections of nicotine, drug associated stimuli (lights associated with drug injections during self-administration), and a brief period of intermittent mild footshock stress. These stimuli induce relapse as indicated by an increase in non-reinforced responding at the lever that previously delivered the drug injections during self-administration training. Reinstatement procedures in rats are conducted in a between session paradigm. In this paradigm, self-administration, extinction, and reinstatement occur over consecutive daily test sessions. The between session paradigm is used for drug pre-treatments that are given on one or each occasion, and reinstatement is tested over a 5 day period following the pretreatment. Some animals in reinstatement studies will be exposed once to mild footshock stress in the operant test chambers at commonly used parameters (0.5 mA/0.5 sec every 30 seconds for 15-30 minutes). Footshock stress is used to reinstate drug seeking behavior, and is thought to represent an animal model of stress induced drug craving and relapse (Self and Choi 2004).

Three stress models in rats

1. Traumatic stress

Animal model has been developed in which exposure to stress provoke a wide range of physiological responses. Intense stress, aversive challenges, and situational reminders of traumatic stress in animal models have resulted in long-term effects on behavioral, autonomic, and hormonal responses that mimic many of the clinical symptoms observed in those with PTSD. We will use an intense stress paradigm developed by Dr. (b)(6) in Psychiatry department. Stress exposure consists of a two-hour per day session of immobilization and tail-shocks. The rat is placed in a clear Plexiglas tube which enables gentle, but secure form of restraint. The size of the tube restricts the animal turning or escaping, but natural posture can be maintained. Animals can breathe naturally through the holes in the tube. Forty electric shocks to the tail (2 mA, 3 s duration) are applied at varying intervals (140 to 180 s) over the course of two hours on three consecutive days. Animals will be weighed between each stress exposure. This stress protocol was adapted from the "learned helplessness" paradigm in which animals undergo an aversive experience under conditions in which they cannot perform any adaptive responses (Seligman and Maier 1967; Seligman 1968). Considering the life span difference between humans and rats, three days of intense stress exposure in rats

are equivalent to three months of stress in humans. This protocol has been approved for Dr. (b)(6) by the IACUC (b)(6)

2. Warrior stress

The Warrior Stress Paradigm combines predator stress with unpredictable environmental stimuli. Predator stress is a non-painful but effective stressor used in rodent models investigating the effects of stress. Predator stress can be manipulated by presenting the actual predator or the odors of the predator. Exposure to predator stress produces increases in stress hormones (Hayley, Borowski et al. 2001). Exposure to predator stress also produces behavioral changes in rodents including differences in food consumption, elevated plus maze, startle response, freezing behavior, withdrawal behavior, and exploratory behavior (Belzung, El Hage et al. 2001; Endres, Apfelbach et al. 2005; Masini, Sauer et al. 2005; Takahashi, Nakashima et al. 2005; Adamec, Head et al. 2006). Predator stress is presented by introducing a cotton ball with commercially available fox urine into a test cage with the rat subject. Unpredictable, non-painful stressors include noise, flashing light, and cage shaking. Unpredictable stress are included because it is a face-valid model of human stress and also has been shown to reliably produced alterations in stress hormones (Fride, Soreq et al. 1986; Weinstock, Matlina et al. 1992), and behavior (Gonzalez Jatuff, Berastegui et al. 1999) in rodent studies. The animals are transferred from their home cage and housing room to the "stress cage" (covered with a Plexiglas lid) to be exposed to the stressors. The stress procedure lasts 20 minutes for 5 days. Fox urine (15mL) is placed on a large cotton ball and placed in varying spots in the stress cage. A bright florescent overhead light remains on during the procedure. Animals will be weighed between each stress exposure. This protocol has been approved for Dr. (b)(6) by the IACUC.

3. Pavlovian fear learning

Sprague-Dawley rats will be placed in a Plexiglas rodent conditioning chamber with a metal grid floor (model E10-10; Coulbourn Instruments, Lehigh Valley, PA, USA), dimly illuminated by a single house light, and enclosed within a sound-attenuating chamber (model E10-20). Rats will be divided into two groups. The paired group will be presented with five pairings of a tone for 20 s (CS: conditioned stimulus; 5 kHz, 75 dB) that co-terminates with a foot shock (US: unconditioned stimulus; 0.5 s, 1.0 mA). The unpaired group (control) will receive five non-overlapping presentations of the CS and US. The unpaired group will be included into the design in order to assess how contextual stimuli not associated with the phasic tone in the paired group differ in freezing response. Animals will be weighed between each stress exposure. This protocol has been approved for Dr. (b)(6) by the IACUC (b)(6)

Flow chart and time line of the study

Animals arrive at the USUHS Animal Facility (CLAM)

↓

Animals acclimate to USUHS Animal Facility — 1 week

↓

Baseline open field activity testing — 1 day

↓

Lever press training (sucrose pellets) — 3 days

↓

IV catheter surgery and recovery — 1 week

↓

Nicotine self-administration — 2-3 weeks

↓

Stress exposure ← drug/vehicle injections before stress — 3-5 days

↓

Post-stress open field activity testing — 1 day

↓

Between session extinction — 5 days

↓

Reinstatement testing — 5-6 days

##Estimated length of one iteration is approximately 7-8 weeks.

Exp. 1: Effects of traumatic stress on anxiety, depression and relapse to nicotine seeking (n=56)

Rationale: The purpose of this experiment is to determine role of traumatic stress exposure on anxiety, depression and relapse to nicotine seeking in rats.

Experimental design (see Table of timeline for details): Rats (n=14 per group) will be tested using open field activity and undergo surgery for implantation of an IV catheter. Following 1 week of recovery, animals will be trained to self-administer nicotine (0.03 mg/kg/infusion) or saline for 2 hr/day in operant chambers for 3 weeks. Animals will be tested again in an open field activity paradigm. After acquisition of nicotine self-administration, rats will be exposed to 3 days of traumatic stress and tested on an open field activity paradigm. Animals will be tested on extinction from nicotine self-administration (across 5 days) and reinstatement of drug seeking using drug associated cue light, priming injection of nicotine (0, 0.1 and 0.5 mg/kg, s.c.) and unpredictable footshock to trigger relapse to nicotine seeking in rats (across 5 days). In order to study potential long-term effects of traumatic stress on drug seeking behavior, same animals will be re-tested on the extinction and reinstatement paradigm 1 week after the initial testing.

Group	IV surgery	Mood/Anxiety behavior	Traumatic Stress	Reinstatement	Pain category	N

Exp. 2: Effects of warrior stress on anxiety, depression and relapse to nicotine seeking (n=56)

Rationale: The purpose of this experiment is to determine role of warrior stress exposure on anxiety, depression and relapse to nicotine seeking in rats.

Experimental design (see Table of timeline for details): Rats (n=14 per group) will be tested in open field activity apparatus and undergo surgery for implantation of an IV catheter. Following 1 week of recovery, animals will be trained to self-administer nicotine (0.03 mg/kg/infusion) or saline for 2 hr/day in operant chambers for 3 weeks. After acquisition and maintenance of nicotine self-administration, rats will be exposed to warrior stress over 5 days and tested in open field activity apparatus. Animals will be tested on extinction from nicotine self-administration (across 5 days) and reinstatement of drug seeking using drug associated cue light, priming injection of nicotine (0, 0.1 and 0.5 mg/kg, s.c.) and unpredictable footshock to trigger relapse to nicotine seeking in rats (across 5 days).

Exp. 3: Effects of fear memory on anxiety, depression and relapse to nicotine seeking (n=56)

Rationale: The purpose of this experiment is to determine role of fear learning on anxiety, depression and relapse to nicotine seeking in rats.

Experimental design (see Table of timeline for details): Rats (n=14 per group) will be tested in open field activity and undergo surgery for implantation of an IV catheter. Following 1 week of recovery, animals will be trained to self-administer nicotine (0.03 mg/kg/infusion) or saline for 2 hr/day in operant chambers for 3 weeks. After acquisition and maintenance of nicotine self-administration, rats will be exposed to fear learning paradigm and tested on open field activity. Animals will be tested on extinction from nicotine self-administration (across 5 days) and reinstatement of drug seeking using drug associated cue light, tone associated with fear memory, priming injection of nicotine (0, 0.1 and 0.5 mg/kg, s.c.) and unpredictable footshock to trigger relapse to nicotine seeking in rats (across 6 days).

Exp. 4: Effects of CB1 agonist during stress exposure on subsequent anxiety, depression and relapse to nicotine seeking (n=112)

Rationale: The purpose of this experiment is to determine effects of CB1R agonist (WIN) during stress exposure on subsequent anxiety, depression and relapse to nicotine seeking in rats. Based on the experiments 1, 2 and 3 described above, we'll determine which stress paradigm has the most robust effects on subsequent anxiety, depression and relapse to nicotine seeking in rats. In this experiment, we'll test the effects of CB1R agonist during stress exposure on subsequent anxiety, depression and relapse nicotine seeking in rats.

Experimental design (see Table of timeline for details): Rats (n=14 per group) will be tested in open field activity paradigm and undergo surgery for implantation of an IV catheter and recover for 5-7 days after the surgery. Animals will be trained to self-administer nicotine (0.03 mg/kg/infusion) or saline for 2 hr/day in operant chambers for 3 weeks. After acquisition of nicotine self-administration, rats will be exposed to a stress paradigm with or without CB1R agonist WIN 55,212-2 (1 mg/kg, i.p.). Animals will be tested on extinction from nicotine self-administration (across 5 days) and reinstatement of drug seeking using drug associated cue light, priming injection of nicotine (0, 0.1 and 0.5 mg/kg, s.c.) and unpredictable footshock to trigger relapse to nicotine seeking in rats (across 5 days).

Exp. 5: Effects of caffeine during stress exposure on subsequent anxiety, depression and relapse to nicotine seeking (n=112)

Rationale: The purpose of this experiment is to determine effects of caffeine during stress exposure on subsequent anxiety, depression and relapse to nicotine seeking in rats. Based on the experiments 1, 2 and 3 described above, we'll determine which stress paradigm has the most robust effects on anxiety, depression and relapse to nicotine seeking in rats. In this experiment, we'll test the effects of caffeine during stress exposure on subsequent anxiety, depression and relapse to nicotine seeking in rats.

Experimental design (see Table of timeline for details): Rats (n=14 per group) will be tested in open field activity paradigm and undergo surgery for implantation of an IV catheter and recover for 5-7 days after the surgery. Animals will be trained to self-administer nicotine (0.03 mg/kg/infusion) or saline for 2 hr/day in operant chambers for 3 weeks. After acquisition of nicotine self-administration, rats will be exposed to a stress paradigm with or without caffeine (20 mg/kg, i.p.). Animals will be tested on extinction from nicotine self-administration (across 5 days) and reinstatement of drug seeking using drug associated cue light, priming injection of nicotine (0, 0.1 and 0.5 mg/kg, s.c.) and unpredictable footshock to trigger relapse to nicotine seeking in rats (across 5 days).

Experimental endpoints

If signs of morbidity are observed over the course of the experiments, the veterinarian is notified and, if necessary, rats are excluded from the study and euthanized. Signs for judging morbidity include rapid breathing; shallow, labored breathing; weight loss (more than 10% of body weight not regained within 48 hr, continuous body weight loss over 5 days of more than 5 g per day), ruffled fur (rough hair coat), hunched posture, hypothermia or hyperthermia, ulceration dermatitis or infected tumors, diarrhea, impaired ambulation, evidence of muscle atrophy or other signs of emaciation, bleeding, or inability to remain upright. In cases of body weight loss, supplemental soft and sweetened food is provided, and if necessary drug self-administration training is withheld until the animal recovers.

V.2. Data Analysis: The number of rats is determined by the number of experimental groups needed for a clear interpretation of the behavioral and neurobiological data.

Revised

Intravenous drug self-administration is a highly regulated and conditioned behavior in rats. Based on our experience, 14 animals per group allows for a sufficient statistical power to detect group differences in drug self-administration behavior as described previously (b)(6),(b)(4) We also performed a power calculation using R statistical language (http://www.r-project.org/). We expect a large effect size (0.5) between groups based on the previous studies (b)(6),(b)(4) (b)(6),(b)(4) Therefore, an effect size (0.5), high power (0.80), and alpha level of 0.05 require a total of 14 animals per group.

Behavioral data will be analyzed using Analyses of Variance (ANOVA). The between-subject independent variables for experiments are Drug (drug vs. saline), Stress (stress vs. no stress), and CB1 agonist (CB1 agonist vs. vehicle). The within-subject independent variable is Time (open field activity). For experiments 1, 2 and 3, data will be analyzed with ANOVA (Stress) with repeated measures on Time (open field activity). Experiments 4 and 5 will be analyzed with ANOVA (Stress x CB1 agonist) with repeated measures on Time (open field activity). Significant interactions will be followed by Newman–Keuls *post-hoc* tests. The level of significance is set at 0.05 for all comparisons. Statistical analyses will be conducted using multiple software such as the Prism (GraphPad, San Diego, CA, USA), the Statistical Package for the Social Sciences (SPSS, Chicago, IL, USA) the R statistical language (http://www.r-project.org/).

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered: This study will require the use of intact living animals; behavioral measurements, such as administration of the stress protocol, anxiety symptoms, relapse to drug seeking cannot be made on cells grown in culture or on a computer simulation or other in vitro systems. Thus, non-animal models were not considered for this project and it is not possible to replace or eliminate the use of animals in this study. Due to ethical considerations, the proposed studies cannot be done with human subjects.

V.3.2. Animal Model and Species Justification: Rats will be used in behavioral paradigms that model stress, anxiety and nicotine dependence in humans. Rats are amendable to pharmacological manipulations needed to study the biological mechanisms involved in traumatic stress and substance abuse. The experimental nature of the work necessitates the use of model organisms rather than human subjects. However, results from our laboratory studies complement data obtained from human clinics and experiments. We will continually evaluate our approaches and adapt experiments for *in vitro* or computer models whenever possible.

V.3.3. Laboratory Animals

	Species #1	Species #2
V.3.3.1. Genus & Species:	R. Norvegicus	
V.3.3.2. Strain/Stock:	Sprague-Dawley	

Experimental endpoints

V.3.3. Laboratory Animals

	Species #1	Species #2
V.3.3.1. Genus & Species:	R. Norvegicus	

V.3.3.2. **Strain/Stock**: Sprague-Dawley

V.3.3.3. **Source/Vendor**: (b)(4)

V.3.3.4. **Age**: 6-10 weeks

V.3.3.5. **Weight**: 250 - 350 gm

V.3.3.6. **Sex**: Male

V.3.3.7. **Special Considerations**: N/A

V.3.4. **Number of Animals Required (by Species)**: Rat 392

V.3.5. **Refinement, Reduction, Replacement (3 Rs)**:

V.3.5.1. **Refinement**: Animals will be monitored on a daily basis and be given pain medication and antibiotic if any sign of pain or distress occurs. In order to reduce stress and anxiety, animals will be acclimated to the facility for 1 week upon arrival.

V.3.5.2. **Reduction**: The number of rats is determined by the number of experimental groups needed for a clear interpretation of the behavioral and neurobiological data. In general, 14 rats are used per experimental manipulation. Based on our experience, we expect about 15% of rats (or 2 per experimental group) to be excluded due to catheter failure or unstable drug self-administration behavior. Therefore, it is expected that 12 rats per experimental group will successfully complete the experiment. Based on our experience, this number allows for a sufficient statistical power to detect group differences in behavior due to the experimental manipulations described above. However, whenever possible, we will utilize repeated measures designs to obtain multiple data points from the same animals.

V.3.5.3. **Replacement**: This study requires the use of intact living animals; behavioral measurement cannot be made on cells grown in culture or with computer models. Thus, it is not possible to replace or eliminate the use of animals in this study.

V.4. **Technical Methods**:

V.4.1. Pain / Distress Assessment during intense stress exposure: For traumatic stress model, electrodes will be attached to the tail of the animal by means of a spring clip in order to minimize any painful irritation that might result from repeated taping of the tail. All animals are monitored by a technician continuously during the two hours when tail shocks are being administered to assure that they do not get into positions that do not allow them to breathe properly. Animals will be monitored daily after the stress sessions

according to CLAM SOPs and continue to be monitored daily for any indication of pain. While the animals are expected to arrest weight gain during the three day stress exposure, any animal that would lose > 20% of its body weight as measured on Day -1 would be withdrawn from the study and euthanized. The stress protocol (Dr [(b)(6)] has been approved by the IACUC [(b)(6)]

V.4.1.1. APHIS Form 7023 Information:

V.4.1.1.1. Number of Animals:

	Species #1	Species #2
V.4.1.1.1.1. Column C:	0	
V.4.1.1.1.2. Column D:	112	
V.4.1.1.1.3. Column E:	280	

The number of animals in Column D indicates that these animals are subjected to either IV catheter surgery or warrior stress (no physical stress) as explained in page 9. The number of animals listed in Column E is based on the premise that these animals are exposed to either stress paradigm or nicotine self-administration which includes reinstatement using mild unpredictable electric footshock. The unalleviated pain and distress resulting from the electric shocks are momentary and cause no physical injury to the tissue of tail or feet.

V.4.1.2. Pain Relief / Prevention: N/A

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization:
For IV catheter surgery, rats will be anesthetized with sodium pentobarbital (60 mg/kg, i.p.) based on a previous study (Choi, Edwards et al. 2011) or ketamine/xylazine (40-80 mg/kg ketamine, 5-10 mg/kg xylazine, i.p.) and penicillin G procaine (200,000 Units/kg, s.c.) will be given as a prophylactic. Rats will also receive atropine sulfate (0.04 mg/kg, s.c.) to reduce pulmonary congestion and facilitate breathing.

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions: Animals will be acclimated for 1 week to the USUHS CLAM. During acclimation to CLAM, animals will be handled briefly each day to acclimate them to being handled; this will reduce any stress that might result from handling of the animals during the procedures described in this study. Following exposure to the stress protocol, animals will be monitored according to CLAM SOPs.

V.4.1.2.3. Paralytics: N/A

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures:

V.4.1.3.1. Sources Searched: PubMed (MeSH), AltWeb, AGRICOLA

V.4.1.3.2. Date of Search: January 13, 2012

V.4.1.3.5. Results of Search: No overlapping studies discovered

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification: A rat model of traumatic stress includes a young adult male rat that is restrained in a Plexiglas tube of appropriate size and receives a series of 40 tail shock (2 mA constant current, 3 sec duration) over a period of two hours daily on three consecutive days. A coiled silver electrode is attached to the tail with a spring clip so that there is no irritation of the tail either from the shocks or from adhesive materials being applied and removed each day. The number and strength of the shocks proposed has been optimized to yield a model

of chronic stress as measured by changes in behavior and by elevated plasma levels of corticosterone. This stress protocol has been approved for Dr. (b)(6) by the IACUC (b)(6) (b)(6) (b)(6)

V.4.2. Prolonged Restraint: All animals are monitored by a technician during the two hours when tail shocks are being administered to assure that they do not get into positions that do not allow them to breathe properly. Also, the electrode can become loose over the two hour period so that the animal no longer receives the shock; monitoring by a technician is required to ensure that the animals receive all of the forty tail shocks.

V.4.3. Surgery:

V.4.3.1. Pre-surgical Provisions: Rats will be maintained on a light-dark cycle (12 hr light/12 hr dark). The habituation period prior to surgery is 5-7 days during which the rats are group-housed.

V.4.3.2. Procedure: All surgery will be performed under aseptic conditions in a clean area. Each surgery will be done on a separate, clean and autoclaved sheet of Whitman Benchkote paper. Surgical instruments are sterilized in a glass bead sterilizer and cleaned/sterilized between successive surgeries. Sterile gloves are used for each rat's surgery and instruments are sterilized before each rat's surgery. Rats (250-350 g) are anesthetized with sodium pentobarbital (60 mg/kg, i.p.) or ketamine/xylazine (40-80 mg/kg ketamine, 5-10 mg/kg xylazine, i.p.) and atropine sulfate (0.04 mg/kg, s.c.) to reduce pulmonary congestion and facilitate breathing. Surgery starts after the rat fails to show the withdrawal reflex after pinching the rear toe (a procedure that is repeated several times during the surgery to ensure full anesthesia level). Supplemental anesthetic dose (0.2-0.4 ml) is given as needed. Intravenous silastic catheter is implanted into the right jugular vein and attached to either the head or the back of the animal.

For the head mount, the surgical areas (the top of the skull and the area above the right jugular vein) are shaved and cleaned with 70% alcohol and betadine scrub for three times, alternating 70% alcohol with betadine scrub. The jugular vein is exposed and the catheter is inserted into the vein and secured to it with a silk suture. The catheter then passes subcutaneously to the top of the skull where it exits into a connector (a modified 22-gauge cannula) mounted to the skull with 4 jeweler's screws and dental cement. The wound areas are sutured, and an antibiotic wound spray is applied to these areas. Rats are also given 2 ml of saline (injected SC) to replace lost fluid during surgery. After surgery, a plastic cap is placed over the open end of the connector. The analgesic buprenorphine (0.1 mg/kg, SC) is given approximately 30 min following the end of surgery. The sutures are removed 10-14 days after surgery.

For the back mount, two incisions will be made, one on the back (2.5 cm), and one on the neck (1 cm). The jugular vein is isolated by teasing apart fatty tissue above the vein with small scissor tips, just above where the vein passes over the clavicle. After isolation, the vein will be punctured with a needle (22 gauge) and the sterile Silastic catheter will be inserted to the level of the sinus vena cava just outside the right atrium. The entry point of the catheter will be secured in place with a 0.5 cm x 0.5 cm mersilene surgical mesh secured to the catheter. The remaining catheter will be pulled from the neck area subcutaneously to the back incision. Then the catheter will exit via premade

22 gauge stainless steel tubing cemented into place with bell shaped dental cement and the bell base (about 0.8 cm diameter) cemented to a 1.5 x 1.5 cm Marlex surgical mesh comprising the back mount. The incisions will be closed using two stainless steel wound clips and treated with topical antibiotic Neosporin ointment (Swabbed To Back Mounted Catheter Exit Area). Animals will receive antibiotic gentamycin sulfate (5-8 mg/kg, s.c.) and the analgesic buprenorphine (0.1 mg/kg s.c.) after each surgery. Animals will receive buprenorphine (0.1 mg/kg s.c.) once every 12 hrs for next 48 hrs and then as needed.

V.4.3.3. Post-surgical Provisions: During recovery (about 30-60 min), the rats are placed in a cage that is kept warm by a heating pad (located under the cage) to prevent hypothermia. The investigators are responsible for post-operative care. The post-operative care includes continuously monitoring the rats until they are fully awake and the animals' health will be monitored and recorded in the animal's medical record for at least 3 days after surgery or until the animal appears normal. The surgery log will be kept in a drawer in the surgery room. If pain or distress such as difficulty in breathing and hypothermia is observed at any time rats will be treated with buprenorphine (0.1 mg/kg s.c.). After the IV catheter surgery, rats are individually housed in the animal facility for 5-7 days. During this time period, the rats are handled and the catheters are flushed daily with 0.2 ml of heparinized (20 U/ml), bacteriostatic saline containing gentamycin sulfate (0.33 mg/ml, i.v.) as described previously (b)(6),(b)(4)

Catheter patency will be verified by infusion of a sodium methohexital (Anesthetic, 7-15 mg/kg, i.v.) solution. Patency is indicated by a brief (about 1 minute) but rapid anesthesia. Using these procedures, catheter life averages about 6–8 weeks for rats. Most catheters are lost due to the growth of the venous wall around the catheter tip. When catheters are no longer patent, animals are either sacrificed as described below, or the original catheter is removed and another one implanted in the left jugular vein. We have observed no weight loss or obvious physical impairment to the animals due to one or two consecutive catheter implantations.

