November 6, 2014

MEMORANDUM FOR DR (b)(6)
(b)(6)

SUBJECT: IACUC Approval of Protocol – Initial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on November 6, 2014:

Animal Protocol Title: (b)(4)
(b)(4)

USUHS Protocol Number: (b)(6)

Expiration Date: November 5, 2017

Supporting Grant(s) Number: TBD

Name of Principal Investigator: Dr (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is (b)(6) The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet your needs.

I. NON-TECHNICAL SYNOPSIS:

The proper regulation of the hypothalamic-pituitary-adrenal (HPA) axis is important for optimum physiological function and survivability of an individual (b)(4) (b)(4) Not only does the HPA axis control hormonal responses to stress, but its activity also synchronizes physiological systems with environmental cues and rhythms. When the HPA axis does not function appropriately and circulating glucocorticoid levels are inappropriate during the day, there is a correlation with the development of numerous physiological and psychological disorders. These include metabolic disruption, cardiovascular disease, immunological variations, sleep/wake inefficiencies (including reduced performance in operational environments), neuropsychiatric disease, neurodegenerative diseases and putative increased cancer risks. *These are all areas of significant concern within the military community.* The goal of this study is to examine how circadian disruption alters the HPA axis. Specifically, we are interested in determining the fundamental changes that occur in the stress axis regulation. Despite known correlations, work environments both in the civilian world as well as in the military does not always allow for the optimal diurnal schedules. This study will tell us how changes to the daily circadian schedule may potentially have impact on the stress physiological systems.

II. BACKGROUND:

II.1. Background:

(b)(4)

(b)(4)

(b)(4)

II.2. Literature Search for Duplication:

II.2.1. Literature Source(s) Searched:

- PubMed
- Biomedical Research Database (BRD)
- RePORTER – The replacement for CRISP is the RePORTER (http://projectreporter.nih.gov/reporter.cfm)

II.2.2. Date of Search:

October 6, 2014

II.2.3. Period of Search:
No Period Restriction

II.2.4. Key Words and Search Strategy:
(b)(4)

II.2.5. Results of Search:

There are over 4000 papers that study the interaction of the stress system and the circadian system (context of rhythm or disruption) going back to 1966. Many of these studies focus on the autonomic system and the response of peripheral organs to stress during circadian shifts or changes. With the identification of CLOCK genes, many of these studies switch their focus on how stress may alter CLOCK genes in brain and periphery. (b)(4)

(b)(4)

The conclusion of our literature search are: a. this is a unique approach and b. these approaches will significantly advance our understanding of the (b)(4) neuronal biology and thus, by default our understanding of the stress system.

A similar conclusion is made from a review of Biomedical Research Database (BRD) and the RePORTER.

(b)(4)

In the NIH RePORTER, a search was conducted in all dates (from 1990 onward) and search terms included title, abstract and terms. There were 163 "hits" representing approximately 50 funded grants. All these studies examine stress in context of hormonal response (b)(4)

III. OBJECTIVE\HYPOTHESIS:

(b)(4)

IV. MILITARY RELEVANCE:

When the (b)(4) does not function appropriately and circulating (b)(4) are inappropriate in amplitude or timing, the development of numerous physiological and psychological disorders is facilitated. These include metabolic disruption, cardiovascular disease, immunological variations, sleep/wake inefficiencies (including reduced performance in operational environments), neuropsychiatric disease, neurodegenerative diseases and putative increased cancer risks. *These are all areas of significant concern within the military community.*

V. MATERIALS AND METHODS:

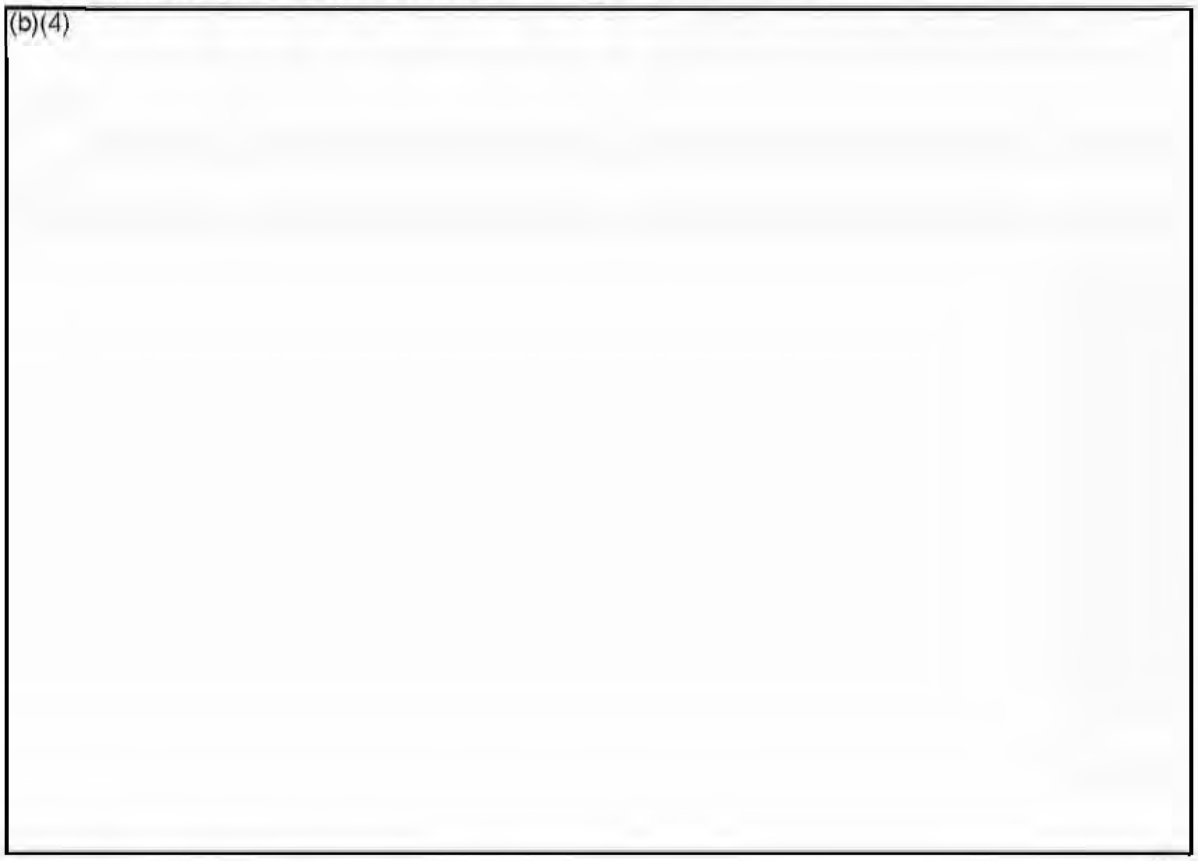
V.1. Experimental Design and General Procedures:

(b)(4)

(b)(4)

To reduce the number of mice used, Experiment 1 will have 2 parts, Exp 1a and Exp 1b; Exp 1a will only examine the 4 week time point. Exp 1b will follow up on the initial examination of global gene expression in Exp 1a.

(b)(4)



(b)(4)

(b)(4)

V.2. Data Analysis:

In Exp 1a, we base our numbers estimated from (b)(4) and from Dr. (b)(6) (b)(6) experiment running RNASeq experiments to examine global gene expression.

For (b)(4) the number of animals per group is based on a culmination of ours and others' previous studies. Group size is determined using a statistical package, SPSS with an alpha = 0.05. A two tailed test with an (b)(4) will give a power of 0.8 to detect differences between group means of 1.33 standard deviations or greater. The differences of this magnitude has been shown in previous studies in response to dexamethasone suppression test and to restraint stress. The data collected for both experiments will be analyzed with the appropriate ANOVA followed by Fishers' LSD post-hoc test.

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered:

This aspect of the study involves whole animals since there are no known current cell models or computer models to (b)(4) (b)(4)

V.3.2. Animal Model and Species Justification:

(b)(4)

(b)(4)

V.3.3. Laboratory Animals

	Species #1	Species #2
V.3.3.1. Genus & Species:	Mice	Mice
V.3.3.2. Strain/Stock:	(b)(4)	
V.3.3.3. Source/Vendor:		
V.3.3.4. Age:	2 – 8 months	2 – 8 months
V.3.3.5. Weight:	20-45 g	20-45 g
V.3.3.6. Sex:	**Male**	**Male**
V.3.3.7. Special Considerations:		

V.3.4. Number of Animals Required (by Species): (b)(4)

	Species #3	Species #4
V.3.3.1. Genus & Species:	Mice	Mice
V.3.3.2. Strain/Stock:	(b)(4)	
V.3.3.3. Source/Vendor:		
V.3.3.4. Age:	2 – 8 months	2 – 8 months
V.3.3.5. Weight:	20-45 g	20-45 g
V.3.3.6. Sex:	**Female**	**Female**

V.3.3.7. Special Considerations:

V.3.4. Number of Animals Required (by Species): (b)(4)

V.3.5. Refinement, Reduction, Replacement (3 Rs):

V.3.5.1. Refinement: Mice will be handled at least 3-4 times a week to reduce stress during experimentation. In addition, mice will be handled at approximately the same time each day. For terminal experiments, the mice will be anesthetized prior to euthanizing. Refinements considered but not used: adjusted early end-point, unless the animals become ill. Under that circumstance, the animals will be euthanized. The decision to euthanize the sick mouse will be in consultation with the PI and the Veterinarian.

(b)(4)

V.3.5.2. Reduction: In experiment 1, we designed the experiment into 2 parts to significantly reduce the number of mice used. If we utilize the original 2X2X2X2X3 (48 total treatment groups), we will utilize a total of (b)(4) mice. By designing the experiment into 2 parts, we reduced the numbers to (b)(4) In addition, we will conduct the studies using a latin square design where once statistical difference is achieved, we can stop the experiment. This allows us to use the minimum number of mice possible to still be statistically significant. In addition, every effort has also been made to use every tissue part for the current and other studies without compromising the integrity of the experimental design and for not compromising data analysis. We will not use any more animals than needed.

V.3.5.3. Replacement: At this time, it is not possible yet to study the impact of the the environment on the animal's stress axis. It is possible that in the future, when more information has been garnered, that we would be able to test behavioral responses, endocrine responses or other physiological responses using computer modeling.

V.4. Technical Methods:

V.4.1. Pain / Distress Assessment:

V.4.1.1. **APHIS Form 7023 Information:**

V.4.1.1.1. **Number of Animals:**

	Species #1	Species #2	Species #3	Species #3
V.4.1.1.1.1. **Column C:**	(b)(4)			
V.4.1.1.1.2. **Column D:**				
V.4.1.1.1.3. **Column E:**				

V.4.1.2. **Pain Relief / Prevention:**

V.4.1.2.1. **Anesthesia/Analgesia/Tranquilization:**
Carbon dioxide (for deep anesthesia).
The mice will be deeply anesthetized by CO_2 prior to decapitation. These will utilize the CO_2 chambers available at DLAM. According to the SOP attached to the DLAM CO_2 chambers, the mice will be in standard mouse cages (5L volume) where the flow rate will displace 20% of the chamber volume per minute by introducing 100% CO_2. This translates to 1 L per minute. Deep anesthesia is tested with toe pinch – a lack of response indicated deep anesthesia. (b)(4)
(b)(4)

V.4.1.2.2. **Pre- and Post-procedural (not surgery) Provisions:**
Not applicable.

V.4.1.2.3. **Paralytics:** NA

V.4.1.3. **Literature Search for Alternatives to Painful or Distressful Procedures:**

V.4.1.3.1. **Sources Searched:**
MEDLINE, AGRICOLA

V.4.1.3.2. **Date of Search:**
October 16, 2014

V.4.1.3.3. **Period of Search:**
1968 to present

V.4.1.3.4. **Key Words of Search:**
Animal, pain, surgery, analgesia, mice, (b)(4)

V.4.1.3.5. **Results of Search:**
Animal studies are needed to further test the physiological and behavioral significance of any result procured from cell culture studies. There are no

alternatives (cell or computer modeling) to study the effect of (b)(4) (b)(4) a complex stress system that is regulated by feedback and through cellular connectivity. The methods described in this proposal are standard procedures that have been used for many decades and have been translated eventually to human studies and drug development.
Based on a literature search:

1. the proposed research is not duplicative of research which has already been done;
2. Alternatives to the use of procedures that may cause more than momentary or slight pain or distress are not appropriate or available. This is to establish an animal model for studying how changes in the circadian rhythm may alter the stress system. The 20 min restraint stress is a commonly used model to test the responsiveness of the (b)(4) (b)(4)
3. We have proposed to utilize the appropriate pain management methods in the protocols.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification: NA

V.4.2. Prolonged Restraint: Not applicable

V.4.3. Surgery: Not applicable

V.4.3.1. Pre-surgical Provisions: NA

V.4.3.2. Procedure: NA

V.4.3.3. Post-surgical Provisions: NA

V.4.3.4. Location: NA

V.4.3.5. Surgeon: NA

V.4.3.6. Multiple Major Survival Operative Procedures:

V.4.3.6.1. Procedures: NA

V.4.3.6.2. Scientific Justification:

V.4.4. Animal Manipulations:

V.4.4.1. Injections:

V.4.4.2. Biosamples: Entire organs will be harvested during routine necropsy – brain, pituitary, liver, uterus. Maximum obtainable trunk blood will be obtained after euthanasia.

V.4.4.3. Adjuvants: Not applicable

V.4.4.4. Monoclonal Antibody (MAbs) Production: NA

V.4.4.5. Animal Identification: The animals will be identified on the cage card and when group housed, they will be identified by a non-toxic marker on the tail.

V.4.4.6. Behavioral Studies: Not applicable

V.4.4.7. Other Procedures: Daily vaginal lavage will be conducted using a well established method described in (b)(4) (b)(4) This is a non-invasive method to stage the estrous cycle. An exception is to use sterile physiological saline as opposed to ddH_2O. Daily lavages will be conducted for at least 2 consecutive estrous cycles. No anesthesia is required.

Briefly, the mouse is firmly grasp by the tail to expose the rear end. The vagina is gently perfused by gently placing about 50 ul physiological saline at the opening of the vaginal canal. Draw the saline back into the tip. Repeat 4-5 times using the same tip. Place the fluid on a glass slide for analysis.

V.4.4.8. Tissue Sharing: Yes. Excess tissues will be made available to other investigators upon request.

V.4.5. Study Endpoint: Based on the respective time-points as described in Exp 1 and 2, animals will be euthanized by deep carbon dioxide anesthesia followed by decapitation (Exp 1) or deep carbon dioxide anesthesia followed transcardiac perfusion by physiological saline and buffered 4% paraformaldehyde (Exp2).

Any mouse that becomes ill, shows a greater than 20% weight loss, becomes lethargic, dehydrated, unkempt, or shows any other clinical signs of a medical problem will be evaluated by the veterinarian and PI (when available). In the event of a debilitating illness or adverse reaction, the PI and the veterinarian will consult on a course of treatment. Mice may be euthanized for humane reasons at the discretion of the veterinarian, but attempts to contact the PI will be made before the mouse is euthanized.

V.4.6. Euthanasia:

All animals will be euthanized by CO2 anesthesia followed by decapitation or cardiac perfused with physiological saline and buffered 4% paraformaldehyde. The mice will be deeply anesthetized by CO_2 prior to decapitation. These will utilize the CO_2 chambers available at DLAM. According to the SOP attached to the DLAM CO_2 chambers, the mice will be in standard mouse cages (5L volume) where the flow rate will displace 20% of the chamber volume per minute by introducing 100% CO_2. This translates to 1 L per minute. Deep anesthesia is tested with toe pinch – a lack of response indicated deep anesthesia. In Exp 1, the mice will be decapitated and in Exp 2, the mice will be pericardially perfused.

Briefly, Perfusion will be conducted using standard methods (eg, described in http://www.ebiomethods.com/methods/mouseperfusion) utilizing a butterly needle (26G) and the sequential perfusion with physiological saline (approximately 20 ml) and buffered paraformaldehyde (approximately 100 ml). CO2 anesthesia will be conducted according to USU Policy 013, "Rodent Anesthesia with CO2 prior to Euthanasia".

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol. Routine cage changes will be conducted by the PI's laboratory staff.

V.5.1.1. Study Room:

Building(s) (b)(6) Room Number(s) (b)(6) (b)(6)

V.5.1.2. Special Husbandry Provisions:

Mice will be house in separate rooms with special light cycles according to the experimental design. It is requested that the mice be placed in:

i. (b)(4) L:D cycle, or

ii. (b)(4) L:D cycle.

(b)(4)

Food Restriction: Yes _____ No ___X___

Fluid Restriction: Yes No X

V.5.1.3. Exceptions:

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care:
Mice will be observed at least once daily by LAM personnel and by investigative staff. Mice will be weighed regularly by investigative personnel. Any mice that becomes ill, shows a greater than 20% weight loss by visual appraisal and by additional weighing if necessary, becomes lethargic, dehydrated, unkempt, or shows any other clinical signs of a medical problem will be evaluated by the veterinarian and PI (when available). In the event of a debilitating the PI and the veterinarian will consult on a course of treatment. Mice may be euthanized for humane reasons at the discretion of the veterinarian, but attempts to contact the PI will be made before the mouse is euthanized.

V.5.2.2. Emergency Veterinary Medical Care: All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: Except as indicated below, all animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies.

Mice will be group housed (up to 4 mice per cage) for both male and female mice and all Enrichment Strategies will be conducted in accordance to USU Policy 008 (Laboratory Animal Exercise and Environmental Enrichment Program). The mice will be give nestlets as enrichment (Section F under Environmental Enrichment).

V.5.3.2. Enrichment Restrictions: NA

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
Basic Training	(b)(6)	Greater than 20 years	(b)(6)

Course			Rodent Handling Course (Taught by Dr. (b)(6) USUHS Investigator Training (between January and June, 2001)
Euthanasia	(b)(6)	Greater than 20 years	(b)(6) Euthanasia Course (Taught by Dr. (b)(6) (b)(6) DVM, PhD) (b)(6) USUHS Euthanasia Training Course (I don't remember the exact date)
CITI Training		Completed	9/10/2014

CITI Training		In progress	

VII. BIOHAZARDS/SAFETY:

When handling animals all personnel will wear personal protective equipment including lab coats, face masks and gloves to minimize exposure to rodent allergens. The personnel will also annually visit the nurse to discuss their needs.

All perfusions with a paraformaldehyde-based buffer will be conducted to minimize exposure to vapors. Precautions include personnel wearing gloves, lab coats and face masks to protect from noxious fumes and perfusions be conducted in a fume hood or a ventilated table (DLAM necropsy room).

VIII. ENCLOSURES:

(b)(4)

(b)(4)

IX. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User

(b)(6)

Principal Investigator Signature Date

G. Training: The following personnel will attend the next USUHS Investigator/Animal User Training Course:

H. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely, "Responsibility" for implementing animal use alternatives where feasible and conducting hum

Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL** or **WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

June 3, 2016

MEMORANDUM FOR DR (b)(6) DEPARTMENT OF OBSTETRICS AND GYNECOLOGY

SUBJECT: IACUC Approval of Protocol – Initial Review

The following application was reviewed and approved by the Uniformed Services University of the Health Sciences (USUHS) Institutional Animal Care and Use Committee (IACUC) via Designated Member Review on June 3, 2016:

Title of Application: (b)(4)
(b)(4)

USUHS Protocol Number: (b)(6)

Expiration Date: June 2, 2019

Supporting Grant(s) Number (b)(6)

Name of Principal Investigator: Dr. (b)(6)

The USUHS has an Animal Welfare Assurance on file with the Office for Laboratory Animal Welfare (OLAW), National Institutes of Health (NIH). The Assurance Number is A3448-01. The IACUC approved the above referenced application as submitted.

An annual review is required for each of the three years of this protocol. This review must be completed by the anniversary date of the protocol. If work is to be continued past the expiration date, a triennial review must be completed prior to the expiration date in order for work to be uninterrupted. Protocol expiration dates may not be extended, and no animal work may be done without an approved protocol. Although the IACUC may send reminders, it is the investigator's responsibility to submit an annual review form (Form 3206A) at least 30 days in advance, or a new Form 3206 for triennial review at least 60 days in advance of expiration.

Prior to placing your first animal order, please contact MAJ (b)(6) to schedule a pre-protocol planning meeting (b)(6) This meeting must occur to ensure animal numbers are loaded in the CART system and LAM resources are available to meet yoar needs.

I. NON-TECHNICAL SYNOPSIS:

The consequences of sleep loss and sleep disorders are dire. Sleep loss has been attributed to some of the sensational result in significant financial loss as well as long term impact on the environment and human health (b)(4) (b)(4) The economic cost is in the millions (b)(4) According to the CDC, "more than one-quarter of the US population report occasionally not getting enough sleep, while nearly 10% experience chronic insomnia (b)(4) " It is well documented that there is a strong correlation between sleep disorders and neuropsychiatric disorders, such as post-traumatic stress disorder (PTSD) and depression (b)(4) the relationship between sleep and neuropsychiatric disorders remain to be determined. To date, the underlying mechanism mediating the transition to neuropsychiatric disorders is limited. (b)(4) (b)(4)

II. BACKGROUND:

II.1. Background:

The consequences of sleep loss and sleep disorders are dire. Sleep loss has been attributed to some of the sensational result in significant financial loss as well as long term impact on the environment and human health (b)(4) (b)(4) The economic cost is in the millions (b)(4) According to the CDC, "more than one-quarter of the US population report occasionally not getting enough sleep, while nearly 10% experience chronic incomnia (b)(4) " It is well documented that there is a strong correlation

between sleep disorders and neuropsychiatric disorders, such as post-traumatic stress disorder (PTSD) and depression (b)(4) the relationship between sleep and neuropsychiatric disorders remain to be determined. It is interesting to note that sleep disruption (or partial disruption) may be a predictor of developing PTSD and depression

(b)(4)

(b)(4)

II.2. Literature Search for Duplication:

II.2.1. Literature Source(s) Searched: DTIC, Pubmed, RePORTER

II.2.2. Date of Search: February 19, 2016

II.2.3. Period of Search: No Period Restriction

II.2.4. Key Words and Search Strategy:

(b)(4)

II.2.5. Results of Search:

Pubmed: Of 2,451 studies published to date on sleep disruption, there are 17 that evaluate (b)(4) after sleep disruption in clinical studies or reviews. (b)(4)

(b)(4)

(b)(4) in a single point representing the altered homeostasis after sleep disruption or apply a stress to examine a behavioral or biochemical outcome. (b)(4)

(b)(4)

The conclusions' of our literature search are: a. this is a unique approach and b. these approaches will significantly advance our understanding of the neuro-circuitry involving the (b)(4) neuronal biology and thus, by default our understanding of (b)(4) (b)(4) and finally, c. there is limited information on how sleep disruption may result in dysregulated biological systems in a sex-dependent manner.

A similar conclusion is made from a review of DTIC and the RePORTER.

In the DTIC, there were 12 citations that study sleep and the HPA axis. There are no studies that examine the impact of sleep on the molecular components of the HPA axis and (b)(4) Most of the studies are in aquatic mammals or clinical studies.

In the NIH RePORTER, a search was conducted in all dates and search terms included title, abstract and terms. There were 17 "hits" in which in which sleep disorders and (b)(4) were mentioned in the same grant representing 7 grants. (b)(4) (b)(4)

III. OBJECTIVE\HYPOTHESIS:

(b)(4)

IV. MILITARY RELEVANCE:

Do changes in the (b)(4) contribute to pathological conditions or do they merely provide evidence of it? Given that many physiological systems are either under circadian input or control, this proposal represents a novel shift in the way one could look at treatment of disease and clinical diagnoses. Particularly, this proposal describes the mechanism(s) whereby circadian and (b)(4) (b)(4) interact can lead to novel approaches to the promotion of warfighter resilience or the prevention or treatment of stress-related problems.

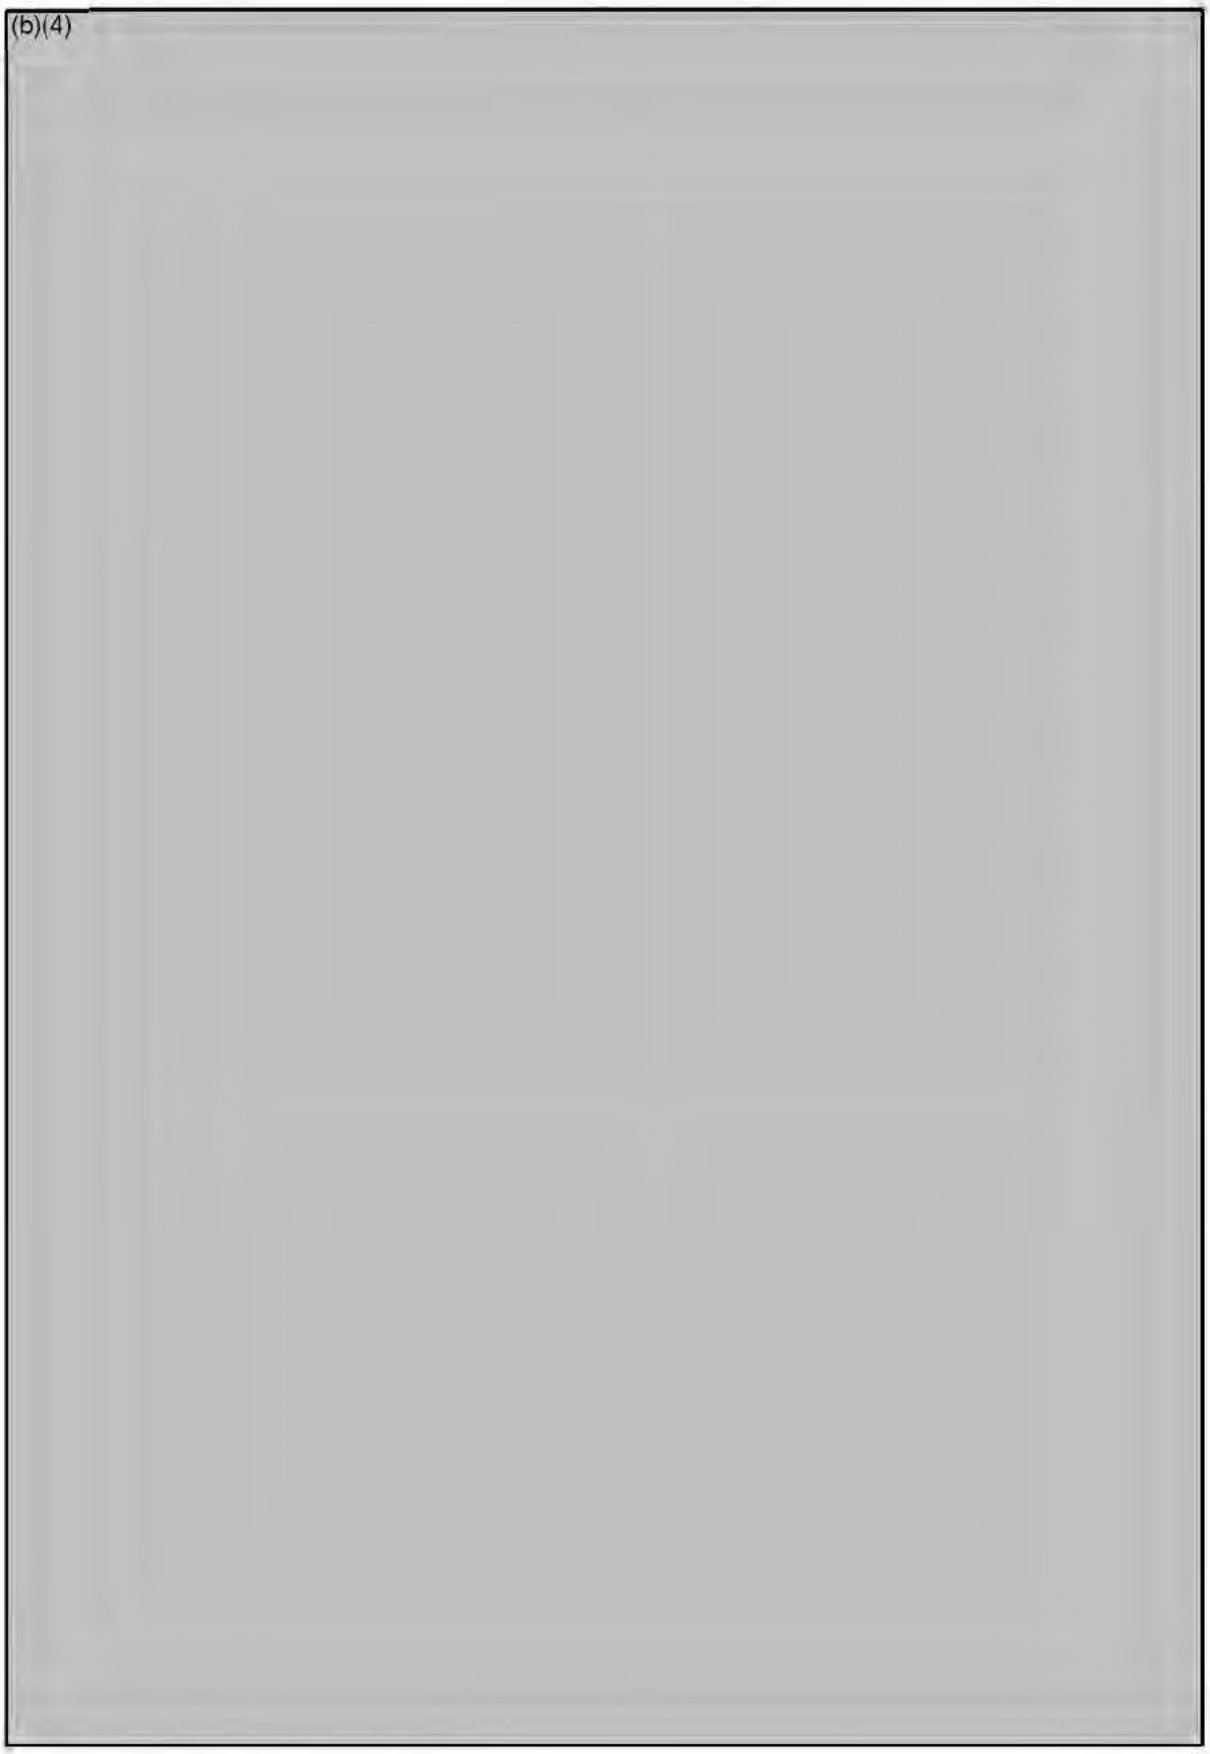
This project will explore the neurobiological consequences of sleep quality that result in long-term alterations (b)(4) The relationship between sleep disorders and the development of neuro-psychological disorders is unknown and there is also little understanding of how sex may be impactful. (b)(4) (b)(4)