V.4.3.4. Location: (b)(6)

V.4.3.5. Surgeon: Please see personnel page 22

V.4.3.6. Multiple Major Survival Operative Procedures: N/A

V.4.3.6.1. Procedures: N/A

V.4.3.6.2. Scientific Justification: N/A

V.4.4. Animal Manipulations:

V.4.4.1. Injections: The drugs will be delivered by intraperitoneal (i.p.) or subcutaneous (s.c.) injection (1ml latex free syringe w/ 27G½ needle, B-D, Franklin Lakes, NJ). Injection volume will be adjusted based on body weight and no more than 1 ml/kg for i.p. and 2 ml/kg for s.c. administration. For i.v. administration, maximum volume will be 0.3 ml.

Sodium pentobarbital (60 mg/kg, i.p.)
Atropine sulfate (0.04 mg/kg, s.c.)
Buprenorphine (0.1 mg/kg s.c.)
Nicotine (0.03 mg/kg/infusion, i.v.)
Nicotine (0, 0.1 and 0.5 mg/kg, s.c.)
Ketamine/xylazine (40-80 mg/kg ketamine, 5-10 mg/kg xylazine, i.p.)
Gentamycin sulfate (5-8 mg/kg, s.c.)
Gentamycin sulfate (0.33 mg/ml, i.v.)
Sodium methohexital (7-15 mg/kg, i.v.)
WIN 55,212-2 (0.1, 0.3, 1 mg/kg, i.p.).
Caffeine (20 mg/kg, i.p.).
Equithesin (400 mg/kg, i.p.)
A mixture of ketamine (100 mg/kg, i.p.) and xylazine (10 mg/kg, i.p.)

V.4.4.2. Biosamples: Trunk blood and brain tissue will be collected when each animal is euthanized. These samples will be analyzed for further biochemical and molecular biology studies.

V.4.4.3. Adjuvants: N/A

V.4.4.4. Monoclonal Antibody (MAbs) Production: N/A

V.4.4.5. Animal Identification: Rats are identified by tail markings and ear punches matched with IDs on the cage cards. Immediately after the IV catheter surgery under anesthesia, small hole on the ear will be made to identify each animal. Ear punching is commonly used for identification of rodents and involves using a special punch to produce a small (0.5 to 1 mm) notch near the edge of the ear. The cutting edge of the punch is disinfected 70% ethanol after each use.

V.4.4.6. Behavioral Studies: See section V (Materials and Methods)

V.4.4.7. Other Procedures: Stress exposure consists of a two hour per day session of immobilization (restraint) and tail-shocks, for three consecutive days. Each animal is restrained in a Plexiglas tube and an electrode is attached to the tail. Forty electric shocks (2 mA, 3 s duration) are applied at varying intervals (140 to 180 s) over a two hour period; then the rats are returned to their cages. Exposure to this three day stress regimen has been shown to be more effective than a single stress session in producing lasting physiological and behavioral abnormalities, such as elevations in basal plasma corticosterone levels, exaggerated acoustic startle responses and reduced body weight (Servatius, Ottenweller et al. 1995). This stress protocol has been approved for Dr. (b)(6) (b)(6) by the IACUC (b)(6)

V.4.4.8. Tissue Sharing: Brain tissue and trunk blood samples will be collected at the study end point and shared for nucleic acid and protein assays. All personnel engaging in this procedure will receive training by IACUC/ARC staff, or trained laboratory personnel. We will examine multiple brain areas involved in stress and substance abuse such as the prefrontal cortex, nucleus accumbens, amygdala, hypothalamus, hippocampus, substantia nigra and ventral tegmental area for nucleic

acids and protein assays. We will study expression levels of the target genes and proteins related to the endocannabinoid system, nicotine and caffeine receptors following stress exposure and nicotine seeking. These genes include *CB1R, CB2R* and *FAAH* for the endocannabinoid system, *CHRNA2, CHRNA3, CHRNA4, CHRNA5, CHRNA6, CHRNA7, CHRNA8, CHRNA9*, and *CHRNA10* for the nicotinic acetylcholine receptors localized in the brain and *ADORA1, ADORA2A, ADORA2B, and ADORA3* for the adenosine receptors.

V.4.5. Study Endpoint: The study endpoint will be the day immediately after the drug seeking testing.

V.4.6. Euthanasia: Animals will be anesthetized with either chloral hydrate such as Equithesin (Sedative, 400 mg/kg, i.p.) or a mixture of ketamine (100 mg/kg) + xylazine (10 mg/kg) and subsequently are perfused with saline and 10% formalin. Thoracotomy will only be performed after failure of the withdrawal reflex and then intracardiac perfusion will be performed. Supplemental anesthetic doses (0.4 ml of Equithesin or 50+5 mg/kg ketamine+xylazine mixture) are given as needed. For the perfusion, the heart is exposed, and a 17-gage needle that is connected to a pump via tubing is inserted to the left ventricle of the heart. Physiological saline (50 ml) is perfused over 2 min with a pump, followed by 4% paraformaldehyde (100 ml). The procedure is performed on the downdraft table in a Procedure/Necropsy Room.

For the collection of fresh brain tissue, cylinder carbon dioxide (CO2) in the LAM will be used as recommended anesthetic for rat euthanasia. Induction of anesthesia with CO2 (2-5%) is conducted with the animal placed in an appropriate-sized clear chamber. The depth of anesthesia will be determined by loss of withdrawal response to rear foot pad pinch, tail pinch and loss of movement in response to eye extra orbital touching.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol.

V.5.1.1. Study Room:

Building(s) (b)(6) Room Number(s) (b)(6)

Euthanasia will be performed in (b)(6) or CLAM.
Behavior testing will be performed in (b)(6)
Rats will be housed in the Central Animal Facility (CAF)

V.5.1.2. Special Husbandry Provisions:

Food Restriction:	Yes X	No
Fluid Restriction:	Yes	No X

For the lever press training before the intravenous nicotine self-administration, animals

are slightly food restricted for three days. This procedure requires an initial 16–20 hrs of food restriction followed by ad lib feeding for a few hrs after each training. This procedure allows transient weight gain overnight, but animals return to 90% initial body weight prior to the next lever press training session on the following day. This procedure lasts for three days and animals are fed ad lib after the training.

V.5.1.3. Exceptions: In addition, our experiments require that animals implanted with intravenous catheters be housed individually in order to prevent them from chewing and destroying each other's catheter exit assemblies. Animals with iv catheters will be housed individually in standard plastic caging. In other cases, non-operated animals will be group housed in standard plastic caging, unless experiments require direct comparison of biochemical or behavioral data with catheterized animals, in which they will be housed similar to experimental groups.

V.5.2. Veterinary Medical Care: N/A

V.5.2.1. Routine Veterinary Medical Care: Animals will be cared for in accordance with LAM SOPs. Animals will be observed daily or more frequently by the veterinary staff. The CLAM veterinary staff will be available for consultation with the PI if any unexpected medical events arise.

V.5.2.2. Emergency Veterinary Medical Care: All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays. Investigators' contact information will be available to the veterinary staff in case a decision about early euthanasia or treatments of an animal needs to be made on the weekend or holiday.

V.5.3. Environmental Enrichment: There won't be any environmental enrichment because animals are housed individually after IV catheter surgery and subsequently tested on nicotine self-administration.

V.5.3.1. Enrichment Strategy: N/A

V.5.3.2. Enrichment Restrictions: N/A

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
Anxiety, depression behavior	(b)(6)	Assistant Professor 16 years of	Conducted animal research at

Stress model IV surgery Drug self-administration		experience in animal research	(b)(6)
Anxiety, depression behavior Stress model IV surgery Drug self-administration	(b)(6) BS	Research Assistant	Attended all training classes required by USU in order to be approved to conduct animal research on Oct 19, 2010. Completed IACUC investigator training (Feb 15, 2011)
Anxiety, depression behavior Stress model IV surgery Drug self-administration	(b)(6) PhD	Post-doc (9 years experience in animal research)	Trained at Oregon Health & Science University (OHSU), VA Medical Center, Portland, OR, and George Mason University. Attended IACUC training at each of the before mentioned institutions. Completed online training on Feb 19, 2009 and completed USU Animal Investigator Training on Mar 26, 2009.
Traumatic stress	(b)(6) M.D., Ph.D.	Associate Professor 12 years of experience in animal research	Developed the protocol
Warrior stress	(b)(6) PhD	Professor	Developed the

			protocol
Fear conditioning	(b)(6) PhD	Assistant Professor 19 years of experience in animal research	Trained at Oxford, Yale and New York Universities. Held a British Home Office license for animal experimentation. Conducted animal experiments at Yale University. Attended all training classes required by USU in order to be approved to conduct animal research on May 30, 2009.
Molecular biology and biochemical Assay	(b)(6) MD	Associate Professor	Over 20 years of experiences in molecular biology
Consultation of the experiments and data analysis	(b)(6) MD	Professor, Chairman	Over 30 years of experiences in PTSD and anxiety disorders research
Anxiety, depression behavior Stress model IV surgery Drug self-administration	(b)(6) PhD	Post-doctoral Researcher	Trained at University of Cincinnati and Cincinnati Children's Hospital Medical Center IACUC mandated facility training at each institution Completed USUHS IACUC investigator training 2/16/10

VII. BIOHAZARDS/SAFETY: In order to protect personnel from chemical hazards (chloral hydrate and paraformaldehyde) all personnel will wear PPE (lab coats, mask,

gloves and safety glasses) to limit exposure to both chemical hazards and also animal allergens. Transcardiac perfusions with paraformaldehyde and glutaraldehyde will be conducted in a certified chemical fume hood with drain for disposal of waste fluids. The laboratory space has been previously evaluated by EHOS and has been in continuous use by the laboratory of Dr (b)(6) (PSY). The laboratory is now a shared space between the (b)(6) labs (PSY).

VIII. ENCLOSURES: N/A

IX. ASSURANCES: As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

(b)(6) 1/20/2012

Principal Investigator Signature Date

G. Training: The following personnel will attend the next USUHS Investigator/Animal User Training Course:

H. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely, "Responsibility" for implementing animal use alternatives where feasible and conducting humane and lawful research.

(b)(6) 1/20/2012

Principal Investigator Signature Date

I. Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress caused by the stress paradigm **WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. However, the potential pain and distress caused by the IV catheter surgery **WILL** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

(b)(6) 1/20/2012

Principal Investigator Signature Date

X. PROTOCOL ABSTRACT:

A. **Animal Protocol Number**:

B. **Animal Protocol Title**: *Stress and drug seeking in rats: Role of the endocannabinoid system and caffeine*

C. **Principal Investigator**: (b)(6) PhD

D. **Performing Organization**: Uniformed Services University of the Health Sciences

E. **Funding**: Center for the Study of Traumatic Stress (CSTS)

F. **Objective and Approach**:

We hypothesize that the endocannabinoid system and caffeine play a significant role in trauma-induced anxiety/depression and relapse to nicotine seeking behavior. Using well-established rat models of stress and drug self-administration, we will investigate

Specific Aim 1: the effects of three stress models (traumatic stress, warrior stress and fear learning) on depression, anxiety and relapse to nicotine seeking in rats.

Specific Aim 2: the effects of CB1R agonist during stress exposure on subsequent depression, anxiety and relapse to nicotine seeking in rats.

Specific Aim 3: the effects of caffeine during stress exposure on subsequent depression, anxiety and relapse to nicotine seeking in rats.

G. **Indexing Terms (Descriptors)**: rat, nicotine self-administration, drug seeking, traumatic stress, psychological stress, fear memory, PTSD, anxiety, depression, endocannabinoid system, caffeine, relapse, reinstatement

MEMORANDUM FOR DR (b)(6) DEPARTMENT OF PSYCHIATRY

SUBJECT: IACUC Approval of Protocol - Triennial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) by Designated Member Review, on October 14, 2014:

Animal Protocol Title: "Identification of Gene Expression Patterns in Brain Tissues and Peripheral White Blood Cells of Rat Model of Post-Traumatic Stress"

USUHS Protocol Number: (b)(6)

Expiration Date: October 13, 2017

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

I. I. NON-TECHNICAL SYNOPSIS:

We have demonstrated that specific gene expression patterns are present in brain tissues when symptoms such as exaggerated startle response are observed in an animal model of post-traumatic stress disorder (PTSD). We further have shown that correlated gene expression patterns are present in peripheral white blood cells; these may result from systemic responses to exposure to traumatic stress and may be useful in the development of diagnostic biomarkers of post-traumatic stress. We now hypothesize that genes that are both stress responsive and related to mitochondria structure and function play a key role in both normal and abnormal adaptive responses of individuals to traumatic stress correlated with combat or other catastrophic events. We therefore propose to:

1. Expand and confirm our gene expression discovery using mutl-well PCR with our established rat PTSD model.
2. Determine the function of stress responsive genes in metabolic and signaling pathways using Ingenuity Pathway Analysis.

To do so rats will be subjected (at USUHS) to the stress protocol developed by Dr. (b)(6) then euthanized so that brain tissues associated with central stress responses and blood samples can be obtained for analysis in Dr. (b)(6) laboratory and pathway analysis can be done in Dr. (b)(6) laboratory.

II. BACKGROUND:

Post-Traumatic Stress Disorder (PTSD) is a complex mental disorder that can develop in response to traumatic events during combat or other catastrophic events. An estimated 70% of adults in the United States have experienced a traumatic event at least once in their lives and up to 20% of these develop PTSD. Those with PTSD display alterations in behavioral (hyperresponsiveness (14), heightened acoustic startle response), emotional (irritability, emotional numbing), biochemical (increased thyroid activity(15), increased levels of corticotrophin-releasing factor (CRF) (16), and low cortisol levels (17)), and physiological function (abnormal activity of the autonomic nervous system (3,4) and of the hypothalamic-pituitary-adrenal (HPA) axis (5,6)). Acute stress has been shown to induce down-regulation of glucocorticoid receptor (GR) RNA (18) and facilitate long-lasting changes in cholinergic gene expression (19). These most

recent findings provide initial evidence that gene expression signatures following trauma identify an evolving neuropsychiatric disorder and are informative of its key clinical features and outcomes. However, large-scale searching for molecular targets underlying PTSD has not been reported to date.

II.1. Background:

PTSD Animal Models have been developed in which different stress paradigms provoke a wide range of behavioral responses. Intensely stressful experiences, aversive challenges, and situational reminders of a traumatic stress in PTSD animal models have resulted in long-term effects on behavioral, autonomic, and hormonal responses that mimic many of the clinical symptoms seen in patients with PTSD. The methodologies used to produce PTSD animal models include electric shock (20), social confrontations, stress-restress or time-dependent sensitization (21), underwater trauma (22), exposure of a rat to a predator (23), and the inescapable tail-shock model of traumatic stress (24-26). To establish a rat model of PTSD using highly stringent criteria we have successfully developed and tested the inescapable tail-shock model of stress in rats and verified that short and long-lasting behavioral, biochemical and physiological alterations result (27). **Importantly, the stress-induced behavioral and neurobiological symptoms in the rat models are very similar to those seen in PTSD patients** (Table 1). In PTSD patients, the amygdala displays hyperexcitability, which is thought to be responsible for the exaggerated startle responses of these individuals to stressful events.

In our animal model, stress exposure consists of a two-hour per day session of immobilization and tail-shocks, for three consecutive days. The animals are restrained in a Plexiglass tube, and 40 electric shocks (2 mA, 3 s duration) are applied at varying intervals (140 to 180 s) over the course of two hours on three consecutive days. This stress protocol was adapted from the "learned helplessness" paradigm in which animals undergo an aversive experience under conditions in which they cannot perform any adaptive response (28;29). We stress the rats for three consecutive days because it has been previously demonstrated that repeated immobilization and tail-shock stress sessions for three days is more effective than a single stress session in producing physiological and behavioral abnormalities, such as elevations in basal plasma corticosterone levels, exaggerated acoustic startle responses and reduced body weight (30). Further exposure to stress does not appear to result in greater physiological and behavioral changes (31). Considering the life span difference between human and rat, three days of stress exposure in a rat may be approximately equivalent to three months of stress in humans.

Our earlier studies have shown that (1)the difference in body weight between stressed and control rats was statistically significant ($p < 0.05$) and stressed rats continued to display reduced body weight gain for as long as body weight was monitored; (2)measurement of acoustic startle response (ASR) on day 7 following completion of the stress protocol revealed that stressed rats exhibited heightened ASR; and (3)tail blood samples from stressed rats had higher plasma corticosterone levels than control animals. Our results with the inescapable tail shock paradigm as a model of PTSD are consistent with those in the literature (34), and while we acknowledge that although the animal model cannot fully represent PTSD patients, it is the best available means to determine the molecular and cellular mechanisms of PTSD pathogenesis. Multi-dimensional validations, such as a combination of both behavioral and biological

criteria, are necessary to provide a solid basis for study of the molecular mechanisms using an animal model, to confirm resultant discoveries in clinical samples by association studies, and then to develop diagnosis and treatment strategies.

Table 1. Symptomatic Similarities of PTSD between Human and Animal Models

PTSD in Humans	**Inescapable tail-shock model of stress in rats**
Weight loss (Sutker et al., 1990;Myers et al., 2005;Braga et al., 2004)	Suppressed feeding and body weight loss (Hu et al., 2000;Harris et al., 2002)
Difficulty falling or staying asleep, nightmares (Maher et al., 2006;Maher et al., 2006)	Altered sleep patterns (Adrien et al., 1991)
Psychomotor numbness (Epstein et al., 1998;Lopez-Ibor, 2002)	Persistent behavioral abnormalities i.e. suppressed open-field activity, longer hanging wire latencies (Minor et al., 1984; Pare, 1994)
Poor concentration; memory deficits (Bremner et al., 2004;Isaac et al., 2006;Green, 2003)	Deficits in escape/avoidance learning and learning of an appetitive task (Maier, 2001)
Hypervigilance and/or exaggerated startle response (Orr et al., 2002;Orr and Roth, 2000;Pitman et al., 1999)	Exaggerated startle (Garrick et al., 2001;Servatius et al., 1995;Manion et al., 2007a)
Hyperresponsiveness of the noradrenergic system (Orr and Roth, 2000;Maes et al., 1999)	Hyperresponsiveness of the noradrenergic system (Simson and Weiss, 1988)

Mitochondrial dysfunction is increasingly recognized as a key component in stress-related mental disorders (35;36). The mitochondrial response to stress may include alterations in molecular pathways and networks involving i) an increase in the number of mitochondria to enhance function; ii) adaptive changes in expression and activity of oxidative phosphorylation genes and ATP production; iii) changes in signal transduction that affect expression of both mitochondrial and nuclear DNA-encoded genes; iv) production of reactive oxygen species (ROS); and v) induction of apoptosis. Most primary stress response mediators, i.e. hormones, immune factors and heat-shock proteins, exert effects on mitochondrial biogenesis, metabolism, ROS generation and apoptosis.

Prolonged physical and psychological stress can each induce long-lasting consequences for an individual and can be the cause of affective disorders such as PTSD. In a recent study, psychological stress was associated with increased blood concentrations of oxidative stress markers and genetic modification, namely telomere shortening (37). Overexpression of two antioxidant enzymes, glyoxalase and glutathione reductase 1, in the mouse brain has also been associated with increases in anxious behavior (38). Thus, oxidative stress could contribute to the complex control of anxious behavior and related conditions, such as panic disorder, post-traumatic stress disorder and social phobias. In fact, exposure of rats to chronic stress (immobilization for six hours during 21 days) inhibits the activities of the first complexes of the mitochondrial respiratory chain (inhibition of 69% in complex I-III and of 67% in complex II-III) indicating that complex intracellular cascades altered in stress-related disorders appear to be intimately associated with the metabolic integrity and capacity of mitochondria to maintain energetic parameters and ultimately cellular stability (39). The steroidogenic acute regulatory protein (StAR), a mitochondrial protein required for stress responses, exerts its activity at the outer mitochondrial membrane (40). Whether other mitochondria function-associated molecules are also altered after exposure to intensive stress is not known. Currently, the altered cellular and molecule markers

associated with PTSD brain are not known. Thus, this proposal will attempt to determine whether traumatic stress alters the expression profiles of mitochondria susceptible genes associated with pathogenesis of PTSD.

Expression patterns of mitochondria-related genes in peripheral lymphocytes and in specific brain regions have been identified in human PTSD and control post-mortem brains. Peripheral blood mononuclear cell gene expression signatures are informative and predictive of the PTSD outcome among survivors of trauma, and correlate with the essential neuropsychiatric symptoms observed in PTSD (58;59). However, a causal relationship between gene expression profiling in peripheral lymphocytes and specific brain regions associated with neuronal circuitry responding to a stressor remains unknown. Thus, determination of the expression of mitochondrial related gene profiles in brain amygdala, hippocampus, hypothalamus, prefrontal cortex and anterior cingulate cortex and in peripheral white blood cells and establishment of a causal relationship with biological and psychiatric stressors in an animal model of PTSD will greatly enhance our capability to objectively, promptly and cost effectively evaluate the status of PTSD associated symptoms. The potential to use the peripheral cells to rapidly determine the effects of stressors on the functions of mitochondria will expedite diagnosis and treatment as well as diminish suffering resulting from exposure to trauma. There is also the possibility that the proposed experiments will reveal biomarkers of PTSD, thus allowing the development of more specific therapeutic interventions that may repair cellular damage rather than just treat symptoms. To date, using a mitochondrial focused gene chip we have discovered that during the development of the exaggerated fear associated with PTSD, 48 genes are significantly upregulated and 37 are significantly downregulated in the amygdala complex based on stringent criteria ($p<0.01$). Ingenuity pathway analysis revealed up- or downregulation in the amygdala complex of four signaling networks – one associated with inflammatory and apoptotic pathways, one with immune mediators and metabolism, one with transcriptional factors, and one with chromatin remodeling..The quantitative RT-PCR (qRT-PCR) array (Chen Y. *et al.* ,2009, *BMC Genomics* 2009, **10**:407 doi:10.1186/1471-2164-10-407) which we will now employ has become commercially available since our last studies. qRT-PCR provides higher sensitivity, allowing deeper drilling into the into the expression profile of genes in response to stress.

II.2. Literature Search for Duplication:

II.2.1. Literature Source(s) Searched: PowEResearch (the USU LRC system that seaches all databases in the LRC)

II.2.2. Date of Search: September 15, 2014

II.2.3. Period of Search: From beginning of each individual database to the present.

II.2.4. Key Words and Search Strategy:

1. Mitochondria AND PTSD AND Brain AND Gene Array AND Animal
2. Mitochondria AND PTSD AND Peripheral White Blood Cells AND Gene Array AND Animal.

II.2.5. **Results of Search**: Only two (2) articles (Ursano *et al.*, 2009; Pushpa *et al.* 2012), both from our group.