V. MATERIALS AND METHODS:

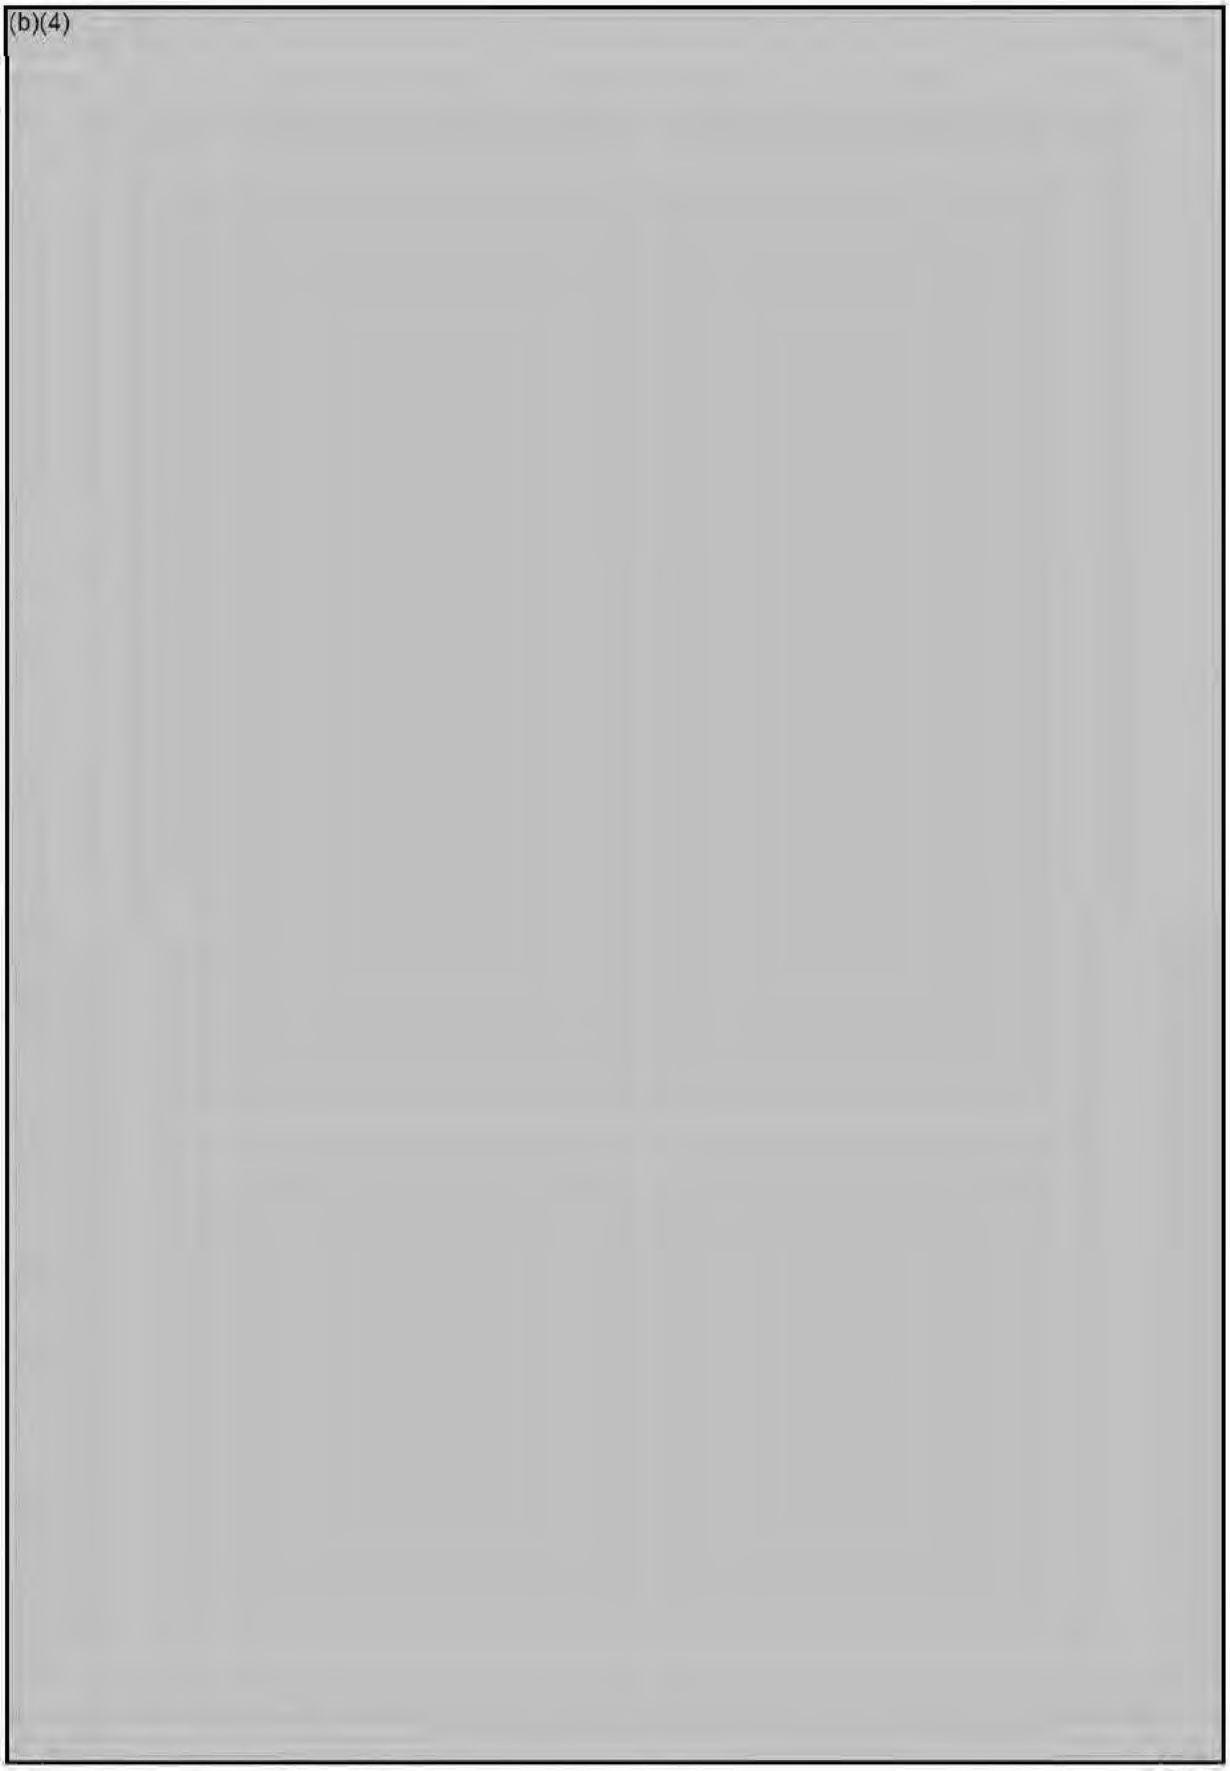
V.1. Experimental Design and General Procedures:

V.1.1. Experiment 1:

(b)(4)



(b)(4)



(b)(4)

(b)(4)

V.2. Data Analysis:

All experiments will be conducted in a block design in which animals from each treatment group will be tested. Standard statistical analyses will be conducted. Briefly, an appropriate analysis of variance (ANOVA) in a block design will be conducted that is specified in each aim. For each run, we will run 2 mice per treatment group.

(b)(4)

(b)(4) the number of animals per group is not only based on a culmination of the literature, our experience and others' previous studies but also by confirming using a power analysis. Group size is determined using a statistical package, SPSS with an alpha = 0.05. A two tailed test with an (b)(4) will give a power of 0.8 to detect differences between group means of 1.33 standard deviations or greater (for the molecular studies). A two tailed test with an (b)(4) will give a power of 0.8 to detect differences between group means of 1.33 standard deviations or greater (for the anatomical studies). The differences of this magnitude has been shown in previous studies in response to dexamethasone suppression test and to restraint. The data collected for both experiments will be analyzed with the appropriate ANOVA followed by Fishers' LSD post-hoc test.

V.3. Laboratory Animals Required and Justification:

V.3.1. Non-animal Alternatives Considered:

This aspect of the study involves whole animals since there are no known current cell models or computer models to simulate sleep disruption to study the hypothalamic-pituitary-adrenal axis regulation.

V.3.2. Animal Model and Species Justification:
We have chosen the mouse as a model for several reasons. The most important reason is that the mouse stress axis is well characterized. Moreover, there are numerous mouse genetic models available allowing us to test our hypothesis. (b)(4)

(b)(4)

(b)(4) To this end and also in response to future NIH policy on inclusion of males and females in pre-clinical studies (Clayton and Collins, 2014), all studies in the present proposal will be conducted using both adult male and female mice (1.5 - 6 months old).

V.3.3. Laboratory Animals

ALTERNATIVES CONSIDERATIONS: Does the protocol have any provisions that would qualify it to be identified as one that Refines, Reduces, or Replaces (3R's) the use of animals in relation to other protocols or procedures performed in the past?

YES

SECTION V.3.5.

Exceptions to the *Guide for the Care and Use of Laboratory Animals* (Please check all applicable):

[ ] Use of Paralytics (V.4.1.2.3.)
[ ] Prolonged Restraint (V.4.2.)
[ ] Multiple Major Survival Surgery (V.4.3.6.)
[ ] Use of Non-pharmaceutical grade chemicals (V.4.4.1.)
[ ] Use of Complete Freund's Adjuvant (V.4.4.3.)
[ ] Death as an endpoint (V.4.5.)
[ ] Food/Water Restriction (V.5.1.2.
[ ] Single Housing of Social Species (V.5.1.3)
[ ] Restriction of Environmental Enrichment (V.5.3.2.)
[ ] Drug Use/Controlled Substances (Appendix A)

IDENTIFICATION OF SPECIES AND STRAIN: In accounting for animal numbers, please ensure that the strain of animal as well as the species is identified. If more than one strain of any species will be used, please list each proposed strain in a separate column. If more than two species/strains are to be used, duplicate Sections V.3.3.1 – V.3.4 , and Section V.4.1.1.1, on subsequent pages to cover all requested strains.

Species #1 **Species #2**

V.3.3.1. **Genus & Species:**	*Mus musculus*	*Mus musculus*
V.3.3.2. **Strain/Stock:** V.3.3.3. **Source/Vendor:**	(b)(4)	
V.3.3.4. **Age:**	2 – 8 months	2 – 8 months
V.3.3.5. **Weight:**	20-45 g	20-45 g
V.3.3.6. **Sex:**	**Male**	**Female**
V.3.3.7. **Special Considerations:**	N/A	N/A
V.3.4. **Number of Animals Required (by Species):**	(b)(4)	

	Species #3	**Species #4**
V.3.3.1. **Genus & Species:**	*Mus musculus*	*Mus musculus*
V.3.3.2. **Strain/Stock:** V.3.3.3. **Source/Vendor:**	(b)(4)	
V.3.3.4. **Age:**	2 – 8 months	2 – 8 months

V.3.3.4. **Age**: 2 – 8 months

V.3.3.5. **Weight**: 20-45 g

V.3.3.6. **Sex**: **Male**

V.3.3.7. **Special Considerations**: N/A

V.3.4. **Number of Animals Required (by Species)**: (b)(4)

V.3.5. **Refinement, Reduction, Replacement (3 Rs)**:

V.3.5.1. **Refinement**: Mice will be handled at least 3-4 times a week to reduce stress during experimentation. In addition, mice will be handled at approximately the same time each day. For terminal experiments, the mice will be anesthetized prior to euthanizing. Refinements considered but not used: adjusted early end-point, unless the animals become ill. Under that circumstance, the animals will be euthanized. The decision to euthanize the sick mouse will be in consultation with the PI and the Veterinarian.

(b)(4)

V.3.5.2. **Reduction**: We will conduct the studies using a factorial design where once statistical difference is achieved, we can stop the experiment. This allows us to use the minimum number of mice possible to still be statistically significant. In addition, every effort has also been made to use every tissue part for the current and other studies without compromising the integrity of the experimental design and for not compromising data analysis. We will not use any more animals than needed.

V.3.5.3. **Replacement**: At this time, it is not possible yet to study the impact of the environment on the animal's (b)(4) It is possible that in the future, when more information has been garnered, that we would be able to test behavioral responses, endocrine responses or other physiological responses using computer modeling.

V.4. **Technical Methods**:

V.4.1. **Pain / Distress Assessment**:

V.4.1.1. **APHIS Form 7023 Information:**

V.4.1.1.1. **Number of Animals:**

Species:	(b)(4)
V.4.1.1.1.1. Column C:	
V.4.1.1.1.2. Column D:	
V.4.1.1.1.3. Column E:	

V.4.1.2. **Pain Relief / Prevention:**

V.4.1.2.1. **Anesthesia/Analgesia/Tranquilization:**
Carbon dioxide (for deep anesthesia).
The mice will be deeply anesthetized by CO_2 prior to decapitation or perfusion. These will utilize the CO_2 chambers available at LAM. According to the SOP attached to the LAM CO_2 chambers, the mice will be in standard mouse cages (5L volume) where the flow rate will displace 20% of the chamber volume per minute by introducing 100% CO_2. This translates to 1 L per minute. Deep anesthesia is tested with toe pinch – a lack of response indicated deep anesthesia. In Exp 1, the mice will be decapitated and in Exp 2, the mice will be pericardially perfused.

V.4.1.2.2. **Pre- and Post-procedural (not surgery) Provisions:**
Not applicable.

V.4.1.2.3. **Paralytics:**
Not applicable.

V.4.1.3. **Literature Search for Alternatives to Painful or Distressful Procedures:**

V.4.1.3.1. **Sources Searched:**
MEDLINE, AGRICOLA

V.4.1.3.2. **Date of Search:**
February 25, 2016

V.4.1.3.3. **Period of Search:**
1968 to present

V.4.1.3.4. **Key Words of Search:**
Animal, pain, surgery, analgesia, mice, (b)(4)

V.4.1.3.5. **Results of Search:**

Animal studies are needed to further test the physiological and behavioral significance of any result procured from cell culture studies. There are no alternatives (cell or computer modeling) to study the effect of changes in circadian rhythms on a complex (b)(4) system that is regulated by feedback and through cellular connectivity. The methods described in this proposal are standard procedures that have been used for many decades and have been translated eventually to human studies and drug development.
Based on a literature search:

1. the proposed research is not duplicative of research which has already been done;
2. Alternatives to the use of procedures that may cause more than momentary or slight pain or distress are not appropriate or available. This is to establish an animal model for studying how (b)(4) may alter the (b)(4) system. The 20 min (b)(4) is a commonly used model to test the responsiveness of (b)(4) (b)(4)
3. We have proposed to utilize the appropriate pain management methods in the protocols.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification:
Not applicable

V.4.2. Prolonged Restraint:
Not applicable

V.4.3. Surgery:
Not applicable

V.4.3.1. Pre-surgical Provisions:

V.4.3.2. Procedure:

V.4.3.3. Post-surgical Provisions:

V.4.3.4. Location:

V.4.3.5. Surgeon:

V.4.3.6. Multiple Major Survival Operative Procedures:

V.4.3.6.1. Procedures:

V.4.3.6.2. Scientific Justification:

V.4.4. Animal Manipulations:

V.4.4.1. Injections:

(b)(4) DEX [redacted] ug/kg, s.c.; Water soluble DEX is dissolved in saline) or no DEX (vehicle = saline, s.c.) with a needle size range between 22-25 gauge. Up to 2 ml will be administered.

V.4.4.2. Biosamples: Entire organs will be harvested during routine necropsy – brain, pituitary, liver, uterus. Maximum obtainable trunk blood will be obtained after euthanasia.

V.4.4.3. Adjuvants: Not applicable

V.4.4.4. Monoclonal Antibody (MAbs) Production: NA

V.4.4.5. Animal Identification: The animals will be identified on the cage card and when group housed, they will be identified by a non-toxic marker on the tail.

V.4.4.6. Behavioral Studies:

(b)(4) will be used to evaluate anxiety-like behaviors

(b)(4) [redacted]

(b)(4) Animals will be placed in an open field environment (40 cm x 40 cm) and allowed to move freely for up to one hour. (b)(4)

(b)(4) [redacted]

(b)(4) These measures allow conclusions regarding exploration, locomotion and anxiety-like states of the rodents.

(b)(4) to assess depressive behavior. (b)(4)

(b)(4) [redacted]

(b)(4)

V.4.4.7. Other Procedures:

1. Daily vaginal lavage will be conducted using a well-established method described (b)(4) This is a non-invasive method to stage the estrous cycle. Daily vaginal lavage (at least 1-2 weeks is needed to determine the stage of the estrous cycle) is conducted to understand which stage of the estrous cycle the mice were tested on and when samples are collected. Because of the significant hormonal fluctuations throughout the estrous cycle and the impact these ovarian steroids have the HPA axis, this method will be used to monitor estrous cycle stage.
   An exception is to use sterile physiological saline as opposed to ddH_2O. Daily lavages will be conducted for at least 2 consecutive estrous cycles. No anesthesia is required. Briefly, the mouse is firmly grasped by the tail to expose the rear end. The vagina is gently perfused by gently placing about 50 ul physiological saline at the opening of the vaginal canal. Draw the saline back into the tip. Repeat 4-5 times using the same tip. Place the fluid on a glass slide for analysis.

Multiple platform method to induce sleep disruption. The image above is an image for rats. The modification is described in the text.

2. Restraint. The mice will be restrained for 20 min and euthanized 10 or 60 minutes after the end of the restraint. Mice will be restrained using a standard plexiglass restrainer (b)(4)
   (b)(4)
   (b)(4) The mice in these restrainers will be awake, unanesthetized and will have no other procedures conducted on them during this 20-min transient restraint. Restraint will be conducted in a LAM facility. (b)(4)
   (b)(4)

3. Transient sleep disruption. We will utilize the well-established multiple platform method used to induce sleep disruption (b)(4)
   (b)(4)
   (b)(4) Experiment groups will comprise of 3-5 mice per run. All mice will be from the same cage. Mice will be able to move around the container by leaping between platforms.

Briefly, mice will be placed on platforms that are submerged in approximately 1 cm of water during the light hours. Each platform is 3 cm in diameter with each mice having access to the platforms (up to 12 platforms per container, 3 cm in diameter each). Mice allocated to receive the sleep disruption treatment will be acclimated in the chambers for 1 h/day for up to 3 days prior to testing during the active circadian phase. On day of testing, the mice will be placed onto the 3-cm platforms that are immersed in water with 1 cm below the surface. Actual testing will occur during the light hours (12 h) for the mice (inactive period) for up to 3 days. To maintain the water temperature (70-76 F), a water-submersible heater(s) will be placed in the tank. Water temperature will be checked during the testing to ensure the stability of temperature. The water tank will be located in a procedure room in DLAM. Each day of treatment is equivalent to a bad night of sleep. Mice will be able to move around the container by leaping between platforms thus allowing the mice to interact with each other. *This model is unique as it prevents stress by controlling social isolation and preserving social hierarchy.*

4. Handling and weighing. The mice will be handled 3-4 times a week. During handling, they will be weighed.

V.4.4.8. Tissue Sharing: Yes. Excess tissues will be made available to other investigators upon request.

V.4.5. Study Endpoint:

Based on the respective time-points as described, animals will be euthanized by deep carbon dioxide anesthesia followed by decapitation (Exp 1 and 2) or deep carbon dioxide anesthesia followed transcardiac perfusion by physiological saline and buffered 4% paraformaldehyde (Exp 3).

Any mouse that becomes ill, shows a greater than 20% weight loss, becomes lethargic, dehydrated, unkempt, or shows any other clinical signs of a medical problem will be evaluated by the veterinarian and PI (when available). In the event of a debilitating illness or adverse reaction, the PI and the veterinarian will consult on a course of treatment. Mice may be euthanized for humane reasons at the discretion of the veterinarian, but attempts to contact the PI will be made before the mouse is euthanized.

V.4.6. Euthanasia:

All animals will be euthanized by CO_2 anesthesia followed by decapitation or cardiac perfusion with physiological saline and buffered 4% paraformaldehyde. The mice will be deeply anesthetized by CO_2 prior to decapitation. These will utilize the CO_2 chambers available at LAM. According to the SOP attached to the LAM CO_2 chambers, the mice will be in standard mouse cages (5L volume) where the flow rate will displace 20% of the chamber volume per minute by introducing 100% CO_2. This translates to 1 L per minute. Deep anesthesia is tested with toe pinch – a lack of response indicates deep anesthesia.

In Exp 1 and 2, the mice will be decapitated and in Exp 3, the mice will be pericardially perfused.

Briefly, Perfusion will be conducted using standard methods (eg, described in http://www.ebiomethods.com/methods/mouseperfusion) utilizing a butterfly needle (26G) and the sequential perfusion with physiological saline (approximately 20 ml) and buffered paraformaldehyde (approximately 100 ml). CO_2 anesthesia will be conducted according to USU IACUC Policy 013, "Rodent Anesthesia with CO_2 prior to Euthanasia".

V.5. Veterinary Care:

V.5.1. Husbandry Considerations: Except as noted below, routine animal husbandry will be provided in accordance with LAM Husbandry SOPs for each species in this protocol. Routine cage changes will be conducted by the PI's laboratory staff.

V.5.1.1. Study Room:

Building(s) (b)(6) Room Number(s) (b)(6) (b)(6)

V.5.1.2. Special Husbandry Provisions:

Mice will be housed (b)(4) (b)(4) standard light cycle of 12:12 L:D. It is requested that lights go off at 1300 h.

V.5.1.2. Special Husbandry Provisions:

Food Restriction: Yes ___X___ No _____

Fluid Restriction: Yes _____ No ___X___

V.5.1.3. Exceptions:

Food is restricted during the sleep disruption period (light hours) when mice do not normally eat.

V.5.2. Veterinary Medical Care:

V.5.2.1. Routine Veterinary Medical Care:

Mice will be observed at least once daily by LAM personnel and by investigative staff. Mice will be weighed at least 2 times a week by investigative personnel. Any mice that becomes ill, shows a greater than 20% weight loss by visual appraisal and by additional weighing if necessary, becomes lethargic, dehydrated, unkempt, or shows any other clinical signs of a medical problem will be evaluated by the veterinarian and PI (when available). In the event of a debilitating the PI and the veterinarian will consult on a course of treatment. Mice may be euthanized for humane reasons at the discretion of the veterinarian, but attempts to contact the PI will be made before the mouse is euthanized.

V.5.2.2. Emergency Veterinary Medical Care: All emergency, weekend, and holiday care is provided by two animal husbandry technicians, one or more veterinary technicians, and an on-call veterinarian. Essential husbandry procedures and health rounds are conducted by LAM personnel once daily during weekend and holidays.

V.5.3. Environmental Enrichment:

V.5.3.1. Enrichment Strategy: Except as indicated below, all animals on this protocol will be provided with routine environmental enrichment in accordance with LAM SOPs and IACUC Policies.

Mice will be group housed (up to 5 mice per cage) for both male and female mice and all Enrichment Strategies will be conducted in accordance to USU IACUC Policy 008 (Laboratory Animal Exercise and Environmental Enrichment Program). The mice will be given nestlets only as enrichment (Section F under Environmental Enrichment).

V.5.3.2. Enrichment Restrictions: n/a

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING:

STUDY PERSONNEL QUALIFICATIONS/TRAINING

Protocol activity or procedure (e.g., tail vein injections, euthanasia)	Name of person performing activity	Qualifications of person performing activity (e.g., research technician, 2 yrs experience)	Specific training in this activity or procedure (e.g., rodent handling class, 1999)
Basic Training Course	(b)(6)	Greater than 20 years	(b)(6) University Rodent Handling Course (Taught by Dr. (b)(6) USUHS Investigator Training (between January and June, 2001)
Decapitation Cardiac perfusion Injections Vaginal lavage Anesthesia monitoring	(b)(6)	Greater than 20 years	(b)(6) Euthanasia Course (Taught by Dr. (b)(6) DVM, PhD) (b)(6) USUHS Euthanasia

			Training Course (I don't remember the exact date)

(b)(4)

IX. EXTRAMUAL COLLABORATION:

Not applicable

X. ASSURANCES:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made a reasonable, good faith effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with an individual who is qualified to evaluate the statistical design or strategy of this proposal, and that the "minimum number of animals needed for scientific validity are used."

D. Biohazard\Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Training: I verify that I have attended the USUHS Investigator/Animal User Training Course.

(b)(6)

2/26/2016

Principal Investigator Signature | Date

G. Training: The following personnel will attend the next USUHS Investigator/Animal User Training Course:

H. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure

that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R" that the DOD has embraced, namely, "Responsibility" for implementing animal use alternatives where feasible and conducting humane and lawful research.

(b)(6)

2/26/2016

Principal Investigator Signature | Date

I. Painful Procedure(s):

I am conducting biomedical experiments which may potentially cause more than momentary or slight pain or distress to animals. This potential pain and/or distress **WILL** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, using the methods and sources described in the protocol, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

DOD ANIMAL CARE AND USE STANDARDIZED PROTOCOL FORMAT WITH EMBEDDED INSTRUCTIONS (JANUARY 2012)

Reference DOD Instruction 3216.01 & AFRRI Instruction 3216.2H

****

Information requested in the following animal use protocol template reflects the requirements of the Animal Welfare Act Regulations (AWAR), the Guide for the Care and Use of Laboratory Animals, and other applicable Federal regulations and DOD instructions.

****

This document is intended to be an aid in the preparation of DOD-sponsored animal use protocols. It is a companion document to an identical protocol template that does not have embedded instructions. Either template may be used to format DOD-sponsored animal research proposals; however, reference to the instructions during protocol preparation is highly recommended. If using the template with instructions, the instructions should be deleted prior to submitting the finished protocol for IACUC review. Please use Arial, regular, size 12, black font to prepare the protocol. With the exception of section headings, all paragraphs require a response. Paragraphs that do not apply should be marked N/A. There is no space limitation for responses to the information requested.

Approved standard operating procedures (SOPs) promulgated by the AFRRI Veterinary Sciences Department (VSD) or similar VSD-validated documents that describe specific procedures may be referenced by SOP number and title in lieu of repeating the details in the protocol. However, it is essential to include general descriptions of all animal manipulations to be carried out under the IACUC-approved protocol and to provide details where no approved references are cited. To do otherwise would constitute a breach of statutory regulations. Manipulations not covered in the originally approved protocol can be initiated only after IACUC approval of a formal amendment adding the new procedures. Additionally, Principal Investigators (PIs), or other delegated research personnel, should maintain accurate experimental records and be able to provide an audit trail of animal expenditures and use that correlates with their approved protocol. Protocol PIs will be required to provide this and other information during annual protocol reviews.

Any supporting information that may be of use to the IACUC during its review may be attached to the completed protocol. Adding subparagraphs within the body of the protocol template is permissible, *provided that the numbering sequence of paragraphs in the original standard format is maintained.* In other words, all of the labeled paragraphs and subparagraphs in this template must be retained, with additional information being presented as sub-numbered paragraphs containing information that supports or complements what is requested.

INTELLECTUAL PROPERTY STATEMENT

Research protocols drafted by Government scientists include intellectual property (e.g., concepts, ideas, experimental approaches, etc.), some of which is innovative or original and therefore considered proprietary to the investigators and/or the sponsoring agency. All Government and non-Government personnel handling this protocol shall exercise EXTREME CARE, to ensure that the information contained herein is NOT DUPLICATED OR DISCLOSED, in whole or part, for any purpose other than to evaluate the protocol, without the written permission of the principal investigator or the sponsoring agency.

I. NON-TECHNICAL SYNOPSIS

Military personnel are potentially exposed to radiation in a variety of scenarios as well as the radioactive heavy metal depleted uranium (DU). It is known that radiation or heavy metal exposure can induce cancer under certain circumstances. To study these carcinogenic phenomena we need to use a murine model. It is therefore important to characterize the carcinogenic effects of these exposures in this murine model to better understand carcinogenic mechanisms and to enable targeted development of safe and efficacious cancer chemoprevention for military personnel using these models. The overall research objective of this proposal is to characterize the ^{60}Co gamma radiation- and depleted uranium (DU) - induced leukemia mouse models used in our laboratory by examining two possible mechanisms i.e., epigenetic (methylation), and genetic (genomic instability). These results, in conjunction with *in vitro* results evaluating non-targeted radiation effects (NTE) will assist in the characterization of these two induced leukemias. This mechanistic information will assist us in developing more effective and safer late radiation effects countermeasures.

II. BACKGROUND

II.1. Background

Radiation health risks of concern to the Department of Defense (DOD) include carcinogenesis and particularly, leukemia. Military personnel can potentially be exposed to a variety of radiation qualities including gamma, neutron, and protons (astronauts) depending on the type of military operation. Internal contamination from military relevant heavy metals like depleted uranium (DU), an alpha particle emitter, during military operations is a potential threat to military personnel as well (1). The health risks of internally deposited alpha-emitters like uranium remain a question for military personnel since it is both a chemical and radiation hazard (2, 3). Our laboratory has demonstrated using cellular models, that the alpha radiation from DU does play a role in the induction of biological damage and neoplastic transformation (4-16). Development and characterization of an effective "late effects" *in vivo* model is critical to a better understanding of radiation- or DU- induced leukemogenic effects and to the development of countermeasures.

The overall goal of this project is to characterize the ^{60}Co- and DU- induced leukemia mouse models used in our laboratory by examining three possible mechanisms. These

include 1) epigenetic, i.e. methylation, 2) genetic, i.e. genomic instability, and 3) non-targeted radiation effects (NTE). The leukemia model used in our studies is unique in comparison to other radiation leukemia mouse models because immature (non-tumorigenic) hematopoietic cells (FDC-P1) are injected into a ^{60}Co-irradiated (17-19) or DU-exposed mice (4, 6, and 7) and the development of acute myeloid leukemia (AML) occurs within 4 to 8 months (4, 6, 7, 17-20). This is in contrast to the 14-18 months in standard murine leukemia models that also require significantly more mice for statistical significance.

A complex picture of radiation leukemogenesis has emerged however in which, additional to any damage induced directly in target stem cells, the hemopoietic microenvironment can be a source of damaging signals and cellular interactions which are involved in the cancer development process (21, 22). To study the process of radiation leukemogenesis, specifically from the standpoint of the hematopoietic microenvironment, we have selected a novel murine model for the development AML which allows an analysis of the indirect effects of irradiation or DU exposure separate from the mutagenic effects on hematopoietic cells (17-19). In this model, murine hematopoietic stem cells of the IL-3-dependent line, FDC-P1, consistently transform to AML when injected into DBA/2 mice irradiated with 1 to 3.5 Gy gamma radiation (17-19) or exposed to internalized DU (4, 6-7). This leukemia model, in which non-tumorigenic immature hematopoietic cells are introduced into an irradiated or DU exposed bone marrow environment, and followed by the development of leukemia, suggests that it could be characterized as a "non-targeted effects" (NTE) leukemia model. In radiation biology, the "Linear No Threshold" hypothesis has been challenged by a large number of observations of the so-called NTE, i.e., genomic instability, bystander effects, which consists of the induction of damage in cells not directly traversed by radiation, most likely as a response to molecular messengers released by directly irradiated cells (23, 24). This DBA/2/FDC-P1model presents the unique opportunity to characterize a leukemia model in which NTEs like genomic instability can be evaluated.