III. OBJECTIVE\HYPOTHESIS:

The **hypothesis** is that (1) specific gene expression patterns are present in brain tissues that are involved in the pathogenesis and neuropsychiatric phenotypes of PTSD; (2) specific gene expression patterns are present in peripheral white blood cells that are a consequence of systemic responses to traumatic stress and can be useful in the development of clinical non-invasive diagnostic biomarkers; and (3) that the mitochondria-centered and stress-responsive genes play a key role in normal and abnormal adaptive responses of individuals to traumatic stress encountered in combat or other catastrophic events.
The **objectives** of this proposal are as follows:
Specific Aim 1: To extend and deepen our currents findings by replacing the previously employed rat cDNA microarray (rMitChip3) design with the more senstivie qRT-PCR array.
Specific Aim 2: To experimentally determine the mitochondrial gene expression patterns and differentially expressed genes and biomarkers in amygdala, hippocampus, hypothalamus, prefrontal cortex, anterior cingulate cortex and peripheral white blood cells using our established rat-PTSD model and rMitChip3.
Specific Aim 3: To bioinformatically determine biochemical and molecular pathways, networks and drug targets from data collected from brain tissues and blood samples and to correlate these changes (in mitochondria associated gene expression profiles) with neuropsychiatric and/or behavioral abnormalities observed in an animal model of PTSD.

IV. MILITARY RELEVANCE: The information obtained from this research is expected to aid in the development of more efficacious therapeutic interventions aimed at preventing or treating stress-induced affective disorders such as PTSD. Active duty military, reservists and veterans exposed to combat related traumatic stress, as well as civilians exposed to traumatic circumstances such as natural disasters, terrorist attacks and auto or plane crashes, may all benefit from the knowledge thus obtained.

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures:

V.1.1. Experiment 1: (b)(6) Laboratory) Male Sprague-Dawley rats, weighing approximately 250 gm, will be subjected to restraint in plexiglas tubes and tailshock (40 shocks (2mA, 3 sec duration) administered over the course of two hours on three consecutive days). All animals will be weighed the day before beginning the stress protocol to obtain baseline readings and on Days 0 and 30 following exposure to the stress protocol. Control and stressed animals will be sacrificed immediately following completion of the stress protocol (Day 0 following stress) or one month after completion of the stress protocol (Day 30 following stress) and brain tissues and lymphocytes will be harvested and frozen for further analysis to determine whether expression changes

of mitochondria-related genes are present and long lasting. Animals will be anesthetized by isoflurane inhalation (using 30% v/v isoflurane in propylene glycol with a nose cone), decapitated and the brains quickly removed and placed in ice-cold artificial cerebrospinal fluid. Brain tissues will be dissected out and stored at -70°C. Trunk blood will be collected and lymphocytes will be isolated from EDTA-anticoagulant treated blood (7.5 mL) by centrifugation using a sterile lymphocyte separation medium. The lymphocyte layer will be washed with phosphate-buffered saline (BioWhittaker) and stored at -70° for further processing

V.1.2. Experiment 2: (b)(6) Laboratory) mRNA will be extracted and purified from frozen pooled brain tissues and pooled lymphocyte samples and used in qRT-PCR. Databases will be compiled for each brain tissue and for lymphocytes at each time point and data will be normalized.

V.1.3. Experiment 3: (b)(6) Laboratory) Bioinformatic tools will be used to analyze the data to determine biochemical and molecular pathways, networks and possible drug targets in brain tissues and blood samples; that may be altered by stress and to correlate these changes with neuropsychiatric and/or behavioral abnormalities.

V.2. Data Analysis:

Determination of Number of Animals Needed: Based on our recently completed work using a mitochondrial focused gene ChIP, we anticipate that thirty rats will be needed in each group to generate enough region specific brain tissues and lymphocytes for RNA extraction as well as to establish a definitive clustering correlation between brain specific regions and peripheral lymphocytes for future clinical implications. The total RNA required for one qRT-PCR array is estimated to be 2 µg and an estimated minimum of 6 qRT-PCR arrays will be needed for each qRT-PCR experiment to allow for adequate statistical analysis. For example, the rat amygdala is the smallest of the region specific brain tissues that we will examine in this project. It is approximately 1 mm in diameter and weighs approximately 1 mg; approximately 2 mg of amygdala tissue can be obtained from one animal. Approximately 10 mg of amygdala tissue (or five animals) will be needed to extract 2 µg of RNA; thus, pooled rat amygdala tissue from 5 rats will be required for one qRT-PCR array. Therefore, a group of 30 rats will be needed for each experiment (5 rats per chip x 6 chips=30 rats). We have proposed a series of four experiments, each using a group of thirty rats (control, euthanize immediately after stress, control + 30 days and euthanize 30 days after stress), therefore, a total of one hundred twenty rats (4 experiments x 30 rats per experiment = 120 rats) will be needed.

A duplicate series of experiments has been proposed after data from the initial series have been analyzed; this duplication of the experiments is essential to allow adequate statistical analysis of the microarray data. Note that there are two distinct control groups in each series of four experiments; neither can be eliminated from the series. The enhancement resulting from duplication of the experiments will increase the statistical power of the project; in fact, the editors of scientific journals and reviewers of manuscripts generally require duplication of experiments to enhance biological consistency in order to convince scientists in the field of the validity of the data and thus

to enhance the impact of the research in the literature. Thus a total of 240 rats is required.

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered: This study requires the use of intact living animals; behavioral measurements, such as administration of the stress protocol, cannot be made on cells grown in culture or on computer models or other *in vitro* systems. Thus, non-animal models were not considered for this project and it is not possible to replace or eliminate the use of animals in this study.

V.3.2. Animal Model and Species Justification: The rat (in this study, *Rattus norvegicus)* is the primary model used in studying the physiology of the amygdala, the brain area primarily involved in the processing of stressful stimuli; consequently, it is helpful to use the same animal in order to make comparisons with the literature (Kohda, et al, 2007). Use of the rat also replaces other animals higher up the phylogenetic scale. (b)(6) has developed and refined this particular animal model of traumatic stress over a period of ten years. It was adapted from a "learned helplessness" paradigm in which animals undergo an aversive experience under conditions in which they cannot perform any adaptive response (Servatius et al., 1995a; Braga et al., 2004; Manion et al., 2007b).

V.3.3. Laboratory Animals

	Species #1	Species #2
V.3.3.1. Genus & Species:	R. Norvegicus	
V.3.3.2. Strain/Stock:	Sprague-Dawley	
V.3.3.3. Source/Vendor:	(b)(4)	
V.3.3.4. Age:	~ 8 weeks	
V.3.3.5. Weight:	~250 grams	
V.3.3.6. Sex:	Male	
V.3.3.7. Special Considerations:	N/A	

V.3.4. Number of Animals Required (by Species): Rats 240

V.3.5. Refinement, Reduction, Replacement (3 Rs):

V.3.5.1. Refinement: Animals will be housed in a climate controlled environment in groups of two per cage with free access to food and water, and will be maintained on a 12 hour reverse light/dark cycle at 22 °C. The use of paired housing for male rats has

not presented problems in the past with our use of this animal model of PTSD; however, it is conceivable that male rats could become aggressive toward one another, especially in the groups that are pair housed for 30 days before euthanization. We and CLAM staff members will observe the animals on a daily basis and will change to one rat per cage if observations indicate any behavior that would have a negative effect on the proposed experiments.

V.3.5.2. Reduction: We anticipate that thirty rats will be needed per group to generate enough region specific brain tissues and lymphocytes for RNA extraction as well as to establish a definitive clustering correlation between brain specific regions and peripheral lymphocytes for future clinical implications. The amygdala is very small and it is necessary to combine amygdala tissue from 30 rats for qRT-PCR array experiments and related immunohistochemistry. It will not be possible to reduce the number of control animals when the experiments are repeated as the bioinformatics tools used for data analysis require the use of matched control/stress groups of animals.

V.3.5.3. Replacement: This study requires the use of intact living animals; behavioral measurements cannot be made on cells grown in culture or with computer models. Thus, it is not possible to replace or eliminate the use of animals in this study.

V.4. Technical Methods:

V.4.1. Pain / Distress Assessment:

V.4.1.1. APHIS Form 7023 Information:

V.4.1.1.1. Number of Animals:

	Species #1	Species #2
V.4.1.1.1.1. Column C:	120	
V.4.1.1.1.2. Column D:	0	
V.4.1.1.1.3. Column E:	120	

V.4.1.2. Pain Relief / Prevention: N/A

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization:

Isoflurane anesthesia will be performed prior to euthanization of rats by decapitation with a guillotine for tissue harvesting. For rats, a mixture of 30% v/v isoflurane in propylene glycol (1,2-Propanediol USP grade Sigma Cat no. P4347) will be prepared. Anesthesia is performed in a certified ducted hood, biosafety cabinet or portable ductless hood equipped with a charcoal filter. While wearing gloves, the operator opens the bottle containing isoflurane in the hood and wets a cotton pad wet with isoflurane.

The pad is placed in a 100 mL beaker so as to not contact the rat, the beaker and then the rat are placed in a jar with a secure lid, made of non-porous material that is

sanitizable and allows for constant visualization of the animal and is of such size as to comfortably accommodate the animal, but not so large as to require excessive anesthetic. The animal is monitored closely. It becomes anesthetized in approximately 2 minutes. When a lack of righting reflex and a 50% reduction in respiratory rate are observed for at least 10 seconds, the rat is removed from the jar, and the jar lid immediately replaced. If there is no response to a noxious stimulus (ie. toe pinch), the operator proceeds (in this protocol) to decapitate the rat with a guillotine and harvest brain tissues and trunk blood.

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions: Animals will be housed in a climate controlled environment in groups of two per cage with free access to food and water, and will be maintained on a 12 hour reverse light/dark cycle at 22 °C. Animals will be acclimated for three days to the USUHS CLAM. During acclimation to CLAM, animals will be handled briefly each day to acclimate them to being handled; this will reduce any stress that might result from handling of the animals during the procedures described in this study. Following exposure to the stress protocol, animals will be monitored according to CLAM SOPs.

V.4.1.2.3. Paralytics: N/A

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures:

V.4.1.3.1. Sources Searched: PowEResearch (the USU LRC system that seaches all databases in the LRC)

V.4.1.3.2. Date of Search: September 15, 2014

V.4.1.3.3. Period of Search: From the beginning of each database to the present.

V.4.1.3.4. Key Words of Search:

- Stress and pain and mitochondria and rat: 0
- Pain and PTSD and mitochondria and rat: 0
- Pain and PTSD and rat: 0

V.4.1.3.5. Results of Search: No relevance

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification:
We have developed a stressed rat model in which a young adult male animal is restrained in a plexiglas tube of appropriate size and receives a series of forty tailshocks (2mA constant current, 3 sec duration) over a period of two hours daily on three consecutive days. A coiled silver electrode is attached to the tail with a spring clip so that there is no irritation of the tail either from the shocks or from adhesive materials being applied and removed each day. The number and strength of the shocks proposed has been optimized to yield a model of chronic stress as measured by changes in behavior and by elevated plasma levels of corticosterone. This stress protocol was adapted from the "learned helplessness" paradigm in which animals undergo an aversive experience under conditions in which they cannot perform any

adaptive response (Seligman and Maier 1967; Seligman and Beagley 1975). We stress the rats for three consecutive days because it has been previously demonstrated that repeated stress sessions for three days are more effective than a single stress session in producing physiological and behavioral abnormalities, such as elevations in basal plasma corticosterone levels, exaggerated acoustic startle responses and reduced body weight (Servatius et al. 1995; Ottenweller et al. 1989). Additional exposures to stress do not appear to result in greater physiological and behavioral changes (Servatius et al. 1995; Ottenweller et al. 1989). Other types of stressors appropriate for an animal model (e.g. restraints only) are not easily quantifiable and have resulted in at least partial habituation rather than chronic stress. Given these considerations, we feel that the painful procedure is justified.

In an earlier study, the startle response and adrenocortical release of rats was assessed following exposure of the animals to stressor presentations similar to that proposed in this study for one, two or three days (Servatius et al., 1994). Rats that were exposed to three days of stress exhibited an exaggerated startle response to an auditory stimulus 4 days poststressor as compared to nonshocked controls (Servatius et al., 1994; Manion et al., 2007). This exaggerated startle response was not evident in rats exposed to either 1 or 2 days of stress (Servatius et al., 1994). Exposure to our 3 day stress regimen produces a chronic stress state in rats, characterized by persistent exaggerated startle response and adrenocortical sensitization, which is appropriate as a model for the study of stress-related psychophysiological illnesses such as PTSD (Servatius et al., 1994).

V.4.2. Prolonged Restraint:

Prolonged restraint will be conducted IAW IACUC Policy 004 "Prolonged Restraint". All animals are monitored by a technician during the two hours when tail shocks are being administered to assure that they do not get into positions that do not allow them to breathe properly. Also, the electrode can become loose over the two hour period so that the animal no longer receives the shock; monitoring by a technician is required to ensure that the animals receive all of the forty tail shocks.

V.4.3. Surgery: N/A

V.4.3.1. Pre-surgical Provisions: N/A

V.4.3.2. Procedure: N/A

V.4.3.6.1. Procedures: N/A

V.4.3.6.2. Scientific Justification: N/A

V.4.4. Animal Manipulations:

V.4.4.1. Injections: N/A

V.4.4.2. Biosamples:
Trunk Blood Samples: **Trunk blood will be collected when each animal is euthanized. Blood lymphocytes will be isolated from EDTA-anticoagulant treated blood (7.5 mL) by centrifugation using a sterile lymphocyte separation medium. The lymphocyte layer will be washed with phosphate-buffered saline (BioWhittaker) and frozen for further analysis..**
Brain Tissue Samples: **Brain tissues will be harvested immediately after the final stress session or 30 days after the final stress session. Animals will be anesthetized by isoflurane inhalation (using 30% v/v isoflurane in propylene glycol, see detailed procedure described in Section V.4.1.2.1), then decapitated and the brains removed as quickly as possible. Brains will be dissected and kept in ice-cold ACSF; hippocampus, hypothalamus, prefrontal cortex, anterior cingulate cortex (Bergman 5.70 mm to -0.80 mm) and the amygdala (500-µm-thick transverse slices) will be cut from tissue blocks with a Vibratome Tissue Slicer (Technical Products International, St. Louis, Missouri). All tissue samples will be stored at –70°C prior to RNA extraction and purification.**

V.4.4.3. Adjuvants: N/A

V.4.4.4. Monoclonal Antibody (MAbs) Production: N/A

V.4.4.5. Animal Identification: Cage cards

V.4.4.6. Behavioral Studies: There is one behavioral component included in this study: exposure to traumatic stress.
Stress exposure consists of a two-hour per day session of immobilization (restraint) and tail-shocks, for three consecutives days. Each animal is restrained in a plexiglas tube and an electrode is attached to the tail. Forty electric shocks (2 mA, 3 s duration) are applied at varying intervals (140 to 180 s) over a two hour period; then the rats are returned to their cages. Exposure to this three day stress regimen has been shown to be more effective than a single stress session in producing lasting physiological and behavioral abnormalities, such as elevations in basal plasma corticosterone levels, exaggerated acoustic startle responses and reduced body weight (Servatius et al., 1995).

The plexiglas restraint tubes used in administration of the stress protocol are designed to accommodate animals of a specified size range. If an animal is near the lower end of the size range, there will be slightly more room for it to move in response to the shock and possibly twist itself into a position that will not allow it to breathe properly. The technician who monitors the stress protocol can release the adjustable end of the restraint tube slightly to allow the animal to return to a position that does not impair breathing, then retighten it. Animals of the size specified in this protocol (~250 gm) do

not usually exhibit severe reactions to the stress protocol. If the animals have been handled when they first arrive in USUHS animal facility, they generally do not resist being put into the restraint tubes. If animals were to exhibit symptoms of extreme respiratory distress or damage to the tail resulting from the electric shocks during the stress procedure or if any animals would lose more than 20% of their initial body weight as a result of exposure to the stress protocol, they would be withdrawn from the study and euthanized

Electrodes will be attached to the tail of the animal by means of a spring clip in order to minimize any painful irritation that might result from repeated taping of the tail. All animals are monitored by a technician during the two hours when tail shocks are being administered to assure that they do not get into positions that do not allow them to breathe properly. Animals will be monitored daily after the first two stress sessions according to CLAM SOPs and those animals that will be euthanized thirty days after the final stress session will continue to be monitored daily for any indication of pain. While the animals are expected to lose weight during the three day stress exposure, any animal that would lose >20% of its body weight as measured on Day -1 would be withdrawn from the study and euthanized by CLAM staff as described in Section V.4.6. The shock administered to the tails of the animals is 2 ma in intensity for a duration of 3 seconds. The animals typically jump and cry out during the duration of the shock and struggle to get away from it. As soon as the shock concludes, the animals lie quietly until the next shock. Four to six animals are shocked at one time (in individual tubes with a single electrode attached to each animal's tail). The size of the animals can vary by as much as 20 gm, while the restraint tubes are rigid and fixed. An animal that is slightly smaller than the ideal weight for which the tubes are designed can sometimes move into a position where its ability to breathe is compromised; if the animal is not being monitored by a technician who can release the end of the tube and allow it to right itself, then retighten the end of the tube, the animal can expire. Rats of the size listed for this protocol usually do not exhibit this difficulty, but will be monitored during the administration of the stress protocol. The electrodes are attached to the tail with a spring clip to prevent irritation of the tail by removal of adhesive stripes each day for three days and to minimize the possibility of infection through a break in the skin on the tail. We have not observed damage to the tail (i.e. burning of the tail) resulting from contact with the electrode during the shocks. Criteria for early termination of the shock experiments would include (1)signs of infection due to a break in the tail skin; (2)severe irritation or burning of the tail resulting from contact with the electrode during administration of the shocks; (3)loss of >20% of body weight as measured on Day -1 before administration of the stress protocol (Note that rats have been consistently observed to lose weight following exposure to stress, but never >20% of their body weight prior to administration of the stress protocol); and (4)observation of pain or infection in the animals that are housed for 30 days after the final stress session. Any animals that must be removed from the study will be given to CLAM personnel for euthanization as described in Section V.4.6.

After each use, the restraint tubes are washed in Alconox detergent solution and allowed to air dry and the electrodes are wiped with 95% ethanol.

V.4.4.7. Other Procedures: Animals will be weighed on Day-1 preceding stress exposure to obtain baseline values and again on Day 0 or Day 30 following exposure to the stress protocol.

V.4.4.8. Tissue Sharing: Frozen brain tissue and frozen lymphocyte samples will be transferred to the laboratory o[(b)(6)] for qRT-PCR array analysis and pathway analysis..

V.4.5. Study Endpoint: The study endpoint will be the third day of the stress protocol (Day 0) or thirty days (Day 30) after the final stress session for all animals that complete the stress protocol. Criteria for withdrawal of animals from the study would include (1)signs of infection due to a break in the tail skin; (2)severe irritation or burning of the tail resulting from contact with the electrode during administration of the shocks; (3)loss of >20% of body weight as measured on Day -1 before administration of the stress protocol; and (4)observation of pain – such as limping, immobility, protection of a body region, biting or squeeling when attempt is made to lift the animal - or infection in the animals that are housed for 30 days after the final stress session. Animals showing any of the above signs will immediately be withdrawn from the study and given over to CLAM personnel for euthanization.

V.4.6. Euthanasia: :

Euthanasia will be performed by CLAM staff per LAM SOPs for rats that are withdrawn from the study or otherwise not used.

All rats that are part of the study will be anesthetized as described in section V.4.1.2.1. When a lack of righting reflex and a 50% reduction in respiratory rate are observed for at least 10 seconds, the rat should be removed from the jar, and the jar lid immediately replaced. If there is no response to a noxious stimulus (ie. toe pinch), the operator may proceed (in this protocol) to decapitate the rat with a guillotine and harvest brain tissues and trunk blood.

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol.

V.5.1.1. Study Room:

Building(s) Bldg Room Number(s) [(b)(6)]

V.5.1.2. Special Husbandry Provisions:

Food Restriction:	Yes		No	X
Fluid Restriction:	Yes		No	X

V.5.1.3. Exceptions: Reverse Light Cycle So that rats, being nocturnal, will be active during the experimental periods.

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care: Animals will be cared for in accordance with LAM SOPs. Animals will be observed daily or more frequently by the veterinary staff. Should any animal lose >20% of its baseline body weight during the course of an experiment, it will be withdrawn from the study and euthanized by CLAM staff (see Section V.4.6). CLAM veterinary staff will be available for consultation with the PI should any unexpected medical events arise

V.5.2.2. Emergency Veterinary Medical Care: All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: All animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents; balls, toys and food enrichment treats for large animal species.

V.5.3.2. Enrichment Restrictions: N/A

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
Stress Protocol	(b)(6)	PI, 10 years experience	Developer
Isoflurane anesthesia Brain dissection & harvesting, trunk blood collection		PI, 15 years exp 20 years experience	NIH, USU Pitt, NIH, USU
Decapitation		20yr experience 20yr experience	NIH, USU PITT,NIH, USU

Dr (b)(6) will not be involved in any hands-on animal manipulations. Dr. (b)(6) will not be doing any animal work here at USUHS; he will be doing genetic analysis of tissues sent to his laboratory at Georgetown University. Dr. (b)(6) has extensive experience with brain tissue harvesting and dissection and trunk blood collection and with the administration of isoflurane anesthesia, both at the NIH and at

USUHS; he is expected to serve in an advisory capacity with regard to these procedures. Any new research associates or graduate students who rotate through the laboratory will be added to the protocol by request for and approval of a minor modification to this protocol before being permitted to do any animal procedures. Dates for attendance at the most recent USUHS Investigator/Animal User Training Course are as follows:

(b)(6) M.D., Ph.D. May 17, 2007
(b)(6) Ph.D. June 2010

VII. **BIOHAZARDS/SAFETY:** Personnel will use personal protective equipment (eye protection, lab coats, gloves, masks) when handling animals to reduce exposure to allergens. All needles will be disposed of in sharps containers. Although the shock administered is 2mA, all personnel will be trained to pause the program and disconnect the electrodes before making adjustments to electrode placement or to the movable end of the restraint tube.

VIII. **ENCLOSURES:** N/A

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

(b)(6) [redacted]

G. Training: The following personnel will attend the next USUHS Investigator/Animal User Training Course:

_____ _____

_____ _____

H. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely, "Responsibility" for implementing animal use alternatives where feasible and conducting humane and lawful research.

(b)(6) [redacted]

Principal Investigator Signature

I. Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to acco[redacted] this proposed experiment.

X. PROTOCOL ABSTRACT:

A. Animal Protocol Number: Pending

B. Animal Protocol Title: Identification of Gene Expression Patterns in Brain Tissues and Peripheral White Bood Cells of Rat Model of Post-traumatic Stress

C. Principal Investigator: (b)(6) M.D., Ph.D..

D. Performing Organization: Uniformed Services University of the Health Sciences and GenProMarker

E. Funding: DoD Awarded to Dr. (b)(6) M.D.

F. Objective and Approach:

The objectives of this proposal are as follows:

Specific Aim 1: To extend and deepen our currents findings by replacing the previously employed rat cDNA microarray (rMitChip3) design with the more senstivie qRT-PCR array.

Specific Aim 2: To experimentally determine the mitochondrial gene expression patterns and differentially expressed genes and biomarkers in amygdala, hippocampus, hypothalamus, prefrontal cortex, anterior cingulate cortex and peripheral white blood cells using our established rat-PTSD model and rMitChip3.

Specific Aim 3: To bioinformatically determine biochemical and molecular pathways, networks and drug targets from data collected from brain tissues and blood samples and to correlate these changes (in mitochondria associated gene expression profiles) with neuropsychiatric and/or behavioral abnormalities observed in an animal model of PTSD.

G. Indexing Terms (Descriptors): Rat, PTSD, Biomarkers, Gene array, Peripheral white blood cells, Brain tissue and Animal.

MEMORANDUM FOR DR. (b)(6) DEPARTMENT OF PSYCHIATRY

SUBJECT: IACUC Approval of Protocol – Triennial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on May 06, 2015:

Animal Protocol Title: "Role of Nicotine and Opioid on Stress and Anxiety in Rats"

USUHS Protocol Number: (b)(6)

Expiration Date: May 5, 2018

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

USUHS Form 3206- Animal Study Proposal Form Instructions

USUHS / DOD – SPONSORED ANIMAL RESEARCH PROPOSALS MUST USE THIS STANDARDIZED FORMAT

Reference DOD Directive 3216.1 & USUHS Instruction 3203

****

Specific information requested in the following animal-use protocol template is a result of requirements of the Animal Welfare Act regulations (AWAR), the Guide for the Care and Use of Laboratory Animals, and other applicable Federal regulations and DOD directives.

****

This document is intended to be an aid in the preparation of a USUHS DOD – sponsored animal use proposal. The instructions and written explanations provided for individual paragraphs (ref. animal-use protocol template in AR 40-33 / USUHSINST 3203, Appendix C) are coded as hidden text. To see the instructions and examples for each section, select the "**Show/Hide ¶**" button on your tool bar. To print the hidden text, select "Print" on the drop down file menu. Under the "Options" button, select "Hidden text" under the "Include with document" section. Use of a word processor makes completion of this template a "fill-in-the-blanks" exercise. Please provide all response entries in the following font: Arial, Regular, 12, Black. Please do NOT submit this page of instructions with your animal protocol submission.

With the exception of title headings, each paragraph and subparagraph in the following template must have a response. Portions of the template that are not applicable to your particular protocol, (i.e. no surgery or no prolonged restraint) should be marked "**N/A**". There are no space limitations for the responses.

Pertinent standing operating procedures or similar documents that are readily available to your IACUC may be referenced to assist in the description of specific procedures. It is critical that only animal studies or procedures documented in an IACUC – approved protocol be performed at your facility. Additionally, Principal Investigators, or other delegated research personnel, should keep accurate experimental records and be able to provide an audit trail of animal expenditures and use that correlates to their approved protocol.

I. NON-TECHNICAL SYNOPSIS:

Posttraumatic stress disorder (PTSD) is a debilitating stress-related disorder affecting military service members and civilians in the U.S. Among the individuals with PTSD, the rate of substance use is quite high. Approximately 29% of the population is current smokers and 47% have smoked at some time in their life (Lasser et al. 2000). Of those with a history of PTSD, 63.3% had smoked daily at some point in their lifetime and 45.3% were current smokers – rates considerably higher than those with no history of PTSD. Also, PTSD patients are more likely to be heavy smokers and relapse to smoking tobacco (Fu et al. 2007). These suggest that nicotine dependence is a serious problem in individuals with PTSD. In addition to nicotine, opioid drug abuse is a growing public health problem in the U.S., especially because of an increasing number of individuals seeking prescription opioids for pain management (Garland et al. 2013). Opioid drugs now rank second only to marijuana among all illicit drugs of abuse (Department of Defense 2008). Adverse consequences of opioid misuse can include metabolic dysfunction, physical dependence, drug overdose, and suicide. A recent report indicated that a large number of active duty service members misused opioid pain medications in the past 12 months (Department of Defense 2010). Although misuse of addictive substances can affect stress and anxiety responses (Koob and Le Moal 2001), biological mechanisms of stress and substance use are not well understood. Using clinically relevant animal models of stress and substance abuse, we will investigate the interaction between stress and substance use in rats. This topic is particularly important for military service members and their long-term behavioral health. We believe that our work will provide valuable information relevant to the health of service members, in particular, and the general population as well.

II. BACKGROUND:

II.1. Background:

Posttraumatic stress disorder (PTSD)
PTSD is a debilitating anxiety disorder that can develop in response to traumatic stress exposure such as combat or other physical/psychological stress. The estimated lifetime

prevalence of trauma exposure is 61% for men and 51% for women with men more likely to report physical attacks, combat experience, being threatened with a weapon, while women likely to report sexual assault, childhood neglect and childhood physical abuse (Kessler et al. 1995). It is well established that the exposure to traumatic stressors predisposes persons to an increased probability of use of psychoactive and addictive drugs (Brown and Wolfe 1994). The use of psychoactive drugs such as nicotine, caffeine and opioids continues to be one of the more damaging squeal to deployment-associated PTSD in military personnel. However, biological mechanisms underlying substance use disorders displayed in individuals with PTSD are not well understood, and therapeutic interventions to reduce subsequent drug abuse in traumatized personnel are empirical and of uncertain efficacy.

Stress and nicotine use

Nicotine use is associated with exposure to traumatic events and PTSD (Feldner et al. 2007a). Individuals with PTSD show higher rates of smoking and worse smoking cessation outcome. For instance, almost 94% of individuals with PTSD relapsed in the first week after quitting in a community sample of daily smokers (Zvolensky et al. 2008). Other studies have shown that smokers exposed to a traumatic event who develop PTSD tend to smoke more than those exposed to trauma that do not develop PTSD, a relationship consistent across age and trauma type (Hapke et al. 2005; Lipschitz et al. 2003; Shalev et al. 1990). Smoking among trauma-exposed adults has been found to range between 32% (Weinbaum et al. 2001) and 58% (Weaver and Etzel 2003). Compared to the non-smokers, smokers were more likely to develop posttraumatic stress symptoms (Ganz 2000), which is in line with the findings that traumatic event exposure facilitates smoking behavior (Feldner et al. 2007b). Although 20% of American civilians smoke cigarettes, over 30% of military personnel currently smoke cigarettes and even more use smokeless nicotine-containing tobacco products (Bray and Hourani 2007). Many young never-smokers and occasional smokers become regular smokers after military basic training (Haddock et al. 1998), suggesting that the military environment (e.g., high stress) may be a factor in smoking initiation. Thus, nicotine consumption may be one of the ways to help attenuate the stress of military lifestyle.

Stress and opioid use

Prescription opioid pain medication is increasingly used in the military population (Holbrook et al. 2010). Iraq and Afghanistan veterans show increasing use of prescription opioid pain medications especially those who experienced traumatic injury and stress (Barry et al. 2011; Seal et al. 2012). Using a large scale samples from the OEF/OIF veteran population (n=141,029), Seal et al (2012) reported that veterans with mental health diagnoses, especially PTSD, showed an increased risk of receiving opioids for pain, high-risk opioid use and adverse clinical outcomes. Among the opioids, morphine is a potent analgesic drug that is used to relieve severe pain. Morphine is a highly addictive substance and it can cause and physical and psychological dependence as well as tolerance, with an addiction potential identical to that of heroin. Not surprisingly, many animal studies have shown that morphine is readily self-administered in rodents including rats (Self and Stein 1993; Yoon et al. 2010) and mice (Elmer et al. 2010). Various aspects of drug seeking and taking behavior were studied using morphine self-administration paradigm (Elmer et al. 2002; Hall et al. 2011; Kuzmin et al. 1996). However, potential effects of stress on morphine seeking behavior have not

been well characterized.

Sex differences in stress and substance use
A growing body of literature described sex differences in stress and substance abuse (Bobzean et al. 2014). Females tend to progress through the phase of addiction differently than men such as faster transition from casual use to addiction, and higher rates of relapse than men. In animal studies, morphine is known to be more powerful analgesic in males than in females (Baamonde et al. 1989; Cicero et al. 1996; Craft et al. 1999). Moreover, stress responses in males have been studied in animals and humans, and can be described as the "fight-or-flight response" (Cannon 1935; Faraday et al. 2005; Mason 1975; Selye 1946; 1973). Males generally become more aggressive (fight) or escape the threatening situation (flight) in response to stress. Although stress responses in females involve similar biological systems (i.e., the sympathetic branch of the autonomic nervous system and the hypothalamic-pituitary-adrenal axis), they also exhibit different behavioral responses that have been called the "tend-and-befriend" responses (Taylor et al. 2000). When a female experiences stress, the fight-or-flight response still occurs but she also increases care for her young and/or seeks social interaction. There has been relatively little experimental examination of sex differences in stress responses and opioid use. It has been shown that female rats display more anxiety- and depression-related behavior after exposure to psychological stress than do male rats (Yarnell 2012). The proposed experiments include male and female rats as subjects to investigate sex differences in effects of stress and nicotine on opioid use.

II.2. Literature Search for Duplication:

II.2.1. Literature Source(s) Searched:
Medline (PubMed), PsycInfo, F1000Biology (and electronic journal review service), BRD, and RePORT

II.2.2. Date of Search: March, 2015

II.2.3. Period of Search:
All years available on each database (ranging from past year to past 30 years)

II.2.4. Key Words and Search Strategy:
Nicotine, chronic nicotine administration, stress, rats, sex differences, locomotor activity, neurobehavioral functioning, hot plate, nociception, acoustic startle reflex, pre-pulse inhibition, fear conditioning, memory, anxiety, traumatic stress, PTSD, morphine self-administration, morphine, cognition (words are entered separately and in combination; rat is entered with each term) have been searched in data base searches.

II.2.5. Results of Search:

Nicotine AND morphine AND rat: 242
Stress AND nicotine AND morphine AND rat: 12
Stress AND nicotine AND morphine self-administration AND rat: 3

There was no study relevant to our proposal among those 3 studies. There has been extensive work on stress, nicotine, and opioid including our own work. However, there has been little work combining these variables in the ways that we propose (e.g., effects stress and nicotine on opioid use). Overall, literature searches on the topics to be covered in our experiments indicate the value of our approaches and have not revealed existing literature or data that would replicate our experiments.

III. OBJECTIVE\HYPOTHESIS:

The current proposal focuses on behavioral and cognitive effects of opioid, nicotine and stress in male and female rats related to fear, anxiety and drug addiction. The overarching aim of this project is to enhance the health of service members under stressful conditions by investigating whether nicotine and opioid drugs alter behavioral responses to stress. We will study the effects of voluntary use of opioid on fear and anxiety behaviors as well as regional glucose utilization in the brain. We will also investigate interaction between unpredictable stress and drug exposure (nicotine and opioid) in male and female rats. We will use the warrior stress paradigm, which combines predator odor stress with unpredictable environmental stimuli. Unpredictable stress has face validity in relation to human stress and has been shown to reliably produce elevations in stress hormones including corticosterone and corticotropin-releasing hormone (Weinstock et al. 1992) and behavior (Gonzalez Jatuff et al. 1999) in rodent studies.

Specific Aim 1: To determine effects of early and late withdrawal from morphine self-administration (MSA) on anxiety and fear behavior in male and female rats. We will use elevated plus maze and acoustic startle as anxiety measures, and Pavlovian fear conditioning and extinction as fear behavior following chronic morphine self-administration. We hypothesize that early and late withdrawal from MSA may have differential effects on fear and anxiety behaviors.

Specific Aim 2: To determine effects of morphine self-administration on anti-nociception and tolerance, and regional glucose utilization in brain. We will use a hot plate test to measure antinociception and ^{18}FDG-PET for regional glucose uptake in brain. We will also investigate individual differences in antinociception, morphine self-administration and locomotor sensitization in males and females. We hypothesize that individual differences in morphine antinociception and morphine self-administration may be associated with brain glucose utilization.

Specific Aim 3: To determine effects of chronic nicotine and/or psychological stress (Warrior Stress) on morphine self-administration and behavioral sensitization. Animals will be exposed to chronic nicotine via minipump and Warrior Stress, and then allowed to acquire morphine self-administration for two weeks. Following acquisition of morphine self-administration, animals will be tested with dose response function. Locomotor sensitization during morphine withdrawal will also be measured. We hypothesize that stress exposure may facilitate opioid abuse and nicotine exposure may attenuate opioid abuse.

IV. MILITARY RELEVANCE:

There is a high comorbidity of PTSD and substance use disorders in the military population (Beckham et al. 2008; Boden et al. 2011; Booth et al. 2011). A substantial number of military veterans and active duty service members relies on licit and illicit substances such as caffeine, nicotine, alcohol, opioids and marijuana to alleviate stress and anxiety symptoms as an active coping strategy (Barry et al. 2011; Boden et al. 2011; Seal et al. 2012). Iraq and Afghanistan veterans with chronic pain and PTSD may be at particular high risk of prescription opioids misuse given the high prevalence of substance abuse and PTSD among veterans (Mills et al. 2005; Seal et al. 2011). The outcome of this study will contribute to the development of more effective therapeutic interventions aimed at preventing or treating a comorbid PTSD and substance use disorders in the military population.

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures: To determine the effects of stress and nicotine on opioid use, we will use multiple behavioral paradigms as shown below.

1. Drug administration

Nicotine administration

Nicotine will be administered chronically via subcutaneous mini-pump implanted in a brief surgical procedure developed by Dr. (b)(6),(b)(4) to model exposure to nicotine comparable to levels achieved by human cigarette smoking. Osmotic minipumps are used to provide animals with continuous drug delivery to establish and maintain fairly constant concentration of drug for many days without the trauma of repeated injections. Minipumps operate because of an osmotic pressure difference between a compartment within the pump and the tissue environment in which the pump is implanted. The high osmolality of the salt sleeve causes water to flux into the pump through a semipermeable membrane, which forms the outer surface of the pump. As the water enters the salt sleeve, it compresses the flexible reservoir, displacing the drug solution from the pump at a controlled, predetermined rate. This paradigm for administering nicotine had produced animals results on body weight and eating behavior comparable to studies of human smokers (Grunberg 1982). Subjects are anesthetized by inhalation anesthetic using LAM anesthetic equipment (vaporizer) and Isoflurane and oxygen. Subjects are placed inside an induction chamber saturated with Isoflurane vapor (3-5%). Subjects are removed from the chamber when tail pinch produces no reflex movement and anesthesia is maintained using a mask/nose cone attached to the anesthetic vaporizer (1-3%). A 3 x 5 cm area between the withers is shaved and cleaned with the antiseptic Betadine. A 2 cm transverse incision within the shaved region approximately 1 cm below the scapulae is made with blunt-nosed, curved-tipped Mayo surgical scissors, a pocket is created by gently spreading the subcutaneous tissues with the scissor tips, and the mini-pump is inserted. Surgical instruments are cleaned and sterilized by the glass bead germinator, 70% ethanol and sterile saline before each procedure and in between animals. Incisions are closed with two-three 9 mm stainless steel wound clips. The wound clips are removed in 2 weeks after the surgery. This procedure takes approx. 4 min per subject. The surgical area is thoroughly cleaned before and after procedures. Investigators wear surgical masks,

gloves, and laboratory coats or surgical scrubs. The procedures are performed under aseptic conditions. Subjects will be returned to their cage and observed post-surgery until they are able to demonstrate recovery such as return of righting reflex, or coordinated voluntary movement. They also will be monitored three times a day until they have completely recovered from the minor surgical procedures. Nicotine (6 mg/kg per day) will be delivered with a rate of 0.5 µl per hour using the Alzet osmotic minipump (model 2002, Durect Corporation, Cupertino, CA).

Intravenous drug self-administration

Apparatus
Eight operant chambers (Med Associates Inc., St. Albans, VT, USA) for drug self-administration are contextually different from the animals' home cage, and located in a different room (b)(6) Each chamber is equipped with an infusion pump assembly consisting of a Razel Model A pump (Stamford, CT, USA) and 10 ml syringe connected to a fluid swivel (Instech, Plymouth Meeting, PA, USA) by Teflon tubing. Tygon® tubing enclosed by a metal spring connected the swivel to the animal's catheter exit port and was secured to Teflon threads on the catheter assembly. Each operant chamber contains two levers, and either one (Fixed Ratio 1) or five (Fixed Ratio 5) 20 g lever press responses on the active lever delivered an i.v. injection of sterile drug solution (Sigma/Aldrich, MO, USA) dissolved in 0.9% saline. During each injection, a cue light above the active lever is illuminated, and the house light is extinguished. Each injection is followed by an additional "time-out" (TO) period in which the cue light is extinguished; lever press responses during the entire injection-TO period are recorded but had no programmed consequences. Responses on the inactive lever are recorded but had no scheduled consequence. A detailed procedure on intravenous drug self-administration in rats has been described previously (b)(6),(b)(4)

Lever press training
Animals are initially trained to press a lever for sucrose pellets in ventilated operant chambers under restricted diet conditions for two to three days. This procedure will facilitate acquisition of drug self-administration training. This procedure requires an initial 16–20 hrs of slight food restriction followed by ad lib feeding for a few hrs after each test session. This procedure allows transient weight gain overnight, but animals return to 90% initial body weight prior to the next test session on the following day.

Intravenous morphine self-administration
After a minimum of 1 week recovery from catheter surgery, animals are placed in operant test chambers and allowed to acquire i.v. morphine (0.5 mg/kg/0.1 ml in a 5 s injection) self-administration on one lever press/injection (Fixed Ratio 1: Time Out 20 sec) reinforcement schedule in a daily 3 to 4 hr self-administration test sessions for 5 days per week (3 weeks for Aim 1 and 2; 4 weeks for Aim 3). Animals are weighed before each self-administration session to adjust drug dosage. We limit the maximum amount of drug intake for morphine (20 mg/kg, iv) across 4 hrs in a single session so that there is a very little chance of drug over-dose during the self-administration.

2. Stress Paradigm

Warrior stress
The Warrior Stress Paradigm combines predator stress with unpredictable environmental stimuli. Predator stress is a non-painful but effective stressor used in rodent models investigating the effects of stress. Predator stress can be manipulated by presenting the actual predator or the odors of the predator. Exposure to predator stress produces increases in stress hormones (Hayley et al. 2001). Exposure to predator stress also produces behavioral changes in rodents including differences in food consumption, elevated plus maze, startle response, freezing behavior, withdrawal behavior, and exploratory behavior (Adamec et al. 2006; Belzung et al. 2001; Endres et al. 2005; Masini et al. 2005; Takahashi et al. 2005). Predator stress is presented by introducing a cotton ball with commercially available fox urine into a test cage with the rat subject. Unpredictable, non-painful stressors include noise, flashing light, and cage shaking. Unpredictable stress are included because it is a face-valid model of human stress and also has been shown to reliably produced alterations in stress hormones (Fride et al. 1986; Weinstock et al. 1992), and behavior (Gonzalez Jatuff et al. 1999) in rodent studies. The animals are transferred from their home cage and housing room to the "stress cage" (covered with a Plexiglas lid) to be exposed to the stressors. The stress procedure lasts 20 minutes for 5 days. Fox urine (15mL) is placed on a large cotton ball and placed in varying spots in the stress cage. A bright florescent overhead light remains on during the procedure. Animals will be weighed between each stress exposure.

3. Behavioral measures

Spontaneous locomotor activity
Open field locomotor activity will be measured using an Accuscan Electronics Digiscan infrared photocell system. Animals are placed singly in a 20 x 20 x 30 cm clear Plexiglas arena and a Plexiglas lid with multiple ventilation holes placed on top of the arena. Data are automatically gathered and transmitted to a computer operating the Fusion 3.4 software system for data collection and analyses. The interfaced software measures two dozen activity variables, including total distance and horizontal and vertical activity. Chambers are cleaned between subjects with Clidox-S base, water, and activator in a 1:18:1 preparation. The duration of locomotor activity testing is a maximum of 60 min per session. Sixteen open field activity boxes from the Dr. (b)(6) Lab will be used.

Elevated plus maze (EPM)
The EPM is a widely used a measure of anxiety (Hogg 1996; Lister 1987). Rats will be placed individually on the center platform facing a closed arm and allowed to explore the maze for 5 min. Behavior will be videotaped via closed circuit TV camera for scoring as described previously (Elliott et al. 2004). Behaviors scored include: percent time spent in the open arms [(time spent in open arms/total time) X100], percentage of open arms entries [(open arm entries/total arm entries) X100], and percentage of closed arm entries [(closed arm entries/total arm entries) X 100]. Percent time spent in the open arms and percentage of open arm entries are chosen to index anxiety because these behaviors repeatedly correlate with anxiety (Hogg 1996; Rodgers and Dalvi 1997). Video recording and use of data will be in compliance with IACUC Policy #25.

Pavlovian fear conditioning
Sprague-Dawley rats will be placed in a Plexiglas rodent conditioning chamber with a metal grid floor (model E10-10; Coulbourn Instruments, Lehigh Valley, PA, USA), dimly illuminated by a single house light, and enclosed within a sound-attenuating chamber (model E10-20). Rats will be divided into two groups. The paired group will be presented with three to five pairings of a tone for 20 sec (CS: conditioned stimulus; 5 kHz, 75 dB) that co-terminates with a foot shock (US: unconditioned stimulus; 0.5 sec, 0.8 mA). Animals will be weighed between each stress exposure. We will measure contextual fear and cued fear extinction in these animals. For contextual fear, animals will be reintroduced to the fear conditioning chamber and freezing to the context will be measured for 10 minutes. In another session, animals will be placed in a novel chamber which is different from the conditioning chamber and the tone (20 sec) will be played 10 times with a random interval (average interval 2 min). The whole session lasts less than 30 minutes and freezing behavior to the tone will be measured. These additional measures do not cause any pain in the animals because no footshock is involved and the animals are tested for previously formed fear memory.

Acoustic startle reflex (ASR) and pre-pulse inhibition (PPI)
The acoustic startle reflex test will be conducted with a Startle Response Acoustic Test System (Coulbourn Instruments, Columbus, Ohio, USA). The system consisted of 8 weight sensitive platforms in 4 sound-attenuated chambers. All acoustic stimuli will be given by a speaker mounted 24 cm above the test cage. During the testing, rats will be individually placed in an animal holder (to gently restrict animal movement) which will be then placed on a weight-sensitive platform within the chamber. A ventilating fan built into the chamber provided background noise. Following a 3-min acclimation period, animals will be exposed to six types of acoustic stimulus trials: 100 dB, 110 dB, 100 dB with pre-pulse (68 dB), 110 dB with pre-pulse (68 dB), pre-pulse alone and no stimulus. Duration for pre-pulse is 100 ms and for pulse (100 and 110 dB) is 20 ms. Each stimulus has a 2 ms rise and decay time such that onset and offset are abrupt, a primary criterion for startle. A frequency for the tones is 1 kHz as shown in previous studies (Acri et al. 1995; Manion et al. 2007). The same animals were tested five times and there was no sign of hearing impairment in those studies. Each trial type will be presented eight times. Trial types will be presented in random order to avoid order effects and habituation. Inter-trial intervals range randomly from 15 to 25s and the testing lasts approximately 20 minutes as described previously (b)(6),(b)(4)

Hot plate test
Hot plate response measures supraspinal nociceptive responses (Berry et al. 2007; Ding et al. 2005). The hot plate task will be performed with an Omnitech/Accuscan Electronics Analgesia Monitor (Model HPrx). Subjects are placed on a 26 x 26 cm square hot plate platform, enclosed on all sides by Plexiglas walls and covered with a removable Plexiglas top. The metal plate heated to 51°C (a temperature that will elicit a nociceptive response without tissue damage). Hotplate latencies are measured as the time from placement on the heated surface until the animal raised and licked a rear paw. To prevent tissue damage, a maximum latency of 60 sec is allowed. Animals that do not lick their paws at all during the 60-sec period are removed from the heated surface. The platform is cleaned between subjects. The total number of tests is no more than 8 with a minimum of 2 days of break between each test.