(b)(4)

AML is a clonal disorder resulting from uncontrolled proliferation of hematopoietic progenitor or stem cells (25) and transformation into a leukemic cell is considered a multistep process implicating both genetic and epigenetic aberrations (25-28). The most important genetic findings in AML are chromosomal translocations involving different transcription factors and activating point mutations in multiple signal transduction pathways (28). Epigenetic disturbances, such as aberrant promoter hypermethylation and covalent histone modifications, have been implicated in the pathogenesis of human leukemia as well (29-32). Signaling pathways such as the Wnt and CDK pathways are involved in hematopoietic malignancies. The Wnt signaling pathway has a key function in stem cell maintenance and differentiation of hematopoietic progenitors. Secreted Frizzled-related protein genes (SFRPs), functioning as Wnt signaling antagonists, have been found to be down-regulated by promoter hypermethylation in AML and have been linked to genetic instability as well (29). This methylation controlled silencing of the Wnt gene is critical in AML development. Another pathway disrupted by aberrant methylation in human AML involves the cyclin dependent kinase inhibitor pathway with the cycle inhibitors p16 (CDKN2A or p16INK4a) and p15 (CDKN2B or p15INK4b) (30-31). These pathways and their methylation status have not been examined in the DBA/2/FDC-P1leukemia models (^{60}Co or DU) and the data from human studies suggest that these pathways would be a good target to evaluate in leukemogenesis in the radiation- or DU-murine models

As stated above, the overall objective of this study is to fill the gap in our understanding of ^{60}Co- or DU- leukemia risks, by focusing on the mechanisms of these induced leukemias. In this project we will concomitantly use *in vitro* studies to address whether NTEs could be involved in ^{60}Co- or alpha particle- induced hematopoietic cells transformation and whether cell-cell communication or reactive oxygen species (ROS) are involved in the NTE. The *in vivo* studies described in this animal use protocol with the murine model will assess whether methylation and genomic instability are involved in the development of ^{60}Co- or DU- induced leukemia. The data collected in this proposal would also assist in determining whether this model can be used to develop biological countermeasures to radiation or DU late effects.

(b)(4)

General Study Design:

Section A. Objective/Hypothesis/Specific Aims

The overall goal of this project is to initiate a characterization of the ^{60}Co- and DU-induced leukemia mouse models used in our laboratory by examining possible

mechanisms, i.e. DNA methylation changes and genomic/chromosomal instability and evaluating whether non-targeted radiation effects (NTEs) may be involved.

Hypotheses and Specific Aims:
Hypothesis# 1: A mechanism of gamma or alpha particle leukemogenesis involves a NTE on hematopoietic stem cells through an initial radiation-induced alteration of supportive bone marrow stromal cells. (*In vitro* studies)
Hypothesis #2: The induction of leukemia by gamma radiation or DU exposure is associated with altered DNA methylation in spleen and bone marrow that occurs within 1 month after exposure. (*In vivo* studies).
Hypothesis #3: The induction of leukemia by gamma radiation or DU exposure is associated with hematopoietic stem cell genetic instability that occurs within one month after exposure. (*In vivo* studies).

The following specific aims are designed to address these hypotheses.

Specific Aim #1: NO ANIMALS INVOLVED.
To determine whether ^{60}Co or alpha particle radiation exposure of murine bone marrow stromal cells (cell line) induces malignant transformation of un-irradiated co-cultivated hematopoietic stem cells.

Specific Aim #2: NO ANIMALS INVOLVED.
To determine whether the induction of malignant transformation of un-irradiated hematopoietic stem cells co-cultivated with murine bone marrow stromal cells (cell line) irradiated with ^{60}Co or alpha particle radiation involves cell-cell communications.

Specific Aim #3: NO ANIMALS INVOLVED
To determine whether the induction of malignant transformation of un-irradiated hematopoietic stem cells co-cultivated with murine bone marrow stromal cells (cell line) irradiated with ^{60}Co or alpha particle radiation involves reactive oxygen species (ROS).

Radiation Safety Issues: This protocol will involve the use of depleted uranium (DU). DU is a radioactive heavy metal. (b)(4),(b)(6)

(b)(4),(b)(6)

(b)(4)

Specific Aim #4/Experiment 1: ***To examine DNA methylation in mouse hematopoiesis before and after in vivo exposure to a leukemogenic exposure of dose of gamma radiation or internalized DU exposure and evaluate whether DNA methylation status has a role in gamma radiation or internalized DU exposure leukemogenesis.***

Experiment #1 will assess methylation in mouse hematopoiesis following gamma radiation or DU exposure. Animals will be either exposed to ^{60}Co radiation (total body irradiation) or DU implants (low and high dose implanted in the hind limb). The methylation studies are divided into two parts, a) to evaluate the global genomic content of 5-methylcytosine in spleen and bone marrow and b) to examine the methylation status of specific genes (Wnt family antagonists, SFRP1, -2, -4, -5, p15, p16), in spleen and bone marrow of ^{60}Co or DU- exposed mice. Methylation status following exposure to a leukemogenic dose of ^{60}Co (0.05, 2.0, 3.5 Gy, 0.6 Gy/min) or implanted DU (2 DU + 4 tantalum (Ta) pellets or 6 DU pellets, 1 month exposure) will be examined in bone marrow and spleen. Immediately following radiation exposure or at 1 month post-DU implant, mice will be tail-vein injected with hematopoietic stems cells (FDC-P1 cells). FDC-P1 cells are obtained from ATCC and they are certified to be pathogen free. Cells (2 to 5 E6 cells) will be tail-vein injected (27 gauge needle) in a volume of 100 to 200 ul of sterile saline. FDC-P1 cells are non-tumorigenic hematopoietic stem cells that were derived from DBA/2 mice (same mice used in this study). They are maintained in cultured using IL-3 as a growth supplement. Sterile IL3 is obtained from BD labs and added to the Dulbecco's media used to culture these cells.

Seven days after cell injection animals will be euthanized. Spleen and bone marrow will be obtained for analysis. Spleen and bone marrow tissues previously obtained from ^{60}Co- and DU- induced leukemic mice will be used for comparison. For Aim 4a, global DNA methylation in bone marrow and spleen will be measured by direct analysis of the 5-methylcytosine content of DNA and by Southern blot analysis of genomic repeat sequences. In Aim 4b, dysregulation of the Wnt signaling antagonists also known as secreted frizzled-related proteins (SFRPs) and cyclin-dependent kinase pathway proteins, p15Ink4b and p16Ink4b will be examined using real-time reverse transcription PCR (RT-PCR) in the same samples analyzed for methylation.

Specific Aim #5/Experiment 2: ***To assess genomic/chromosomal instability by examining chromosomal aberrations in mouse ^{60}Co radiation- and DU- induced leukemia's and the clonal descendants of ^{60}Co- irradiated and DU-exposed bone marrow hematopoietic stem cell and compare to controls.***

Experiment#2 will assess chromosomal/genomic instability following radiation or DU exposure. The induced genetic instability should be detectable in the irradiated target untransformed hematopoietic stem cell population and the clonal ^{60}Co- or DU- induced

leukemia by measuring chromosomal aberrations in leukemic and sub-clonal variants. Bone marrow from animals exposed to ^{60}Co radiation at 3 doses (0.5, 2.0, and 3.5 Gy at 0.6 Gy/min) or implanted DU (2 DU + 4 tantalum (Ta) pellets or 6 DU pellets, 1 month exposure) will be evaluated. Immediately following radiation exposure or at 1 month post-DU implant, mice will be injected with hematopoietic stems cells (FDC-P1 cells). At 7 days post-cell injection, animals will be euthanized. Spleen and bone marrow will be obtained for analysis. Spleen and bone marrow tissues previously obtained from ^{60}Co- and DU- induced leukemic mice will be used for comparison. A comparison to un-irradiated/non-implanted controls will also be done. Fluorescence in situ hybridization (FISH) will be used to screen for chromosomal aberrations in ^{60}Co- or DU- induced leukemias (obtained from previous studies/frozen spleen samples) and in the clonal descendants of control, irradiated, or DU-exposed bone marrow hematopoietic stem cells at 7 days post-radiation/cell injection or 7 days post-DU (30 days)/cell injection, using the *in vitro* clonogenic CFU-A colony assay.

II.2. Literature Search for Duplication

II.2.1. Literature Sources Searched

1) Biomedical Research Database (BRD); 2) Pubmed; 3) RePORTer replaced Retrieval of Information of Scientific Projects (CRISP); 4) Federal Research in Progress (FEDRIP).

II.2.2. Date of Search

BRD **Jan 20, 2012**
Pubmed **Jan 3, 4, 20, 2012**
RePORTer **Jan 5, 20, 2012**
FEDRIP **Jan 5, 20, 2012**

II.2.3. Period of Search

BRD **1970-2012**
Pubmed **1980-2012**
RePORTer **1980-2012**

II.2.4. Key Words of Search

DBA/2, mice, male, female, radiation, depleted uranium, tantalum. Epigenetics, genetic, methylation, DNA damage, cytosine extension assay, LD_{50}, radiation carcinogenesis, leukemia, leukemogenesis, toxicity, animal models, survival, lifespan, pain, suffering.

II.2.5. Results of Search

The searches demonstrated that there have been no previous or current studies that have investigated or are in the process of studying the type of mechanism involved in DU-induced carcinogenic effects in a mouse model. There are studies evaluating the

effects of radiation on leukemia development but they are focusing on a different radiation quality, primarily protons and heavy ions, found in space radiations. Secondly, these mouse models are different than the model I will be using which allows us to examine the role of non-targeted radiation effects. The other studies on radiation leukemia do not evaluate non-targeted radiation effects. The searches demonstrated that there have been no previous or current studies that have investigated or are in the process of studying the extent of DNA damage, methylation status, histone status, or gene expression (p15 or p16) in a DU animal model. Therefore the proposed exposure study evaluating epigenetic processes *in vivo* is not a duplication of current or previous experiments. In terms of specific science issues related to DU-carcinogenesis, the searches revealed the following: 1) that the DBA/2 mouse has been used in carcinogenesis studies; pathology, histology, behavior, morbidity, and mortality are well known [19-20]. 2) the background section above provides a summary of the DU publications regarding their transforming, mutagenic, genotoxic, and carcinogenic characteristics; 3) there is one publication on DU and methylation/epigenetics [7] (PI of this protocol is the first author of that publication).

III. OBJECTIVE / HYPOTHESIS

The overall goal of this project is to initiate a characterization of the ^{60}Co- and DU-induced leukemia mouse models used in our laboratory by examining two possible mechanisms, i.e. methylation and genomic instability. The third mechanism, evaluating whether non-targeted radiation effects (NTEs) *in vitro* may be involved, is conducted with *in vitro* models only. In this animal use protocol, we will compare the methylation status and genomic instability in animals exposed to DU for 1 month to those animals exposed to DU (7 months) that developed leukemia. We will also be able to compare the methylation status/genomic instability in animals exposed to ^{60}Co to those animals exposed to ^{60}Co that developed leukemia.

IV. MILITARY RELEVANCE

Military personnel could potentially be exposed to ionizing radiation or DU during the course of their duties. (b)(4)

(b)(4)

V. MATERIALS AND METHODS

V.1. Experimental Design and General Procedures

General Approach: For the DU experiments, animals will be internally exposed to DU, (high and low doses) for 30 days, injected with non-tumorigenic hematopoietic stem cells (FDC-P1) and at 7 days post-cell injection, euthanized. The spleen and bone marrow will be obtained for analysis of epigenetic (methylation changes, gene silencing) and genetic alterations (genetic instability). These samples will be contemporaneously compared to samples previously collected (and stored/frozen) from DU-exposed mice diagnosed with leukemia. For the ^{60}Co experiments, animals will be irradiated and at 7 days post-radiation/cell injection, will be euthanized. The spleen and bone marrow will be obtained for analysis of epigenetic (methylation changes, gene silencing) and genetic alterations (genetic instability). These samples will be compared to samples previously collected from ^{60}Co exposed mice diagnosed with leukemia.

V.1.1. Experiment 1 – Aim 4 of Intramural Proposal

Experiment 1: ***To examine DNA methylation in mouse hematopoiesis before and after in vivo exposure to a leukemogenic exposure of dose of gamma radiation or internalized DU exposure and evaluate whether DNA methylation status has a role in gamma radiation- or internalized DU exposure- leukemogenesis.***

Hypothesis Experiment 1: The induction of leukemia by ^{60}Co radiation or DU (embedded exposure) in this murine model is associated with altered DNA methylation status in spleen and bone marrow that occurs within 1 month post exposure.

Rational Experiment 1: Previous studies have demonstrated that hypomethylation is associated with DU-induced leukemia and human leukemia (7, 21-23).

Methodology Experiment 1: Experiment #1 will assess methylation in mouse hematopoiesis following gamma radiation or DU exposure. The methylation studies are divided into two parts, a) to evaluate the global genomic content of 5-methylcytosine in spleen and bone marrow and b) to examine the methylation status of specific genes (Wnt family antagonists, SFRP1, -2, -4, -5, p15, p16), in spleen and bone marrow of ^{60}Co or DU- exposed mice. Methylation status following exposure to a leukemogenic dose of ^{60}Co (0.5, 2.0, 3.5 Gy, 0.6 Gy/min) or DU (2, 6 pellets, 1 month exposure) will be examined in bone marrow and spleen. Immediately following radiation exposure or at 1 month post-DU implant, mice will be injected with hematopoietic stems cells (FDC-P1 cells). FDC-P1 cells are obtained from ATCC and they are certified to be pathogen free. Cells (2 to 5 E6 cells) will be tail-vein injected (27 gauge needle) in a volume of 100 to 200 ul of sterile saline. Seven days after cell injection animals will be euthanized. Spleen and bone marrow will be obtained for analysis. Bone marrow will be obtained from both femurs. Spleen and bone marrow tissues previously obtained from ^{60}Co- and DU- induced leukemic mice will be used for comparison. These mice were diagnosed approximately 4 to 12 months post exposure. For Aim 4a, global DNA methylation in bone marrow and spleen will be measured by direct analysis of the 5-methylcytosine content of DNA and by Southern blot analysis of genomic repeat sequences. In Aim 4b, dysregulation of the Wnt signaling antagonists also known as secreted frizzled-related proteins (SFRPs) and cyclin-dependent kinase pathway proteins, p15Ink4b and p16Ink4b will be examined using real-time reverse transcription PCR (RT-PCR) in the same samples analyzed for methylation. Bone marrow and spleen of control, ^{60}Co-irradiated mice (0.5, 2.0, and 3.5 Gy doses; 0.6 Gy/min), and internalized DU-exposed

(2 DU + 4 Tantalum (Ta) pellets, 6 pellets + No Ta; 1 month) mice will be assessed. Table 1 details the control and exposure groups. Groups A, B, C, and D are control groups (± FDC-P1 cell injection ± ^{60}Co or DU exposure) and will be immediately euthanized following exposure. Group E will be ^{60}Co exposed, injected with FDC-P1 cells and euthanized at 7 days post-cell injection. Group F (un-irradiated mice) will be injected with ^{60}Co-irradiated FDC-P1 cells and euthanized at 7 days post-cell injection. Group G will be DU exposed (30 days), injected with FDC-P1 cells and euthanized a 7 days post-cell injection. For group H, FDC-P1 cells will be exposed to DU-uranyl nitrate (1, and 100 uM, 4 hrs) prior to injection into non-DU exposed mice and euthanized at 7 days. Following euthanasia, tissues will be prepared for methylation analyses. To accomplish Exp 1a global DNA methylation will be measured in bone marrow and spleen by direct analysis of the 5-methylcytosine content of DNA and by Southern blot analysis of genomic repeat sequences. In Exp 1b, dysregulation of the Wnt signaling antagonists also known as secreted frizzled-related proteins (SFRPs) and cyclin-dependent kinase pathway proteins, p15Ink4b and p16Ink4b will be examined using real-time reverse transcription PCR (RT-PCR) in the same samples analyzed for 5-methylcytosine analysis. Frozen spleen tissues and bone marrow cells obtained in a previous study of ^{60}Co and DU leukemia will be concomitantly used to evaluate bone marrow and spleen samples from animals diagnosed with leukemia. These animals were generally 5-8 months post radiation or DU exposure. These tissues are from our previous studies here at AFRRI and will not be brought into VSD; they are currently stored in my laboratory. No tissue sharing agreement is necessary since they are tissues from my previous studies in which I was also the principal investigator.

Table 1 is on the next page for ease of reading.

Table 1 – Experiment 1. Exposure and Control Groups

	Status of FDC-P1 Cells (± Inj or ± Rad or ± DU)	Status of Mouse ± Rad or DU	Euthanasia	Number of animals
A	No Cell Injection	No Rad/No DU	Day 0	5
B	With Cells Injected	No Rad/No DU	Day 7	5
C	No Cell Injection	With Mouse ^{60}Co Rad	Day 7	15 (5 ea @ 3 doses 0.5 Gy, 2 Gy, 3.5 Gy)
D	No Cell Injection	With Mouse DU Implant	Immediately post-37 Days DU	10 (5 ea @ 2 doses; 2 DU, 6 DU pellets)
E	With Cells Injected	With Mouse ^{60}Co Rad	7 days post-rad	15 (5 ea @ 3 doses 0.5 Gy, 2 Gy, 3.5 Gy)
F	With ^{60}Co Irradiated Cells Injected	No Mouse Rad	7 days post- cell rad	15 (5 ea @ 3 doses 0.5 Gy, 2 Gy, 3.5 Gy)
G	With Cells Injected	With DU Implant	37 days post DU implant (7 days post cell injection)	10 (5 ea @ 2 doses; 2 DU, 6 DU pellets)
H	With DU Exposed Cells Injected	No DU Implant	7 days post cell injection exposure to cells	10 (5 ea @ 2 doses, 1, 100 uM)
I	With cells Injected	No Rad No DU + Tantalum	37 days post Ta implant (7 days post cell inject)	5 (5 ea @ 6 Ta)

This aim will allow us to determine if methylation alterations are involved in ^{60}Co-or DU-exposure and with ^{60}Co-, or DU- induced leukemia in this unique leukemia model. There will be 5 animal tissues per dose point. Bone marrow cellularity and spleen weight will be analyzed as well.

V.1.2. Experiment 2 - Aim 5 of Intramural proposal: *To assess genomic instability by examining chromosomal aberrations in mouse ^{60}Co radiation- and DU-induced leukemia's and the clonal descendants of ^{60}Co- irradiated and DU-exposed bone marrow hematopoietic stem cell and compare to controls.*

Hypothesis Exp 2: Following ^{60}Co- or DU- exposure, genetic instability occurs within 1 month post exposure.

Rationale Experiment 2: Published studies have shown that DU induces genomic instability *in vitro* (2, 5, and 13) and that gamma-induced leukemia is associated with chromosomal instability (22-24). Both indicate genetic damage.

Methodology Experiment 2 To address this hypothesis, we intend to employ fluorescence *in situ* hybridization (FISH) to screen for chromosomal aberrations in mouse ^{60}Co- and DU- induced leukemias (obtained from frozen samples) and in the clonal descendants of control, ^{60}Co-irradiated bone marrow hematopoietic stem cells

(0.5, 2.0, and 3.5 Gy doses; 0.6 Gy/min), and internalized DU-exposed (either 2 DU + 4 Ta pellets or 6 DU + No Ta pellets; 1 mo.) bone marrow hematopoietic stem cells using the *in vitro* clonogenic CFU-A colony assay. The induced genetic instability should be detectable in the gamma irradiated or DU-exposed untransformed hematopoietic stem cell population and the clonal radiation-, or DU- induced leukemia by measuring chromosomal aberrations in leukemic and sub-clonal variants. Groups A, B, C, and D are control groups (± FDC-P1; ± ^{60}Co or DU) and will be euthanized at 7 days post exposure. Group E will be ^{60}Co exposed, injected with FDC-P1 cells and euthanized at 7 days post-cell injection. Group F (un-irradiated mice) will be injected with ^{60}Co-irradiated FDC-P1 cells and euthanized at 7 days post-cell injection. Group G will be DU exposed (30 days, either 2 DU + 4 Ta pellets or 6 DU + No Ta pellets) and will be injected with FDC-P1 cells; euthanasia will occur at 7 days post-cell injection. For group H, FDC-P1 cells will be exposed to DU-uranyl nitrate (1, and 100 uM, 4 hrs) prior to injection into non-DU exposed mice and euthanized at 7 days. Following euthanasia, bone marrow will be collected from both femurs. Bone marrow cells will be obtained by flushing the femurs. FISH will be used to screen for chromosomal aberrations in the clonal descendants of control-, irradiated, or DU exposed- bone marrow hematopoietic stem cells at 7 days post-radiation or 7 days post-pellet removal and in ^{60}Co- or DU-induced leukemias (obtained from previously frozen bone marrow cell samples), using the *in vitro* clonogenic CFU-A colony assay to assess genetic instability (30-34). Seven days post-radiation was selected since radiation or DU exposure may induce cell cycle arrest. Bone marrow cells from control, irradiated, or DU-exposed mice will be cultured *in vitro* for 6 to 8 days post-euthanasia to generate CFU-A colonies as described (36-40) and will then be selected and fixed for FISH analysis (36-40).

Table 2 is on the next page for ease of reading.

Table 2 – Experiment 2. Exposure and Control Groups

	Status of FDC-P1 Cells (± Inj or Rad)	Status of Mouse ± Rad or DU	Euthanasia	No animals
A	No Cell Injection	No Rad/No DU	Day 0	5
B	With Cells Injected	No Rad/No DU	Day 7	5
C	No Cell Injection	With Mouse ^{60}Co Rad	7 Days post-rad	15 (5 ea @ 3 doses 0.5 Gy, 2 Gy, 3.5 Gy)
D	No Cell Injection	With Mouse DU Implant	Immediately post-37 Days DU	10 (5 ea @ 2 doses; 2 DU, 6 DU pellets)
E	With Cells Injected	With Mouse ^{60}Co Rad	7 Days post-rad	15 (5 ea @ 3 doses 0.5 Gy, 2 Gy, 3.5 Gy)
F	With ^{60}Co Irradiated Cells Injected	No Mouse Rad	7 Days post-cell injection	15 (5 ea @ 3 doses 0.5 Gy, 2 Gy, 3.5 Gy)
G	With Cells Injected	With Mouse DU Implant	37 Days post-DU implant	10 (5 ea @ 2 doses; 2 DU, 6 DU pellets)
H	With DU Exposed Cells Injected	No Mouse DU	7 Days post-DU cell exposure	10 (5 ea @ 2 doses; 1 , 100 uM)
I	With Cells Injected	No DU No Rad + Tantalum	37 days post Ta implant (7 days post cell inject)	5 (5 ea @6 pellets)

General Methods:

Mice

Six- to 10- week old male DBA/2 mice will be purchased from the appropriate vendor and be housed (5 per cage) in an air-conditioned facility accredited by the Association for the Assessment and Accreditation of Laboratory Animal Care International. The mouse facility room is maintained at 64-79°F with 10-15 hourly cycles of fresh air and a relative humidity of 30 to 70%. The mice will be held in quarantine for two weeks upon arrival. Microbiology, serology, and histopathology examination of representative samples will ensure the absence of *Pseudomonas aeruginosa* and common murine diseases. Mice will receive certified rodent rations (Harlan Teklad Rodent Diet, Harlan

Teklad, WI) and acidified water (with HCL, pH 2.5-2.8) *ad libitum*. All mice will be kept in rooms with a 12h light/dark cycle with lights on from 0600 to 1800. All animal procedures will be performed based on a protocol approved by the AFRRI Institutional Animal Care and Use Committee. Research will be conducted according to the most recent *Guide for the Care and Use of Laboratory Animals*, prepared by the Institute of Laboratory Animal Resources, National Research Council, and US National Academy of Sciences.

Surgical Procedures.

Metal pellets. Each pellet (DU or Tantalum (TA)) will be a cylinder 1 mm in diameter and 2 mm long. *Surgery.* Pellets will be cleaned and chemically sterilized prior to implantation. Pellets will be immersed in absolute alcohol (15 mins), soaked in 50% nitric acid solution for 3 min, and then thoroughly rinsed 2X with sterile saline (0.9%). The procedure has been shown to remove the oxide formation on the surface of the DU pellet. A small heating pad will be used during surgery to maintained body temperature. Thirty to sixty minutes prior to surgery, each animal will receive 1 SC injection (27 gauge sterile needle) of buprenorphine (0.05 mg/kg) in the back of the neck. If mice appear to be in pain following implantation surgery they will receive another injection of the buprenorphine (same, dosage, same location). In our recent experiences with mouse DU surgery a second injection was not necessary but the project personnel will be prepared to provide additional analgesia as required. The criteria for analgesia following surgery will be 1) limping; 2) not eating/drinking; 3) ruffled coat; or 4) huddling. One criterion is sufficient to require analgesia. Anesthesia will be induced with isoflurane (~2-4%) and then maintained with isoflurane at the lowest possible rate (~1-2%). The animal will remain under isoflurane anesthesia for 5-8 minutes. Pellets will be implanted in the gastrocnemius muscle of each back leg, spaced approximately 2-4 mm apart. A single surgical site per rear limb will be shaved prior to surgery and then cleaned with betadine (i.e. standard sterile surgical preparation). A single scalpel incision (using a sterile surgical blade, #15 for example) will be made through the skin and pellets inserted into the muscle with a 16-gauge needle with plunger. The 16-gauge needle resembles a trochar and the pellets are loaded in order either (3 DU pellets) of 1 Ta + 1 DU + 1 Ta pellet. Each animal will receive a total of 6 pellets - three per hind limb. For high DU dose there are 3 DU pellets per limb. For the low DU dose there are 2 Ta and 1 DU pellet per hind limb. There is little chance that an air bolus could be introduced and it has never been seen in our previous pellet surgeries. The incision is generally 5-7 mm in length. One incision will enable the implantation of 3 pellets per limb. The syringe is preloaded with the pellets to be implanted. The incision will be closed with absorbable sutures (for example, 5-0 vicryl or, as recommended by the veterinarian). Mice will be closely monitored following surgery until ambulatory (usually within 10 mins). Animals will be monitored every 1 hr for the first 4 hrs post-surgery to determine if another dose of analgesia is necessary. However animals will be monitored closely for up to 6-8 hrs after surgery. Analgesia (buprenorphine, 0.05 mg/kg SC; injection back of neck) will be used if an animal demonstrates 1 criterion of pain. The criteria for analgesia will be 1) limping; 2) not eating/drinking; 3) ruffled coat; or 4) huddling. Animals will then be monitored by project personnel a minimum of 2X daily for the duration of the experiment but, during the first two weeks, four or more daily

observations by project personnel will be made if a single animal behaves as if he is in distress at any time point. An attending veterinarian will be consulted if any abnormalities are found. A technician experienced in this surgical technique, and previously observed by VSD veterinarians, will perform the surgeries. *Animal Observations/assessment of health status.* Mice will be monitored after pellet implantation and the PI or PI's technician will observe the mice a minimum of 2X daily for morbidity and mortality. Body weights will be recorded weekly. Moribund animals (NOT EXPECTED) will be euthanized, and necropsied. Previous studies in our laboratory have demonstrated that adverse effects following pellet surgery are rare [1-8].

Euthanasia:
At the appropriate time, the animal will be euthanized by CO_2 inhalation followed/confirmed by cervical dislocation.

Tissues Collection for Data Analysis:
Tissues will be collected following animal euthanasia.

V.2. Data Analysis

Experiment 1:
The endpoint for 1A will be southern blot/gel analysis of DNA methyl content. The endpoint of 1B will be southern gel analysis of methylation of the promoter region of two gene. The gels will be analyzed using laser densitometry. Levels of global genome DNA methylation in the spleen and bone marrow of exposed and control mice will be measured by the cytosine extension assay on treatment of DNA with a methylation-sensitive restriction enzyme HpaII that cleaves CCGG sequences when internal cytosine residues are unmethylated on both strands. The enzyme leaves a 5V-guanine overhang after DNA cleavage that is used for subsequent single nucleotide extension with labeled [3H]dCTP. The extent of [3H]dCTP incorporation opposite the exposed guanine is directly proportional to the number of cleaved and thus unmethylated CpG sites and inversely proportional to the levels of methylation (i.e., the higher the methylation, the lower is the incorporation of [3H]dCTP). A significant difference from control will be obtained by ANOVA (Analysis of variance of groups).

Experiment 2:
The endpoint of Experiment 2 will be the measurement of chromosomal aberrations in the CFU-A colonies derived from either the ^{60}Co-exposed bone marrow or the DU-exposed bone marrow. These chromosomal aberrations will be compared to the chromosomal aberrations measured in the bone marrow samples of mice previously diagnosed with leukemia following either radiation or DU exposure.

For gene expression studies signals will be quantified using NIH Image J 1.63 software and normalized relative to glyceraldehyde-3-phosphate dehydrogenase or the Mr 50,000 protein band. A comparison of the bands will be made using ANOVA analysis.

V.3. Laboratory Animals Required and Justification

V.3.1. Non-animal Alternatives Considered

Approaches using cellular models have already been conducted to study both radiation and DU-induced leukemic cell transformation. (b)(4),(b)(6)

(b)(4),(b)(6)

(b)(4) Radiation studies have demonstrated that methylation and histone modification (epigenetic changes) are observed following radiation exposure (23, 24). These *in vitro* studies implicate epigenetic mechanisms in the development of radiation late effects. However these findings must be confirmed in an *in vivo* model before they will be accepted by the risk assessment community (US ARMY Public Health Command (Prov.) and NCRP). Risk assessment requires that animal models be used to verify *in vitro* findings. Secondly, *in vitro* models do not allow us to evaluate whether the mechanism involved in the neoplastic transformation of cells *in vitro* would be affected by physiological, genetic, and environmental factors that are important to cancer induction *in vivo*. Finally, computer modeling could not be used to answer the research question I am addressing because modeling is dependent upon established *in vivo* results and there are currently no results regarding the mechanism of heavy metal induced late effects *in vivo*.

V.3.2. Animal Model and Species Justification

This murine model for toxicity studies is a well-characterized animal model system used in a variety of toxicological studies [41]. It has also been commonly used to study the mechanisms involved in the induction of biological effects following exposure to radiation and heavy metals [4-5, 7-8]. (b)(4)

(b)(4)

V.3.3. Laboratory Animals

V.3.3.1. Genus / Species

Mus musculus

V.3.3.2. Strain / Stock

DBA/2

V.3.3.3. Source / Vendor

Jackson Labs, NCI Frederick, Taconic, or Charles River

V.3.3.4. Age
6-10 weeks

V.3.3.5. Weight
18 – 30 grams

V.3.3.6. Sex
Male

V.3.3.7. Special Considerations
None

V.3.4. Number of Animals Required (by species)
180 mice

V.3.5. Refinement, Reduction, Replacement (3 R's)

V.3.5.1. Refinement
Based upon our current *in vitro* human cell methylation studies we are ready to evaluate mechanisms in an *in vivo* model. (b)(4)

(b)(4)

V.3.5.2. Reduction
By using tissue samples from previous studies we are reducing the number of animals needed in this study. We are able to compare the results from this study in which the tissues are collected at a short time after exposure (1 month) to results from animals that had a longer exposure (7 months) and had been diagnosed with AML.

V.3.5.3. Replacement
None

Totals:		70	50	60	180

V.4.1.2. Pain Relief / Prevention

V.4.1.2.1. Anesthesia / Analgesia / Tranquilization

Anesthesia (isofluorane) will be used to anesthetize the mice during the pellet implantation procedure. We have been doing this in our recently completed project. One hr prior to surgery, each animal will receive 1 SC injection (27 gauge sterile needle) of buprenorphine (0.05 mg/kg) in the back of the neck. If mice appear to be in pain following implantation surgery they will receive another injection of the buprenorphine (same, dosage, same location). The criteria for analgesia following surgery will be 1) limping; 2) not eating/drinking; 3) ruffled coat; or 4) huddling. One criterion is sufficient to require analgesia. During surgery and anesthesia administration, the animals will be placed on a small heating pad.

V.4.1.2.2. Pre- and Post-procedural Provisions

Pre-procedural Provisions: None needed.

Post-procedural Provisions: For the all aims/Experiment 1: Animals will be monitored a minimum of twice daily for 5 days post-pellet implantation procedure. Animals will be weighed weekly by trained personnel on the PI's staff. The pellet implantation procedure is not expected to cause pain, suffering or morbidity. At 30 days post-pellet implantation, animals will be euthanized and tissues collected. While it is unexpected, any animal in pain will be immediately euthanized. We will monitor the animals as described and any animal that appears to be in pain based upon the following specific criteria will be immediately euthanized. Mice will be closely monitored following surgery until ambulatory (usually within 10 mins). Animals will be monitored every 1 hr for the first 4 hrs post-surgery to determine if another dose of analgesia is necessary. However animals will be monitored closely for up to 6-8 hrs after surgery. Analgesia (buprenorphine, 0.05 mg/kg SC; injection back of neck) will be used if an animal demonstrates 1 criterion of pain. A VSD veterinarian will also be consulted if any abnormalities are encountered. The abnormal criteria include: dehydration, changes in body weight (>10% increase or decrease from baseline), abnormal posture, hypothermia (shivering), swelling, tissue masses, ruffled fur, eye discharge, head tilted, excessive salivation, dyspnea, diarrhea, hypo activity, and prostration. The endpoint of this study is euthanasia (to collect tissues for mechanism studies).

V.4.1.2.3. Paralytics

None used.

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures

V.4.1.3.1. Sources Searched

AltWeb
PubMed
Agricola

V.4.1.3.2. Date of Search

Jan 20, 23, 2012
Jan 20, 2012
Jan 23, 2012

V.4.1.3.3. Period of Search

1967-2011

V.4.1.3.4. Key Words of Search

Radiation, Depleted uranium, leukemia, alpha radiation, DBA/2, euthanasia, lethality, survival, pellets, implantation, epigenetics, leukemogenesis, model, pain, suffering, alternatives, distress, carcinogenesis, injection.

V.4.1.3.5. Results of Search
The implantation of heavy metals into the gastrocnemius muscle does not appear to cause pain in rodents based on the published results with similarly implanted heavy metals [1-7]. Studies have been published indicating that the surgical addition of prosthetic devices involving the heavy metal tantalum, a normal component to prosthetic limb attachments, do not cause medical problems or pain due to the surgical implantation of the heavy metal [1-8]. Furthermore, medical surveillance studies from soldiers wounded with DU shrapnel do not discuss whether the symptomology of the soldiers includes pain at the sites of the metal shrapnel; these papers do not indicate that the soldiers are in pain [6].

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification
The animals in this protocol will receive a dose of 0.5, 2.0 or 3.5 Gy of radiation and will not receive any analgesia. In my experience with this mouse model (11 years) the animals have not exhibited any signs of being in pain from these low doses of radiation. Furthermore, the effects of analgesia administration on the study endpoints are unknown and could compromise the experiment so no analgesia will be used unless the animals unexpectedly exhibit pain criteria. The criteria include but are not limited to: dehydration, changes in body weight (>10% increase or decrease from baseline), abnormal posture, hypothermia (shivering), swelling, tissue masses, ruffled fur, eye discharge, head tilted, excessive salivation, dyspnea, diarrhea, hypo activity, and prostration.

V.4.2. Prolonged Restraint
None Used.

V.4.3. Surgery

V.4.3.1. Pre-surgical Provisions
None Used.

V.4.3.2. Procedure(s) Surgical Procedures.
Each pellet (DU) will be a cylinder 1 mm in diameter and 2 mm long. *Surgery*. Pellets will be cleaned and chemically sterilized prior to implantation. Pellets will be immersed in absolute alcohol (15 mins), soaked in 50% nitric acid solution for 3 min, and then thoroughly rinsed 2X with sterile saline (0.9%). The procedure has been shown to remove the oxide formation on the surface of the DU pellet. Thirty to sixty minutes prior to surgery, each animal will receive 1 SC injection (27 gauge sterile needle) of buprenorphine (0.05 mg/kg) in the back of the neck. If mice appear to be in pain

following implantation surgery they will receive another injection of the buprenorphine (same, dosage, same location). The criteria for analgesia following surgery will be 1) limping; 2) not eating/drinking; 3) ruffled coat; or 4) huddling. One criterion is sufficient to require analgesia. Anesthesia will be induced with isoflurane (~2-4%) and then maintained with isoflurane (~1-2%). The animal will be under isoflurane anesthesia for 5-8 minutes. Fragments will be implanted in the gastrocnemius muscle of each back leg, spaced approximately 2-4 mm apart. A single surgical site per rear limb will be cleaned with betadine and shaved prior to surgery (i.e. standard sterile surgical preparation). A single scalpel incision (using a sterile surgical blade, #15 for example) will be made through the skin and pellets inserted into the muscle with a 16-gauge needle with plunger. One incision will enable the implantation of 3 pellets. The syringe is preloaded with the pellets to be implanted. The incision will be closed with absorbable sutures (for example, 5-0 vicryl or, as recommended by the veterinarian). Mice will be closely monitored following surgery until ambulatory (usually within 10 mins). However animals will be monitored closely for up to 4 hrs after surgery. Analgesia (buprenorphine, 0.05 mg/kg SC; injection back of neck) will be used if an animal demonstrates 1 criterion of pain. The criteria for analgesia will be 1) limping; 2) not eating/drinking; 3) ruffled coat; or 4) huddling. Animals will be monitored a minimum of 2X daily for the duration of the experiment but, during the first two weeks, three or more daily observations will be made if a single animal behaves as if he/she is in distress. An attending veterinarian will be consulted if any abnormalities are present. *Animal Observations/assessment of health status.* Mice will be monitored after pellet implantation and observed a minimum of 2X daily for morbidity and mortality. Body weights will be recorded weekly. Moribund animals (NOT EXPECTED) will be euthanized immediately and necropsied. Previous studies in our laboratory have demonstrated that adverse effects following pellet surgery are rare [1-7, 15-19].

V.4.3.3. Post-surgical Provisions
Mice will be closely monitored following surgery until ambulatory. Analgesic (buprenorphine 0.05/mg/kg, SC back of neck) will be used if necessary. Animals will be monitored a minimum of 2x daily for duration of experiment.

V.4.3.4. Location
Surgery location is (b)(6) or other suitable room as designated by VSD staff.

V.4.3.5. Surgeon
Trained technicians on the PI's staff

V.4.3.6. Multiple Major Survival Operative Procedures

V.4.3.6.1. Procedures
None Used.

V.4.3.6.2 Scientific Justification

None Used.

V.4.4. Animal Manipulations
1) Permanent individual identification using the ear notching method: This method requires a special tool to punch or notch holes at various positions in the ears; this technique is commonly used in rodents. Procedure will take place under sterile conditions in VSD after released from quarantine. Manual restraining is required to perform this technique.

V.4.4.1. Injections
Experiment 1 and Experiment 2

1) Animals will receive an injection of sterile cells (sterile FDC-P1 cells; 2-5 E6 cells/0.1-0.2 ml) immediately (within 30 mins) post-radiation into the tail vein. A 25-28 gauge needle will be used. Choice of needle gauge size can vary based on the animal size. This is necessary since this cell injection was required in the previous studies in which leukemia was induced.

V.4.4.1.1. Pharmaceutical Grade Drugs
None

V.4.4.1.2. Non-Pharmaceutical Grade Drugs
None

V.4.4.2. Biosamples
None, animals will be euthanized and samples will be taken post-mortem. My understanding is that biosamples are obtained from a live animal. However, after euthanasia, blood samples, liver, spleen, and bone marrow from both femurs will be taken.

V.4.4.3. Adjuvants
None used.

V.4.4.4. Monoclonal Antibody (MAb) Production
None used.

V.4.4.5. Animal Identification
Ear notches and cage cards will be used.

V.4.4.6. Behavioral Studies
None used.

V.4.4.7. Other Procedures
None used.

V.4.4.8. Tissue Sharing
Not at this time.

V.4.4.9. Animal By-Products
None.

V.4.5. Study Endpoint
The study endpoint for the animals is euthanasia at 1 month + 7 days post-metal implantation or 7 days post-gamma radiation.

V.4.6. Euthanasia
All mice will be euthanized by CO_2 inhalation. Euthanasia will be conducted using a euthanasia chamber. Compressed CO_2 gas in a cylinder with a regulator will be used for euthanasia in accordance with the 2007 AVMA Panel on Euthanasia. Cervical dislocation will then be used to ensure that the animal has been euthanized.

V.5. Veterinary Care

V.5.1. Husbandry Considerations
Animals will be housed no more than 5 per cage in a micro-isolator cage. Animals will receive food and water ad libitum. Cages are changed three times weekly in accordance with the current VSD Rodent Husbandry SOP. Animals will have a 12 hour/12 hour light and dark cycle. Radiation safety procedures as detailed in the general experiment section pages 7 and 8 will be followed. While it is unexpected based on previous experience with this model, if an animal dies prior to the study endpoint VSD staff has been trained to put the carcass in freezer that is posted for radioactive materials. Before we begin this entire study (involving DU) VSD staff and project personnel will be re-trained by the RSO with a radiation safety refresher lecture. All these procedures will be reviewed.

V.5.1.1. Study Room
Assigned by VSD.

V.5.1.2. Special Husbandry Provisions
None

V.5.1.3. Exceptions
None

V.5.2. Veterinary Medical Care

V.5.2.1. Routine Veterinary Medical Care
Study personnel will monitor all animals 2X daily for 5 days post metal implantation. The animals will be individually observed at each observation period and weighed weekly. At euthanasia, the appropriate tissues for the *in vitro* analyses will collected and a necropsy will be performed by project personnel and hematological and molecular

assessment will be made by project personnel. This information could assist with the assessment of animals in future studies.

If an animal becomes ill or debilitated during the course of the study (prior to a planned euthanasia), the principal investigator, study personnel and the clinical veterinarian or VSD technical staff will be notified immediately to determine severity of condition.

VSD animal care technicians will observe all colony animals during morning and afternoon rounds in addition to the husbandry caretakers' twice daily observations (b)(4) (b)(4)

Criteria used for health evaluation: dehydration, changes in body weight (>10% increase or decrease), abnormal posture, hypothermia (shivering), swelling, tissue masses, ruffled fur, eye discharge, head tilted, excessive salivation, dyspnea, diarrhea, hypo-activity, and prostration.

V.5.2.2. Emergency Veterinary Medical Care

Emergency veterinary medical care will include euthanasia (and necropsy) if the animal meets the criteria described in section V.5.2.1.

V.5.3. Environmental Enrichment

V.5.3.1. Enrichment Strategy

Animals can be given items in accordance with VSD/IACUC policy.

V.5.3.2. Enrichment Restrictions

None

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING

NAME	DEGREE	TRAINING	DATE	PROCEDURES	YRS/MOS EXPERIENCE
(b)(6)				Surgical pellet implantation, Radiation, Injection, Euthanasia, Ear notch, Tail vein injection; All procedures are currently used in other projects. Codes 1-6	(b)(6)
				General animal handling, Radiation, drug Injection; Codes 1; 5	
				General animal handling; Codes 1; 3; 5	

NAME	DEGREE	TRAINING	DATE	PROCEDURES	YRS/MOS EXPERIENCE

Procedure and manipulation codes:
Code 1= Animal handling and euthanasia
Code 2= Surgery (aseptic technique) pre- and post-operative care
Code 3= Injections (3a–ip, 3b-sc, 3c-gavage) - can say 3 if trained in all manipulations or add 3d-iv
Code 4= Blood collection under anesthesia (4a-cardiac, 4b-posterior vena cava)
Code 5= Tissue collection (after euthanasia) - doesn't need to be specific
Code 6 = Implantation (DU pellet implantation; provide detail here)
Code 7 = Others - (provide protocol specific manipulations or procedures for e.g., retro-orbital bleeding, tail vein injection, or drug delivery)

VII. BIOHAZARDS/SAFETY

(b)(4),(b)(6)

This project involves radiation hazards. The hazards were initially detailed in a paragraph in the general procedures section. It is repeated here for additional clarity.

(b)(4),(b)(6)

(b)(4) The VSD room where the mice will be housed will be posted as a "radiation materials work area". As in our currently approved DU protocol we (and all personnel handling mice and the cages) will have special safety wear (gloves, gowns); radiation safety practices will be used in Rad posted rooms in VSD in regard to waste/trash collection, and the carcasses will be stored in a locked frig/freezer. The VSD room will be posted with a sign indicating that the use of radioactive materials is occurring in that room. The animal bedding will be collected after each cleaning and will be inspected for any unexpected loss of DU pellets. The

bedding will be stored as radioactive waste. After the animals are euthanized, the DU pellets will be removed and accounted for.

In all non-radioactive procedures, standard laboratory safety precautions and programs will be observed in this project.

VIII. ENCLOSURES

None

X. ASSURANCES

Protocol Title: Evaluation of Mechanisms and Involvement of Non-targeted Radiation Effects in Radiation and Depleted Uranium Induced Leukemia's in mice (*Mus musculus*) (Intramural)

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made every effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with a qualified individual who evaluated the experimental design with respect to the statistical analysis, and that the minimum number of animals needed for scientific validity will be used.

D. Biohazard / Safety: I have taken into consideration and made the proper coordinations regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R", namely, "Responsibility," which the DOD has embraced for implementing animal use alternatives where feasible and conducting humane and lawful research.

G. Scientific Review: This proposed animal use protocol has received appropriate peer scientific review and is consistent with good scientific research practice.

H. Painful Procedure(s): I **AM / AM NOT** conducting biomedical experiments, which may potentially cause more than momentary or slight pain or distress to animals. If applicable, potential pain and/or distress **WILL / WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

I. NON-TECHNICAL SYNOPSIS

The terrorist attack of September 11, 2001 against the United States has increased the concern that terrorists may acquire and use radioactive sources (e.g. dirty radioactive bombs) to expose military and civilian populations to ionizing radiation. However, despite this concern, there are currently no FDA approved drugs that can be used for the general population to prevent death that is likely to result from exposure to ionizing radiation (b)(4) irradiation in humans can result in both (b)(4) (b)(4) injuries. However, because rodents are more resistant to (b)(4) injuries than humans, there is currently no murine model that has been developed to study both (b)(4) radiation injuries in the same animal.

(b)(4)

protects (b)(4) from radiation-induced genotoxicity, and that (b)(4) treatment increases the mean survival time from (b)(4) irradiation by 50%. (b)(4) (b)(4) Several laboratories have shown that a naturally occurring, non-toxic drug (b)(4) an inhibitor of (b)(4) is a protective agent against (b)(4) induced by chemotherapy agents (b)(4) (b)(4) enhances the activity of (b)(4) for the prevention of (b)(4). Our proposed studies here will examine the effects of (b)(4) in combination with (b)(4) for protection of (b)(4) radiation injuries in an animal model for both injuries. Our aim is to develop an effective, non-toxic radioprotectant/radiotherapeutic treatment strategy that can be used for protection against both (b)(4) effects of radiation exposure in a murine model for both types of radiation injury.

(b)(4),(b)(6)

II. BACKGROUND

II.1. Background

The acute toxic effects of exposure to high doses of ionizing radiation in humans have been shown to occur due to two sequential effects: first the ablation of immune cells, resulting in loss of immune function and increasing likelihood of pathogenic infection (b)(4) and subsequently the loss of epithelial progenitor cells of the gastrointestinal (GI) crypt (b)(4) Both of these events have been shown to be due to the loss of fast-growing pluripotent and/or progenitor cell types. The time course of the acute injuries correlates with the life span of the mature cell types of the tissue, which are not replaced because of radiation damage to the adult pluripotent cells and adult stem cells. There is currently no FDA approved prophylactic or treatment for prevention of acute radiation injuries following high-dose (b)(4) radiation exposure.

In some cases supportive measures can be used to treat acute radiation syndrome, and survival from (b)(4) radiation exposure is now possible (b)(4) This results in current efforts to mitigate or treat later stage effects of ionizing radiation exposure. (b)(4)

(b)(4)

In humans, death from radiation (b)(4) can occur following survival from (b)(4) Cumulative evidence from a number of laboratories, including our own, shows that there is a threshold dose of radiation of (b)(4) to induce sufficient (b)(4) for the (b)(4) to occur in mice; below these doses, no permanent injury manifests, although some short-term effects are observed (b)(4) (b)(4) However, in humans, there is currently no accepted protocol for preventative treatment of radiation-induced (b)(4) and morbidity as high as 50% is associated with each phase (b)(4) (b)(4) injuries from radiation is considered to be a serious problem in the field for the development of agents to prevent these radiation injuries.

(b)(4) **as a radioprotectant:** The biochemical properties of the isoflavones and the investigation of (b)(4) as a protectant against gamma radiation-induced lethality have been investigated by (b)(4),(b)(6) (b)(4),(b)(6) (b)(4) A single i.p. dose of (b)(4) administered (b)(4) hr prior to a lethal dose of radiation resulted in (b)(4) day survival rates of 65%, 91%, and 85% respectively. Mice receiving saline or PEG vehicle alone survived at 8% and 15% respectively. All doses of (b)(4) protected mice significantly ($p < 0.001$) better than vehicle or saline control groups.

The behavioral toxicity was investigated for male mice receiving a single i.p. injection (0.1 ml) of saline, PEG vehicle, or (b)(4) Locomotor activity (total distance traveled), grip strength and motor coordination were evaluated on days (b)(4) post-injection and body weight was measured over (b)(4) days. On day (b)(4) tissues from the testes, liver, adrenal gland, mesenteric lymph node, spleen, and bone marrow of the femur and sternum were collected, fixed in buffered formalin, paraffin embedded, sectioned, and stained by hematoxylin and eosin. The results indicated that there were no significant effects of (b)(4) or vehicle on locomotor activity, grip strength, motor coordination, or body weight, compared to the saline-treated control group. In addition, no gross morphological changes or histopathological alterations were observed (b)(4)

(b)(4) **as a radioprotectant and an antifibrotic agent:** (b)(4) and its proteolytic product (b)(4) are believed to have their primary biological functions in blood pressure homeostasis. However, (b)(4) have been demonstrated to be upregulated in fibrotic tissues. Inhibition of (b)(4) or blockade of the (b)(4) receptors on cells has been shown to ameliorate drug-induced (b)(4) in murine and rat models for (b)(4) (b)(4) receptor antagonists also prevent cardiac remodeling following ischaemia/reperfusion in rat models of cardiac remodeling diseases (b)(4) Several studies have also shown that inhibition of (b)(4) signaling mitigates radiation-induced injuries, including to the heart and (b)(4) One study shows that the (b)(4) reduces acute damage to the jejunal mucosa in mice following exposure to (b)(4) This work examined only initial tissue injury and did not extend findings past days, and did not examine mortality. A second (b)(4) study found a reduction in (b)(4) in rats exposed to (b)(4) radiation (b)(4)

Preliminary Studies:

II.2. Literature Search for Duplication

II.2.1. Literature Sources Searched

1) Biomedical Research Database (BRD) (http://www.dtic.mil/biosys/org/brd/)
2) Computer Retrieval of Information of Scientific Projects (RePORTER) database (http://projectreporter.nih.gov/reporter.cfm)
3) PubMed (http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed)

II.2.2. Date of Search

Data base searches conducted on 8/06/12.

II.2.3. Period of Search

Searches conducted for the entire time periods available in each data base. For BRD, 1998-2012; for RePorter, 1972-2012. For PubMed, 1970-2012.

II.2.4. Key Words of Search

Searches were performed using the following key word combinations:

(b)(4)

[redacted]

II.2.5. Results of Search

1) BRD: (b)(4) [redacted] returned 0 results.
One grant was funded to examine the activity of (b)(4) [redacted]

(b)(4)

2) A RePORTER search revealed 8 current grants studying the effects of radiation on (b)(4)

(b)(4)

None of the funded studies duplicate our research of (b)(4)

(b)(4)

3) PUBMED Search *8/3/09*

None of the publications available described a murine model for both (b)(4)

(b)(4 injuries from radiation.

(b)(4)

(b)(4)

Summary of other publications:

(b)(4)

III. OBJECTIVE / HYPOTHESIS

Our objective is to: 1) continue development of a murine model for both the (b)(4) (b)(4) injuries; and 2) examine protective effects of (b)(4) against these two

injuries in the developed model. (b)(4)
(b)(4)

IV. MILITARY RELEVANCE

The Department of Defense is prepared to execute military missions within radiation environments, to manage radiation crises associated with terrorist activities, and to manage consequences in the event of nuclear weapons detonation. Recent studies indicate that there is an increasing risk of exposure to ionizing radiation (IR) to military personnel due to increasing terrorist activities, including potential use of stolen nuclear weapons or dispersal of radioactive material in a "dirty bomb" (b)(4) Because of potential exposure of military personnel to radiation, the DoD is committed to protect members of the Armed Services from the adverse health effects of ionizing radiation. High dose IR causes short term, acute injuries including hematopoetic and GI syndromes. However, both high and low dose IR (as may result from a radiation dispersal device) can cause (b)(4) as demonstrated by Japanese atomic bomb survivor data as well as accidental exposures to Russian populations (b)(4) (b)(4) While early effects of radiation injury now have treatment/ prophylactic strategies, the delayed effects currently have no treatment. Lack of treatment for late effects of radiation, including (b)(4) will likely lead to delayed morbidity and mortality for personnel exposed to IR.

The Department of Defense (DoD) Chemical and Biological Defense Program 2007 Annual Report to Congress, Chapter 2.7.6 Medical Radiological Defense, addresses the requirements for the development of radioprotectants. This priority is outlined for the development of protectants for both acute and delayed radiation injuries, with an emphasis on (b)(4) According to this report, the mitigation of (b)(4) is a major research thrust area (b)(4)
(b)(4)

V. MATERIALS AND METHODS

V.1. Experimental Design and General Procedures

The goal of this project is to: 1) finish development of a murine model for both (b)(4) (b)(4) effects of radiation; and 2) investigate the protective effects and mechanisms of (b)(4) treatment for radiation-induced (b)(4) injuries.

(b)(4)

(b)(4)

(b)(4) Mice will be exposed to both (b)(4) (b)(4) irradiation to induce the total radiation doses required to induce both acute and delayed injuries, to simulate the injuries that occur in humans as a result of (b)(4) irradiation.

(b)(4) irradiation will be performed (b)(6) using the standard Lucite holders for irradiation. Sham irradiation will be performed by placing the mice in Lucite holders for equal time periods without irradiation. These experiments will involve short end points (less than days) for examination of (b)(4)
(b)(4) five criteria. Survival at days will be used to evaluate the (b)(4)

(b)(4) radiation used to induced (b)(4) For (b)(4) irradiation, we will utilize (b)(6) and modified Lucite jigs designed based on those used in the Radiation Research Branch, NIH/NCI. The use of these jigs was reviewed and approved by AFRRI veterinary staff. Sham irradiation will be performed by placing the mice in jigs for equal lengths of time with no irradiation. As measurements of (b)(injury and cellular injury in the (b) from radiation, five criteria will be examined:

(b)(4)

V.1.1. Experiment 1

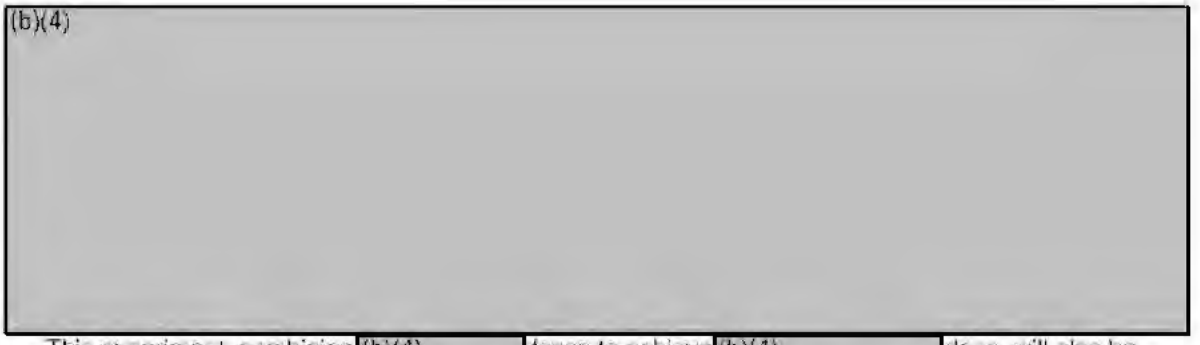
Experiment 1 Final development of a murine model that incorporates both (b)(4) radiation injuries.

(b)(4) mice: n pain category E)

Rationale: (b)(4)

(b)(4)

(b)(4)



This experiment, combining (b)(4) doses to achieve (b)(4) dose, will also be used to determine that we do not encounter a significant effect from (b)(4) the dose. To minimize a possible (b)(4) effect, we will keep the interval between radiation exposures as low as possible, (b)(4) min.

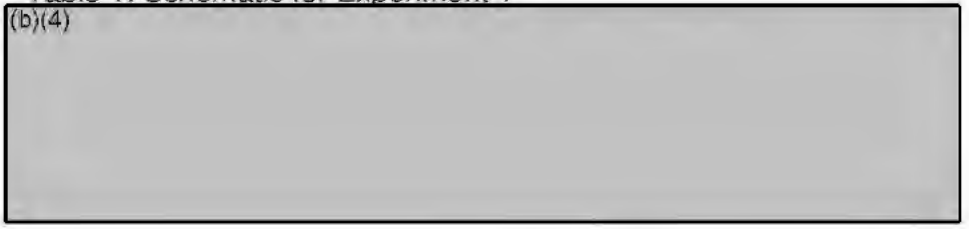
To complete our development of the model, we will use five doses of (b)(4) between (b)(4) (b)(4) Groups will be: 1) (b)(4) irradiation only; and 2) (b)(4) irradiation + (b)(4) irradiation. Time points will be: survival at (b)(4) days postirradiation. (b)(4) irradiation will be given to equal a total exposure of (b)(4) irradiated mice. Mice will first be exposed to (b)(4) irradiation in the (b)(6) facility, (b)(4) then anesthetized and exposed to X-ray irradiation of the (b)(6) facility, dose rate (b)(4) Control mice will be anesthetized and placed in holders to provide a sham for (b)(4) irradiation. This will control experiment will be performed to determine whether anesthesia given after (b)(4) irradiation affects survival. (b)(4) showed that anesthetics decrease bone marrow sensitivity to radiation; (b)(4) showed that pentabarbitol and steroids provide protection from radiation (b)(4) but not from (b)(4) In our experiments, we have observed significant radiation-induced (b)(4) injury although all of our experiments utilized anesthesia (telazol/xylazine) for the duration of the (b)(4) irradiation. Telazol is a combination of equal parts by weight of base of tiletamine hydrochloride (2-[ethylamino]-2-[2-thienyl]-cyclohexanone hydrochloride), an arylaminocycloalkanone dissociative anesthetic, and zolazepam hydrochloride (4-[o-fluorophenyl]-6, 8-dihydro-1,3,8-trimethylpyrazolo [3, 4-e] [1,4] diazepin-7 [1H]-1-hydrochloride), a non-phenothiazine diazepinone having minor tranquilizing properties. Tiletamine is a dissociative anesthetic and pharmacologically classified as an NMDA receptor antagonist. In comparison, ketamine is not a drug combination as is telazol, and is also classified as an NMDA receptor antagonist. Since tiletamine and ketamine are both NMDA receptor antagonists, we do not anticipate large alterations in the (b)(4) response to irradiation. The experiment will be repeated because it is a generally accepted principle of the scientific method that experiments must be repeated to evaluate a hypothesis.

(b)(4) Mice needed for experiment: (b)(4) group to reach statistical significance for survival.
(b)(4) (b)(4) mice/group) x (6 conditions) x (1 time point) = (b)(4) animals.
The experiment will be repeated 1 time to confirm findings (total (b)(4) animals).

(b)(4) Endpoint: The endpoint will be (b)(4) days. We will measure survival at both (b)(4) days for the study. Early time points will be taken if any animal exhibits signs or symptoms of morbidity or moribundity in accordance with AFRRI IACUC Policy #10 (score of >11 as described in the AFRRI IACUC pain score sheet). Such animals will be euthanized at the time of observation.

Table 1: Schematic for Experiment 1

(b)(4)



(b)(4)

V.1.2. Experiment 2

Experiment 2. Determine the effect and mechanism of (b)(4) on (b)(4) following (b)(4) (b)(4) irradiation. (mice: in category E)

Rationale: Experiment 1 will be used to determine overlapping effects of (b)(4) irradiation on (b)(4) injury by (b)(4) irradiation. This section objective will be to determine the effects and the mechanisms of (b)(4) for the prevention of (b)(4) induced by exposure to (b)(4) irradiation. The approach will be to use murine model of both (b)(4) (b)(radiation injuries developed in Experiment 1. We will assess the mechanisms of protection using (b)(4) cellular, histological, molecular, and biochemical markers. The rationale for undertaking this research is that once the mechanisms of (b)(4) prevention of (b)(4) are known, these may help designing therapeutic strategies against radiation-induced (b)(injury.

PEG-400 (0.1 ml/mouse) vehicle only or (b)(4) will be administered by a single (b)(4) i.p. injection (b)(4) before radiation exposure. (b)(4) will be provided in the drinking water at (b)(4) to give a dosage of (b)(4) per day for the duration of the experiment starting on day 0. Mice will be exposed to (b)(4) using (b)(4) dose rate. Subsequently, mice will be anesthetized and exposed to (b)(4) x-ray irradiation to give exposures equal to (b)(4) irradiation, (b)(4) dose rate. Treatment groups will be: 1) PEG; 2) PEG + (b)(4) 3) (b)(4) We will not use (b)(4) alone as we have already determined that it is not effective alone for injury. Acidified water will be provided until after irradiation, and at which time it will be replaced with (b)(4) in acidified water (b)(4) water bottles will be prepared by the laboratory, and will be replaced 2X per week in accordance with VSD protocols. Extra water bottles will be prepared in advance in case they are needed to replace a leaking water bottle.