Tail flick test
A recent study showed that the effects of opioid drugs on anti-nociception measured by the hot plate and the tail flick methods are different in rats (South et al. 2009). The tail flick method is one of the most commonly used models to measure analgesic responses in rodents (Cecchi et al. 2008; Hardy et al. 1957). Animals will be placed and gently restrained by hand on the test platform (Tail-Flick Analgesia meter, Columbus Instrument) and the lower one-third of the tail will be placed on top of the small hole which gradually increases thermal radiation. When the animal flicks its tail, both the heat source and timer are stopped automatically. The average tail withdrawal time is supposed to be between 5 and 10 seconds and the maximum exposure time will be 20 seconds to prevent potential tissue damage. The total number of tests is no more than 8 with a minimum of 2 days of break between each test. We will try to use the hot plate test as a first choice and if some animals don't respond very well, we will switch to the tail flick test as an alternative way of measuring nociception in rats.

Oral stereotypy
Immediately following MSA, animals will be observed in their home cages for 30 min. The frequency of stereotypic behaviors will be recorded. For example, stereotypic self biting (biting of tail or digits) and biting other objects (bedding, cage, cage bars) will be recorded. The other behaviors, rearing (standing on hind legs), grooming (cleaning behavior), locomotion (walking from one side of the cage to another), catalepsy (immobile with eyes open), sleep (immobile with eyes closed and lying down), inactivity (immobile but not cataleptic), will be recorded as described previously (Wennemer and Kornetsky 1999).

Locomotor activity with morphine administration
Locomotor activity will be measured using an Accuscan Electronics Digiscan infrared photocell system in the (b)(6) inside the LAM. Animals will be placed singly in a 20 x 20 x 30 cm clear Plexiglas arena and a Plexiglas lid with multiple ventilation holes placed on top of the arena. Animals will be habituated to the boxes for 60 minutes as a baseline. Following MSA, locomotor activity will be monitored for 60 minutes. During morphine withdrawal, animals will be tested with either intravenous (0, 0.5 and 2 mg/kg) or subcutaneous (0, 1, and 5 mg/kg) morphine in a single session. Animals will be habituated to the open field activity boxes (60 min), ascending doses of morphine will be injected with 60 min interval and locomotor activity will be monitored continuously.

Morphine withdrawal signs
Quantifying withdrawal signs will provide information about an organism's level of addiction and dependence to drug. Animals will be observed in either a home cage or a clean plexiglass cage for 30 min. Withdrawal signs include ptosis, piloerection, mouth and teeth chattering, abnormal grooming, jumping, chewing/biting, stereotypy, wet dog shake, and locomotor activity (horizontal and vertical) as reported previously (Guitart et al. 1992; Guitart et al. 1993; Malin et al. 1992; O'Dell et al. 2004; Pinelli and Trivulzio 1997; Rasmussen et al. 1990; Stephens and Riley 2009). Each episode will be counted as one occurrence or symptom. This procedure does not cause any stress or pain in the animals.

^{18}FDG μPET/μCT imaging

The imaging will be conducted in accordance with the approved IACUC animal imaging SOP# 3 from the Translational Imaging Facility (CNRM). The animal will be anesthetized with 3% isoflurane/oxygen mixture. FDG will be administered via an i.v. catheter or a tail vein at less than 5 ml/kg. After FDG injection, the animal will either be placed back to its cages awake or placed on a heated surface and maintained under anesthesia during 45-60 minutes of FDG uptake period. After the uptake period, the anesthetized rat will be transferred to a special rodent holder (m2m Imaging) with an integrated 'flow through' nosecone and active waste gas removal via the facility vacuum. A 45-60 minute μPET acquisition will be conducted with anesthesia maintained and animals continuously monitored for signs of movement or changes in respiration. A rectal probe will be used to monitor body temperature. A 5 min μCT scan will also be performed. The bed automatically translates the animal from the μPET to the μCT without disturbing the rodent or anesthesia. After the imaging, anesthesia will be halted, the animal placed on a heating pad, and recovery monitored. The rodent will be returned to its cage, which will be labeled with the following information: injection time, activity amount, volume injected, on-cage survey results and time of survey and free release time. *This procedure will be conducted by the trained personnel at the TIF and is considered as a pain category C.*

Specific Aim 1: To determine effects of early and late withdrawal from morphine self-administration (MSA) on anxiety and fear behavior in male and female rats. We will use elevated plus maze and acoustic startle as anxiety measures, and Pavlovian fear conditioning and extinction as fear behavior following chronic morphine self-administration. We hypothesize that early and late withdrawal from MSA may have differential effects on fear and anxiety behaviors.

Experiment 1: Effects of early withdrawal from morphine self-administration on anxiety and fear behavior.

Following one-week recovery from the catheter surgery, rats will be tested on baseline open field activity (OFA) for 60 min in the morning and tested with ASR for 20 min in the afternoon. Next day, animals will be trained to self-administer intravenous morphine (0.5 mg/kg/infusion) in the operant conditioning chambers (5 days per week) for three weeks. OFA will be measured immediately after MSA on day 5, 10 and 15 to monitor drug-induced locomotor activity. During spontaneous withdrawal from morphine, animals will be tested on the EPM for anxiety behavior (withdrawal day 2) and fear conditioning for fear memory (withdrawal day 3-5).

Timeline

Animals arrive and acclimate to USUHS Animal Facility (LAM) (1 week)

Experiment 2: Effects of late withdrawal from morphine self-administration on anxiety and fear behaviors.

Following one-week recovery from the catheter surgery, rats will be tested on baseline open field activity (OFA) for 60 min in the morning and tested with ASR and PPI for 20 min in the afternoon. Next day, animals will be trained to self-administer intravenous morphine (0.5 mg/kg/infusion) in the operant conditioning chambers (5 days per week) for three weeks. OFA will be measured immediately after MSA on day 5, 10 and 15 to monitor drug-induced activity. During late withdrawal from chronic MSA (between 1 and 2 weeks), animals will be tested on the EPM for anxiety behavior and fear conditioning and memory test for fear memory.

Specific Aim 2: To determine effects of morphine self-administration on anti-nociception and tolerance, and regional glucose utilization in brain. We will use a hot plate test to measure antinociception and ^{18}FDG-PET for regional glucose uptake in brain. We will also investigate individual differences in antinociception, morphine self-administration and locomotor sensitization in males and females. We hypothesize that individual differences in morphine antinociception and morphine self-administration may be associated with brain glucose utilization.

Experiment: Effects of morphine self-administration on anti-nociception and regional glucose uptake in the brain.

Following one-week recovery from catheter surgery, animals will be tested on baseline OFA (morning) and nociception (afternoon) in one day. Next day, a baseline brain glucose uptake will be measured with ^{18}FDG-PET/CT. Animals will be trained to self-administer intravenous morphine (0.5 mg/kg/infusion) in operant conditioning chambers

(5 days per week) for 3 weeks. Anti-nociception will be measured in MSA day 1, 3, 5, and withdrawal day 1. OFA will be measured in day 5, 10 and 15 of self-administration, and in withdrawal day 1. Animals will be scanned with ^{18}FDG-PET/CT (second scan) in withdrawal day 2. One week later, the animals will be tested with morphine challenge (1 mg/kg) and scanned with ^{18}FDG-PET/CT for the third time.

Specific Aim 3: To determine effects of chronic nicotine and/or psychological stress (Warrior Stress) on morphine self-administration and behavioral sensitization. Animals will be exposed to chronic nicotine via minipump and Warrior Stress, and then allowed

to acquire morphine self-administration for two weeks. Following acquisition of morphine self-administration, animals will be tested with dose response function. Locomotor sensitization during morphine withdrawal will also be measured. We hypothesize that stress exposure may facilitate opioid abuse and nicotine exposure may attenuate opioid abuse.

Experiment: Effects of nicotine and stress on morphine self-administration and behavioral sensitization.

Following one week of acclimation in the housing room (a reversed light/dark cycle), each animal will be implanted with osmotic minipump to deliver chronic nicotine (6 mg/kg/day, s.c.). During the second-week period of nicotine administration, animals will be exposed to Warrior Stress (20 min a day) for 7 days and OFA behavior will be measured. After three weeks of nicotine exposure, minipump will be removed and catheter will be implanted in the jugular vein in a single surgery. Following 1 week of recovery from catheter surgery, animals will be allowed to self-administer intravenous morphine (0.5 mg/kg/infusion, FR1) in operant conditioning chambers (3 hr/day, 5 days per week) for 2 weeks. Upon stabilization of morphine self-administration, animals will be tested with a dose-response function (0, 0.1, 0.3, 0.5 and 1 mg/kg/infusion, i.v.) for 2 weeks. Following 1-week withdrawal from MSA, animals will be tested with morphine challenge (0, 0.5 and 2 mg/kg) to measure locomotor sensitization.

Experimental endpoints

If signs of morbidity are observed over the course of the experiments, the veterinarian is notified and, if necessary, rats are excluded from the study and euthanized. Signs for judging morbidity include rapid breathing; shallow, labored breathing; weight loss (more than 10% of body weight not regained within 48 hr, continuous body weight loss over 5 days of more than 5 g per day), ruffled fur (rough hair coat), hunched posture, hypothermia or hyperthermia, ulceration dermatitis or infected tumors, diarrhea, impaired ambulation, evidence of muscle atrophy or other signs of emaciation, bleeding, or inability to remain upright. In cases of body weight loss, supplemental soft and sweetened food is provided, and if necessary drug self-administration is withheld until the animal recovers.

V.2. Data Analysis:

The number of rats is determined by the number of experimental groups needed for a clear interpretation of the behavioral and neurobiological data. Intravenous drug self-administration is a highly regulated and conditioned behavior in rats. Based on our experience, 12 animals per group allows for a sufficient statistical power to detect group differences in drug self-administration behavior as described previously (b)(6),(b)(4) (b)(6),(b)(4) We also performed a power calculation using R statistical language (http://www.r-project.org/). We expect moderate to large effect sizes (0.5) for behavioral measures to drugs based on the previous studies (Choi et al. 2006; Self et al. 1994). Therefore, an effect size (0.5), high power (0.80), and alpha level of 0.05 with a two-sided test requires a total of 12 animals per group. The data will be analyzed by parametric or non-parametric tests with repeated measures as appropriate. Tukey HSD *post hoc* tests or Dunnett's t will be used to compare differences between the groups. All analyses will be two-tailed with alpha = 0.05. Statistical analyses will be conducted

using software such as the Prism (GraphPad, San Diego, CA, USA), the Statistical Package for the Social Sciences (SPSS, Chicago, IL, USA), and the R statistical language (http://www.r-project.org/).

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered:
This study will require the use of intact living animals. Behavioral measurements, such as self-administration of drug, stress and anxiety responses, addiction behavior cannot be observed on cells grown in culture or on a computer simulation. Non-animal alternatives such as computer modeling and cell cultures were considered but are not suitable to assess behaviors in organisms because there currently are no non-animal alternatives that provide information about effects of stress, drug and behavior in living organisms. Due to ethical considerations, the proposed studies cannot be done with human subjects.

V.3.2. Animal Model and Species Justification:
Rats will be used in behavioral paradigms that model stress, anxiety and substance abuse in humans. Rats are amendable to pharmacological manipulations needed to study the biological mechanisms involved in stress and substance abuse. The experimental nature of the work necessitates the use of model organisms rather than human subjects. However, results from our laboratory studies complement data obtained from human clinics and experiments. We will continually evaluate our approaches and adapt experiments for *in vitro* or computer models whenever possible.

	Species #1	Species #2
V.3.3.1. Genus & Species:	*Rattus norvegicus*	
V.3.3.2. Strain/Stock:	Sprague-Dawley	
V.3.3.3. Source/Vendor:	(b)(4)	
V.3.3.4. Age:	Adult (about 55 days)	
V.3.3.5. Weight:	Adult males (about 250 grams); adult females (about 170 grams)	
V.3.3.6. Sex:	Male and Female	
V.3.3.7. Special Considerations:	N/A	

V.3.4. Number of Animals Required (by Species): 280

Subjects. Subjects are male and female Sprague-Dawley rats, the most commonly used laboratory rats in various studies, including investigations of stress and drug

effects. Sprague-Dawley albino rats are considered to be the standard test rat for nicotine and stress experiments. Adult animals are approximately 55 days old upon arrival and in consultation with the breeder.

V.3.3. Laboratory Animals

Please note: Each experiment will be run as a series of smaller sub-experiments for logistical reasons:
Experiment 1 = 96 rats (plus 16 additional rats) = 112 rats
Experiment 2 = 48 rats (plus 8 additional rats) = 56 rats
Experiment 3 = 96 rats (plus 16 additional rats) = 112 rats

Additional animals are necessary due to loss of catheter patency in some animals before the end of the study and training students on surgery and other procedures.

V.3.5. Refinement, Reduction, Replacement (3 Rs):

V.3.5.1. Refinement: Animals will be monitored on a daily basis and be given pain medication and antibiotic if any sign of pain or distress occurs. In order to reduce stress and anxiety, animals will be acclimated to the facility for 1 week upon arrival. If there are any indications of pain or distress, then the LAM staff will be consulted. With regard to logistical and technical refinements, many of the behavioral assessments use automated equipment interfaced with computers to allow for the collection of multiple parameters simultaneously. The use of sophisticated software and computerized technologies allows us to collect fine-grained and complete data sets for every animal included in the experiment, eliminating the need for additional studies that might otherwise have been necessary.

V.3.5.2. Reduction:
The sample sizes for the proposed work were derived from power analyses of pilot data and past work in our laboratory and in other laboratories. These sample sizes, therefore, constitute the minimum number of animals necessary to obtain meaningful results and represent a useful application of knowledge of statistical effect size and the concept of power. In addition, in each experiment, multiple dependent variables are measured. Measurement of many variables in the same animals markedly reduces the total number of experiments conducted.

V.3.5.3. Replacement: This study requires the use of intact living animals; behavioral measurements cannot be made on cells grown in culture or with computer models. Thus, it is not possible to replace or eliminate the use of animals in the proposed study.

V.4. Technical Methods:
V.4.1. Pain / Distress Assessment:
Animals will be anesthetized during implantation of mini-pumps or catheters. Animals will be observed daily by investigators and by LAM staff to check health and well-being and to insure that there is no undue pain or distress based on behaviors and vocalizations. Any indications of pain or distress will be dealt with by alleviating the cause of the problem and/or by contacting LAM personnel for assistance and guidance

V.4.1.1. **APHIS Form 7023 Information**:

V.4.1.1.1. **Number of Animals**:

	Species #1	Species #2
V.4.1.1.1.1. **Column C**:		
V.4.1.1.1.2. **Column D**:	112	
V.4.1.1.1.3. **Column E**:	168	

The number of animals listed in Column E is based on the premise that these animals are exposed to fear conditioning experiment which requires exposing animals to mild and brief footshock (0.8 mA in 0.5 sec) three to five times or distress from the Warrior Stress paradigm. The pain and distress resulting from footshock during the fear conditioning are momentary and do not cause any physical injury to the tissue of animals.

V.4.1.2. **Pain Relief / Prevention**:

V.4.1.2.1. **Anesthesia/Analgesia/Tranquilization**:

For nicotine minipump implantation, subjects are first anesthetized by inhalation anesthetic to prevent pain. Isoflurane is mixed with oxygen (3–5% Isoflurane; with an oxygen flow rate of 0.5-1.0 liters/minute). Subjects are placed inside an induction chamber saturated with Isoflurane vapor. Subjects are removed from the chamber when tail pinch produces no reflex movement and anesthesia is maintained using a mask/nose cone attached to the anesthetic vaporizer (with Isoflurane concentration ranging from 1–3% to maintain appropriate depth of anesthesia). Animals receive buprenorphine (0.01-0.05 mg/kg i.v.) once every 12 hrs for next 48 hrs.

For i.v. catheter surgery, subjects are briefly anesthetized by inhalation anesthetic isoflurane mixed with oxygen (i.e., 3–5% Isoflurane; with an oxygen flow rate of 0.5-1.0 liters/minute) inside an induction chamber. Subjects will receive an injection of either sodium pentobarbital (40-50 mg/kg, i.p.) or ketamine/xylazine (40-80 mg/kg ketamine and 5-10 mg/kg xylazine, i.p.). For sodium pentobarbital injection, rats will also receive atropine sulfate (0.04 mg/kg, s.c.) to reduce pulmonary congestion and facilitate breathing. Animals receive buprenorphine (0.01-0.05 mg/kg i.v.) once every 12 hrs for next 48 hrs. Catheter patency will be verified by infusion of a sodium methohexital (Anesthetic, 7-15 mg/kg, i.v.) solution. Patency is indicated by a brief (about 1 minute) but rapid anesthesia. Using these procedures, catheter life averages about 8-10 weeks for rats.

V.4.1.2.2. **Pre- and Post-procedural (not surgery) Provisions**: Animals will be acclimated for 1 week to the USUHS LAM. During acclimation to LAM, animals will be handled briefly and weighed to acclimate them to being handled. This will reduce any stress that might result from handling of the animals during the procedures described in this study. The non-surgical procedure that may induce momentary discomfort (e.g., hot

plate test and tail flick test of nociceptive responses) is included for scientific purposes and is short in duration (less than 60 sec for hot plate and less than 20 sec for tail flick). Animals are observed daily by investigators and by LAM staff to check on their health and well-being and to assure that there is no undue pain or distress. Animals also are carefully monitored during behavioral testing procedures. In addition, animals are closely monitored during all procedures that involve any pain or potential distress (e.g., during and after surgery; during and after stress exposure). Pain/distress is assessed based on behaviors and vocalizations. Any indications of pain or distress are dealt with by alleviating the cause of the problem or by contacting LAM personnel for assistance and guidance.

V.4.1.2.3. Paralytics: N/A

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures:

V.4.1.3.1. Sources Searched: Medline (PubMed), PsycInfo, F1000Biology, AGRICOLA

V.4.1.3.2. Date of Search: March, 2015

V.4.1.3.3. Period of Search: All years available on each database are searched (from recent work up to 30 years in the past).

V.4.1.3.4. Key Words of Search:
osmotic minipumps, intravenous catheters, minipump implantation, catheter surgery, chronic self-administration, foot shock, pain, alternatives, analgesia, surgery, anesthesia, acute drug administration, rat (these words are searched in various combinations)

V.4.1.3.5. Results of Search: No alternatives to the minipump and the catheter implantation procedures have been found. No alternatives to the nociception procedures have been found. No milder alternative for the stress manipulation has been found. No alternatives are available to avoid using live animals for the assessment of effects of stress, opioid, and nicotine in intact rats and the procedures that are followed.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification:

Animals in specific aim 1 are exposed to fear conditioning experiment to study fear behavior. This experiment requires exposing animals to mild and brief footshock (0.8 mA in 0.5 sec) three to five times. The pain and distress resulting from these shocks during the fear conditioning are momentary and do not cause any physical injury to the tissue of animals.

V.4.2. Prolonged Restraint: N/A

V.4.3. Surgery:

V.4.3.1. Pre-surgical Provisions:

All surgeries will be performed in the LAM facility by the (b)(6) Lab and the (b)(6) Lab and in consultation with LAM staff to insure proper preparation and safeguards. Implantation of osmotic minipumps and catheters uses aseptic technique. For the minipump, subjects will be anesthetized by inhalation anesthetic LAM equipment (vaporizer) and Isoflurane mixed with oxygen. Subjects will be placed inside an induction chamber saturated (at 3-5%) with Isoflurane vapor. Subjects will be removed from the chamber when tail pinch produces no reflex movement and anesthesia will be maintained (at 1-3%) using a mask/nose cone attached to the anesthetic vaporizer.

V.4.3.2. Procedure:

Minipump implantation
Subjects are anesthetized by inhalation anesthetic using LAM anesthetic equipment (vaporizer) and Isoflurane and oxygen. Subjects are placed inside an induction chamber saturated with Isoflurane vapor. Subjects are removed from the chamber when tail pinch produces no reflex movement and anesthesia is maintained using a mask/nose cone attached to the anesthetic vaporizer. A 3 x 5 cm area between the withers is shaved and cleaned with the antiseptic Betadine. A 2 cm transverse incision within the shaved region approximately 1 cm below the scapulae is made with blunt-nosed, curved-tipped Mayo surgical scissors, a pocket is created by gently spreading the subcutaneous tissues with the scissor tips, and the minipump is inserted. Incisions are closed with two-three 9 mm stainless steel wound clips. This procedure takes approx. 4 min per subject. The surgical area is thoroughly cleaned before and after procedures. Investigators wear surgical masks, gloves, and laboratory coats or surgical scrubs. The procedures are performed under aseptic conditions.

Intravenous catheter implantation
All surgery will be performed under aseptic conditions in a clean area. Each surgery will be done on a separate, clean and autoclaved sheet of Whitman Benchkote paper. Surgical instruments are sterilized in a glass bead sterilizer and cleaned/sterilized between successive surgeries. Sterile gloves are used for each rat's surgery and instruments are sterilized before each rat's surgery. Rats are anesthetized with sodium pentobarbital (40-50 mg/kg, i.p.) or ketamine/xylazine (40-80 mg/kg ketamine, 5-10 mg/kg xylazine, i.p.). Injection volume is 1 ml/kg for both drugs. Surgery starts after the rat fails to show the withdrawal reflex after pinching the rear toe (a procedure that is repeated several times during the surgery to ensure full anesthesia level). Supplemental anesthetic dose (0.1-0.4 ml) may be given as needed. Intravenous silastic catheter is implanted into the right jugular vein and attached to either the head or the back of the animal. Two incisions are made, one on the back (2.5 cm), and one on the neck (1 cm). The jugular vein is isolated by teasing apart fatty tissue above the vein with small scissor tips, just above where the vein passes over the clavicle. After isolation, the vein is punctured with a needle (22 gauge) and the sterile Silastic catheter is inserted to the level of the sinus vena cava just outside the right atrium. The entry point of the catheter is secured in place with a 0.5 cm x 0.5 cm mersilene surgical mesh secured to the catheter. The remaining catheter is pulled from the neck area subcutaneously to the back incision. Then the catheter exits via premade 22-gauge stainless steel tubing cemented into place with bell shaped dental cement and the bell

base (about 0.8 cm diameter) cemented to a 1.5 x 1.5 cm Marlex surgical mesh comprising the back mount. The incision is closed using three stainless steel wound clips and treated with topical antibiotic Neosporin ointment (Swabbed To Back Mounted Catheter Exit Area). Animals receive antibiotic gentamycin sulfate (5-8 mg/kg, iv) after the surgery. Gentamycin is also included in sterile saline solution that we use to flush catheter to maintain the patency. Animals receive buprenorphine (0.01-0.05 mg/kg i.v.) once every 12 hrs for next 48 hrs.