Mice will be monitored monthly using non-invasive, unrestrained (b)(4) to determine (b)(4) (b)(4) For these studies mice are required per radiation dose. The time point for (b)(4) is days, based on data from previous studies by others (b)(4) The time point for (b)(4) is (b)(4) days, based on previous studies by others (b)(4) The experiment will be repeated because it is a generally accepted principle of the scientific method that experiments must be repeated to evaluate a hypothesis.

(b)(4) (mice per group) x (3 treatment groups) x (1 time point) x (3 radiation levels) = (b)(4)

(b)(4) mice/experiment) x (2 experiments) = mice

Endpoints: The final endpoint for the experiment is days. Mice displaying obvious dyspnea, extreme lethargy, or other markers of morbundity as described in the AFRRI IACUC pain score sheet (score of >11), and which appear to be in distress will be euthanized in accordance with AFRRI IACUC Policy #10 (b)(4) will be histologically examined for (b)(4) remodeling.

Table 2: Schematic for Experiments 2 and 3.

(b)(4)

V.1.3. Experiment 3

Experiment 3: Determination of the mechanism of reduction of (b)(4) injury by (b)(4)

(b)(4) (b)(4) mice/ in category C; in category E)

(b)(4) We have determined that between (b)(4) days, cells exhibit markers o (b)(4) (b)(4) following (b)(4) rradiation. We will investigate the mechanism of action of (b)(4) and (b)(4) examining these markers of cell injury.

We will use 4 time points (b)(4) days postirradiation, using the same doses of radiation listed in Table 2. Treatment groups will be: 1) PEG; 2) PEG + (b)(4) 3) (b)(4) (b)(4) The experiment will be repeated because it is a generally accepted principle of the scientific method that experiments must be repeated to evaluate a hypothesis.

(b)(4) mice per group) x (3 treatment groups) x (4 time points) x (3 adiation levels) = (b)(4) (b)(4)
(b)(4) (b)(4 mice/experiment) x (2 experiments) = mice
(b)(4) **sham-irradiated mice will be required as controls.**

Endpoint: Endpoints for the experiments will be (b)(4) days. Early time points will be taken if any animal exhibits signs or symptoms of morbidity or moribundity (scoring over 11 on the AFRRI IACUC-recommended pain score sheet) in accordance with AFRRI IACUC Policy #10. Such animals will be euthanized at the time of observation.

V.2. Data Analysis Mean with standard error, or percentage will be reported if applicable. A significance level is set at 5% for each test. All statistical tests are two-sided. A statistical software, SAS will be used for statistical analyses.

Experiment 1: Log-Rank test will be used for comparison among groups. If significant, Fisher's exact test will be used to detect significant differences across the groups in survival rates at day Kaplan (b)(4)
(b)(4) Meier curves will be displayed. N = mice per group will have 80% power in detecting a significant difference between two groups if any, given type I error of 5% where the treatment group survival rate is at least 68%, compared to a control group survival rate of 20%. Similar statements would apply, if the treatment group survival rates are at least 83%, 78%, or 73%, compared to vehicle group survival rates of 35%, 30%, and 25%, respectively (b)(4)

Experiments 2 and 3: Analysis of variance (ANOVA) will be used to detect significant difference among the groups. If significant, then the pair-wise comparison by Tukey-Kramer will be used to identify which group is different from the other. For experiment 2, N = mice per group could have 80% power (b)(4) to detect any significant difference between groups if any, given type I error of 5% and delta/sigma has at least 1.4, where the delta is the estimated mean differences between the two groups and sigma is the pooled standard deviation of the two groups (b)(4) For experiment 3, we only need N = (b)(4) based on our current data from radiation experiments and induction of (b)(4) markers.

V.3. Laboratory Animals Required and Justification

V.3.1. Non-animal Alternatives Considered

For the last 8 years, we have utilized primary cell culture systems to examine anti-apoptotic mechanisms; however, we must determine whether our culture findings are relevant in whole animals. We will continue to use primary cell culture whenever possible to avoid unnecessary use of animals. We have also considered computer models as alternatives to animals. However, this alternative also lacks the knowledge base and complexity needed to evaluate radioprotective and radiotherapeutic agents.**V.3.2. Animal Model and Species Justification**Tissue culture conditions cannot fully substitute for the

complexities of whole organisms in response to radiation injury. Such injury involves the interactions between the (b)(4) system and other organ systems. In order to develop viable treatments for humans, we find that our research must be conducted in whole animals.

Work by (b)(6) also advocates the mouse as the best species to use for radiation protection and radiotherapy protocols: 1) mice provide the least sentient species available whose response to radiation has been clearly identified, with physiological responses to radiation and radioprotectants that are similar to human physiology, 2) extensive literature is available on responses of mice to radiation and countermeasures, 3) more reagents are available to study the relevant cell types and molecules in mice than in any other species except humans, and the availability of transgenic and knockout mice make this model extremely attractive for further research into molecular mechanisms, and 4) (b)(6) have extensive experience with this model in radiation injury and radioprotection research (b)(6)

V.3.3. Laboratory Animals

V.3.3.1. Genus / Species *Mus musculus*

V.3.3.2. Strain / Stock CBA, female. CBA mice have (b)(4) (b)(4) in a shorter time course than C57BL/6 mice, and in a pattern that more closely resembles (b)(4) in humans (b)(4)

V.3.3.3. Source / Vendor
(b)(4) for CBA (fully accredited by AAALAC Int)

V.3.3.4. Age 10-15 weeks

V.3.3.5. Weight Normal adult weight range for this strain: 17-21 g.

V.3.3.6. Sex
Female. Only females will be used in this study for the following reasons: 1) we have so far utilized female mice to lay the foundation of our studies for radiation-induced (b)(4) injuries; 2) because of long housing periods, it is advantageous to use female mice that are less aggressive toward each other.

V.3.3.7. Special Considerations Commercially procured animals must be adventitious disease free. Mice- Pathogen-free, including *Pseudomonas aeruginosa*, and Pasteurella: All mice need to be free of the following agents: Sendai, Pneumonia Virus of Mice (PVM), Reovirus-3 (Reo 3), Mouse Adenovirus (MAD-1, MAD-2), Mouse Cytomegalovirus Virus (MCMV), Ectromelia, K virus, Lymphocytic Choriomeningitis Virus (LCM), Epidemic Diarrhea of Infant Mice (EDIM), Hantaan virus, Rotavirus, Mouse Parvovirus (MPV), Polyoma Virus, Mouse Minute Virus (MMV), Mouse Thymic Virus (MTV), Theiler's Mouse Encephalomyelitis Virus (TMEV/GDVII), *Encephalitozoon cuniculi*, CAR bacillus; *Helicobacter* spp. *Mycoplasma pulmonis*, and *Clostridium piliforme*. Endoparasite- and ectoparasite-free.

V.3.4. Number of Animals Required (by species) *Mice* (b)(4)

V.3.5. Refinement, Reduction, Replacement (3 R's)

V.3.5.1. Refinement Animals demonstrating moribundity due to radiation exposure (b)(4) (b)(4) will be considered to have arrived at the study endpoint and will be immediately euthanized (See sections V.4.5 Study Endpoint and V.4.6 Euthanasia). (b)(4) will likely minimize pain and

(b)(4) distress, while [redacted] has been shown in studies of chemotherapy agents to function as a repair and [redacted] factor.

Ketamine/xylazine anesthesia will be used during X-ray irradiation to prevent stress from the time the mice are placed in restraint. Under the training protocol at AFRRI, under the supervision of AFRRI veterinary staff, we found that in female C57BL/6J mice, ~12 weeks old, i.p. injection of 150 mg/kg ketamine plus 18 mg/kg xylazine results in 60-80 min anesthesia with no morbidity or mortality [redacted] We propose to use this range of concentration of anesthetics, together with a heating pad to keep mice warm during the period of recovery from anesthesia. Standard intraperitoneal injection methods are used for injection of the anesthesia, as recommended and approved by the AFRRI veterinary staff and for which all laboratory personnel have received training at AFRRI.

V.3.5.2. Reduction Whenever possible, control groups will be shared between experimental groups for our experiments. Tissues will be collected for multiple assays from the same animals further reducing the total number of animals needed. At every stage of the research, planned experiments will be reevaluated, in an attempt to reduce the numbers of experiments and eliminate repeats of experiments where statistical significance has already been obtained. We also plan to take as many tissues as we can reasonably analyze for experiments examining protein oxidation.

V.3.5.3. Replacement At this time, it is not feasible to use non-animal systems in place of animal models to address the research questions in this protocol.

V.4. Technical Methods

V.4.1. Pain / Distress Assessment

V.4.1.1. APHIS Form 7023 Information

V.4.1.1.1. Number of Animals

V.4.1.1.1.1. Column C [redacted] (# of animals)

V.4.1.1.1.2. Column D [redacted] (# of animals)

V.4.1.1.1.3. Column E [redacted] *(# of animals)*

V.4.1.1.1.4. Pain Category Assignments

[redacted]

V.4.1.2. Pain Relief / Prevention

V.4.1.2.1. Anesthesia / Analgesia / Tranquilization We will be unable to use analgesics since they have effects on [redacted] function that would interfere with the interpretation of our results [redacted] Some sedatives have been reported to contribute to postoperative [redacted] which likely reduce some functions of radiation. Additionally, it has been shown that the biometabolism of analgesics can induce protein oxidation, which would interfere with sample analysis [redacted]

Animals in experiments involving blood collection will be deeply anaesthetized immediately prior to sample collection. For blood draws we will use 150 mg/kg ketamine plus 18 mg/kg xylazine given i.p. with a 25 G needle. For euthanasia, animals will be given 0.1-0.2 ml/mouse pentobarbital (50 mg/ml) given i.p. with a 25 G needle.

An anesthesia protocol has been developed for use during the X-ray irradiation. Ketamine will be used with xylazine for longer anesthesia in mice to be place in restraints for (b)(4) irradiation. Under the training protocol at AFRRI in conjunction with the AFRRI veterinary staff, we found that in female CBA mice, ~12 weeks old,i.p. injection of 150 mg/kg ketamine plus 18 mg/kg xylazine results in 60-80 min anesthesia (25 G needle) with no morbidity or mortality (b)(4) We propose to use this range of concentration of anesthesia, together with a heating pad to keep mice warm during the period of anesthesia. Standard i.p. injection methods are used for injection of the anesthesia, as recommended and approved by the AFRRI veterinary staff and for which all laboratory personnel have received training at AFRRI.

V.4.1.2.2. Pre- and Post-procedural Provisions Animals will be housed and cared for as described in Section V.5. Veterinary Care both before and after dose administrations and irradiation procedures.

V.4.1.2.3. Paralytics N/A

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures

V.4.1.3.1. Sources Searched Sources searched: DoD Bioedical Research Data Base (BRD), CRISP, PubMED

V.4.1.3.2. Date of Search 8/7/12

V.4.1.3.3. Period of Search
Search covered published manuscripts from ~1965-present. (BRD search included all available years 1998 -2012)

V.4.1.3.4. Key Words of Search
Pain, analgesia, anesthesia, mice, radiation, ionizing radiation, humane, (b)(4)

V.4.1.3.5. Results of Search
The literature search revealed that, at present, there are no alternative procedures for irradiation because its effects cannot be otherwise duplicated. In some cases radiation has been demonstrated to reduce pain in laboratory mice (b)(4) and has been in humans reported to alleviate cancer related bone pain (b)(4) A recent report showed that administration of botulinum toxin A was effective for reduction of pain and muscle spasms after clinical radiation for treatment of tumors (b)(4) Application of natural honey 20 min prior to radiation exposure was also shown to reduce mucositis with associated pain in humans following head/neck radiotherapy (b)(4) it has not been determined whether honey acts as a local radioprotectant. Spinal cord stimulation has also been reported in humans to alleviate pain resulting from radiotherapy (b)(4) however, this method would not be practical for use in mice because of the extensive spinal cord manipulation required. Human administration of morphine also relieves pain (b)(4) but again this would not be practical for mice in our experiments because of side effects of the drug. In humans, exposure to (b)(4) irradiation may induce vomiting and diarrhea, causing pain and distress. However, mice are not susceptible to vomiting. The animals that will be administered (b)(4) will likely receive pain relief as phytoestrogens have been

reported to reduce neuropathic pain in rodents (b)(4) preliminary results also indicate that (b)(4) ameliorates acute radiation-induced injuries (b)(4)

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification

Anesthesia will be used before (b)(4) irradiation to avoid stress from restraint (b)(4) (b)(4) (b)(4) we will be unable to use analgesics after irradiation since they have effects on (b)(4) function that would interfere with the interpretation of our results (b)(4) (b)(4) (b)(4) In experiments where tissue collection is needed, animals will be euthanized with pentobarbitol prior to sample collection as described elsewhere.

V.4.2. Prolonged Restraint

No prolonged restraint *is* required for (b)(4) irradiation. Whole body (b)(4) is non-invasive and unrestrained. (b)(4) irradiation will require restraint in designed jigs for 20-40 min to receive X-ray exposure (b)(4) ; animals will be anesthetized during this period (see Anesthesia above) and tails will be taped to one side with surgical tape. The jigs for use during (b)(4) irradiation were examined and approved by the AFRRI Veterinary staff. Under the training protocol at AFRRI in conjunction with the AFRRI veterinary staff, we found that in female CBA mice, ~12 weeks old, i.p. injection of 150 mg/kg ketamine plus 18 mg/kg xylazine results in 60-80 min anesthesia (25 G needle) with no morbidity or mortality (b)(4) We propose to use this range of concentration of anesthesia, together with a heating pad to keep mice warm during the period of anesthesia. Standard i.p. injection methods are used for injection of the anesthesia, as recommended and approved by the AFRRI veterinary staff and for which all laboratory personnel have received training at AFRRI. AFRRI Veterinary staff have provided training and supervision for the placement of anesthetized animals in the approved jigs for irradiation.

V.4.3. Surgery

V.4.3.1. Pre-surgical Provisions N/A

V.4.3.2. Procedure(s) N/A

V.4.3.3. Post-surgical Provisions N/A

V.4.3.4. Location N/A

V.4.3.5. Surgeon N/A

V.4.3.6. Multiple Major Survival Operative Procedures

V.4.3.6.1. Procedures N/A

V.4.3.6.2 Scientific Justification N/A

V.4.4. Animal Manipulations

V.4.4.1. Injections

Intra-peritoneal injections of pentobarbital for euthanasia 0.1-0.2 ml/mouse Fatal Plus (39-78 mg pentobarbital/mouse), will be performed with a 25 G needle. I.p. injection of 150 mg/kg ketamine plus 18

mg/kg xylazine will be done using a 25 G needle. This has been extensively examined by the AFRRI Veterinary staff and shown to effectively produce non-lethal anesthesia (b)(4)

V.4.4.1.1. Pharmaceutical Grade Drugs

(b)(4)

V.4.4.1.2. Non-Pharmaceutical Grade Drugs

(b)(4),(b)(6)

Endotoxin in the drugs will be measured by the PI, or information from the company will be provided prior to administration of drugs to the animals.

V.4.4.2. Biosamples

Blood will be taken under deep anesthesia. All other biosamples will be taken after euthanasia (b)(4) (b)(4) or analysis will removed *en bloc*. Intestinal tissue will be taken in smaller amounts (the first segment of the small intestine). All other tissues will be available to other researchers for tissue sharing.

For some experiments, blood will be obtained from the animals. Blood will be taken by percutaneous intra-cardiac collection using a 23 – 22 g needle. All other tissues will be available for tissue sharing with other investigators. Intra-cardiac puncture must be performed under deep anesthesia and is considered a non-survival procedure. The mouse is deeply anesthetized and toe pinch response will be used to determine the depth of anesthesia. The ventral chest will be wiped with 70% ethanol. A 23 – 22 g needle will then be inserted at the base of the sternum, bevel up (b)(4) at a 15-20° angle directed to the left of the midline. Once the needle is inserted, the blood is slowly aspirated. If no blood is observed, the needle is repositioned with slow aspiration. Once the blood volume is collected, the mouse is euthanized by cervical dislocation while still under deep anesthesia. Typically 0.5-0.75 ml of blood are collected; sometimes less blood is available after radiation exposure

V.4.4.3. Adjuvants N/A

V.4.4.4. Monoclonal Antibody (MAb) Production N/A

V.4.4.5. Animal Identification

All cages will have cage cards identifying the treatment groups for each experiment. For experiments 2 and 3, each animal within a cage will receive ear punches for individual identification (1 = no cut; 2 = right ear upper corner; 3 = left ear upper corner; 4 = both ears).

V.4.4.6. Behavioral Studies N/A

V.4.4.7. Other Procedures

(b)(4) **irradiation**

(b)(4) radiation exposures will be carried out within (b)(4),(b)(6) facility (b)(4) Mice will be irradiated at (b)(4) minutes in order to deliver the radiation doses required (b)(4) experiments 1 and 2). Mice will be placed in well-ventilated Plexiglas boxes (standardized for (b)(6) facility) for up to 45 min, but usually less time, during acute irradiation procedures. Following radiation exposures mice will be immediately moved to standard sized cages that house either 4-8 animals per cage. Holders will be sanitized after each use.

(b)(4) irradiation

The methodology for (b)(4) irradiation of mice in (b)(6) facility, including approval of holding jigs and development of anesthesia, was developed in conjunction with the AFRRI Veterinary Staff.

(b)(4) irradiation will be performed using (b)(6)
Three mice can be irradiated in one group (b)(6) Groups of three mice will be brought to the (b)(6) facility. The mice will be anesthetized by injection and placed in ventilated jigs, which restrain the animals to prevent lateral or vertical movement. Prior to irradiation, scans will be performed to identify the (b)(4) region to be targeted for radiation; this will take approximately 2 minutes per animal. Mice will be irradiated at (b)(4) doses, including dosage from (b)(4) For studies with (b)(4) irradiation prior to (b)(4) irradiation, for which only (b)(4) min of radiation will be required per animal, three animals will be prepared at one time. For animals that require the full (b)(4) irradiation, one animal will be irradiated at a time. Following radiation exposure, mice will be immediately returned to the VSD and allowed to recover from anesthesia under supervision, with heating pads. Immediately upon recovery, animals will be returned to standard cages that house 4-8 animals per cage. Lucite jigs will be sanitized after each use.

Whole body, non-invasive (b)(4)
Non-anesthetized, unrestrained (b)(4) will require individual animals to be placed in a clean plexiglass chamber (~ 12 cm in diameter, ~15 cm high) for 45-60 min. Animals will not have food or water during this time, but they will have a continuous flow of fresh room air. Their (b)(4) is measured based on warming and humidifying of the air in the chamber. The animals will experience no restraint, no anesthesia, no drugs, or other manipulation during this time. Following the measurement, to be performed in the room in which they are housed, the animals will be returned to their original cages. Chambers will be sanitized after each use.

Ear punch

The ear punch will be soaked in alcohol to disinfect it before use and between animals. The device will be placed on the pinna of the ear (external ear) in a location where the mouse will be marked for identification. The punch will be pressed firmly to punch a circular hole through the ear, being careful not to rip the delicate membrane of the pinna. The ear will then be gently separated from the device. The ear punch will be cleaned and disinfected in alcohol before use in another mouse.

V.4.4.8. Tissue Sharing For most studies (b)(4) (b)(4) will be obtained. All other tissues will be available for tissue sharing with other investigators. Our laboratory has made extensive use of shared tissues for training and technique development (b)(4) tissue.

V.4.4.9. Animal By-Products None.

V.4.5. Study Endpoint

The endpoint for (b)(4) survival studies will be [redacted] days and pattern of survival over the [redacted] day (b)(4) post-irradiation period. The endpoint for radiation-induced (b)(4) will be [redacted] days postirradiation (b)(4) and the endpoint for the (b)(4) studies will be (b)(4) days postirradiation. Early endpoints will be used in the case of morbidity and morbundity. Specific health assessment criteria including rapid weight loss, ruffled fur, dried lacrimal fluid accumulated in the cul-de-sac of their eyes, are cool to the touch, decreased appetite, diarrhea, difficulty breathing or panting (b)(4) will used to determine early study endpoints for euthanasia. Mice exhibiting these signs will be considered morbid and will be monitored by the PI or other members of the investigative team at least twice daily, early morning and late afternoon. Mice will be considered moribund when, in addition to showing some or all of the signs of morbidity, they exhibit labored breathing plus either an inability to remain upright or are unmotivated to move. Morbid or moribund mice will be automatically euthanized as described in

accordance with IACUC Policy 10. Moribund mice scoring above 11 on the AFRRI IACUC-recommended pain score sheet will be euthanized.

V.4.6. Euthanasia

Animals will be euthanized at the stated endpoints of the experiments by injection of 0.1-0.2 ml/mouse Fatal Plus (39-78 mg pentobarbital/mouse), IP using a 25 G needle. Euthanasia will be confirmed by cervical dislocation. Animals which appear to be experiencing pain or distress as a result of radiation exposure or are found moribund will also be euthanized by pentobarbitol and necropsied. At the end of experiments, unused animals will be transferred to other protocols or euthanized by exposure to 100% CO_2 from a compressed gas cylinder in accordance with the current American Veterinary Medical Association (AVMA) Guidelines for Euthanasia. Exsanguination, cervical dislocation, and/or (b)(4) will be used to ensure euthanasia.

V.5. Veterinary Care

V.5.1. Husbandry Considerations All of the animals used in this study will be housed in the VSD facility in cages of 4-8 mice. Food and acidified (2.5 – 3.0 pH) water (to minimize *Pseudomonas* infection) and Harlan Teklad Rodent Diet #8604 will be available *ad libitum*. The 12:12 hr (lights off at 6 pm) VSD room light cycle is fine for all the studies.

V.5.1.1. Study Room

(b)(6)

V.5.1.2. Special Husbandry Provisions

V.5.1.3. Exceptions

Mice will be group housed except during the irradiation procedures as described above or in the event that their cage mates have had to be removed from the study. Under these circumstances they may be housed individually

V.5.2. Veterinary Medical Care

V.5.2.1. Routine Veterinary Medical Care

Experimental animals will be observed at least twice a day by one of the study investigators or technicians. VSD personnel will also monitor the animals twice a day during their rounds. As described in another section (study endpoint) morbid animals will be monitored at least twice daily, morning and afternoon. The experimental design does not contemplate supportive therapy. The justification for not providing supportive care has been described in the study end point section as well as in the pain category section. Criteria to be used for health evaluation while the animals are on study include: weight loss (mice will be weighed every other day), ruffled fur, dehydration, decreased activity, and hunched body position, dyspnea, or panting. Animals exhibiting these signs may be euthanized, and considered to be at the study endpoint.

V.5.2.2. Emergency Veterinary Medical Care

Emergency veterinary medical care is available 24 hours a day, 7 days a week, including weekends and holidays.

V.5.3. Environmental Enrichment

V.5.3.1. Enrichment Strategy Environment enrichment for the mice will be provided with the addition of nestlets and/or hiding tubes to each cage. Group housing of the mice also provides social enrichment.

V.5.3.2. Enrichment Restrictions None.

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING

NAME	DEGREE	TRAINING	DATE	PROCEDURES	YRS/MOS EXPERIENCE
(b)(6)	Ph.D.	(b)(6)		1, 3a, 5, 7b	7 yr
	Ph.D.			1	8+ yr
	Ph.D.			1,3a, 5	5 yr
	Ph.D.			1,5	>10 yr
	B.S.			1,3a,5	4 yr
	B.S.			1, 3a, 3b, 4a, 5, 7a, 7b, 7c	8+yrs
	B.S.			1, 3, 5	6 months

Procedure and manipulation codes:
Code 1= Animal handling and euthanasia
Code 2= Surgery (aseptic technique) pre- and post-operative care
Code 3= Injections (3a–ip, 3b-sc, 3c-gavage) - can say 3 if trained in all manipulations or add 3d-iv
Code 4= Blood collection under anesthesia (4a-cardiac, 4b-posterior vena cava)
Code 5= Tissue collection (after euthanasia) - doesn't need to be specific
Code 6 = Implantation (provide details)
Code 7 = Others - (provide protocol specific manipulations or procedures for e.g., retro-orbital bleeding, tail vein injection, or drug delivery)
7a: tail vein injection for drug delivery
7b: plethysmography
7c: ear punch

VII. BIOHAZARDS/SAFETY

All the personnel will be trained as radiation users on a regular basis. All investigators and technicians while in the vivarium will use appropriate procedures as described by VSD, including the wearing of appropriate PPE, during observation of mice. No additional biohazards will be used for these experiments.

VIII. ENCLOSURES

Drug safety sheet for (b)(4) is attached.

(b)(4)

X. ASSURANCES

Protocol Title: (b)(4)

(b)(4)

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made every effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with a qualified individual who evaluated the experimental design with respect to the statistical analysis, and that the minimum number of animals needed for scientific validity will be used.

D. Biohazard / Safety: I have taken into consideration and made the proper coordinations regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R", namely, "Responsibility," which the DOD has embraced for implementing animal use alternatives where feasible and conducting humane and lawful research.

G. Scientific Review: This proposed animal use protocol has received appropriate peer scientific review and is consistent with good scientific research practice.

H. Painful Procedure(s): I **AM** / ~~**AM NOT**~~ conducting biomedical experiments, which may potentially cause more than momentary or slight pain or distress to animals. If applicable, potential pain and/or distress **WILL** / **WILL NOT** **(both)** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

(b)(6)

DOD ANIMAL CARE AND USE STANDARDIZED PROTOCOL FORMAT WITH EMBEDDED INSTRUCTIONS (AUGUST 2012)

Reference DOD Instruction 3216.01 & AFRRI Instruction 3216.2H

****

Information requested in the following animal use protocol template reflects the requirements of the Animal Welfare Act Regulations (AWAR), the Guide for the Care and Use of Laboratory Animals, and other applicable Federal regulations and DOD Instructions.

****

This document is intended to be an aid in the preparation of DOD-sponsored animal use protocols. It is a companion document to an identical protocol template that does not have embedded instructions. Either template may be used to format DOD-sponsored animal research proposals; however, reference to the instructions during protocol preparation is highly recommended. If using the template with instructions, the instructions should be deleted prior to submitting the finished protocol for IACUC review. Please use Arial, regular, size 12, black font to prepare the protocol. With the exception of section headings, all paragraphs require a response. Paragraphs that do not apply should be marked N/A. There is no space limitation for responses to the information requested.

Approved standard operating procedures (SOPs) promulgated by the AFRRI Veterinary Sciences Department (VSD) or similar VSD-validated documents that describe specific procedures may be referenced by SOP number and title in lieu of repeating the details in the protocol. However, it is essential to include general descriptions of all animal manipulations to be carried out under the IACUC-approved protocol and to provide details where no approved references are cited. To do otherwise would constitute a breach of statutory regulations. Manipulations not covered in the originally approved protocol can be initiated only after IACUC approval of a formal amendment adding the new procedures. Additionally, Principal Investigators (PIs), or other delegated research personnel, should maintain accurate experimental records and be able to provide an audit trail of animal expenditures and use that correlates with their approved protocol. Protocol PIs will be required to provide this and other information during annual protocol reviews.

Any supporting information that may be of use to the IACUC during its review may be attached to the completed protocol. Adding subparagraphs within the body of the protocol template is permissible, *provided that the numbering sequence of paragraphs in the original standard format is maintained.* In other words, all of the labeled paragraphs and subparagraphs in this template must be retained, with additional information being presented as sub-numbered paragraphs containing information that supports or complements what is requested.

INTELLECTUAL PROPERTY STATEMENT

Research protocols drafted by Government scientists include intellectual property (e.g., concepts, ideas, experimental approaches, etc.), some of which is innovative or original and therefore considered proprietary to the investigators and/or the sponsoring agency. All Government and non-Government personnel handling this protocol shall exercise EXTREME CARE, to ensure that the information contained herein is NOT DUPLICATED OR DISCLOSED, in whole or part, for any purpose other than to evaluate the protocol, without the written permission of the principal investigator or the sponsoring agency.

I. NON-TECHNICAL SYNOPSIS

In all potential radiation exposure scenarios, it is unlikely that radiation exposure detectors will be available for dose assessment to aid clinical management of mass casualties. Strategies for early-phase rapid diagnostic triage of the injured, contaminated and non-contaminated casualties are needed. The Armed Forces Radiobiology Research Institute (AFRRI) monkey biodosimetry study is part of a Biomedical Advanced Research and Development Authority (BARDA) Interagency Agreement (IAA) - Phase 3 plans to generate samples that will be used in the development of a device to determine injury from potential radiation exposures by measuring various biomarkers in a blood sample. Baseline or pre-irradiated samples will be taken from all animals to establish normal baseline levels of candidate biomarkers. Most studies will involve total-body irradiation (TBI) exposures to graded doses of gamma rays and the use of "Minimum Supportive Care Therapy" model reflecting the anticipated limited medical-care situation in the early-phase of a mass-casualty radiological incident. A pilot high-dose discovery study will be performed to identify and develop new biomarkers. A treatment experiment will be completed to characterize the influence of cytokine and conventional treatment on candidate biomarkers. In this study, we plan to use a "Conventional Treatment Supportive Care Therapy" approach that will include more aggressive therapy (i.e., cytokine treatment (granulocyte colony stimulating factor or G-CSF), administration of intravenous (IV) fluids, antibiotics, blood transfusion, etc.) similar to current treatment practice to characterize any effects of these treatments on the radiation biomarkers profile. See Table 1 below for a comparison of the two therapies. A dose-

and time-course experiment will then be performed to validate the selected biomarkers for the dose and injury assessment. Tissue sharing to test other candidate biomarkers will be considered via amendments to maximize the benefits from the study. Early and rapid dose estimates will be required in radiation disasters that involve a large number of victims and a finite amount of medical resources available to responders and healthcare providers. Our expectations are that this project will contribute to bridge a gap that exists in the current capabilities to identify and then rapidly as well as effectively to assess radiation exposure early after a radiation exposure and especially after a mass-casualty radiological incident. In particular, these efforts contribute to validating an early test to distinguish individuals exposed and injured by radiation in order to assist the physicians to choose the appropriate medical treatments and hence reducing the adverse acute effects or long-term risks associated with radiation exposure.