V.4.3.3. Post-surgical Provisions:

During recovery (about 30-60 min), the rats are placed in a cage that is kept warm by a heating pad (located under the cage) or under the heating lamp to prevent hypothermia. The investigators are responsible for post-operative care. The post-operative care includes continuously monitoring the rats until they are fully awake and the animals' health will be monitored and recorded in the animal's medical record for at least 3 days after surgery or until the animal appears normal. The surgery log will be kept in a drawer in the surgery room. If pain or distress such as difficulty in breathing and hypothermia is observed at any time rats will be treated with buprenorphine (0.01-0.05 mg/kg s.c.). After the IV catheter surgery, rats are individually housed in the animal facility for 5-7 days. During this time period, the rats are handled and the catheters are flushed daily with 0.2 ml of heparinized (20 U/ml), bacteriostatic saline containing gentamycin sulfate (0.33 mg/ml, i.v.) as described previously (b)(6),(b)(4)

Catheter patency will be verified by infusion of a sodium methohexital (Anesthetic, 7-15 mg/kg, i.v.) solution. Patency is indicated by a brief (about 1 minute) but rapid anesthesia. Using these procedures, catheter life averages about 6–8 weeks for rats. Most catheters are lost due to the growth of the venous wall around the catheter tip. When catheters are no longer patent, animals are either sacrificed as described below, or the original catheter is removed and another one implanted in the left jugular vein. We have observed no significant weight loss or obvious physical impairment to the animals due to one or two consecutive catheter implantations.

V.4.3.4. Location: Surgeries to implant the minipumps will be conducted in the LAM facility. Behavioral measures will be conducted in the laboratories assigned to Drs. (b)(6) in the LAM and (b)(6) at USUHS.

V.4.3.5. Surgeon: PI and all co-investigators and technicians

V.4.3.6. Multiple Major Survival Operative Procedures: N/A

V.4.3.6.1. Procedures: N/A

V.4.3.6.2. Scientific Justification: N/A

V.4.4. Animal Manipulations:

V.4.4.1. Injections: The drugs will be delivered by intraperitoneal (i.p.) or subcutaneous (s.c.) injection (1ml latex free syringe w/ 27G½ needle, B-D, Franklin Lakes, NJ). Injection volume will be adjusted based on body weight and no more than 1

ml/kg for i.p. and 2 ml/kg for s.c. administration. For intravenous administration, each bolus infusion volume will be less than 0.5 ml.

Sodium pentobarbital (40 - 50 mg/kg, i.p.)
Atropine sulfate (0.04 mg/kg, s.c.)
Buprenorphine (0.01 - 0.05 mg/kg i.v.)
Nicotine (0.5 - 6 mg/kg, s.c.)
Morphine (0.5 - 2 mg/kg, i.v.) & (1 - 5 mg/kg, s.c.)
Ketamine/xylazine (40 - 80 mg/kg ketamine, 5 - 10 mg/kg xylazine, i.p.)
Gentamycin sulfate (5 - 8 mg/kg, i.v.)
Sodium methohexital (7 - 15 mg/kg, i.v.)
Chloral hydrate (400 mg/kg, i.p.)

V.4.4.2. Biosamples:

Blood sampling from indwelling i.v. catheters
Animals have indwelling catheters implanted to the jugular vein and self-administer intravenous morphine on a daily basis. We maintain the catheter patency during the entire period of the study. We will draw a small volume of blood from the catheter for biochemical assays. For the volume of blood and the frequency of blood drawing, we will follow the NIH guidelines (http://oacu.od.nih.gov/ARAC/documents/Rodent_Bleeding.pdf) and published references (Evans 1994). For a 300 gram rat, approximately 1% of circulating blood volume (0.2 ml) can be safely drawn every 24 hrs according to the guidelines. We will draw 1% of circulating blood volume from each animal with a minimum of 2-day break between drawings. Each animal is gently held and catheter is flushed with 0.3 ml of heparinized saline. This is the same procedure to maintain catheter patency in animals. One cc syringe is connected to the catheter and 1% circulating blood volume (e.g. 0.2 cc in 300 g rat) is slowly drawn. The whole procedure takes less than 5 min and animal is returned to its home cage. This procedure does not cause any pain or distress in animals and they show normal weight gain after the procedure. Previous study also reported that the same procedure does not cause any pain or stress in rats (Thrivikraman et al. 2002). There is no anesthesia required for this procedure. Blood samples will be collected at baseline, during morphine self-administration and during spontaneous withdrawal. Total number of sample collection will not exceed 10. At the end of the experiment, animals will be euthanized as described below. Blood samples and brain tissue samples will be collected and stored for later analysis.

V.4.4.3. Adjuvants: N/A

V.4.4.4. Monoclonal Antibody (MAbs) Production: N/A

V.4.4.5. Animal Identification: Rats are identified by tail markings and ear punches matched with IDs on the cage cards. Immediately after the IV catheter surgery under anesthesia, small hole on the ear will be made to identify each animal. Ear punching is commonly used for identification of rodents and involves using a special punch to produce a small (0.5 to 1 mm) notch near the edge of the ear. The cutting edge of the punch is disinfected 70% ethanol after each use.

V.4.4.6. Behavioral Studies: Please see section V.1. (Materials and Methods)

V.4.4.7. Other Procedures: N/A

V.4.4.8. Tissue Sharing:
Blood samples and brain tissue will be collected and shared with other investigators for molecular and biochemical assays. All personnel engaging in this procedure will receive training by IACUC/LAM staff, or trained laboratory personnel.

V.4.5. Study Endpoint: The study endpoint is euthanasia in each experiment (9 weeks for Specific Aim 1 and 2, and 10 weeks for Specific Aim 3). Each experiment will be run in counter-balanced cohorts. Considering pilot work, time between cohorts, and time to run each cohort, each experiment will require about 6 months to collect behavioral data and blood samples. Biochemical assays and data analyses will require several additional months per experiment.

V.4.6. Euthanasia:
Rats in Aim 1 will be euthanized using carbon dioxide inhalation from a compressed gas cylinder. Euthanasia will be done in a LAM designated procedure room followed by rapid decapitation by guillotine. This euthanasia procedure is in compliance with the 2013 AVMA Guidelines on Euthanasia. For brain tissue collection in Aim 2 and 3, chloral hydrate (400 mg/kg) or ketamine/xylazine (40-80 mg/kg and 5-10 mg/kg) will be administered at a dose of 1.0 ml/kg body weight via i.p. (intraperitoneal) injection with a 26 3/8 gauge, 0.5 inch, needle and 1ml syringe. The depth of anesthesia will be determined by loss of withdrawal response to rear foot pad pinch, tail pinch and loss of movement in response to eye extra orbital touching. Thoracotomy will only be performed after failure of the withdrawal reflex and then intra-cardiac perfusion will be performed. Supplemental anesthetic doses (200 mg/kg of chloral hydrate or a mixture 20-40 ketamine and 5 mg/kg xylazine) will be given as needed. After the deep anesthesia, the heart will be exposed, and a 17-gage needle that is connected to a pump via tubing is inserted to the left ventricle of the heart. Rats will be transcardially perfused with isotonic saline (50-100 ml) followed by a 4% paraformaldehyde/1% glutaradlehyde/50% phosphate buffer fixative (200-300 ml).

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol.

V.5.1.1. Study Room:
Building(s) (b)(6) Room Number(s) (b)(6) (b)(6)

V.5.1.2. Special Husbandry Provisions: Animals will be single housed.

Food Restriction: Yes X No _____

Fluid Restriction: Yes No X

For the lever press training prior to the intravenous drug self-administration, animals are slightly food restricted for two to three days. This procedure requires an initial 16–20 hrs of food restriction followed by ad lib feeding for a few hrs after each training. This procedure allows transient weight gain overnight, but animals return to 90% initial body weight prior to the next lever press training session on the following day. After the procedure, the animals are fed *ad lib* throughout the experiment.

V.5.1.3. Exceptions: N/A

V.5.2. Veterinary Medical Care: N/A

V.5.2.1. Routine Veterinary Medical Care: Animals will be cared for in accordance with LAM SOPs. Animals will be observed daily or more frequently by the veterinary staff. The LAM veterinary staff will be available for consultation with the PI if any unexpected medical events arise.

V.5.2.2. Emergency Veterinary Medical Care: All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays. Investigators' contact information will be available to the veterinary staff in case a decision about early euthanasia or treatments of an animal needs to be made on the weekend or holiday.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: N/A

V.5.3.2. Enrichment Restrictions: Animals will be single housed without toys because these experiments are designed to determine effects of several interventions. Animals are housed individually because of indwelling catheters after catheter surgery and tested on drug self-administration.

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Personnel	Procedure	Qualifications/Training
(b)(6) Ph.D. (Principal Investigator)	Animal Handling	(b)(6) (b)(6) > 20 years experience with rats and other rodents

	Drug Administration	USUHS Investigator Training and Animal Handling courses; > 20 years experience with rats and other rodents
	Surgical Implant of mini-pumps and catheters	U of A/UTSW Med Ctr training courses; > 20 years experience with rats and other rodents

IX. **ASSURANCES:** As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

I. Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress caused by the stress paradigm **WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. However, the potential pain and distress caused by the IV catheter surgery **WILL** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

X. **PROTOCOL ABSTRACT:**

A. **Animal Protocol Number:**

B. Animal Protocol Title: Role of nicotine and opioid on stress and anxiety in rats

C. **Principal Investigator:** (b)(6) PhD

D. **Performing Organization:** Uniformed Services University of the Health Sciences

E. **Funding:** USUHS

F. **Objective and Approach:**

Posttraumatic stress disorder (PTSD) is a debilitating consequence of trauma in military and civilian settings. PTSD is often comorbid with substance use and other psychological disorders. Nicotine-containing products (including cigarettes and smokeless tobacco) are used by more than 50% of military personnel, well above the 18% of civilians who smoke. This high use of nicotine among military personnel may be partially explained by the fact that nicotine and tobacco self-administration increase under stressful situation. Moreover, opioid pain medication abuse is increasing and this is of growing concern among military personnel. We will study effects of stress and two widely used drugs (nicotine and opioid) on psychological behaviors using animal models including intravenous drug self-administration in rats. In specific aims 1 and 2, we will study effects of morphine self-administration and withdrawal on behaviors such as fear, anxiety, and antinociception as well as brain glucose uptake in male and female rats. In specific aim 3, we will study interaction between psychological stress (Warrior Stress) exposure and drugs (nicotine and opioid) in male and female rats. For behavioral outcome measures, we will utilize paradigms such as elevated plus maze, classical fear conditioning, acoustic startle reflex, antinociception and spontaneous locomotor activity. The goal of this study is to better understand the biological mechanisms contributing to stress responses and substance use as well as individual differences in vulnerability and resilience to these environmental factors.

G. **Indexing Terms (Descriptors):** Stress, nicotine, opioid, behavioral responses of rats to stress, nicotine, drug self-administration, drug seeking, psychological stress, fear memory, PTSD, anxiety, depression,

MEMORANDUM FOR DR (b)(6) DEPARTMENT OF PSYCHIATRY

SUBJECT: IACUC Approval of Protocol - Initial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) by Designated Member Review, on June 8, 2015:

Animal Protocol Title: "Neurophysiology of Escalation of Aggression in a Rat Model of PTSD"

USUHS Protocol Number: (b)(6)

Expiration Date: June 7, 2018

Supporting Grant(s) Number: (b)(6)

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

TECHNICIANS(S):

I. NON-TECHNICAL SYNOPSIS:

Escalated aggression is a comorbidity of post traumatic stress disorder (PTSD), appearing as angry outbursts and reckless or destructive behavior. To elucidate the underlying neurophysiology and discover pharmacotherapy, an animal model is needed for experimentation. The rat is the lowest animal on the phylogenetic scale that corresponds to humans in anatomy, physiology, and behavior sufficiently to study the neurophysiology of aggression.

Stress is produced by restraint and tail shock for two hours on each of three consecutive days. This restraint/tail shock paradigm has been running in the laboratory for fifteen years and an IACUC protocol (PSY-14-667) is currently active. Sleep deprivation is to be achieved by giving the restraint/tail shock procedure during the final hours of the light cycle, when the animal would normally be in REM sleep.

(b)(4)

II. BACKGROUND:

(b)(4)

[redacted]

PTSD Animal Models (b)(4)

(b)(4)

[redacted]

To establish a rat model of PTSD we have successfully developed and tested the inescapable tail-shock model of stress in rats and verified that short and long-lasting behavioral, biochemical and physiological alterations result. Importantly, the stress-

induced behavioral and neurobiological symptoms in the rat models are very similar to those seen in PTSD patients.

(b)(4)

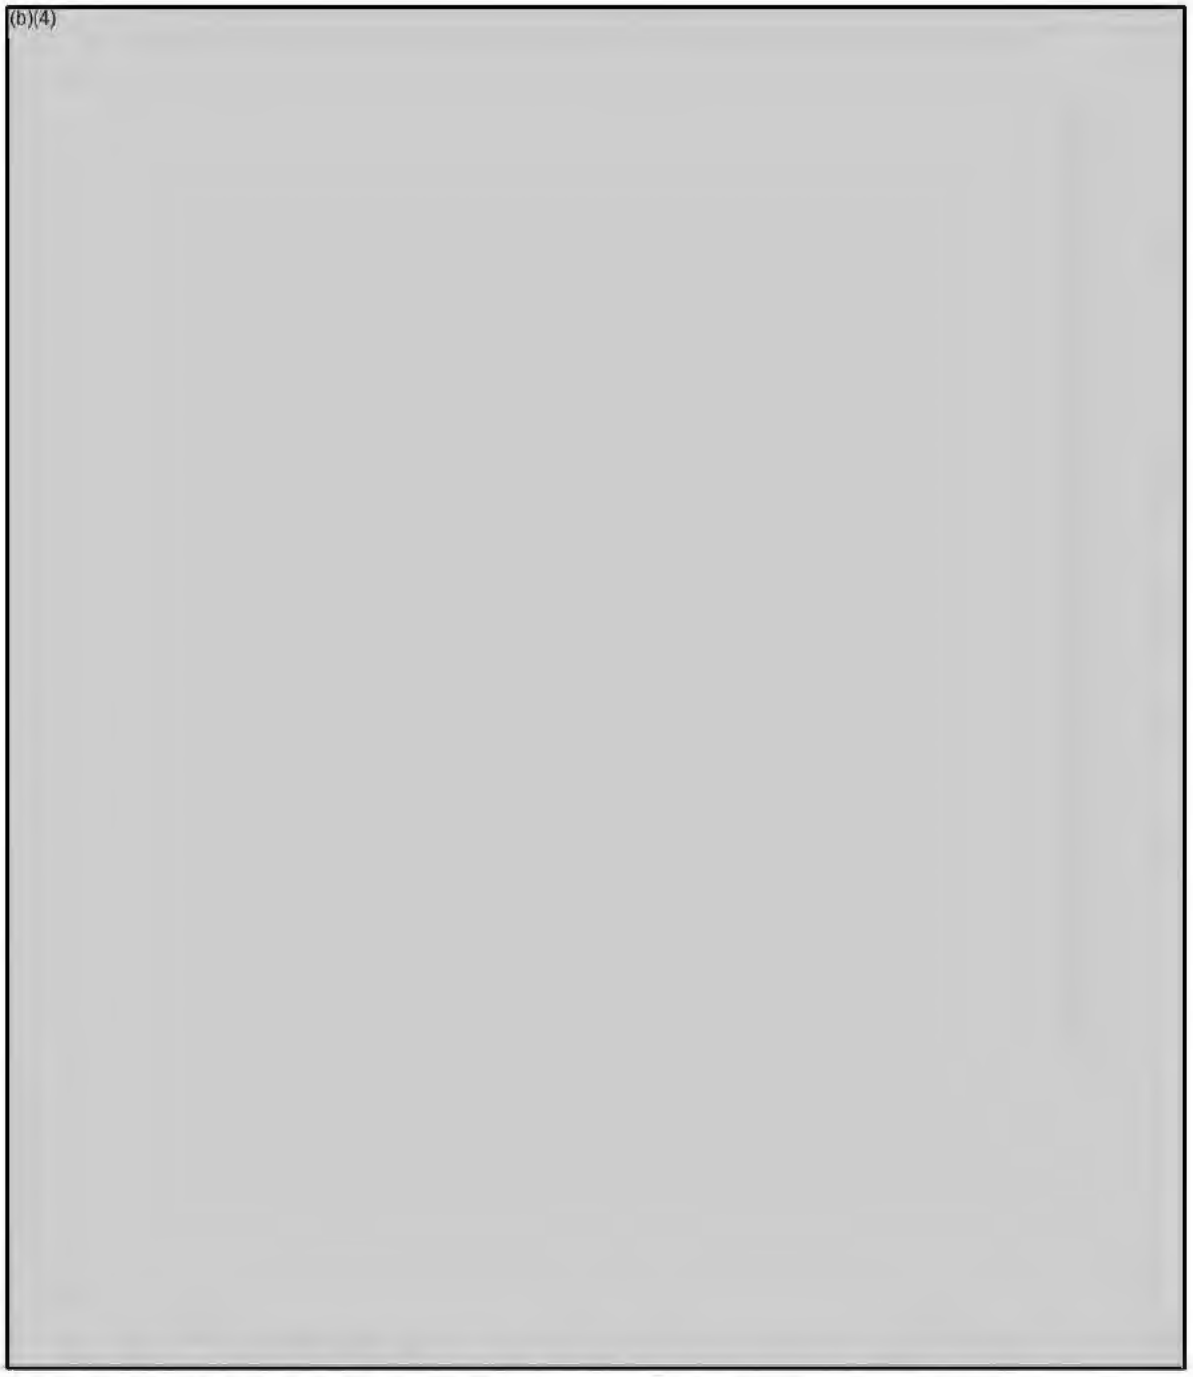
NIH RePorter – 1 grant, none overlapping
AltWeb – 1 article, none overlapping
BRD – 5 related grants, none overlapping

III. OBJECTIVE\HYPOTHESIS:

The overarching hypothesis under which these experiments are proposed is that the distress that leads to PTSD, and the sleep deprivation that is intrinsic to PTSD, promote the anger, hostility, aggression, and violence that are frequently comorbid with PTSD.

(b)(4)

(b)(4)



IV. **MILITARY RELEVANCE**: Irrational, angry attack stemming from PTSD presents an ever increasing danger to society and the patient as more and more troops return from Iraq and Afghanistan. The proposed experiments are intended to lay the ground work for clinical trials of pharmacotherapy for anger in PTSD.

V. MATERIALS AND METHODS:

V.1. Experimental Design and General Procedures:

V.1.1. Experiment 1: Testing Hypothesis 1 and 3.2.: (b)(4)

(b)(4)

Species: Rat – Fischer: 30 rats – unstressed group - Pain category C
Timeline:

- Animal arrives in LAM
- Animal remains in LAM at least one week prior to experiment
- Animal is anesthetized per V.4.1.2.1. Anesthesia/Analgesia/Tranquilization
- Animal is mounted in stereotax and electrodes lowered into place per V.4.3.2. Procedure: Experiment 1
- Electrophysiology and pharmacology are collected during a period of no more than 24 hours
- Animal is euthanized per section V.4.6. Euthanasia: and brain is saved for histology to confirm electrode positions.

Species: Rat – Fischer: 24 rats – Stressed group Pain category E – NOTE: These rats are stressed by, "social defeat" (Koolhaas *et al.*, 1997), that is, being attacked, in Experiments 2 and 3. Per V3.5 "Reduction", these rats are then to be taken after completion of Experiment 3 to complete Experiment 1.
Timeline: (Note: The following timeline may take place more than a year after the timeline just above, since Experiments 2 and 3 intervene.

- After Experiment 3 is completed, as described in section V.1.3. Experiment 3, the 24 Fischer rats are entered into Experiment 1, and electrophysiology is recorded from these rats under urethane anesthesia as follows:
- Animal is anesthetized per V.4.1.2.1. Anesthesia/Analgesia/Tranquilization
- Animal is mounted in stereotax and electrodes lowered into place per V.4.3.2. Procedure: Experiment 1

- Electrophysiology and pharmacology are collected during a period of no more than 24 hours
- Animal is euthanized per section V.4.6. Euthanasia: and brain is saved for histology to confirm electrode positions.

V.1.2. Experiment 2: Testing Hypothesis 2:

Behavior: For one (1) to two (2) months twenty four (24) male Long-Evans rats, 3 months of age or older, are to be housed four (4) to a large, 30"x24"x14" cage. These are to be the experimental animals. This group housing is meant to bring out the aggressiveness innate to male rats. During this period the experimenter will, by observation, hierarchically categorize these rats according to aggressiveness. Normal intermale aggression in rats functions to establish hierarchy and does not cause serious injury. Any rat that does not play by these rules will be removed from the experiment and either transferred to animal research protocol (b)(6) another USU rat protocol which does not entail interaction between rats, or euthanized.

Surgery: After the group housing period, Dr. (b)(6) will perform the electrode implantation in the CNRM Surgery (b)(6) as described in "V.4.3.2. Procedure: Experiment 2 and 3: Stereotaxic Surgery". Subsequent to implantation, the rat will be revived and taken care of as described in V.4.3.3. "Post-surgical Provisions. Behavior".

(b)(4)

(b)(4)

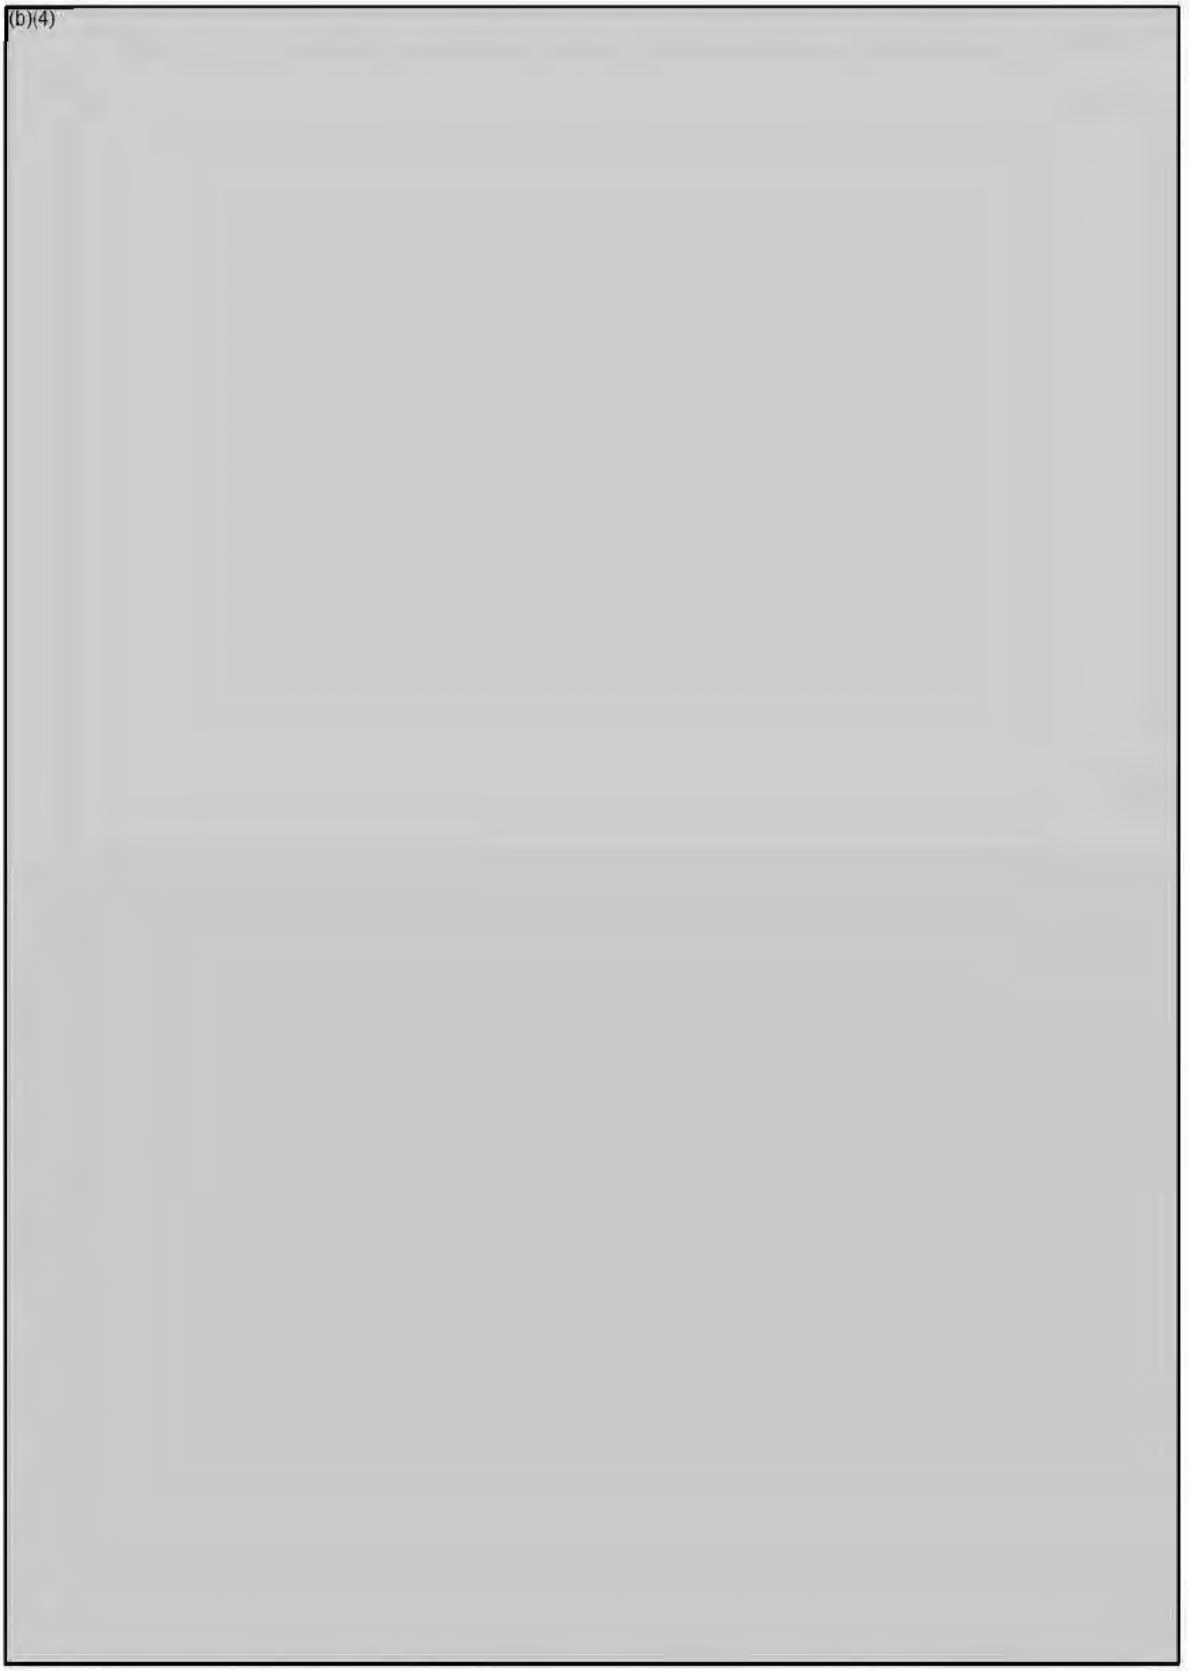
Electrophysiology: As described in V.4.3.2. Procedure: "Electrophysiology"

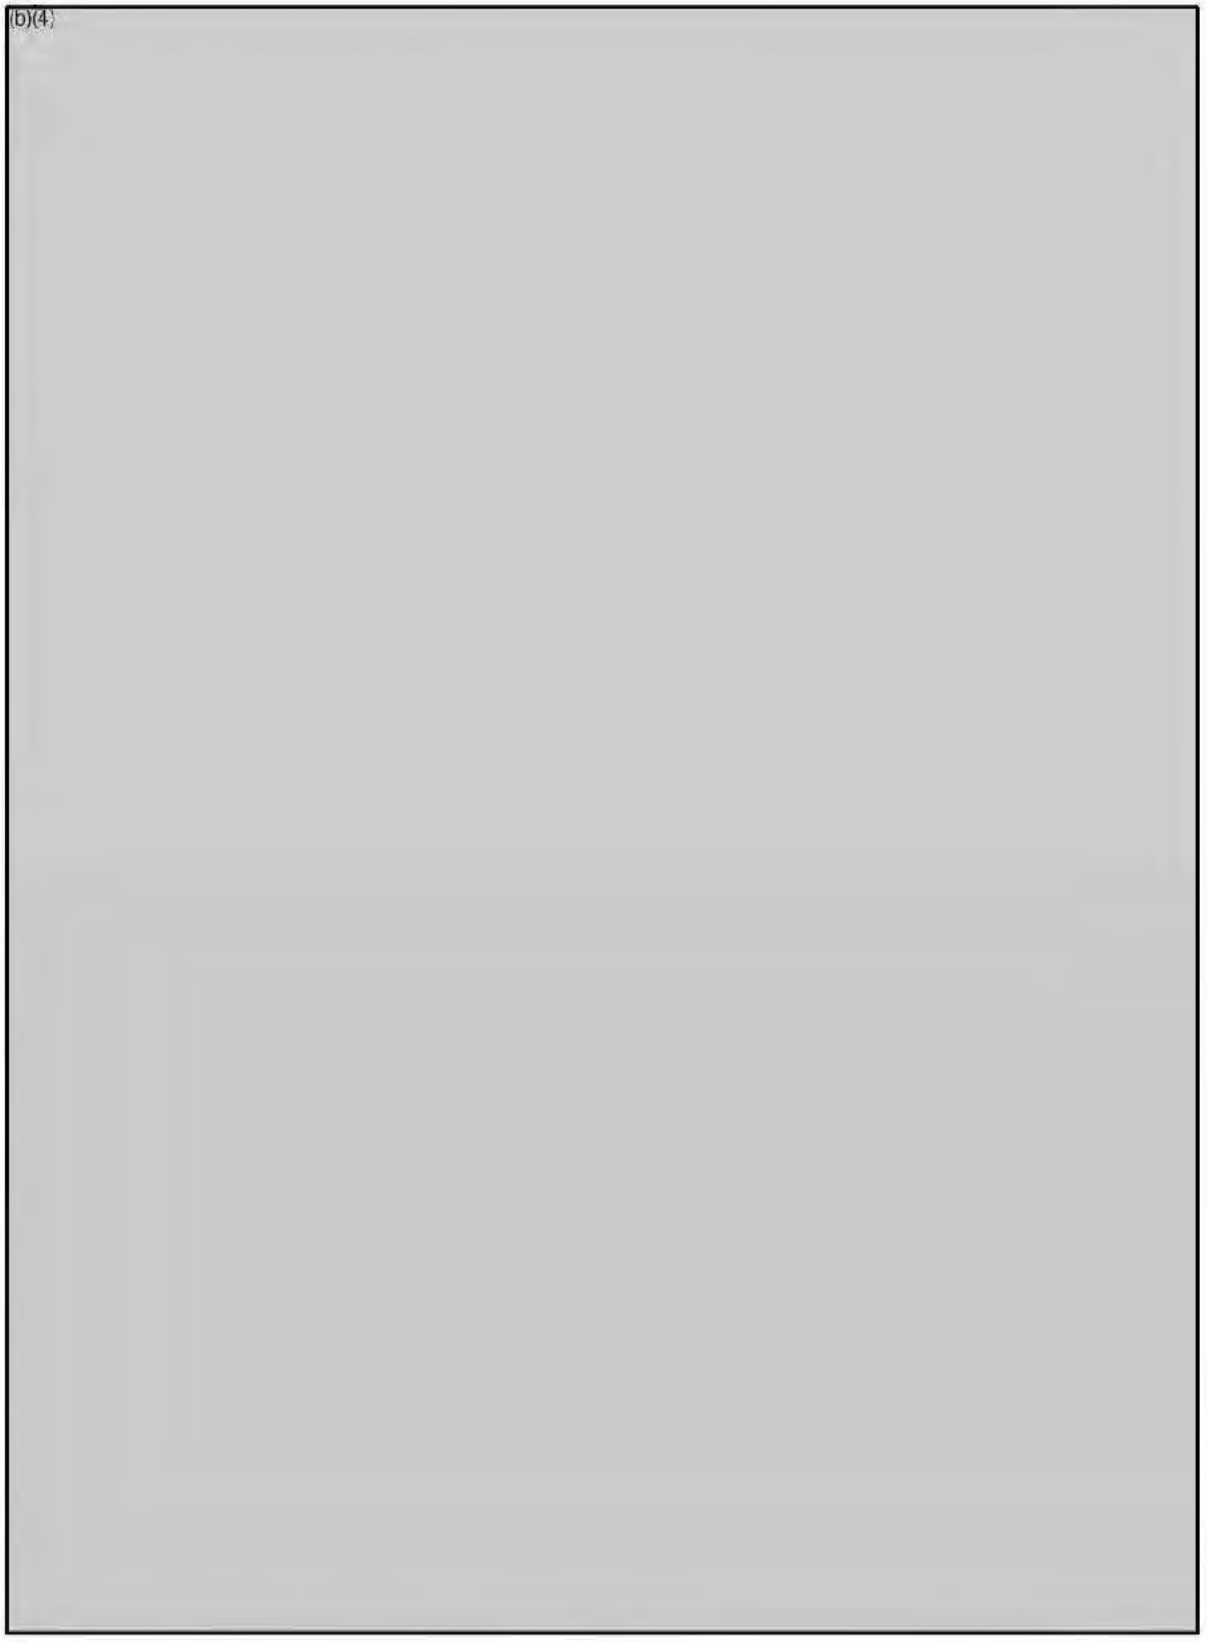
Species: Rat:

Pain Category	Number of rats
B	288 pups (24 litters of up to 12 pups each)
C	24 females
E	24 resident males; 24 intruder males already counted for in Exp 1

(b)(4)

(b)(4)





(b)(4)

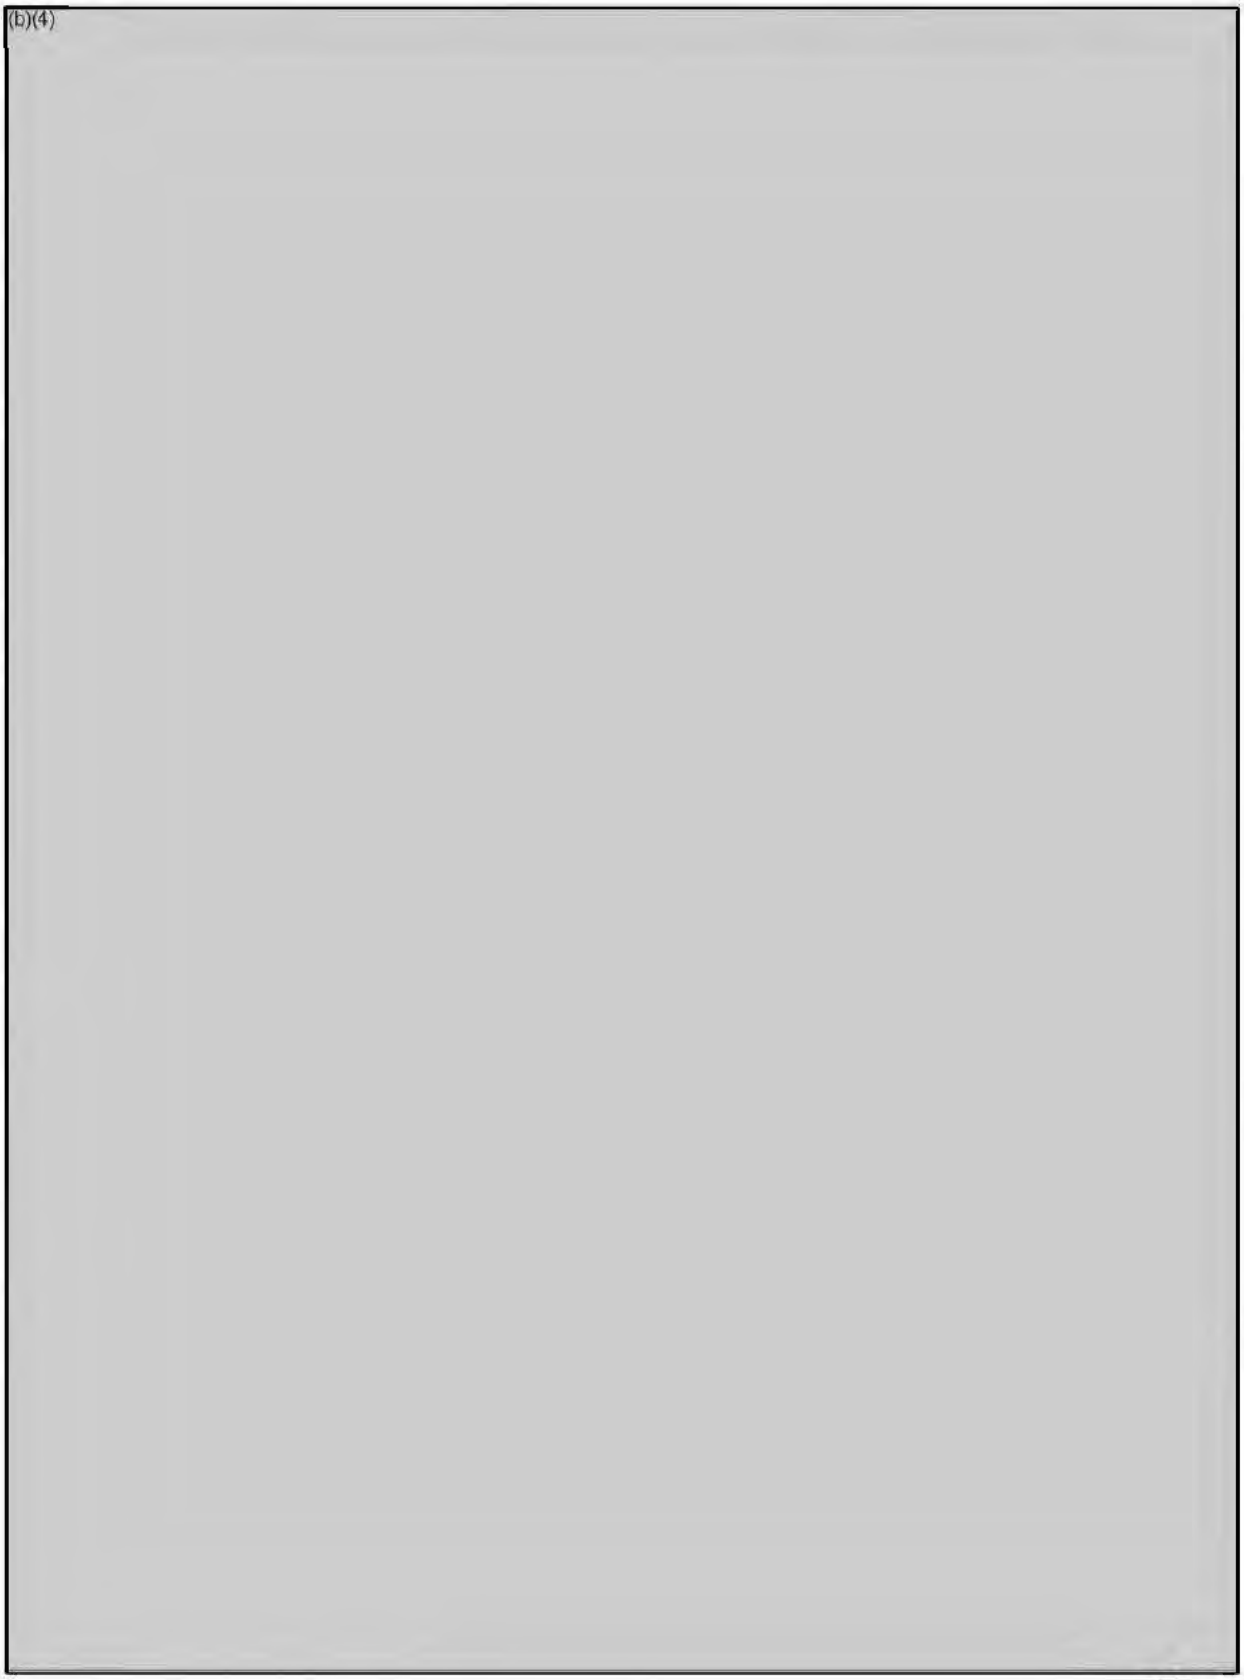
(b)(4)

Species: Rat:

Pain Category	Number of rats
B	288 pups (24 litters of up to 12 pups each)
C	24 females (same animals as in Experiment 2)
E	24 resident males; 24 intruder males, same animals as Experiment 2

(b)(4)

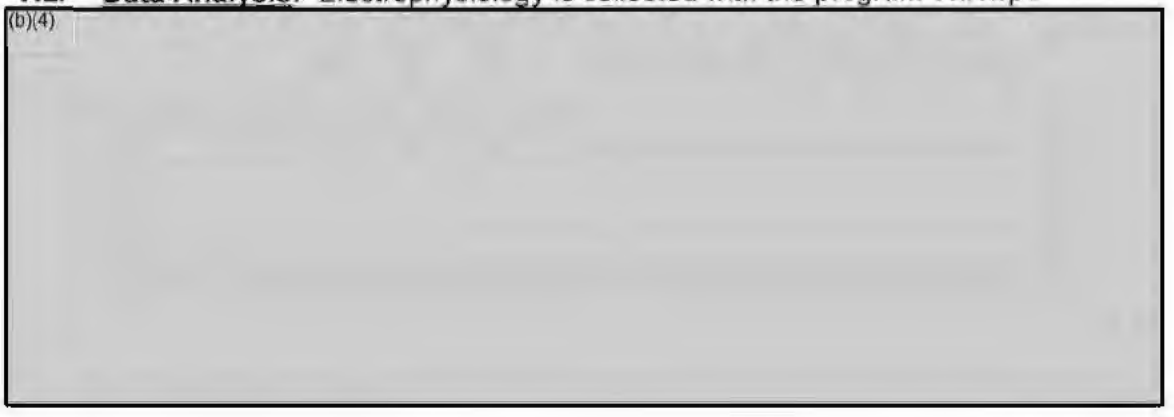
(b)(4)



(b)(4)

V.2. Data Analysis: Electrophysiology is collected with the program WINwpc

(b)(4)



(b)(4)

Power: Number (n) of rats required = 16 (b)(4) experimental) rats in Experiment 2 and 16 (b)(4) (experimental) rats in Experiment 3, for power (π). Since the concern is the rejection of the null hypothesis H_0: $\mu_{experimental} = \mu_{control}$, we take $\pi = 0.8$, where $\pi = \beta/\alpha$, β = risk of false negative = 0.2, α = risk of false positive = 0.05, and a meaningful difference (Δ) = 0.25. Within group standard deviation (σ) for the different parameters is expected to be within 0.5. From experience it all comes out to about sixteen (16) rats for each experiment, Experiment 2 and Experiment 3.

Eight (8) additional experimental rats per group to fill in for any technical failures, particularly since the standard deviation for coordinates in the rat brain is 400μ (Paxinos *et al.*,1985).

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered: Employing animals in this research is necessary to assess the effects of PTSD on brain anatomy and in vivo behavioral performance. These data will provide a means for relating behavioral responses to CNS structure and function in vivo. Non-animal alternatives do not replicate the three dimensional structure or temporal change that occur as a function of complex behavioral responses to tasks presented to a live animal. We can only do research in an animal model that displays anger and aggression.

V.3.2. Animal Model and Species Justification: The animal model is the rat (*Rattus norvegicus*), in our case the Long-Evans rat. The rat is the lowest animal in the phylogenetic scale which displays aggression relatable to human aggression and which has a basal forebrain in the pattern of the human basal forebrain. The rat, unlike the mouse, has a large enough brain in which to do the necessary multi-electrode evoked field potential electrophysiology.

V.3.3. Laboratory Animals

		Species #1	Species #2
V.3.3.1.	Genus & Species:	Rattus norvegicus	
V.3.3.2.	Strain/Stock:	Long Evans code 006 Fischer CDF code 002	
V.3.3.3.	Source/Vendor:	(b)(4)	
V.3.3.4.	Age:	Newborn - Juvenile – 3 years	
V.3.3.5.	Weight:	Newborn - 200g – 500g	
V.3.3.6.	Sex:	Male and Female	

V.3.3.7. **Special Considerations:** Colony cage < surgery.
Single cage > surgery
Male female pairing.
Wean pups

V.3.4. **Number of Animals Required (by Species):**

702 rats as follows:
Experiment 1: 54 Fischer rats. (30 of these Fischer rats are exclusively for Experiment 1. The remaining 24 Fischer rats, per V.3.5.2 Reduction, are to be used here in Experiment 1 after being used in Experiments 2 and 3.
Experiment 2: 24 Long-Evans male rats and 24 Long-Evans female rats. Plus up to 288 Long-Evans rat pups (24 liters of up to 12 pups each) to be delivered in the course of Experiments 2. (24 Fischer rats are already counted under Experiment 1.)
Experiment 3: 24 Long-Evans male rats. Plus up to 288 Long-Evans rat pups (24 liters of up to 12 pups each) to be delivered in the course of Experiments 3. (24 Fischer rats are already counted under Experiment 1. 24 Long-Evans female rats are already counted under experiment 2.)

V.3.5. **Refinement, Reduction, Replacement (3 Rs):**

V.3.5.1. **Refinement:** Animals are to be handled regularly so as to get use to the experimenter and thus minimize their stress

V.3.5.2. **Reduction:** The same female and intruder rats are used in Experiment 3 as in Experiment 2. The rat pups generated will be transferred to other protocols, when possible, rather than simply euthanized.

V.3.5.3. **Replacement:** N/A

V.4. **Technical Methods:**

V.4.1. **Pain / Distress Assessment:**

V.4.1.1. **APHIS Form 7023 Information:** N/A (APHIS Form 7023 does not list rats or mice.)