Table 1. Definition of Minimum and Conventional Treatment Supportive Care Therapy

Specific supportive care regime	**Minimum supportive care therapy**	**Conventional treatment supportive care therapy**
Supplementary oral fluids, citrus-free and soft food, analgesic for distress and mouth ulcers or bloody stools, therapeutics for anti-gas, anti-gastric reflux, anti-emesis, anti-diarrhea, elevated temperature, and topical antiseptic for local infection	Yes	Yes
Analgesic for prolonged restraint due to conventional treatment supportive care, cytokine (G-CSF) countermeasure, systematic antibiotics for bacterial infection, IV fluids for dehydration, anti-ulcerative therapeutic for bloody stool, and whole blood transfusion for platelet depression.	No	Yes
Note. See Appendices D and E for additional details		

II. BACKGROUND

II.1. Background

Since the terrorist attack of 9/11/2001, risks of potential radiation exposure scenarios include the of detonation of nuclear weapons, terrorist attacks on nuclear reactors, covert placement of large sources in public places, and dispersal of radioactive substances with the use of conventional explosives. Lack of availability or inaccurate initial absorbed dose estimates can result in suboptimal medical intervention. In the early-phase of a radiation incident, we currently rely on clinical signs (i.e., hematology changes), symptoms (i.e., onset of vomiting), and chromosome biodosimetry. Gaps have been identified in triage tools to aid first-responders, especially in the case of a mass-casualty radiological incident to rapidly identify individuals at risk of life-threatening exposures, exposed but not life-threatening, and non-exposed or worried well.

Early treatment of populations exposed to ionizing radiation requires accurate and rapid biodosimetry with a precision as high as possible to determine an individual's exposure dose, organ-specific radiation injury level, and severity levels for potential life-threatening acute radiation syndromes (ARS). The early medical-management situation requires quantitative

indications for early initiation (within one day after radiation exposure) of cytokine therapy in individuals exposed to life-threatening radiation doses and/or bone marrow ARS as well as effective triage tools for first-responders in mass-casualty radiological incidents (MacVittie et al. 2005; Waselenko et al. 2004).

There are two radiation scenarios for which radiological countermeasures are being developed. The first scenario is a small scale incident where victims will have access to medical facility and clinical support. This proposal, however, focuses primarily on the second scenario, a catastrophic event involving large number of casualties. In this scenario, there will be limited medical and physical resources. Our interests are to develop biodosimetric assays to permit early and rapid radiation exposure assessment applicable for a forward-field application. The focus of the main study design here is modeled to permit assessment of radio-responses prior to use of supportive-care medical treatment.

AFRRI scientists have advocated use of multiple parameter biodosimetry with emphasis on use of hematology and plasma biomarkers to assist in early-phase biodosimetry triage (b)(6),(b)(4) (b)(6),(b)(4) Studies have been performed in mouse and non-human primate models following total-body irradiation (TBI) exposures to gamma radiation; see publications at AFRRI's (b)(6),(b)(4) (b)(6),(b)(4) and in Appendix J. The radioresponse for hematology and body-weight changes from our earlier dose-response study is shown in Appendix A. Proteomic biodosimetry provides diagnostic information both to estimate absorbed dose and for the assessment of the severity of injury for relevant organ systems associated with the ARS (b)(6),(b)(4) Sigal et al. 2012). Plasma (cell free) blood-cell surface markers were recently used as surrogates for blood-cell counts and demonstrated to be diagnostically useful for dose assessment in the early-phase after irradiation. Recent mouse studies involving combined injury (i.e., radiation and wounding) identified a subset of radiation biomarkers that are not influenced by wounding, which were successfully used to accurately estimate radiation absorbed dose. A similar biodosimetry panel was used to accurately estimate radiation absorbed dose using archived samples from a prior NHP dose-response study using Meso Scale Diagnostics' (MSD) technology that permits multiplex measurements over a wide dynamic range.

BARDA has asked us to sustain our interactions with their contractor (MSD), who has adopted AFRRI's biodosimetry panel and collaborated with AFRRI to expand the panel to include additional organ-specific biomarkers additional to the panel described in three patent applications (see Appendix J). Follow-on studies using animal model systems are needed to further develop this diagnostic system.

Planned experiments include: 1) baseline measurements of candidate biomarkers in all animals prior to irradiation, 2) high-dose discovery experiment to provide key samples for testing of candidate antibody pairs of novel biomarkers of organ injury, 3) treatment experiment to evaluate the influence of conventional treatment supportive care therapy (i.e., G-CSF, IV fluids, antibiotics, etc.) (See Appendix E) on candidate biomarkers, and 4) dose-response study to permit testing of selected biomarkers for dose assessment accuracy.

In addition, a second goal of the study is to characterize the time course for biomarkers of acute phase and ARS organ injuries expressed during the evolution of the clinical case (0- 60 d). Note that full supportive care treatments involve IV injections likely to affect the plasma levels of some biomarkers and hematological parameters. We will request histopathology on selected animals and measure ARS severity levels in this model using a NHP ARS severity-scoring system developed in our laboratory. This will allow us to use biomarkers levels as prognostic indicators of radiation injury effects. We also plan to include tissue sharing when possible to maximize the benefits from the study.

The planned studies are needed to further discovery and validation of radiation-responsive biomarkers and develop a validated biodosimetry device, which represents the major goal of the biodosimetry program at AFRRI.

II.2. Literature Search for Duplication

II.2.5. Results of Search

Searches were performed using BRD, RePORTER, and PubMed on September 11, 2012.

Using the above keywords, the literature search of DoD Biomedical Research (BRD) showed no past or ongoing project that was duplicative to our proposed study to evaluate the combined blood-based proteomic and hematological approach on biodosimetry endpoints dose-response relationships for radiation dose assessment, dose-dependent discrimination index of radiation exposure, and the response category severity score of ARS in non-human primate TBI model. In the literature search using the PubMed data base, one of the identified publications focused to compare the efficacy of autologous cell therapy after irradiation combined with G-CSF injections with G-CSF treatment alone in a heterogeneous model of irradiation representative of an accidental situation (Int. J. Radiation Oncology Biol. Phys., Vol 63, No. 3, pp 911-920, 2005). In another PubMed publication two cytokines G-CSF and interleukin-6 (IL-6) were identified as the candidate biomarkers of CBLB502's radioprotective/mitigative efficacy (J Pharmacol Exp Ther. 2012 Jul 26). In our study the focus is to investigate the modifying effects of cytokine (G-CSF) treatment on panel of biomarkers in non-human primate TBI model to identify and validate panels of protein biomarkers that can be used in the radiation dose and injury assessment, ARS diagnosis, and the influence of cytokine and conventional treatments (i.e., blood transfusion, antibiotic therapy, etc.).

The search in Research Portfolio Online Reporting Tools electronic resource (Reporter) does not show any duplicative projects to our proposed study.

Searches were performed using BRD, RePORTER, and PubMed on November 1, 2012.
The 1 Nov 2012 keyword literature search for duplication, omitting the word "whole body", revealed few more hits. Notably, in PubMed search with keyword "radiation and non-human primates and G-CSF", one study (J. Rad. Res. 2012, 53, 640-853) with mice showed that the survival-enhancing effects of 5-AED (5-androstendiol) are dependent on endogenous G-CSF and are associated with functional activation of innate immune cells during the acute radiation syndrome (ARS). Another report popped up under BRD database with the keyword "ionizing radiation and NHP and G-CSF" regarding a study initiated at AFRRI in 2008. The study was aimed to determine the ability of G-CSF and CBLB612 to mobilize stem cells into the peripheral blood of NHP after transfusion against gamma-irradiation. Later the study was abandoned due to technical difficulties and expenses. Other 10 hits with RePORTER-database with the keyword, "radiation and non-human primates and G-CSF and blood" were found to be irrelevant to the mode of our study.

III. OBJECTIVE / HYPOTHESIS

General Hypothesis:
Multiple blood protein biomarkers along with hematological surrogates will provide enhanced diagnostically useful indices to discriminate between injured and irradiated individuals. A panel of protein biomarkers, each with different radiation responses, coupled with peripheral blood cell counts or hematology surrogates will provide accurate assessment as well as an enhanced discrimination index of radiation exposure.

Using a NHP total-body radiation model the proposal's **objectives** are to:

1) Establish baseline levels of candidate biomarkers (Experiment #1).

2) Perform a pilot high dose experiment to permit testing of the measurement of novel organ specific biomarkers in isolated peripheral blood using commercially available antibodies (Experiment #2).
3) Evaluate the effects of "Conventional Treatment Supportive Care Therapy (G-CSF, IV fluids, antibiotics, blood transfusion, etc.) for radiation injury on the candidate biomarkers (Experiment #3).
4) Measure biomarker responses in a time- and dose-response study to evaluate the suitability of the selected biodosimetry biomarker panel to accurately assess radiation dose (Experiment #4).
5) Characterize radioresponse of animals following radiation exposure to permit correlation of biomarker levels to effect as measured by severity score of histopathology or ARS (Experiments #1-4).
6) Consider tissue sharing (i.e., urine, fingernail clippings, etc.) in these studies to maximize benefit from the study (Experiments #1-4) via subsequent amendments/tissue sharing if required.

IV. MILITARY RELEVANCE

Radiological terrorist attack or accidental mass-casualty exposures is highly possible. Military personnel responding to such emergencies can be exposed to radiation. Recognizing unpredictable mass casualties, U.S. Department of Defense has given top priority, as stated in the "Defense Technology Objectives (DTO)" to the development of medical countermeasures to radiation exposure" against both early- and late-arising health effects. In the case of mass casualties, it is difficult to screen out the severely exposed patient from the less exposed or not exposed individuals due to lack of immediate and convenient dose measurement technology. This study will determine if the combined proteomic and hematological approach is feasible for biodosimetry whole-body radiation dose assessment and also provide an enhanced discrimination index of radiation exposure to effectively manage radiation-casualty incidents or nuclear events. In the case of such an event, rapid and accurate assessment of radiation dose would be necessary to guide treatment decisions. This strategy addresses the need for developing a high-throughput multiparametric "***Field Radiological Biodosimetry***" system and promotes effective command decisions and force structure planning to ensure mission success. This system should be compatible with military field laboratories, homeland security applications, as well as with radiation therapy centers to assess radiation exposure based on blood protein biomarkers capability. In addition, assessment of a population's exposure in other radiation threats, such as nuclear accidents and terrorism mass-casualty scenarios addresses the need for a "***Clinical Radiological Biodosimetry***" system to provide physicians with the ability to triage radiation victims, make appropriate treatment decisions, and reduce uncertainties associated with the variability of individual response to radiation exposure. This proposed study is designed to support a BARDA funding contractor (MSD) to develop and validate a biodosimetry device. In a recent survey of requirements from the warfighters conducted by the Joint Requirements Office, medical diagnostics including radiation biodosimetry was rated with the highest priority (#14) among the radiological countermeasure requirements (i.e., medical countermeasures – protectant, treatment).

V. MATERIALS AND METHODS

V.1. Experimental Design and General Procedures

Baseline levels of candidate biomarkers and an ARS severity score will be measured in all animals pre-irradiation (**Experiment #1**). Non-human primates (NHPs), rhesus monkeys will be exposed to total-body gamma irradiation in AFRRI's Cobalt Facility. Pilot single high-dose discovery (**Experiment #2**) and conventional treatment supportive care therapy (**Experiment #3**) experiments will be performed for discovery and evaluation of promising new biomarkers as well as for evaluation of G-CSF cytokine treatment and additional supportive care therapy on the candidate radiation biomarker profile. In support of Experiment #3, six NHPs will be used as whole blood donors. These donor animals will be permitted a 30-60 d recovery period and if they demonstrate a normal hematology profile, they will be used as study animals in other experiments. In addition a range of radiation doses (0, 1, 3.5, 5, 6.5, and 8.5 Gy at ~0.56 Gy/min) will be used to explore the dose dependency of the various technologies (**Experiment #4**). See section "Study Endpoint (V.4.5.) for details regarding the expected outcome for NHPs in this study. Samples will be acquired at a range of time points before and after radiation (as below) to determine the time course of the biomarkers in this system.

An ARS response severity score will be assessed prior to radiation (baseline; **Experiment #1**), 3 - 4 times per week after irradiation, including complete blood counts with differentials (CBC/diff), body weights, body temperatures, etc. (see attached ARS Severity Scoring System sheet, Appendix B). Body widths will be measured prior to irradiation to support accurate dosimetry. CBC/diff will be determined using the VSD clinical hematology analyzer or in another approved laboratory (e.g., Bio Reliance). Other biomarkers will be assessed at multiple time points as described below.

Rhesus macaques (*Macaca mulatta*) will be housed singly in stainless steel cages. On the morning of irradiation, animals will not be fed.

The times of emesis for each animal will be recorded during the first 12 h after irradiation as described in Appendix B. Each animal will be observed at least twice daily for evidence of pain or distress by VSD techs or caretakers during rounds. Research staff will also monitor the status of NHPs daily. As the animals start to become ill, the research staff will increase the monitoring frequency accordingly. A rhesus macaque ARS response severity scoring system has been developed and will be used in these studies (See Appendix B). Clinical assessment of the NHPs will be conducted throughout the study. This would include such parameters as hydration status, presence or absence of fever, lethergy or diarrhea, assessment of the respiratory and cutaneous systems and changes in the CBC. Blood for CBC will be collected and analyzed at 1 and 2 weeks before irradiation and at least 3 times per week after irradiation. Body temperature will be determined 3 times per week using implanted microchips (IPTT-200; BMDS, Seaford, DE) in chaired monkeys in daily rounds beginning approximately one week prior to the first treatment. (Balcombe et al. 2004). The time of each temperature collection will be recorded for each monkey. Body weights will be determined at least once prior to radiation exposure and at least 3 times per week after irradiation for 60 days. The primary endpoint for the studies is the radioresponse of plasma biomarkers. AFRRI's additional primary study endpoints will be mortality (or moribundity) along with ARS- subsyndromes biomarkers (i.e., kinetics of neutrophil, platelet, and lymphocyte counts, other blood count and differential leukocyte count variables, GI severity score), acute injury- and ARS organ injury plasma biomarkers, and serum amylase activity.

Figure 1 illustrates the overall schedule for the four experiments. The Summary Tables – Schedule A, B, and C shown below provide a more detailed sequence for individual animals.

Code: S = Survival	X = Expectant		N: Necrospy									

V.1.1. Experiment 1

PRE:

Animals: all animals in the protocol study (36)
Injection: microchips will be injected into animals under ketamine (10 mg/kg; via intramuscular (IM) injection using 12 gauge needle and syringe; see Section V.4.4.1.
Radiation doses: NA
Radiation exposure: NA
Treatment: NA
Assays: baseline levels of body weights, body widths, body temperatures, hematology (see Appendix C), blood chemistry (see Appendix C), proteomic biomarker parameters (see Appendix C), and ARS severity scores (see Appendix B) will be measured prior to irradiation
Time course: 1-2 times per week, 2-3 weeks (see Appendix C for specific details)

V.1.2. Experiment 2

Pilot high-dose discovery study:

Animals: 2 per dose (n = 4)
Radiation doses: 0 and 6.5 Gy [2 doses].
Radiation exposure: TBI will be given as a single exposure
Treatment: "Minimum supportive care therapy"; See Appendix D for additional details.
Assays: body weights, body temperatures, hematology (see Appendix C), blood chemistry (see Appendix C) proteomic biomarker parameters, and ARS severity scores (see Appendix B) will be measured after irradiation.
Time course: (Pre), 5 h, 1, 2, 3, 4, 5, 6, 7, 10 days and later time-points (2-3x weeks up to 60 days) in survived animals; see Appendix C for specific details.

V.1.2. Experiment 3

Pilot "Conventional Treatment Supportive Care Therapy" study:

Animals: 4 per dose (n = 8)
Radiation doses: 0 and 6.5 [2 doses].
Exposure: TBI will be given as a single exposure.
Treatment: "Conventional Treatment Supportive Care Therapy" including G-CSF treatment (10 µg/kg, once a day; 22-25 G needle; SC, 1-ml syringe) starting on day 1 after exposure and continuing until the recovery of absolute neutrophil count (ANC) >= 2,000 μL^{-1} for 2 consecutive days along with "conventional supportive care therapy" approach that will include more aggressive therapy (i.e., administration of IV fluids, whole blood transfusions, etc.); see Appendices E and H for additional details. In the case of 6.5-Gy irradiated NHPs where we expect to perform whole blood transfusions, we expect the duration of G-CSF treatment to continue for ~20 days.

Assays: body weights, body temperatures, hematology (see Appendix C), blood chemistry (see Appendix C) proteomic biomarker parameters, and ARS severity scores (see Appendix B) will be measured after irradiation.
Time course: (Pre), 5 h, 1, 2, 3, 4, 5, 6, 7, 10 days and later time points (2-3x weeks up to 60 days) in survived animals; see Appendix C for specific details.

Whole blood donor animals: n=6 [Study animals are planned to be used for blood donation. If there is a need where study blood donor animals are not available, then Protocol PIs will request for use of VSD residence pool animals, which have been approved for use for this purpose].

Radiation dose: NA
Exposure: NA
Treatment: NA
Assays: baseline levels of body weights, body widths, body temperatures, hematology (See Appendix C), blood chemistry (see Appendix C) and ARS severity scores (see Appendix B) will be measured to assure health suitability for blood donation.
Note. Guidelines for blood donations volumes for whole blood transfusions to support the G-CSF Treatmont Study guidelines (See Appendix E) are shown in Appendix H. Six animals will be used to this purpose in the early-phase of the study design. Animals selected for donation will be rotated to assure sufficient recovery period (1 month) between repeated whole blood donations. The recovery period for repeated blood donation is expected to be 1 month, which will be confirmed by a normal hematology profile.

V.1.2. Experiment 4

Dosimetry algorithm study:

Animals: 6 per dose (36) (We plan to re-use surviving sham animals for later use in radiation cohorts).
Radiation doses: 0, 1, 3.5, 5, 6.5, and 8.5 Gy [6 doses].
Exposure: TBI will be given as a single exposure.
Treatment: "Minimum Supportive Care Therapy"; See Appendix D for additional details.
Assays: body weights, body temperatures, hematology (see Appendix C), blood chemistry (see Appendix C) proteomic biomarker parameters (see Appendix C), and ARS severity scores will be measured after irradiation
Time course: (Pre), 5 h, 1, 2, 3, 4, 5, 6, 7, 10 days and later time points (2-3x weeks up to 60 days) in survived animals; see Appendix C for specific details.

V.2. Data Analysis

All hematology, vital signs (including weights), serum chemistry, plasma protein biomarkers levels data will be summarized using descriptive statistics on each assessment time for each dose cohort. Continuous variables will be summarized using sample size, mean, standard deviation, minimum and maximum values.

Statistical software, PC SAS, will be used for statistical analyses. If applicable, analysis of variance or multivariate analysis of variance (MANOVA) will be used for comparison among

the groups. If significant, appropriate pairwise comparisons will be used. The significance level will be set at 5% for each test. Linear regression, Fisher's exact test or McNemar test will be used if applicable. All statistical tests will be two-sided. Adjustment of multiple tests will not be made.

Justification of sample sizes: for any primary outcome variable in each experiment, the sample size of 6 monkeys will give 80% power to detect any difference between any two groups, if any, by assuming that type I error = 5%, type II error = 20%, and delta/sigma at least 1.8, where delta is equal to the absolute difference between the means of two groups, and sigma = the pooled standard deviation in the applicable statistical model.

V.3. Laboratory Animals Required and Justification

V.3.1. Non-animal Alternatives Considered

The purpose of this study is to evaluate radiation biodosimetry diagnostics involving use of organ specific targets that have been initially evaluated in rodent models, tested in NHP models, and in selected cases used in human radiation accidents. This technology is expected to be used with human samples in a forward deployment scenario, considering portability, accuracy, and ease-of-use. It is not possible to experimentally irradiate human subjects to test this technology, nor can presently available computer modeling or cell cultures studies adequately meet the research objectives.

V.3.2. Animal Model and Species Justification

The FDA has accepted rhesus macaque as an appropriate animal model for testing radiation countermeasures under the "Animal Efficacy Rule", where it cannot be performed in humans. Rhesus macaques are the model of choice for measurements of experimental radiation dose by using the current radiation biomarker panel. The biomarker technology has already been demonstrated in rodent animal radiation models and in selected cases in NHP radiation models. NHPs are more relevant to humans than other animals. Antibodies for NHP biomarkers are more readily available for measurement of candidate radiation biomarkers than in the minipig model. Therefore, this study in rhesus macaques is being undertaken to guide future development of the radiation blood plasma biomarker panel device.

V.3.3. Laboratory Animals

V.3.3.1. Genus / Species *Macaca mulatta*

V.3.3.2. Strain / Stock N/A

V.3.3.3. Source / Vendor

Animals will be obtained from Veterinary Sciences Department (VSD) approved vender.

V.3.3.4. Age 3 to 7.5 yrs

V.3.3.5. Weight 3 to 8 kg

V.3.3.6. Sex Males and Females (~50% split requested from vendor)

V.3.3.7. Special Considerations

Healthy NHPs are ordered in accordance with VSD requirements outlined in the NHP procurement contract. NHPs will be pole and collar trained by the vendor.

V.3.4. Number of Animals Required (by species)

Rhesus monkey (Macaca mulatta): 36

V.3.5. Refinement, Reduction, Replacement (3 R's)

V.3.5.1. Refinement

Implantable microchips (IPTT-200; BMDS, Seaford, DE) will be injected for ID and temperature measurements to lessen animal stress during the observation period. See Appendix I for a detailed description of the subcutaneous microchip implantation using a needle (12 Gauge) and syringe like device. The endpoint currently mandated by the FDA for approval of radiation countermeasures is mortality. Moribundity will be used as a surrogate for mortality, and euthanasia will be used in order to minimize pain and distress, using an extensive set of criteria. See Appendix G for a detailed description of the clinical observations with criteria for euthanasia.

V.3.5.2. Reduction

A total of 36 NHPs will be used in this protocol. We have made significant efforts to maximize research use of this model. Non-irradiated animals in Experiments #2 and #3 will be reused in the subsequent Experiment #4. We plan to consider tissue sharing and collaborations, via IACUC protocol amendments, to enhance the benefits of the study. At every stage of the protocol, plans will be reevaluated in light of incoming data in an attempt to reduce the number of experiments. If it is determined at any point that the proof of principal studies are inconclusive, then the rest of the experiments using other NHPs will not be performed.

V.3.5.3. Replacement

None.

V.4.1.2. Pain Relief / Prevention

V.4.1.2.1. Anesthesia / Analgesia / Tranquilization

A. Anesthesia for Subdermal Implantable Microchip Temperature Monitor Insertion

This procedure will be performed by a veterinarian or a trained veterinary technician with the primate not fed in the morning.

1. The AFRRI veterinarians will access the general health of the NHPs prior to anesthesia to ensure that each animal is healthy enough to undergo the procedure.

2. Fast 12 hours prior to anesthesia (water OK).

3. The primate is sedated with ketamine 10mg/kg via intramuscular (IM) injection to sedate.

4. See Table entitled "Provisions for Both Pre- and Post-Procedural Care" below and Appendix D and E for additional details.

B. Tranquilization for loading into radiation boxes, transport to ^{60}Co facility, measurement of mid-body widths, irradiation of NHPs, and transport back to VSD facility.

This procedure will be performed by a veterinarian or a trained veterinary technician with the primate fasted over night prior to procedure.

1. The AFRRI veterinarians will access the general health of the NHPs prior to anesthesia to ensure that each animal is healthy enough to undergo the procedure.

2. Fast 12 hours prior to anesthesia (water OK).

3. The primate is sedated with ketamine 10mg/kg IM and positioned in the radiation box.

4. Additional ketamine 10mg/kg IM is used to sedate animal as necessary during irradiation and transit to and return from the VSD vivarium to the ^{60}Co facility.

5. See Table entitled "Provisions for Both Pre- and Post-Procedural Care" below Appendix D and E for additional details.

C. Antipyretic Therapy for Fever

1. If body temperature rises above 104^0 F, NHP will be administered Rimadyl 2.2mg/kg BID or 4.4mg/kg QD,IM,IV,PO or 5-10mg/kg PO TID).

2. See Table entitled "Provisions for Both Pre- and Post-Procedural Care" below and Appendix D and E for additional details.

D. Analgesic for Radiation-Induced Distress

This procedure will he performed by a veterinarian or a trained veterinary technician with the primate.

1. The analgesic, Buprenorphrine HCL (0.01 mg/kg up to 0.02 mg/kg BID will he administered to all irradiated (1, 3.5, 5, 6.5, 8.5 Gy) animals from 5 to 35 days after radiation exposure; See Appendix D and E.

2. The protocol staff will daily monitor the animals for clinical signs and symptoms including using an ARS severity scoring system; See Appendix B. Animals demonstating an ARS severity level of 3 will he monitored more frequently as described in the protocol monitoring plan; See Appendix F. Protocol staff will notify the Protocol PIs and AFRRI Veterinarian of the health status of these animals.

3. The protocol staff will monitor animals for clinical observations identified as criteria for euthanasia consideration; see Appendix G.

4. The AFRRI veterinarians will access the general health of the NHPs and order analagesic (Buprenorphrine HCL, 0.01 mg/kg up to 0.02 mg/kg BID, IM 22-25 G needle) for distress if not aleviated by treatment.

4. See Table entitled "Provisions for Both Pre- and Post-Procedural Care" helow and Appendix D and E for additional details.

E. Analgesic for Mouth Ulcers or Bloody Stools

This procedure will he performed by a veterinarian or a trained veterinary technician with the primate.

1. The protocol staff will daily monitor the animals for clinical signs and symptoms including using an ARS severity scoring system; See Appendix B. Animals demonstrating amouth ulcers or bloody stools will be identified and reported to the Protocol PIs and AFRRI veterinarians.

2. *The* AFRRI veterinarians will access the general health of the NHPs and order analagesic (Bupivacaine HCL, 0.1 ml of 25% solution with a dab of surgical lubricant and administered locally using a cotton-tipped applicator to a restrained animal.

3. See Table entitled "Provisions for Both Pre- and Post-Procedural Care" below and Appendix D and E for additional details

F. Anesthesia to calm NHP while in restraint during prolonged IV fluid treatments, blood donation, and whole blood transfusion

This procedure will he performed by a veterinarian or a trained veterinary technician with the primate.

1. Criteria to identify animals for treatment by prolonged IV fluid are described in Appendix G. Criteria to identify animal selection for blood donation and whole blood transfusion are described in Appendix H.

2. The AFRRI veterinarians will access the general health of the NHPs prior to anesthesia to ensure that each animal is healthy enough to undergo the procedure.

3. Fast 12 hours prior to anesthesia (water OK).

4. The primate is sedated with ketamine 10mg/kg via intramuscular (IM) injection to sedate.

5. Isoflurane gas (2% in O2) will be administered via mask as determined by the AFRRI veterinarian.

6. See Table entitled "Provisions for Both Pre- and Post-Procedural Care" below and Appendix E for additional details.

V.4.1.2.2. Pre- and Post-procedural Provisions

Provisions for Both Pre- and Post-Procedural Care		
Procedures*/Location	**Anesthesia/Analgesic***	**Criteria to Assess for Pain or Distress**
Microchip injection/ (b)(6)	Ketamine#/NA	NA
Placement of NHP in Rad Box (b)(6) Procedural Room; Transport to ^{60}Co Facility (b)(6) Measurement of mid-body widths and irradiation/^{60}Co Facility; Transport to NHP holding residence (b)(6)	Ketamine#/NA	NA
Distress from radiation exposure/animal room/NHP residence holding room	NA/Buprenorphine HCL	Observation of any criteria shown in Appendix G – Clinical Observations with Criteria for Euthanasia
Mouth ulcers or bloody stools/animal room/NHP residence holding room	NA/Bupivacaine HCL	Observation of mouth ulcers or bloody stools
Calm NHP while in restraint during prolonged IV fluid treatments, blood donation, and blood transfusion (b)(6) (b)(6)	Ketamine and 2% Isoflurane in O_2/NA	NA
*See Appendices D, E, and F for additional details regarding clinical observation that trigger procedures, drug dosages, route of administration, protocol monitoring plan, etc. # Ketamine 10 mg/kg, IM, will be the anesthetic of choice and additional doses of ketamine are given as required based on assessment of VSD veterinarian.		

V.4.1.2.3. Paralytics N/A

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures

Because the **principal purpose** of this study is to evaluate dosimetric technology to determine the radiation dose, there are no alternatives to the irradiation. Supporting information such as selection of hematological, proteomic analysis in blood measurement, etc. will help identify the usefulness or problems associated with the technology going to be tested for detection of early response after mass-casualty irradiation scenarios.

V.4.1.3.5. Results of Search
A thorough search of databases using keywords listed revealed no animal alternatives for the investigation involving total body irradiation.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification
One needs to irradiate animals to study biodosimetric endpoints using a NHP radiation dose-response model, and to investigate the correlation between these endpoints and dose, ARS response severity response, and survival. *There are no alternative procedures for irradiation because it is a unique stimulus that cannot be otherwise duplicated.*

Irradiation itself is not a painful process but it induces various changes in the body (i.e., vomiting and nausea, changes in hematology cells numbers, etc.). Although radiation does not induce pain, animals in these experiments might experience pain and distress prior to death because of sequelae. Radiation compromises the immune system. As a result of a compromised immune response, various types of infections can initiate and become painful. The sequelae of nausea, vomiting, and diarrhea may cause pain and distress in humans observed in the early post-irradiation period, when lethal doses are used. All study animals that show any pain from radiation-induced distress as judged by exhibition of any euthanasia criteria as listed in Appendix G will be administered analgesic as described above and in Appendices D and E. In addition, analgesics (acetaminophen/Rimadyl) are considered as a way of minimizing discomfort during the onset of opportunistic infections as judged by temperature changes as described in Appendices D and E. *We will humanely euthanize animals when unrelieved pain and severe distress occurs as described in Appendix G.*

See Section IV. Military Relevance for additional details. *These studies are scientifically justified based on the national interest to identify, optimize, and validate FDA-approved biodosimetry devices for potential radiological threats including mass-casualty incidences.*

V.4.4.1. Injections

Microchips. The animals will be anesthetized at the beginning of the study for microchip implantation, see V.4.1.2.1; see Appendix I for additonal details and illustrations. Briefly the microchip is located inside of a needle (12 Gauge) and syringe like device. The animal skin between the shoulder blades is lifted up and the microchip is injected subcutaneously. A small amount of tissue glue may be applied to the exit area, in order to ensure that the microchip stays in the place as the animal begins to move around. These devices facilitate monitoring from a distance, the subcutaneous body temperature without having to anesthetize the primates. The use of microchip is a further refinement in that it does reduce stress and provides improvement diagnosis without the intervention of staff to handle the animals. IM injections will be administered in the cranial or caudal thigh muscles using a 25 – 22 gauge needle.

Minimum vs. Conventional Treatment (G-CSF) Supportive Care Therapy. The Table below illustrates the study design relative to use of "Minimum" vs. Conventional Treatment Supportive Care Therapy.

Minimum vs. Conventional Treatment (G-CSF +) Supportive Care Therapy Study Design			
Experiment		Supportive Care	
	Doses (Gy)	Minimum	G-CSF and Conventional
		Number of animals	
1 PRE Study			
n=36	NA	–	–
2 High Dose Study			
	0	n= 2	–
	6.5	n=2	
3a Treatment Study			
	0		n=4
	6.5		n=4
3b Blood donation			
n=6	NA		
4 Dose Algorithm Study			
	0	n=6	
	1	n=6	
	3.5	n=6	
	5	n=6	
	6.5	n=6	
	8.5	n=6	

Minimum Supportive Care Therapy. Experiments 2 and 4 involve use of "Minimum Supportive Care Therapy". The scope of this approach is described in detail in Appendix D and Section V.4.2. (Pain Relief/Prevention). Appendix D provides information about the indication, drug, dosage, route of administration, etc. for nutritional support, anesthesia and analgesic, antiemetics and antigastric reflux, antigas, antidiarrheal, antipyretic, antiseptic, dehydration, and antiulcerative therapy.