V.4.1.1.1. **Number of Animals:** Total: 702

	Species #1 Fischer	Species #2 Long-Evans
V.4.1.1.1.1. Column B:		576 (pups)
V.4.1.1.1.2 Column C:	30 (Exp.1)	24 (females in Exp 2,3)
V.4.1.1.1.3. Column D:		

V.4.1.1.1.4. Column E: 24 (Intruders) Total: 54 48 (Residents) Total: 648

V.4.1.2. Pain Relief / Prevention:

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization: Urethane (general, 1.4g/Kg given IP with a 23 gauge needle) and bupivacaine (Marcaine, local given with a 25 gauge needle) for acute recording (Experiment 1). Urethane will only be used as an anesthetic for the non-recovery electrophysiologic recording to be conducted in Experiment #1. Isoflurane (general) and bupivacaine (Marcaine, local) for electrode implants preparatory to behavior (Experiments 2 and 3). The NSAID Carprofen (Zenecarp) 5 mg/Kg SC BID will be given with a 25 gauge needle during the post-operative 24 hours as a routine procedure. Deep barbiturate anesthesia (Fatal Plus preparation of pentobarbital) prior to fixation perfusion for electrode confirmation histology. Induction of all anesthesia is with isoflurane.

Induction of anesthesia with isoflurane: All anesthesias are induced with isoflurane, as follows: The rat is placed in a an induction box connected to an isoflurane vaporizer ("Matrix VIP 3000", Midmark) mounted with oxygen. Isoflurane concentration is gradually raised to 4%. When a lack of righting reflex and a 50% reduction in respiratory rate are observed for at least 10 seconds, the next stage of anesthesia commences.

Isoflurane is suitable as a general anesthetic for chronic implant based experiments (Experiments 2 and 3) because the isoflurane has departed long before the experiment, and leaves no known residual effects. Isoflurane is not suitab e for acute experiments (Experiment 1) because isoflurane drastically depresses all central brain function. Urethane is standard for acute experiments because it preserves some central brain function at the same time as producing surgical anesthesia.

Urethane as a general anesthetic for electrophysiology: As early as 1917, urethane was already "well known" to be a "very uniform anesthetic" in animal experimentation (Stewart & Rogoff, 1917). Current policy statement, from the University of Florida, for instance, describes urethane in small animal experimentation, as follows: "Urethane is a long-lasting anesthetic acceptable for use in non-recovery animal experiments only. Urethane anesthesia is recommended for neurophysiological studies that require stable autonomic physiological status, reduced depression of brainstem neural activity and in animals breathing spontaneously free of a gas anesthesia circuit. Urethane also produces long lasting anesthesia with minimal cardiovascular and respiratory system depression. Studies in rodents have shown that urethane has a rapid onset after IP administration. Advantages of urethane anesthesia are that it produces excellent muscle relaxation and analgesia sufficient for surgical manipulations. ("Urethane Anesthesia Policy", University of Florida adopted 7/24/07.)

For the complete description of anesthesia procedure see V.4.3.2. "Procedure".

V.4.1.2.2. Pre- and Post-procedural (not surgery) Provisions: Animals will be housed in a climate controlled environment with free access to food and water, and will be maintained on a 12 hour reverse light/dark cycle between 20-26°C. Animals will be

acclimated for three days to the USUHS LAM. During acclimation to LAM, animals will be handled briefly each day to acclimate them to being handled; this will reduce any stress that might result from handling of the animals during the procedures described in this study. Following protocols, animals will be monitored according to LAM SOPs.

V.4.1.2.3. Paralytics: None

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures:

Painful procedure: Recovery subsequent to the electrode implant is understood to expose the animal to some pain. The pain is minimized by local anesthetics given prior to the surgery and by the NSAID Carprofen (Zenecarp) given postop. There is no way to record intracerebral electric field potentials in the absence of surgical implantation of electrodes. The surgery as described meets LAM and IACUC guidelines.

Distressful procedure: The very nature of the experiment is to study stress. Restrain/tail-shock repeated on each of three days is a fundamental procedure in stress, particularly PTSD, research. Alternatives in the literature such as fox odor and one day stress do not yield a prolonged stress response indicative of PTSD.

V.4.1.3.1. Sources Searched: PubMed, entire database; AGRICOLA, entire database; NIH RePorter, entire database; AltWeb, entire database; DoD Biomedical Research Database (BRD) entire database.

V.4.1.3.2. Date of Search: February 8, 2015

V.4.1.3.3. Period of Search: No limit

V.4.1.3.4. Key Words of Search: (b)(4)

V.4.1.3.5. Results of Search: Eighteen (18) journal articles, 1 relevant, none overlapping.

Literature search to check for possible new alternatives to painful and distressing procedure: The surgery as described meets LAM and IACUC guidelines. Restrain/tail-shock repeated on each of three days is a fundamental procedure in stress, particularly PTSD, research. Alternatives in the literature such as fox odor and one day stress do not yield a prolonged stress response indicative of PTSD.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification:
We stress the rats for three consecutive days because it has been previously demonstrated that repeated stress sessions for three days are more effective than a single stress session in producing physiological and behavioral abnormalities, such as elevations in basal plasma corticosterone levels, exaggerated acoustic startle responses and reduced body weight (Servatius *et al.*, 1995). Additional exposures to stress do not appear to result in greater physiological and behavioral changes (Servatius *et al.*, 1995). Other types of stressors appropriate for an animal model (e.g. restraints only) are not easily quantifiable and have resulted in at least partial habituation rather than chronic stress. Given these considerations, we feel that the painful procedure is justified.

V.4.2. Prolonged Restraint: In Experiment 3 prolonged restraint will be conducted per IAW IACUC Policy 004 "Prolonged Restraint". All animals are monitored during the two hours when tail shocks are being administered to assure that they do not get into positions that do not allow them to breath properly.

V.4.3. Surgery:

V.4.3.1. Pre-surgical Provisions: None special. Rats do not vomit.

V.4.3.2. Procedure:

Experiment 1: Aseptic technique using 70% ethanol as described and justified under "Experiment 2 and 3: Stereotaxic surgery" immediately below, is to be employed. In the Center for Neuroscience and Regenerative Medicine (CNRM) Surgery (b)(6) the Fischer rat is placed in an induction box connected to an isoflurane vaporizer ("Matrix VIP 3000", Midmark) mounted with oxygen tank and isoflurane scavenger. Isoflurane concentration is gradually raised to 4%. When a lack of righting reflex and a 50% reduction in respiratory rate are observed for at least 10 seconds, the rat is removed from the box and given the IP injection urethane (1.4g/Kg in water). Urethane is an effective long duration anesthetic for experiments with rats (see Section V.4.1.2.1. "Anesthesia/Analgesia/Tranquilization") The rat is maintained on 100% oxygen for half an hour to allow time for the isoflurane to depart from the blood and fat stores since the animal may become hypoxic if left to breath plain room air. During that half hour the urethane anesthesia takes effect, which is confirmed by the absence of the pedal withdrawal reflex to pinch of the foot web. To block subsequent pain from the ear bars in the stereotax, bupivacaine (0.25%, 0.2 mL) is then injected at the anterior bulla (by following the zygomatic arch to its posterior base) and posterior bulla (palpated by the mastoid process), bilaterally. Bupivacaine (0.25%, 0.4 mL) is further injected along the scalp midline subcutaneous to the incision site prior to the incision. The rat is placed on a heating pad and temperature maintained at 37^{O}C referenced to a rectal thermometer. The rat is then mounted in the stereotax for surgery and electrode implant. Breathing rate is monitored. Increase in rate of breathing or any movement is responded to with incremental IP injections of urethane (0.1g/Kg). (b)(4)

(b)(4)

(b)(4)

Experiment 2 and 3:

Stereotaxic surgery: Stereotaxic surgery, largely following Valenstein *et al.* (1961) will be performed in the CNRM Surgery (b)(6) using aseptic technique, including surgical prep, sterile glove, sterile instruments. All surgical instruments and implantation articles - including electrodes, stainless steel screws, socket, and crimp tube - will be disinfected in 70% ethanol for 20 minutes. "Ethanol is rapidly bactericidal and fungicidal against vegetative organism. While killing spores requires a prolonged contact time, spore forming organisms only rarely cause post procedural infections, at least in humans." (Cooper *et al.* 2000). Thus, "alcohol, because of its convenience, low cost, and lack of antisepsis-associated drawbacks specifically in rats and mice, has an appropriate role in the preparation of surgical instruments for survival surgery in these species." (Huerkamp, 2002). Ethanol kills bacteria by coagulation of protein and is generally used as a 70% solution (Mitchell & Berg, page 161). The dental acrylic used for holding the implantation is sterilized by the methyl methacrylate that cures it. The stereotax will be scrubbed clean and wrapped in gauze saturated with 70% ethanol for twenty minutes prior to surgery. Cottonoid and gelfoam will be from sterile packets. Wound closure will be with wound clips, sterilized.

Long-Evans male rats (300g+) will be anesthetized with isoflurane. The rat is placed in an induction box connected to an isoflurane vaporizer ("Matrix VIP 3000", Midmark) mounted with oxygen. Isoflurane concentration is gradually raised to 4%. When a lack of righting reflex and a 50% reduction in respiratory rate are observed for at least 10 seconds the rat is removed from the isoflurane box, bupivacaine nerve blocks are applied as described in section "V.4.3.2. Procedure: Experiment 1", and the rat is replaced in the isoflurane box. Once the rat is deeply anesthetized, as judged by an absence of the pedal withdrawal reflex to a hard pinch of the foot web, the rat will be placed in a David Kopf stereotaxic apparatus, where isoflurane anesthesia is maintained at 1% through a mask that is integral to the stereotax. Any skeletomotor movement during surgery will be interpreted as response to pain; surgery will be temporarily halted, and the isoflurane concentration will be raised to 2% until response to paw web pinch ceases. A 0.5-1.0 mm hole will be drilled in the skull over each of the brain nuclei to be stimulated or recorded – five (5) holes all together. (b)(4)

(b)(4)

(b)(4) The scalp

wound will be closed around the dental acrylic using stainless steel wound clips as necessary. (b)(4)

(b)(4)

(b)(4) Finally the isoflurane anesthesia is discontinued and the rat is removed from the stereotax and returned to the anesthesia box to be maintained on 100% oxygen for half an hour. Isoflurane departing the blood into the alveoli during that half hour could render the animal hypoxic if left to breath plain room air. The rat is singly housed during recovery for one week post surgery.

(b)(4)

Recovery: See V.4.3.3. Post-surgical Provisions

Electrophysiology: Electrophysiology will be done in the (b)(6) laboratory. The rat will be

(b)(4)

(b)(4)

Histology: Following completion of Experiments 1 and 3, the rat will be anesthetized with pentobarbital (Fatal Plus preparation;100 mg/Kg, IP; Petty C., Research Techniques in the Rat, C. Thomas, Springfield IL, p. 7 provides 3 hours of anesthesia. The pentobarbital sodium will be stored in a locked cabinet bolted to the wall in (b)(6) per DEA regulation.) After deep anesthesia is verified by absence of pedal withdrawal to hard pinch of the foot web, the position of each stainless steel recording electrode is marked with an iron deposit by connecting the positive terminal of an ordinary 9V battery to the electrode and completing a circuit by connecting the negative terminal to the skull screw that serves as the reference electrode. Iron atoms (Fe^{++} and Fe^{+++}), by virtue of their charge, will move away from the electrode and into the immediate vicinity of the tissue. By Ohm's Law, V = RI, where V = voltage = 9V and R = resistance = 9 Kohm, I = current = 1mA. The sternum will then be transected sagittally, the thorax retracted, the right atrium cut to pass out fluid, and the rat will be perfused with formaldehyde containing potassium hexacyanoferrate(II) to turn the iron deposit blue via a syringe connected to an 18 gauge needle puncturing the left ventricle. Then the brain is removed and sectioned to confirm location of the blue deposit marking the position of the electrode tips. (The nichrome stimulating electrodes, which do not contain iron, are located by the impression these leave in the formaldehyde fixed tissue.)

V.4.3.3. Post-surgical Provisions:
Recovery (Experiment 2 and 3): Following surgery, animals will be kept warm and observed until conscious. Bupivacaine nerve block of the skin and fascia should last several hours. Incisions in periosteum and dura are not known to produce protracted pain. The skull and the brain do not have pain innervation. The implanted rat will be housed singly for a week of recovery. Paper chip bedding will be requested to minimize chance of wound infection. The NSAID Caprofen (Zenecarp) 5 mg/Kg SC BID will be given with a 25 gauge needle during the post-operative 24 hours as a routine procedure. There will be a follow-up evaluation of the need for analgesia again the next day, with further dosing provided if the rat does not show normal locomotor activity and appetite. This regimen is particularly effective for incisional and musculoskeletal pain (Mook D. (2005) . Thereafter the rat will be monitored at least twice daily (at least once during their dark - active - period). Infection, though unlikely, will be monitored by inspection of the implant site and be addressed by requesting appropriate antibiotics from LAM. Rats that do not move normally and eat by two days post surgery will be euthanized. Otherwise, one week will be allowed for recovery prior to proceeding with the experimental protocol.

V.4.3.4. Location: (b)(6) (CNRM Surgery)

V.4.3.5. Surgeon: Dr. (b)(6)

V.4.3.6. Multiple Major Survival Operative Procedures: N/A

V.4.3.6.1. **Procedures**: N/A

V.4.3.6.2. **Scientific Justification**: N/A

V.4.4. **Animal Manipulations**:

V.4.4.1. **Injections**: Urethane for anesthesia (Section 4.3.2), bupivacaine for nerve block analgesia (Section 4.3.1), Caprofen post-surgical analgesia (Section V4.3.3)., pentobarbital (Fatal Plus) for histology perfusion (Section 4.3.2 – Histology), prazosin (0.1mg/Kg IP in water), paroxetine (1 mg/Kg IP in water).

V.4.4.2. **Biosamples**: Formaldehyde fixed brain slices for histologic verification of electrode position, as described in Section 4.3.2 – Histology.

V.4.4.3. **Adjuvants**: None

V.4.4.4. **Monoclonal Antibody (MAbs) Production**: N/A

V.4.4.5. **Animal Identification**: Ear punch (B.Y.T. Co, MI), "Sharpie" permanent marker on tail, and cage card.

V.4.4.6. **Behavioral Studies**:

Stress exposure consists of a two-hour per day session of immobilization (restraint) and tail-shocks, for three consecutive days. Each animal is restrained in a Plexiglas tube and an electrode is attached to the tail. Forty electric shocks (2 mA, 3 s duration) are applied at varying intervals (140 to 180 s) over a two hour period; then the rats are returned to their cages. Exposure to this three day stress regimen has been shown to be more effective than a single stress session in producing lasting physiological and behavioral abnormalities, such as elevations in basal plasma corticosterone levels, exaggerated acoustic startle responses and reduced body weight (Servatius et al., 1995).

The Plexiglas restraint tubes used in administration of the stress protocol are designed to accommodate animals of a specified size range. If an animal is near the lower end of the size range, there will be slightly more room for it to move in response to the shock and possibly twist itself into a position that will not allow it to breathe properly. The technician who monitors the stress protocol can release the adjustable end of the restraint tube slightly to allow the animal to return to a position that does not impair breathing, then retighten it. Animals of the size specified in this protocol (~250 gm) do not usually exhibit severe reactions to the stress protocol. If the animals have been handled when they first arrive in USUHS animal facility, they generally do not resist being put into the restraint tubes. If animals were to exhibit symptoms of extreme respiratory distress or damage to the tail resulting from the electric shocks during the stress procedure or if any animals would lose more than 20% of their initial body weight as a result of exposure to the stress protocol, they would be withdrawn from the study and euthanized.

Electrodes will be attached to the tail of the animal by means of a spring clip in order to minimize any painful irritation that might result from repeated taping of the tail. All

animals are monitored during the two hours when tail shocks are being administered to assure that they do not get into positions that do not allow them to breathe properly.

Animals will be monitored daily by Dr (b)(6) and LAM staff after stress sessions. The stress protocol results in a decrease of eating for a few days, during which time the rat may lose body weight, and later regain it. (Jia, Smerin,..,Li, 2014, "Corticosterone mitigates the stress response in an animal model of PTSD", *J. Psychiatric Res.* 60:29). Beyond that small loss in weight, laboratory rats normally plateau in weight at about the fourth month of age, the same time that the experiments begin, and at least maintain that weight for the next two years. Thus the loss of 20% of body weight over any period is grossly abnormal and indicative of extreme dysfunction. Whether that dysfunction is an eating disorder or other metabolic disorder is beyond the scope of this protocol or experiment to deal with. Therefore we propose euthanizing the rat in response to this criterion. Therefore, any animal that would lose >20% of its body weight as measured on Day -1 would be withdrawn from the study and euthanized per Section V.4.6. Euthanasia.

The shock administered to the tails of the animals is 2 mA in intensity for a duration of 3 seconds. The animals typically jump and cry out during the duration of the shock and struggle to get away from it. As soon as the shock concludes, the animals lie quietly until the next shock. Four to six animals are shocked at one time (in individual tubes with a single electrode attached to each animal's tail). The size of the animals can vary by as much as 20 gm, while the restraint tubes are rigid and fixed. An animal that is slightly smaller than the ideal weight for which the tubes are designed can sometimes move into a position where its ability to breathe is compromised; if the animal is not being monitored by a technician who can release the end of the tube and allow it to right itself, then retighten the end of the tube, the animal can expire. Rats of the size listed for this protocol usually do not exhibit this difficulty, but will be monitored during the administration of the stress protocol. The electrodes are attached to the tail with a spring clip to prevent irritation of the tail by removal of adhesive stripes each day for three days and to minimize the possibility of infection through a break in the skin on the tail. We have not observed damage to the tail (i.e. burning of the tail) resulting from contact with the electrode during the shocks. Criteria for early termination of the shock experiments would include (1) signs of infection due to a break in the tail skin; (2)severe irritation or burning of the tail resulting from contact with the electrode during administration of the shocks; (3) loss of >20% of body weight as measured on Day -1 before administration of the stress protocol (Note that rats have been consistently observed to lose weight following exposure to stress, but never >20% of their body weight prior to administration of the stress protocol); and (4)observation of pain or infection in the animals that are housed for 30 days after the final stress session. Any animals that must be removed from the study will be given to LAM personnel for euthanization as described in Section V.4.6.

After each use, the restraint tubes are washed in Alconox detergent solution and allowed to air dry and the electrodes are wiped with 95% ethanol.

(b)(4)

(b)(4),(b)(6)

V.4.4.7. Other Procedures:

V.4.4.8. Tissue Sharing: Once the brain of the formaldehyde perfused animal is removed for histologic verification of electrode tracks, all other tissues are available. This availability will be broadcast at USUHS by word of mouth to LAM personnel and other colleagues.

V.4.5. Study Endpoint:
Experiment 1: Recordings under anesthesia are expected to be completed within the first year. Each individual rat is ordered to arrive at about one month of age and be used during the following two months. Each recording lasts less than 24 hours, after which the rat is euthanized as described in Section V.4.3.2 – Histology.
Experiment 2 : Experiment 2 is expected to begin during the first year and conclude at the end of the second year, at which time the resident rats will be euthanized for histology. The female and intruder rats will go forward into Experiment 3.
Experiment 3: Experiment 3 is expected to begin during year 2 and conclude at the end of year 3, at which time the resident rats will be euthanized for histology of electrode positions, the intruder rats will be utilized in the Experiment 1 paradigm, and the females, now three years old, will be euthanized.
V.4.6. Euthanasia: For histology, the experiment calls for deep pentobarbital (Fatal Plus preparation) anesthesia followed by vascular perfusion (Section 4.3.2. - Histology). Rats that require euthanasia because of illness (V.4.3.3. Post-surgical Provisions; V.4.4.6.Behavioral Studies: Stress exposure) will be deeply anesthetized with isoflurane by the experimenter until the pedal withdrawal reflex to foot web pinch is absent and then decapitated with a rat guillotine. When euthanasia is requested by LAM technicians, they will follow LAM protocol which consists of carbon dioxide asphyxiation followed by a secondary method (i.e. cervical dislocation, bilateral thoracotomy).

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol. Upon arrival, animals will be housed two (2) to a cage. Post surgery, rats will be housed one (1) to a cage for one week of recovery. For two (2) weeks to one (1) month, a male and a female are to cohabit in a large cage, possibly with pups, as described in Section V.1.2.Experiment 2: Testing Hypothesis 2: Behavior.

V.5.1.1. Study Room:
Building(s) USUHS (b)(6) Room Number(s) (b)(6)

V.5.1.2. **Special Husbandry Provisions**:

Food Restriction:	Yes	_____	No	X
Fluid Restriction:	Yes		No	X
V.5.1.3. **Exceptions**:		_____		X

V.5.2. **Veterinary Medical Care**:

V.5.2.1. **Routine Veterinary Medical Care**: Animals will be monitored for health, humane treatment, and husbandry considerations, twice daily by LAM personnel during routine weekday rounds and at least once daily on weekends/holidays. This is in addition to, and not in place of, the monitoring that is done by the PI and their staff. In the event of a debilitating illness or adverse reaction, the decision to treat or euthanize an animal will be made by either the veterinarian and/ or the PI.

V.5.2.2. **Emergency Veterinary Medical Care**: All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays.

V.5.3. **Environmental Enrichment**:

V.5.3.1. **Enrichment Strategy**: Except as indicated below, all animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents; balls, toys and food enrichment treats for large animal species.

V.5.3.2. **Enrichment Restrictions**: None

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience	Specific training in this activity or procedure
(b)(4)	(b)(6)	Coinvestigator20yrs	In lab; USUHS PI training course, June 2010
		Coinvestigator20yrs	In lab
		Coinvestigator25yrs Coinvestigator 5yrs	Walter Reed In lab
Restraint/Tail Shock		PI – 15 years	Colburn (Manufacturer); USUHS PI training

			course, May 2007

Dr (b)(6) Dr. (b)(6) and Dr (b)(6) will not be involved in the hands-on animal manipulations. Any new research associates or graduate students who rotate through the laboratory will be added to the protocol by request for and approval of a minor modification to this protocol before being permitted to do any animal procedures.

VII. BIOHAZARDS/SAFETY: To minimize exposure to animal allergens when working with animals, lab personnel will wear lab coats and/or scrubs, gloves and masks.

VIII. ENCLOSURES: References

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Cour (b)(6)

I. **Painful Procedure(s):**

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL** or **WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

(b)(6) [redacted] 2-11-15

Principal Investigator Signature Date

X. PROTOCOL ABSTRACT:

A. Animal Protocol Number: Pending

B. Animal Protocol Title: Neurophysiology of Escalation of Aggression in a Rat Model of PTSD

C. Principal Investigator: (b)(6)

D. Performing Organization: USUHS

E. Funding: Dept of Defense/USUHS - O/M funds

F. Objective and Approach: Objective is to elucidate the neurophysiology of stress promoted anger and aggression, particularly in PTSD, and lay the groundwork for future pharmacotherapy. The approach is to measure the escalation of aggression in rats subjected to restrain/tail shock and sleep deprivation, the two of which of which correspond to the stress and sleep disorder of PTSD. Potentiation of synaptic field potentials recorded from nuclei in the basal forebrain during escalation of aggression indicate which nuclei are involved. Serotonin and norepinephrine pharmica are tested for efficacy in diminishing the potentiation in the synaptic field potentials and mitigating the escalation of aggression.

G. Indexing Terms (Descriptors): PTSD, aggression, anger, social defeat, bullying, anxiety, panic, basal forebrain, amygdala, BNST, hippocampus, prefrontal cortex, serotonin norepinephrine, corticotrophin releasing factor, CRF, long-term potentiation, LTP, short term potentiation, STP