Conventional Treatment (G-CSF) Supportive Care Therapy. Experiment #3 involves use of conventional supportive-care therapy with use of cytokine treatment (G-CSF) as a countermeasure used as a mitigator, as required IV saline fluids for dehydration, systematic antibiotics, and whole blood transfusions. The scope of this approach is described in detail in Appendix E and Section V.4.2 (Pain Relief/Prevention). Appendix E provides information about the indication, drug, dosage, route of administration, etc. for nutritional support, anesthesia and analgesic, antiemetics and antigastric reflux, cytokine treatment, antigas, antidiarrheal, antipyretic, antiseptic, dehydration, antiulcerative, and blood product (whole blood transfusion) support therapy. Conventional treatment supportive care therapy evokes use of components of "minimum supportive care therapy" but supplemented with cytokine treatment and as needed whole-blood transfusion, systemic antibiotic, and more aggressive dehydration therapy.

G-CSF. In the "*Conventional Treatment Supportive Care Therapy*" Experiment #3 animals are scheduled for G-CSF treatment (10 µg/kg, once a day; 22-25 G needle, 1ml subcutaneous bolus) will start one day after irradiation and continue until recovery of absolute neutrophil counts (ANC) $\geq$ 2,000 μL^{-1} for 2 consecutive days, anticipated to last up to 23 days after irradiation. Injection sites will vary starting initially in the lower extremities and then sequentially move up the limb. See Appendix E for additional details.

IV-Fluids for Dehydration. In the "*Conventional Treatment Supportive Care Therapy*" Experiment #3 dehydration will be treated more aggressively that in the "Minimum Supportive Care Therapy" described above by use of slow IV push-fluids (isotonic saline). See Appendix E for additional details including indications for treatment, isotonic fluid volumes, and needle gauge.

Whole-Blood Transfusions. In the "*Conventional Treatment Supportive Care Therapy*" Experiment #3 whole blood transfusions will be performed when platelet counts drop below 75-100 x 10^9/L. If an anaphylactic reaction is observed, then transfusion is stopped until resolution/improvement of signs for an anaphylactic reaction. See Appendices E and H for additional details including indications for treatment, blood volumes, needle gauge, etc.

The animal is monitored for anaphylactic reaction (swelling, urticarial, hives, rash, difficult breathing). If reaction occurs, the transfusion is stopped (at least temporarily), and corticosteroids (dexamethasone at 1 mg/kg IV, 19-23 gauge needle) and /or histamine (diphenhydramine 2.2 mg/kg, IM, 19-23 gauge needle) are given. After resolution/improvement of signs, the transfusion may be re-started at ½ to 1/3 the original rate.

V.4.4.1.1. Pharmaceutical Grade Drugs

Amgen Pharmaceuticals - Neupogen® (Filgrastin) - recombinant methionyl human granulocyte colony-stimulating factor (r-metHuG-CSF).

The same pbarmaceutical grade formulation of G-CSF will be used for the current study as has been used previously in nonhuman primate studies conducted at AFRRI[(b)(4)] [(b)(4)] Filgrastim is the common trade name (brand name NEUPOGEN), manufactured by Amgen Pharmaceuticals. The drug is provided as sterile vials of 480 µg of human recombinant methionyl human G-CSF in 1.5 ml aqueous solution (Amgen G-CSF Product Insert). The solution also contains sorbitol.

Neupogen is typically used to treat myelosuppression resulting from hematologic disease or as a side effect of chemotherapy regimens (Amgen G-CSF Product Insert).

G-CSF is provided as a 300 µg/ml stock and will be diluted in sterile 5% dextrose solution prior to administration. NEUPOGEN® will be stored in the refrigerator at 2° to 8°C (36° to 46°F). Avoid shaking. Prior to injection, NEUPOGEN® may be allowed to reach room temperature for a maximum of 24 hours. Any vial or prefilled syringe left at room temperature for greater than 24 hours will be discarded. Parenteral drug products will be inspected visually for particulate matter and discoloration prior to administration. If particulates or discoloration are observed, the container will be discarded.

All other pharmaceutical grade drugs will be obtained from VSD.

V.4.4.1.2. Non-Pharmaceutical Grade Drugs

V.4.4.2. Biosamples

Blood will be collected under appropriate SOPs by following the procedure described with sterile 20-23 gauge needle attached to a needle holder or sterile syringe from saphenous, cephalic or any alternative vein as selected by the AFRRI vet; see Appendices C and H. Manual pressure will be used to reduce the chances of hematoma formation after blood collection. Typically blood volumes 0.8 to ≥4 ml are taken routinely for study purposes. Larger blood volumes are taken in the case of blood donation as described in Appendix H. For specific animals the blood volume collected will vary depending on the health status of the animal, animal weight, and guidance from the VSD veterinarians. Blood collection schedule is shown in the Appendices C and H.

V.4.4.3. Adjuvants N/A

V.4.4.4. Monoclonal Antibody (MAb) Production N/A

V.4.4.5. Animal Identification

Animals are identified by the ID number that is tattooed on the chest or inner thigh and by implantable microchips.

V.4.4.6. Behavioral Studies N/A

V.4.4.7. Other Procedures

A) Transport Plan: The animals for irradiation will be moved through the first floor hallway to the High Level Gamma Radiation (HLGR) facility. At no time will the animals be removed from the irradiation boxes and secured while outside of the VSD vivarium. Once within the HLGR facility the animals will be moved (still sedated in the irradiation box) down to the radiation source area. The animals in the irradiation boxes will be lifted onto the irradiation platform. The AFRRI dosimetrists will assure that the irradiation boxes are placed accurately in the radiation field. During irradiation, the irradiation box will be secured to prevent movement. The NHP's arms and legs will be secured to limit the ability to turn in the collar. Animals are expected to be in the irradiation box for no more than 60 minutes. The animals will be closely monitored by remote TV during the irradiation. After irradiation, the NHPs in their irradiation boxes will be removed from the platform and returned to the vivarium along the same route.

B) Blood Collection: Peripheral blood collection from NHP will be performed using standard procedures. VSD staff will assist, as able, the PI and PI staff to obtain blood samples if advanced preparations are made and sufficient VSD personnel are available.

C) ARS response severity scoring system (includes hematology, body temperatures, and body weights)

Clinical signs and symptoms for ARS subsyndromes including body weights and hematology changes will be assessed prior to and following irradiation to characterize the time course and dose response in the NHP radiation model (see Appendix C for a detailed schedule for blood draws, etc.). We plan to use a rhesus macaque ARS response severity scoring system (see Appendix B) in these studies. Typically blood draws and body weights can be obtained using NHP collar and chair without anesthesia. Blood drawas and body weights can also be obtained with NHP under anesthesia for another reason as determined by the Attending Veterarian. Several of the GI system dehydration measurements are only measured if the NHPs are planned to be placed under anesthesia for another reason. Subdermal body temperatures will be measured using the radiotelemetry detector.

The schedule for animal monitoring is shown in Appendix F. Once an animal has been determined to be in a critical period or morbid (See Appendix G) that animal will be monitored late at night on all days, for a minimum of 3 times per day including weekends. Night checks are the responsibility of the lab unless provisions are made in special circumstances for VSD to cover (if available).

D) Procedures for Selection and Preparing Animals for Blood Donation & Procuring, Processing, and Administration of NHP Donor Blood for Whole Blood Transfusions

Procedures for selection and preparing animals for blood donation as well as procuring, processing and administration of NHP donor blood for whole blood transfusion are described in Appendix H.

E) Criteria for euthanasia:

Criteria for euthanasia are described in Appendix G.

F) Histopathology:

In selected animals in dose/drug cohorts, histopathology will be requested to contribute to the assessment of radiation and treatment effects; see table below.

Exp. #	Experimental/Control Group	Histopathology
1	Pre	NA
2	High dose pilot (sham)	NA
2	High dose pilot (6.5 Gy)	NA
3	Treatment (0 Gy -> G-CSF/treatment)	NA
3	Treatment (6.5 Gy -> G-CSF/treatment)	n=2

Exp. #	Experimental/Control Group	Histopathology
4	Dose response (sham)	NA
4	Dose response (1 Gy)	n=2
4	Dose response (3.5 Gy)	n=2
4	Dose response (5 Gy)	n=2
4	Dose response (6.5 Gy)	NA
4	Dose response (8.5 Gy)	NA
Totals:		8

V.4.4.8. Tissue Sharing

Tissue sharing will be considered and be allowed with the submission of appropriate IACUC forms and approvals.

V.4.4.9. Animal By-Products

V.4.5. Study Endpoint

Surviving animals will be monitored up to 60 days after irradiation. Expected outcome for animals in the experiments are shown in the Table below. Animals will be monitored using the NHP ARS severity scoring system to support assessment of our defined euthanasia criteria. All moribund animals will be humanely euthanized.

Exp. #	Experimental/Control Group	Outcome expected	Totals
1	Pre	Recovery	36
2	High dose pilot (sham)	Recovery	2
2	High dose pilot (6.5 Gy)	60% risk for euthanasia/death	2
3	Treatment (0 Gy -> G-CSF/treatment)	Recovery	4
3	Treatment (6.5 Gy -> G-CSF/treatment)	70% recovery; 30% euthanasia/death	4
4	Dose response (sham)	Recovery	6
4	Dose response (1 Gy)	Recovery; of these 2 animals will be euthanized for histopathology	6
4	Dose response (3.5 Gy)	Recovery; of these 2 animals will be euthanized for histopathology	6
4	Dose response (5 Gy)	70% recovery; 30% euthanasia/death; 2 animals will be euthanized for histopathology	6
4	Dose response (6.5 Gy)	60% risk of euthanasia/death	6
4	Dose response (8.5 Gy)	Euthanasia/death	6

Exp. #	Experimental/Control Group	Outcome expected	Totals
Totals:			36
Note. NHP (non-irradiated) from Experiments #2, 3, and 4 will be used in Experiment #4.			

V.4.6. Euthanasia

Animals will be euthanized according to current American Veterinary Medical Association (AVMA) Euthanasia Guidelines. Animals will first be anesthetized with ketamine (IM, 10 mg/kg). Then the animal will be euthanized with an appropriate dose of Beuthanasia-D or other commercial euthanasia solutions (IV, 1ml/4.5 kg, 390 mg Pentobarbital/ml). For additional details regarding criteria for euthanasia, see Appendix G.

V.5. Veterinary Care

V.5.1. Husbandry Considerations Appropriate VSD SOPs will be followed.

V.5.1.1. Study Room

NHPs will be located for the duration of the study in AFRRI VSD vivarium. NHP waiting to be used in baseline experiment (PRE) will be paired housed, if the wait period is ≥4 weeks. NHP selected for baseline experiment (PRE), usually less than 4-5 weeks prior to irradiation, will be individually housed but with visual and/or tactile contact with other animals in stainless-steel cages in an environmentally controlled and continuously monitored animal rooms, as assigned by VSD per guidance from the AFRRI IACUC Chair (23 Nov 2012 MEMO).

V.5.1.2. Special Husbandry Provisions

Water will be provided to all irradiated NHPs via water sipping tubes.

NHP will be fed commercial primate biscuits ad libitum supplemented with fresh fruits (i.e., apples, bananas, oranges, etc.). Following irradiation NHP food will include soft food and non-citrus fruits. (b)(6) and other experts recommended that citrus fruits be restricted in the NHP radiation model (b)(6) It is thought that acid from the citrus fruits can cause irritation of the intestinal system (b)(6) In addition citrus fruits in the diet can interfere with candidate radiation biomarkers (i.e., citrulline, citrullinated proteins) under study.

V.5.1.3. Exceptions

NA

V.5.2. Veterinary Medical Care

V.5.2.1. Routine Veterinary Medical Care

The animals in this study will undergo an additional quarantine at AFRRI (45 d) using VSD's NHP quarantine standard operating procedures.

Each animal will be observed for evidence of pain or distress; see Appendix F – Monitoring Plan. Body weights will be determined prior to and after exposure; see Appendix C. Body temperature will be determined using subcutaneously implanted chips that will also serve to identify individual animals; see Appendix C for schedule. The time of each temperature

collection will be recorded for each NHP. The general health of experimental animals will be qualitatively assessed by the research staff twice daily (a.m. and p.m.) for general behavioral status and food consumption, in addition to VSD's normal health check procedures. If animals show evidence of severe clinical signs and symptoms of ARS, then VSD staff will be alerted to check the animal and to assess the NHPs. Appropriate standard operating procedures will be followed by staff veterinarians in the event of pain or distress.

The planned number and blood volume draws scheduled will be reviewed by the AFRRI veterinarians and staff and if determined to place the individual animals under severe health risk will be drastically reduced or suspended until the animal shows adequate recovery.

The 5-HT3 receptor antagonists: Ondansetron (1 or 2 mg/kg) or Granisetron (0.25 mg/kg) can be administered either orally, intravenous (IV), or subcutaneous (SC) after observation of vomiting or signs of emesis to decrease subsequent radiation-induced vomiting in NHPs as described in paper published by Martin et al. "Anti-emetic Effect of Ondansetron and Granisetron after Exposure to Mixed Neutron and Gamma Irradiation" (Radiation Research 149: 631-636 (1998). Authors demonstrated that two deliveries of 5-HT3 receptor antagonists seem to disrupt serotonergic transmission at the brain stem structures and to affect the peripheral release of serotonin from the gut, thus completely preventing radiation-induced vomiting".

In the case of Experiments # 2 and 4 irradiated animals, additional supportive care should be minimal; platelet counts may dip below 20,000/µl for several days, but whole blood will not be transfused as this would negate the purpose of the study. The extent of dehydration and diarrhea will be monitored for each animal. Based on the ARS response severity score animals' status will be graded as: normal, mild, moderate, or severe. In the case of mild dehydration and diarrhea, supplemental oral fluids (type and volume as judged appropriate by the veterinarian) will be offered when not counter-indicated due to severe drops in platelet counts. In the case of a moderate dehydration and diarrhea subcutaneous fluids and /or over the counter (OCT) anti-diarrheal (e.g., loperamide 1mg PO BID, bismuth subsalicylate 40mg/kg PO BID), anti-emesis (Cerenia, 1mg/kg, SC; 2mg/kg PO), anti-gastric reflux (e.g., Famotidine 0.5mg/kg PO or IM SID) or anti-gas (e.g., "TUMS" 1 tablet PO PRN) medications will be administered by VSD staff. If body temperature rises above 103 F, NHP will be administered Carprofen (Rimadyl 2.2 mg/kg, BID; QD/IM/IV/PO); see Appendices D and E.

V.5.2.2. Emergency Veterinary Medical Care

Experiments #2 and 4 in this study design involve use of "minimal supportive care" treatment. In the case of severe dehydration and or diarrhea or if pain /distress are noted, clinical staff veterinarian will be notified immediately and to evaluate the animal to determine the best course of medical care under the broad scope of a study design involving minimum treatment. VSD will provide a veterinarian availability 24/7 to provide emergency care as care is needed. There will be a veterinarian available to provide back-up to the on call veterinarian if necessary. Additional medical diagnostic beyond the described ARS response severity scoring system (i.e., body temperature, hematology, etc.) may be performed as judged by the AFRRI veterinarian. Symptomatic therapy will be provided with the development of abnormal clinical signs. For example, fruit or treats may be given in case of anorexia, topical antiseptics may be used for open wounds with significant defects following skin necrosis due to subcutaneous infections.

Inappetence or dehydration with or without signs of gastrointestinal distress will be treated with either fluid supplementation or Liquid Primate Diet at the request of the staff veterinarian. Antibiotic cream may be administered topically in order to ameliorate discomfort due to skin lesions. Euthanasia will be carried out according to pre-defined criteria as determined by veterinarians.

V.5.3. Environmental Enrichment

V.5.3.1. Enrichment Strategy

Forms of psychological and environmental enrichment will include fruit, vegetable or additional supplements (that do not require analyses) and various cage-enrichment devices as well as contact with staff personnel. Fruits and vegetables that are not root vegetables will be disinfected by washing with a fruit and vegetable disinfectant solution, recommended by AFRRI veterinarians. If root vegetables such as sweet potatoes are given, the vegetable skin will be removed to reduce exposure to microorganisms.

V.5.3.2. Enrichment Restrictions

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING

X. ASSURANCES

Protocol Title: Evaluation of novel biodosimetry technologies using non-human primates (NHP; *Macaca mulatta*) radiation model

As the Principal Investigator on this protocol, **I** acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made every effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that **I** have consulted with a qualified individual who evaluated the experimental design with respect to the statistical analysis, and that the minimum number of animals needed for scientific validity will be used.

D. Biohazard / Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Responsibility: **I** acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and **I** assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R", namely, "Responsibility," which the DOD has embraced for implementing animal use alternatives where feasible and conducting humane and lawful research.

G. Scientific Review: This proposed animal use protocol has received appropriate peer scientific review and is consistent with good scientific research practice.

H. Painful Procedure(s): I **AM / AM NOT** conducting biomedical experiments, which may potentially cause more than momentary or slight pain or distress to animals. If applicable, potential pain and/or distress **WILL / WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

Appendix A. Hematology and Body Weights in NHP TBI Radiation Model

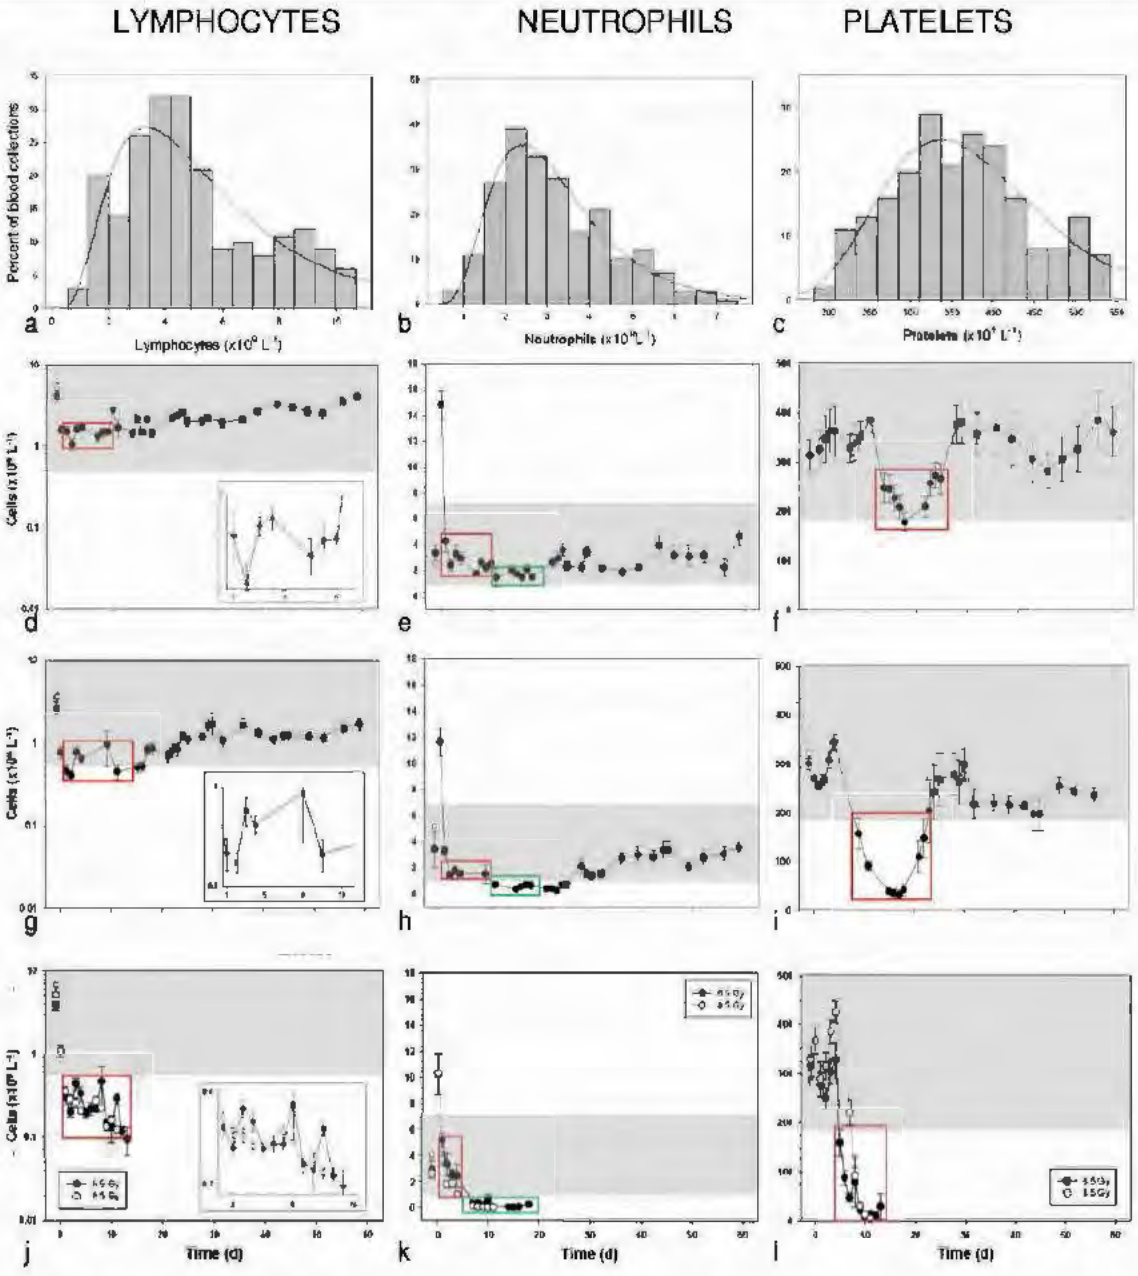

Figure A-1. Hematology parameters in NHP radiation model. Baseline distributions of lymphocytes (a), neutrophils (b), and platelets (c) are shown. The 95% confidence levels are shown in the shaded area in respective panels following exposure to 1 Gy (d, e, f), 3.5 Gy (g, h, i), and 6.5 (closed symbols) and 8.5 Gy (open circles) (j, k, l).

Continue Appendix A.

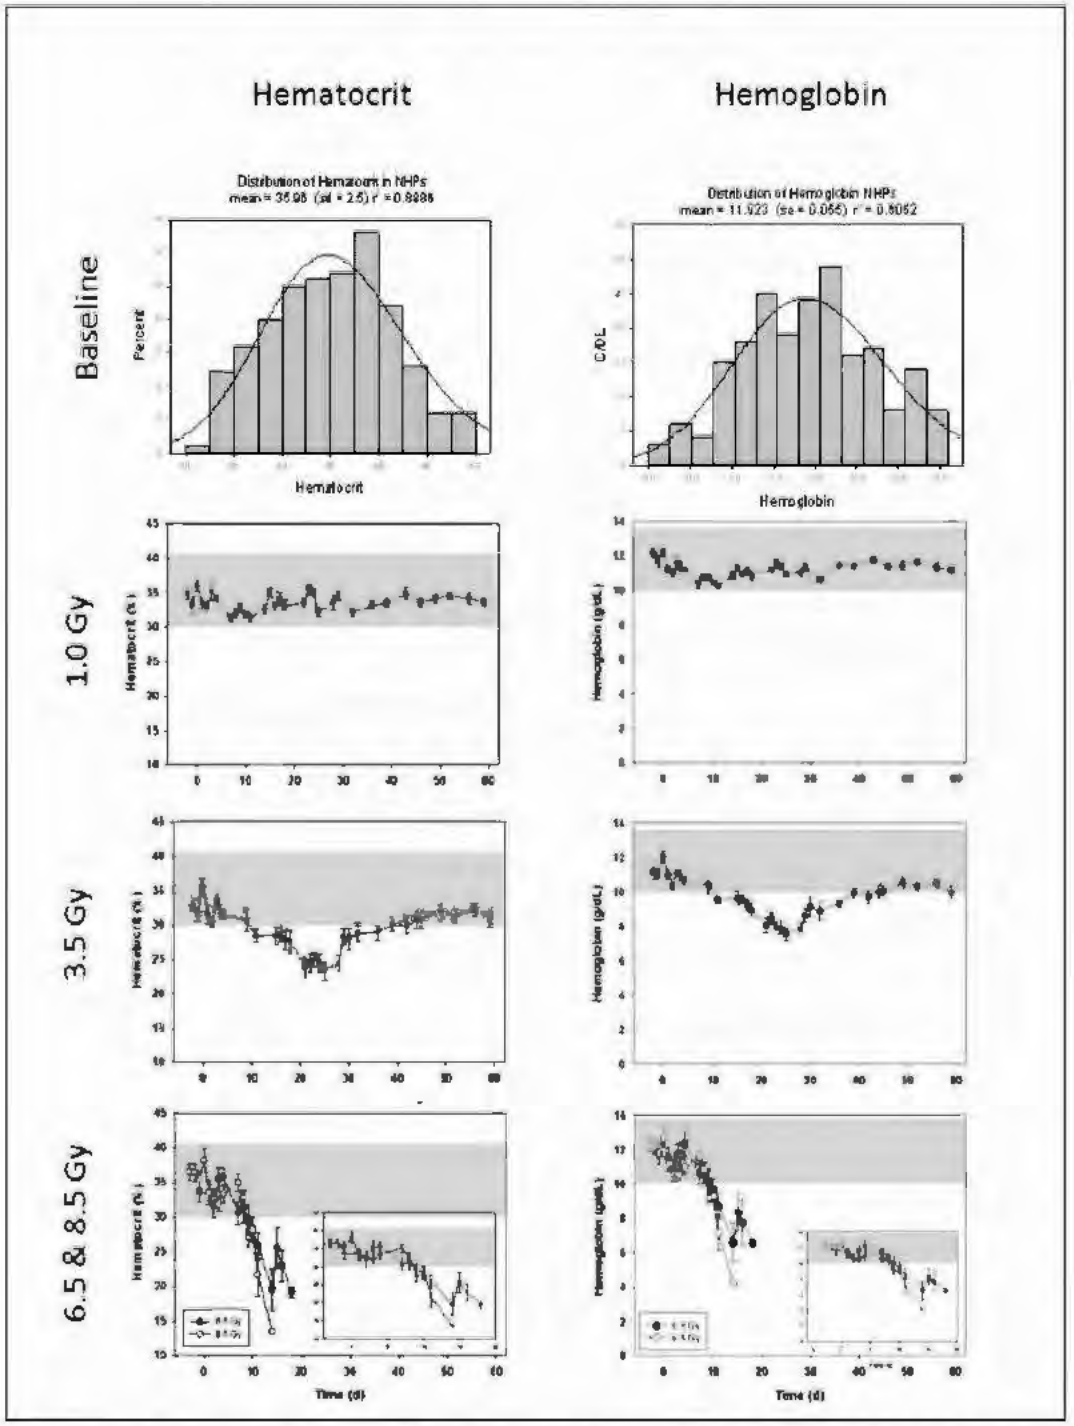

Figure A-2. Time course of hematocrits and hemoglobin in a NHP radiation model. Data are normalized to initial body weights. The hematocrits are following exposure to 0 Gy, 1 Gy, 3.5 Gy 6.5 Gy, and 8.5 Gy. Symbols represent mean values (n = 6) with error bars the SEM.

Continue Appendix A.

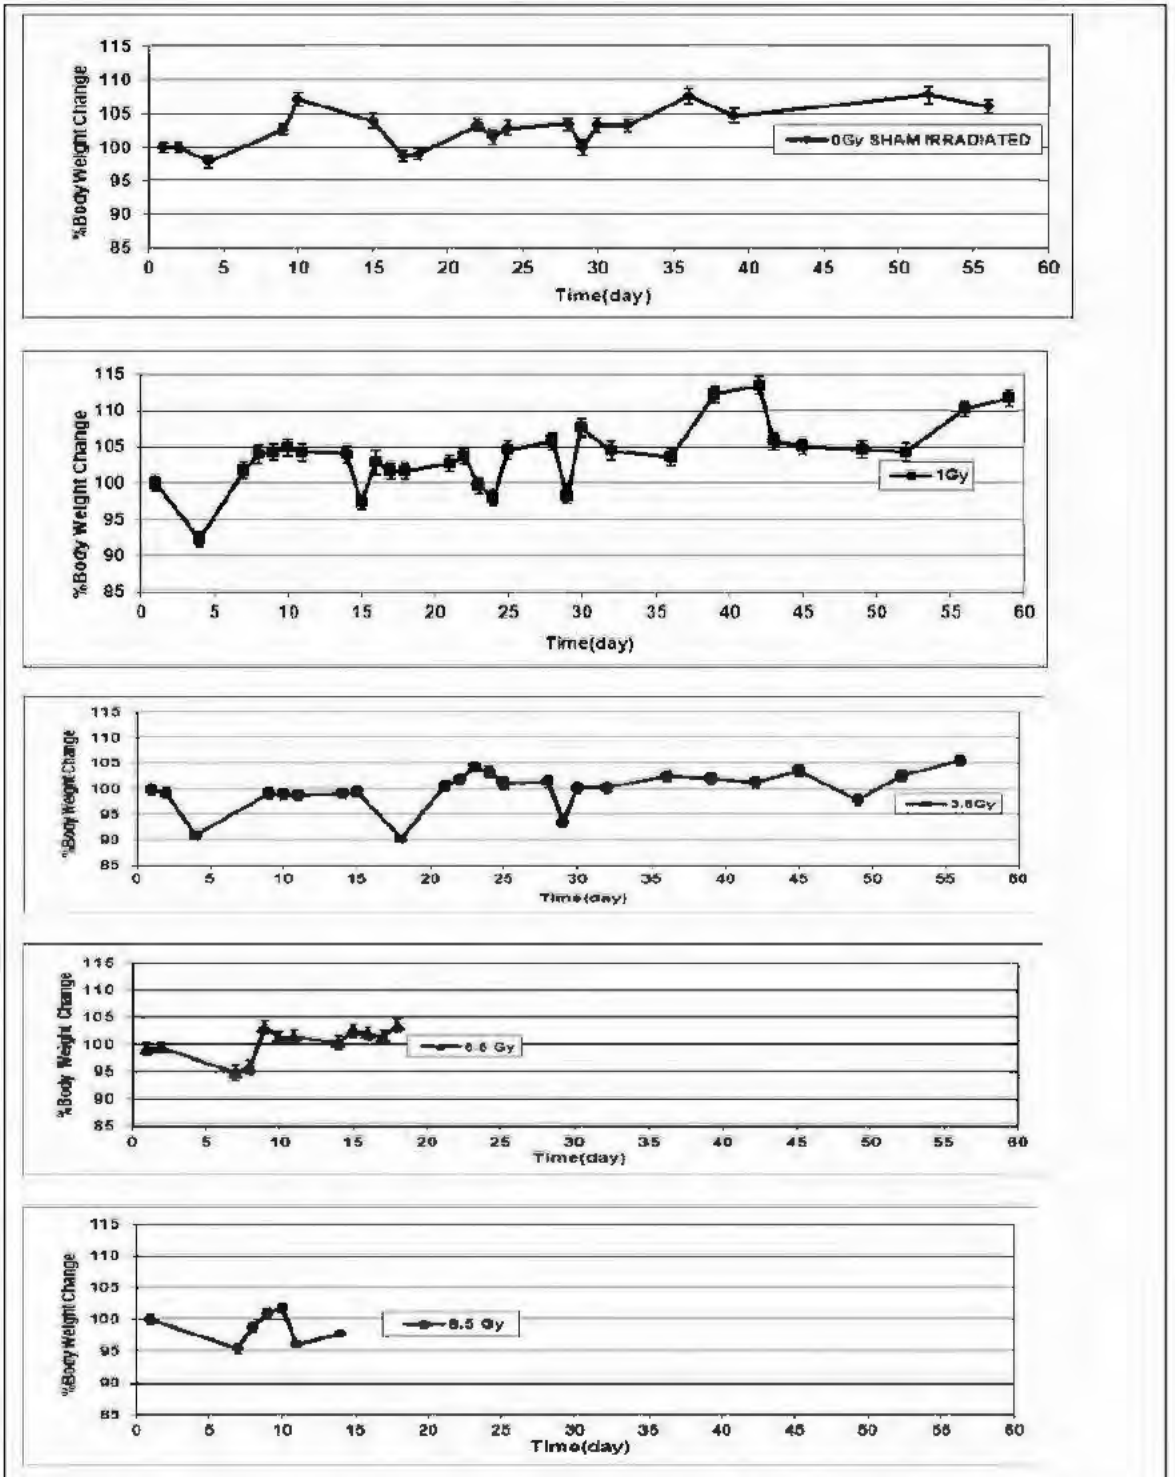

Figure A-3. Time course of body weights changes in NHP radiation model. Data are normalized to initial body weights. The time course of body weights are following exposure to 0 Gy, 1 Gy, 3.5 Gy 6.5 Gy, and 8.5 Gy. Symbols represent mean values (n = 6) with error bars the SEM.

Appendix B: NHP Procedures

"NHP ARS-Response Severity Scoring System (ARS-RS^3) PROTOCOL"

Note. Protocol PI (NIO) and co-PI (WFB) will meet with staff individuals to discuss the ARS-RS^3 protocol and assessment criteria prior to initiation of the study.

Sample Requirements.
Annotated ARS-RS^3 scoring sheet for experimental animals 3-4 times per work week including a measurement on Fridays. [Note. In cases of animal under crisis due to severe ARS, this frequency may be increased to include weekends, because it contributes to an assessment for euthanasia decision.]

Prior to Measurements.

1. ARS-R^3 form copies are made available in the individual NHP cage records.
2. Pre-labeled tubes (Animal ID, Date, Time) for collection of feces.
3. Pre-labeled tubes (Animal ID, Date, and Time) for collection of blood into serum separator tubes, and EDTA vacucontainers.
4. Measure weights for chairs; label chair weights.

During Rounds by Vet. Tech. and Animal Care Taker (twice a day/3-4 times a week) and by Research Staff (once a day/3-4 times a week).

1. At any time the animal is observed to be retching./.vomiting, record date and time.
2. Before any replacement of the cage tray for urine collection, if appropriate, check for vomitus.
3. Assess for shivering, fatigue/lethargy, response to stimuli, and piloerection; then record,
4. Count respiratory rate for a full minute and record.
5. Observe for abdominal distension and wounds; record.
6. Observe and record for consistency and color of feces; record.

During window of the workday by Research Staff (once a day/3-4 times a week).

1. At any time the animal is observed to be retching/vomiting or there is evidence of vomitus, record date and time.
2. Observe and record for consistency and color of feces; record.

During blood draw without anesthesia [NHP will be collared and chaired; frequency as described in the individual NHP schedule for biosampling].

1. Collect blood into appropriate tubes and volume as shown on the schedule for each specific NHP and record date and time.
2. If NHP defecates during blood draw, record consistency and color of feces.
3. Weight animal in chair and record NHP body weight.
4. Observe and record NHP SC temperature.

Procedures done under anesthesia [frequency as described in the individual NHP schedule for biosampling:

1. Collect blood into appropriate tubes and volume as shown on the schedule for each specific NHP and record date and time
2. Weight animal and record NHP body weight.
3. Observe and record both SC and rectal temperatures.
4. Measure dehydration status (skin turgor, gum capillary refill, buccal mucosal / tongue hydration).

Grading System for Rhesus Macaque ARS Response of Gastrointestinal, Neurovascular, Respiratory, Hematopoietic Systems				
	NORMAL (DEGREE 0)	MILD (DEGREE 1)	MODERATE (DEGREE 2)	SEVERE (DEGREE 3)
Gastrointestinal system				
- Dehydration				
% of weight loss	± 5	10	15	20
Skin turgor (anesthesia)	1 sec	2 sec, < 3 sec	3 sec	> 3 sec
Gum capillary refill (anesthesia)	1 sec	2 sec, < 3 sec	3 sec	> 3 sec
Buccal mucosal / tongue hydration (anesthesia)	Normal	< Normal amount of saliva, yet still some shine to membrane, tacky	Dry, no saliva, mucus membranes not shiny, tacky, sunken eyes	Dry and inflamed? Tongue parched
Inappetance	Normal eating habits, consumes all or most of food	Moderately slow to respond to meals & treat	Portions of meal & treat remain uneaten, picks up food but may abandon it	Ignores food when delivered, all (or most) of food remains uneaten
Retching / Vomiting	None	Mild – some evidence of vomitus on cage floor	Moderate – much evidence of vomitus on cage floor	Severe – actively R/V upon inspection
- Diarrhea				
Abdominal distension	None	Mild	Moderate	Severe
Stool consistency	Formed	Soft	Loose/watery	Bloody watery
Stool color	Normal	Other (eg, green, yellow)	Black	Bright red
Neurovascular system				
Response to stimuli	Vigilant and reactive; stands on perch inside cage; looks around room; follows personnel and procedures	Vigilant and mildly reactive; stands on perch; looks around room; follows personnel and procedures	Generally sits on the perch; appears depressed; moves with difficulty when provoked	Always sits on the perch or floor of cage, even with personnel in the room; appears depressed or 3++ (unresponsive; lies on floor or perch)
- Fever				
Rectal body temperature (°C) with anesthesia	~ 101.5	~ 103.5	~ 105	> 107
Subcutaneous body temperature (°C) / with anesthesia	TBD	TBD	TBD	TBD
Subcutaneous body temperature (°C) / without anesthesia	TBD	TBD	TBD	TBD
Shivering	None	Mild	Moderate	Severe
Piloerection (unrelated to fear or aggression)	None	Any	NA	NA
Respiratory system				
Respiratory rate	RR = 35 – 50	RR > 60	RR > 60 + shallow	Labored or gasping
Behavioural				
Fur Grooming	Good (groomed)	2 areas not groomed	3-4 areas not groomed	Not groomed
Aggression/Vocalization	No sounds/Calm	Makes sound 1-2 times	Sounds 2 or more times	Frequent sounds
Hematopoietic system				
Lymphocytes (reference value, X 10^3 cells/L)	± 10 % of baseline value: 0.06 – 9.78	1-14d: 1.0 - 2.0	1-14d: 0.4 - 1.0	1-14d: < 0.5
Neutrophils (reference value, X 10^3 cells/L)	± 10 % of baseline value: 0.47 – 5.83	< 1d: 13 - 18	< 1d: 10 - 13	< 1d: 8 - 10
		10-20d: 1.2 - 2.2	10-20d: < 1.2	5-20d: < 1.0
Platelets (reference value, X 10^3 cells/L)	± 10 % of baseline value: 194 – 525	≥ 12d: < 300	≥ 8d: < 180	≤ 8d: < 180
Hemoglobin (reference value: G/DL)	± 10 % of baseline value: 10.3 – 13.5	> 20d: 8 - 10	10-20d: 8 - 10	≤ 10d: < 10
			≥ 20d: < 8	10-20d: < 8
Hematocrit (reference value, %)	± 10 % of baseline value: 30.96 – 40.96	> 20d: 25 - 30	10-20d: 25 - 30	≤ 10d: < 30
			≥ 20d: ≤ 25	10-20d: ≤ 25

7th wk (2X)	--	1.2	1.35	1.5	1.65	1.8	2.0	2.2	2.35	2.5
8th wk (2X)	0.225 (~50d)	1.2	1.35	1.5	1.65	1.8	2.0	2.2	2.35	2.5
60d	0.225	1.2	1.35	1.5	1.65	1.8	2.0	2.2	2.35	2.5
*Note. For repeated daily blood draws the maximum daily amount of blood volume should be ≤1% of total blood volume, typically estimated based on the animal body weight. For Rhesus the blood volume per body weight is 54 ml/kg (Laboratory Animals 27:1-22, 1993). Sample calculation: Assume a 4.5 kg NHP this represents a daily blood draw of 2.4 ml (4.5 kg x 54 ml/kg x 0.01).										

Appendix D. Minimum Supportive Care Therapy					
Nutritional Support					
Fluids	Unlimited access to filtered water; Following irradiation animals are provided flavored fluids.				
Food	Commercial primate biscuits ad libitum supplemented with fresh fruits (i.e., apples, bananas, oranges, etc.); Following irradiation all citrus removed from their diets, diets include soft food				
Indication	**Drug**	**Dosage**	**Route**	**Needle gauge**	**Syringe size**
Anesthesia					
Placement of NHP in rad box; measurement of mid-body widths; microchip injection	Ketamine	10mg/kg	IM or SC	22-25 G	3 ml
Analgesic					
Distress from radiation exposure (5 to 35 days after radiation exposure)	Buprenorphine HCL	0.01 mg/kg up to 0.02 mg/kg BID	IM	22-25 G	variable
Mouth ulcers or bloody stools	Bupivacaine HCL	0.1 ml of 25% bupivacaine HCL with a dab of surgical lubricant)	Locally using cotton-tipped applicator	NA	NA
Antiemetic/AntiGastric Reflux					
Gastric reflux	famotidine	0.5mg/kg	PO or IM SID	22-25 G	variable
Emesis	Cerenia	1mg/kg (SC); 2mg/kg (PO)	PO or SC	22-25	variable
Emesis	Ondansetron Granisetron	1 or 2 mg/kg 0.25 mg/kg	PO or SC or IV	22-25	variable
Antigas					
gas	TUMS	tablet	PO PRN	NA	NA
Antidiarrheal					
Observation of diarrhea	Loperamide	0.1 – 0.2 mg/kg	PO BID, SC, IM	NA; 22-	1-3 ml

	Hydrochloride (Imodium)			25 G	
Persistent diarrhea (3 successive days with Imodium treatment) or if watery stool without any signs of formed stool	Diphenoxylate hydrochloride	0.1 mg/kg	PO BID for 3 d	NA	NA
Diarrhea >3 d	Loperamide Hydrochloride (Imodium)	0.1 – 0.2 mg/kg	PO BID, SC, IM	NA; 22-25 G	1-3 ml
Antipyretic					
Body temperature >104 °F	Carprofen (Rimadyl)	2.2 mg/kg; 4.4 mg/kg	BID; QD,/IM/IV/PO		
Continued for 48 h after the 1st d body temperature <104°F	Carprofen (Rimadyl)	2.2 mg/kg; 4.4 mg/kg for 2 days	BID; QD/IM/IV/PO		
Antiseptic (Local)					
Local infection	Neobacimyn	NA	Topical	NA	As clinically determined
Dehydration					
Mild – presence of tacky mucus membranes without signs of gastrointestinal (GI) distress	Flavored fluid supplementation	NA	Use of water bottles	NA	As needed
Moderate- mild criteria plus dry mucous, sunken eyes with signs of GI distress	Flavored fluid supplementation along with antidiarrheal treatments	NA	Use of water bottles	NA	As needed
Severe – Any of mild and or moderate criteria plus pale mucous membranes, rapid and weak pulse, cold extremities, lethargy, or rapid breaching	Flavored fluid supplementation along with antidiarrheal treatments	NA	Use of water bottles; See above for anti-diarrheal treatments	NA	As needed
Antiulcerative					
Bloody stool	Sucralfate (Carafate)	1g/day	BID	NA	

Appendix E. Conventional Treatment Supportive Care Therapy					
Nutritional Support					
Fluids	Unlimited access to filtered water; Following irradiation animals are provided flavored fluids.				
Food	Commercial primate biscuits ad libitum supplemented with fresh fruits (i.e., apples, bananas, oranges, etc.); Following irradiation all citrus removed from their diets, diets include soft food.				
Indication	**Drug**	**Dosage**	**Route**	**Needle gauge**	**Syringe size**
Anesthesia					
Placement of NHP in rad box; measurement of mid-body widths; microchip injection	Ketamine	10mg/kg	IM or SC	22-25 G	3 ml
Analgesic					
Calm NHPs while in restraint during prolonged IV fluid treatments	Midazolam HCL	0.2 mg/kg	IM	22-25 G	variable
Distress from radiation exposure (5 to 35 days after radiation exposure)	Buprenorphine HCL	0.01 mg/kg up to 0.02 mg/kg BID	IM	22-25 G	variable
Mouth ulcers or bloody stools	Bupivacaine HCL	0.1 ml of 25% bupivacaine HCL with a dab of surgical lubricant)	Locally using cotton-tipped applicator	NA	NA
Antiemetic/AntiGastric Reflux					
Gastric reflux	famotidine	0.5mg/kg	PO or IM SID	22-25 G	variable
Emesis	Cerenia	1mg/kg (SC); 2mg/kg (PO)	PO or IM	22-25 G	variable

Emesis	Ondansetron Granisetron	1 or 2 mg/kg 0.25 mg/kg	PO or SC or IV	22-25	variable
Cytokine Treatment					
Treatment group 1 d after irradiation or sham exposure until the post-irradiation recovery of ANC ≥2,000 μL^{-1} for 2 consecutive days	G-CSF	10µg/kg; once a day until no indication (recovery of ANC, ≥2,000 μL^{-1}	SC	22-25 G	variable
Antigas					
gas	TUMS	tablet	PO PRN	NA	NA
Antidiarrheal					
Observation of diarrhea	Loperamide Hydrochloride (Imodium)	0.1 – 0.2 mg/kg	PO BID, SC, IM	NA; 22-25 G	1-3 ml
Persistent diarrhea (3 successive days with Imodium treatment) or if watery stool without any signs of formed stool	Diphenoxylate hydrochloride	0.1 mg/kg	PO BID for 3 d	NA	NA
Diarrhea >3 d	Loperamide Hydrochloride (Imodium)	0.1 – 0.2 mg/kg	PO BID, SC, IM	NA; 22-25 G	1-3 ml
Antipyretic					
Body temperature >104 °F	Carprofen (Rimadyl)	2.2 mg/kg; 4.4 mg/kg	BID; QD,/IM/IV/PO		
Continued for 48 h after the 1st d body temperature <104°F	Carprofen (Rimadyl)	2.2 mg/kg; 4.4 mg/kg for 2 days	BID; QD/IM/IV/PO		
Antiseptic (Local)					

Local infection	Neobacimyn	As clinically determined	Topical	NA	NA
Antibiotic Therapy					
ANC <500 μL^{-1} and continued until animal maintained ANC >500 μL^{-1} for 48 h.	Enrofloxacin (Baytril)	5mg/kg	QD: PO, IV, IM	22-25G	variable
ANC <500 μL^{-1} and continued until animal maintained ANC >500 μL^{-1} for 48 h (Baytril) and 24 h (GentaMax) with body temperature ≥103°F	Enrofloxacin (Baytril)	5mg/kg	QD: PO, IV, IM	22-25G	variable
	Gentamicin sulfate (GentaMax)	4 mg/kg	QD: IM or IV	22-25G	variable
ANC <500 μL^{-1} and continued until animal maintained ANC >500 μL^{-1} with body temperature ≥103°F when microbial resistance demonstrated to enrofloxacin or gentamicin	Primaxin	5-10 mg/kg:	BID: IM	22-25 G	variable
Dehydration					
Mild – presence of tacky mucus membranes without signs of gastrointestinal (GI) distress: Use of isotonic saline provided only if platelets >10 x 10^9/L	Flavored fluid supplementation	NA	Use of water bottles	NA	NA
	Isotonic saline	10-15ml/kg	Slow IV push	18-23 G	variable

Moderate- mild criteria plus dry mucous, sunken eyes with signs of GI distress; Use of isotonic saline provided platelets >10 x 10^9/L	Flavored fluid supplementation along with antidiarrheal treatments	NA	Use of water bottles	NA	NA	
	Isotonic saline	20-39 ml/kg	Slow IV push	18-23 G	Variable	
Severe – Any of mild and or moderate criteria plus pale mucous membranes, rapid and weak pulse, cold extremities, lethargy, or rapid breaching; Use of isotonic saline provided platelets >10 x 10^9/L	Flavored fluid supplementation along with antidiarrheal treatments	15±5 ml/kg/h over a period of 2-4 h	Slow IV push	18-23 G	Variable	
	Isotonic saline; animals in a restraint device, allowed to awaken, and sedated (Midazolam HCL)					
Antiulcerative						
Bloody stool	Sucralfate (Carafate)	1g/day	BID	NA	NA	
Blood Product Support*						
Platelets less than 70-100 x10^9/L or uncontrolled hemorrhage	Whole blood (exposed to 20 Gy) transfusion	7-14 ml/kg	IV using an 18µ blood filter (Hemo Nat Filter, Utah Medical Products)	18-23 G	variable	

*See Appendix H for additional details regarding whole blood transfusions.

Appendix F. Protocol Monitoring Plan						
Time Window	Animal Care Takers (VSD)	Vet. Tech (VSD)	Vets (VSD)	Research Techs (PI)		Principal Investigators
				ARS Severity Assessments (± blood draws)	Careside Observations *	Careside Observations*
Prior to irradiation exposure						
M->F	Twice a day (<6:30 am; ~1pm)	Twice a day (~9am; 2-3pm)	As needed	Once a day (AM)	Once a day (Afternoon)	Once a day (TBD)
Sat, Sun, Holidays	Once a day (6:30am-Noon)	Once a day (afternoon)	On call	NA	Once on SAT or SUN	Once on Sun or SAT and Holidays
Post-radiation exposure						
M->F	Twice a day (<6:30 am; ~1pm)	Twice a day (~9am; 2-3pm) or as needed	As needed or on call	Once a day (AM)	Once a day (Late afternoon) or ass needed	Once a day (TBD) or as needed
Sat, Sun, Holidays [Routine]	Once a day (6:30am-Noon)	Once a day (afternoon)	On call as needed	Once a day (TBD)	Once on SAT or SUN (TBD)	Once on SUN or SAT (TBD)
Sat, Sun, Holidays [NHPs with ANC <500 μL^{-1}; NHPs given whole blood transfusions (24h after transfusion)]	Once a day (6:30am-Noon)	At least once a day (afternoon)	On call as needed	Once a day (AM)	Once a day (Afternoon/Early Evening) or as needed	Once a day (TBD) or as needed
*Note. If a NHP exbibits clinical observations with criteria of "morbid", then Researeh Teehs & PIs will monitor animal late at night, for a minimum of 3 to 4 times a day, to include weekends.						

Appendix G. Clinical Observations with Criteria for Euthanasia (NHPs)		
PARAMETER	**OBSERVATIONS**	
	COMBINATION CRITERIA (two or more of the following combined is sufficient to consider euthanasia)	**ABSOLUTE CRITERIA** (any of these signs alone is criteria for euthanasia)
General appearance	Ocular discharge; Mildly to moderate dehydrated (aggressively treat)*; Hair shedding	Paralysis of one or more extremities; Cyanosis (bluish color to skin or mucus membranes); Moderate to severe emaciated/dehydrated (skin tent) (uncontrolled by treatment)
Stool appearance	Mild to moderate loose stools (treat)*; Mild blood present in the stools (treat)*	Uncontrolled loose stools with frank blood in the stools even after treatment
Bleeding	Mild generalized petechiation on the body with no signs of active bleeding*; Platelets < $50x10^3$/uL; Hematocrit <30%	Uncontrolled bleeding Precipitous drop of hematocrit (>20% in 48 hours) Hematocrit <15% and platelets <$3x10^3$/uL with lethargy
Respiratory rate	Mild dyspnea (shortness of breath with rapid and shallow breathing; Mild abdominal breathing	Gasping/open mouth breathing
General behavior	Decreased mobility; Mild inappetence (eats treats, eats parts of meals), assuming animal has recovered from anesthesia	Weakness/inability to obtain food or water; Inappetence for 3 meals, assuming animal has recovered from anesthesia; Repeated and uncontrollable self trauma; Seizures
Provoked behavior	Subdued responsive to gentle prodding, assuming the animal has recovered from anesthesia	Decreased or absent response to stimulation, assuming the animal has recovered from anesthesia;
Weight loss	10-20 % of baseline body weight	More than or equal to 20% from the baseline weight
Core body temperature, °C	Uncontrollable fever (≥4°C of baseline) (treat)*	<35.5 °C following a period of febrile neutropenia
Note	***If any one of the designated parameters is exhibited, notify responsible personnel immediately for treatment of NHPs.**	

Appendix H.

Date last updated: Dec 7, 2012 (b)(6)

(SOP. NIO-XXX)

Procedures for Selection and Preparing Animals for Blood Donation & Procuring, Processing, and Administration of NHP Donor Blood for Whole Blood Transfusions

Ref:

(a) Farese AM, Cohen MV, Katz BP, Smith CP, Jackson III W, Cohen DM, and MacVittie TJ. A nonhuman primate model of the hematopoietic acute radiation syndrome plus medical management. Health Physics 103(4): 367-382.

(b) (b)(6)

(c) NHP Whole Blood Transfusion, Standard Operating Procedures 5011, Armed Forces Radiobiology Research Institute, Veterinary Science Department, Oct 2009.

(d) Diehl K-H, Hull R, Morton D, Pfister R, Rabemampianina Y, Smith D, Vidal J-M, van de Vorstenbosch C. A good practice guide to the administration of substances and removal of blood, including routes and volumes.

I. Purpose. The purpose of this protocol specific Standard Operating Procedures (SOP, NIO-XXX) is to specify the required procedures to be used for the proper procuring, processing, and transfusion of donor irradiated whole blood to recipient animals.

II. Scope. This SOP applies to planned studies at AFRRI by staff personnel in support of BARDA funded studies awarded to Dr. (b)(6) and under the co-direction of Dr. (b)(6) (b)(6) for selection of animals for blood donation, preparing animals for blood transfusion.

III. Responsibility. Drs (b)(6) are responsible for reviewing and updating this SOP as needed.

IV. Procedures.

A. Supplies. See Appendix H - Attachment A.

B. Identify Donor Animals. Ideally, animals with high body weight (~≥5 kg) should be used for blood donation. Select from pre-approved healthy individuals with matched infectious disease status.

C. General Monitoring of Donor Animals. Animals on this protocol will be monitored for general health including: body weight, body temperature, hydration status, hematology

and chemistry parameters. AFRRI's Veterinarian will be notified if any unusual weight tends, body temperature, abnormal complete blood counts (CBC) or abnormal serum chemistries are observed. See Appendix H - Attachment B for the conditions and blood volumes withdraw for this purpose.

D. Anesthesia. Animals will be anesthetized with ketamine (10 mg/kg, IM in the quadriceps muscle using a 22-25 gauge needle) for transport to the treatment room, clinical observations requiring animal compliance, blood donation, and blood transfusion. Isoflurane gas (2% in O2) will be administered via mask as determined by the AFRRI Veterinarian, per the request of AFRRI's Veterinarian.

E. Physiologic Measurements. Body temperatures will be monitored using the injected microchips on days when the animals are biosampled or assessed for clinical observations. Body weights will be obtained each day the animals are anesthetized for other procedures. The body weight is obtained prior to administration of any fluids support including fluid replacement at time of blood donation. Protocol staff will notify AFRRI's Veterinarian of any abnormal body temperatures or weights.

F. Phlebotomy.

a) Peripheral Blood for Routine Health Monitoring. VSD staff will assist, as able, the PI and PI staff to obtain blood samples if advanced preparations are made and sufficient VSD personnel are available. Blood will be collected under appropriate SOPs by following the procedure described with sterile 20-23 gauge needle attached to a needle holder or sterile syringe from saphenous, cephalic or any alternative vein as selected by the AFRRI Veterinarian. Manual pressure will be used to reduce the chances of hematoma formation after blood collection. Typically blood volumes ≤1 ml are taken routinely. For specific animals the blood volume collected will vary depending on the health status of the animal, animal weight, and guidance from the VSD veterinarians. Blood collection schedule for donor animals is shown in Appendix H - Attachment B.

b) Peripheral Blood for Blood Donation and LRS infusion. Put on sterile gloves. Venipuncture site is prepared by cleansing with Betadine, allowed to dry, then clean the area with an alcohol swab and allow it to dry. Repeat this process for a total of 3 scrubs. Blood will be collected under appropriate SOPs by following the procedure described with sterile 20-23 gauge needle attached to a needle holder or sterile syringe from saphenous, cephalic or any alternative vein as selected by the AFRRI Veterinarian. Manual pressure will be used to reduce the chances of hematoma formation after blood collection. Label a 30ml syringe containing 3ml of citrate phosphate dextrose (CDP-a) anticoagulant "NHP blood: with the animal ID, date

collected, time of donation, and expiration date. Then withdraw no more than 27 ml of blood into a 30-ml syringe. The filled syringe will be removed from the infusion set and capped. Prepare a syringe with lactated Ringer's Solution (LRS) with volumes as described in Appendix H - Attachment B. Attach the syringe containing the LRS to the infusion set and infuse this solution. The infusion set will be removed and pressure will be applied over the venipuncture site with gauze until bleeding stops.

G. Blood Donation.

Healthy animals will be selected from the donor pool. Donor animal will be anesthetized with ketamine (10 mg/kg, IM in the quadriceps muscle using a 22-25 gauge needle). The body temperature and weight will be obtained. Blood will be collected (19-23 gauge needle) for a CBC (0.4 ml). If CBC levels are within acceptable limits, then withdraw whole blood volumes from the animals and infuse LRS volumes as described in Attachment B from the animals as described in "Peripheral Blood for Blood Donation" section above. The date and amount of blood withdrawn during each phlebotomy procedure is recorded. As donations are required, the donor animals will be selected on a rotating basis (e.g., animals who have donated most recently will be at the end of the rotation) and evaluated as a possible donor according to the date and amount of previous donations and established blood draw volume limits.

H. Processing and Storage of Donor Blood.

Typically whole blood is administered within 48 hours of donation. Donor blood will be irradiated prior to transfusion into the recipient NHP or before refrigeration storage. Research staff will use all appropriate personal protective equipment (gloves, mask, goggles, lab coat, etc.) and the blood will be processed under a biosafety cabinet prior to and following irradiation (25 Gy).

The50-ml tube(s) is labeled "NHP blood" with the animal's identification number, date, and time of donation, and expiration date. Using sterile technique a cell strainer (70 micro [µm]) will be opened and placed on an open 50ml centrifuge tube and the donor blood from the syringe will be slowly transferred into the 50ml tube. The tube is capped and the top is wrapped with parafilm and placed on a mechanical mixer until it is irradiated. Whole blood expires 48 hours after collection and will be discarded if not used using biohazard safety guidelines. If whole blood is not needed immediately, then it is stored in a chilled centrifuge tube.

The NHP donor blood in the 50ml centrifuge tube will be placed into a secondary 250ml tube and then into a spill proof transport container for transport to and return from the Irradiation Facility. Irradiation will be to a dose of 25 Gy to eliminated donor stem cells and lymphocytes that could result in donor cell-initiated hematopoietic engraftment.

cellular sensitization and graft-versus-host disease. No cross-typing or blood-typing will be performed.

If whole blood is to be administered, the unit of blood is placed on a rocker for continuous mixing at room temperature in order to preserve platelet function and administered with 48 hours of donation.

I. Justification and Criteria for Selection of Animal for Whole Blood Transfusion.
In this model we know the radiation dose (6.5 Gy) and also assume that adequate biodosimetry assessments will support medical treatment decisions. In our previous study NHP were euthanized 16 ±2.5d (range: 14 to 20d) after exposure to 6.5 Gy. In this treatment study arm of the protocol, our goal is to rescue the 6.5 Gy NHPs. Dr. (b)(6) used a whole-blood transfusion trigger of <25% hematocrit that was reached ~10 d after exposure in our previous study of 6.5 Gy irradiated NHPs (See Appendix A). We think that platelet levels were critical and plan to rely on low platelet levels as the trigger for whole-blood transfusions to provide donor platelets to allow the animals to bridge over until recovery. We are concerned about bleed out when performing whole blood transfusions due to low platelets so have elected to trigger whole blood transfusion a little before the precipitous decline in platelets (See Appendix H). At AFRRI there is limited experience in whole blood transfusions with NHPs, so we are being conservative in using a trigger of platelet level of 70 to 100 x 10^9/L would occur as early as 6-7 d.

Whole blood transfusions will be performed on appropriate protocol study irradiated (6.5 Gy) animals when platelet counts drop below 75 to 100 x 10^9/L. Based on prior studies we expected to need to transfuse whole blood to 6.5 Gy irradiated animals as early as 8 days after irradiation and likely a second time several days later while the animals are undergoing radiation-induced thrombocytopenia; see Appendix H - Attachment C.

J. Whole Blood Transfusion.
The site of venipuncture on anesthetized animals will be cleansed with betadine, and then alcohol swabs X 2 prior to the infusion of whole blood.

Animals will not be give antihistamine or corticosteroid before transfusion of whole blood. Whole blood is usually administered slowly (approximately 30 ml over 5 minutes, 19-23 gauge needle, using a sterile disposable 18 micron (µm) mesh filter).

The animal will be monitored for anaphylactic reaction (swelling, urticarial, hives, rash, difficult breathing). If reaction occurs, the transfusion will be stopped (at least temporarily), and corticosteroids (dexamethasone at 1 mg/kg IV, 19-23 gauge needle) and /or histamine (diphenhydramine 2.2 mg/kg, IM, 19-23 gauge needle) will be given.

After resolution/improvement of signs, the transfusion may be re-started at ½ to 1/3 the original rate.

Appendix H – Attachment A (List of Supplies)

Equipment

1. VSD scale for measurement of animal body weight
2. Temperature wand
3. Temperature controlled centrifuge with appropriately sized rotors
4. Mechanical mixer
5. Refrigerator

Personal Protection Equipment

1. Gloves
2. Masks
3. Goggles
4. Lab coat
5. Sleeves
6. Hairnets
7. Foot booties

Supplies

1. Hazardous waste containers
2. Preprinted labels for syringes and centrifuge tubes
3. Ice buckets
4. Secondary transport container

Chemicals

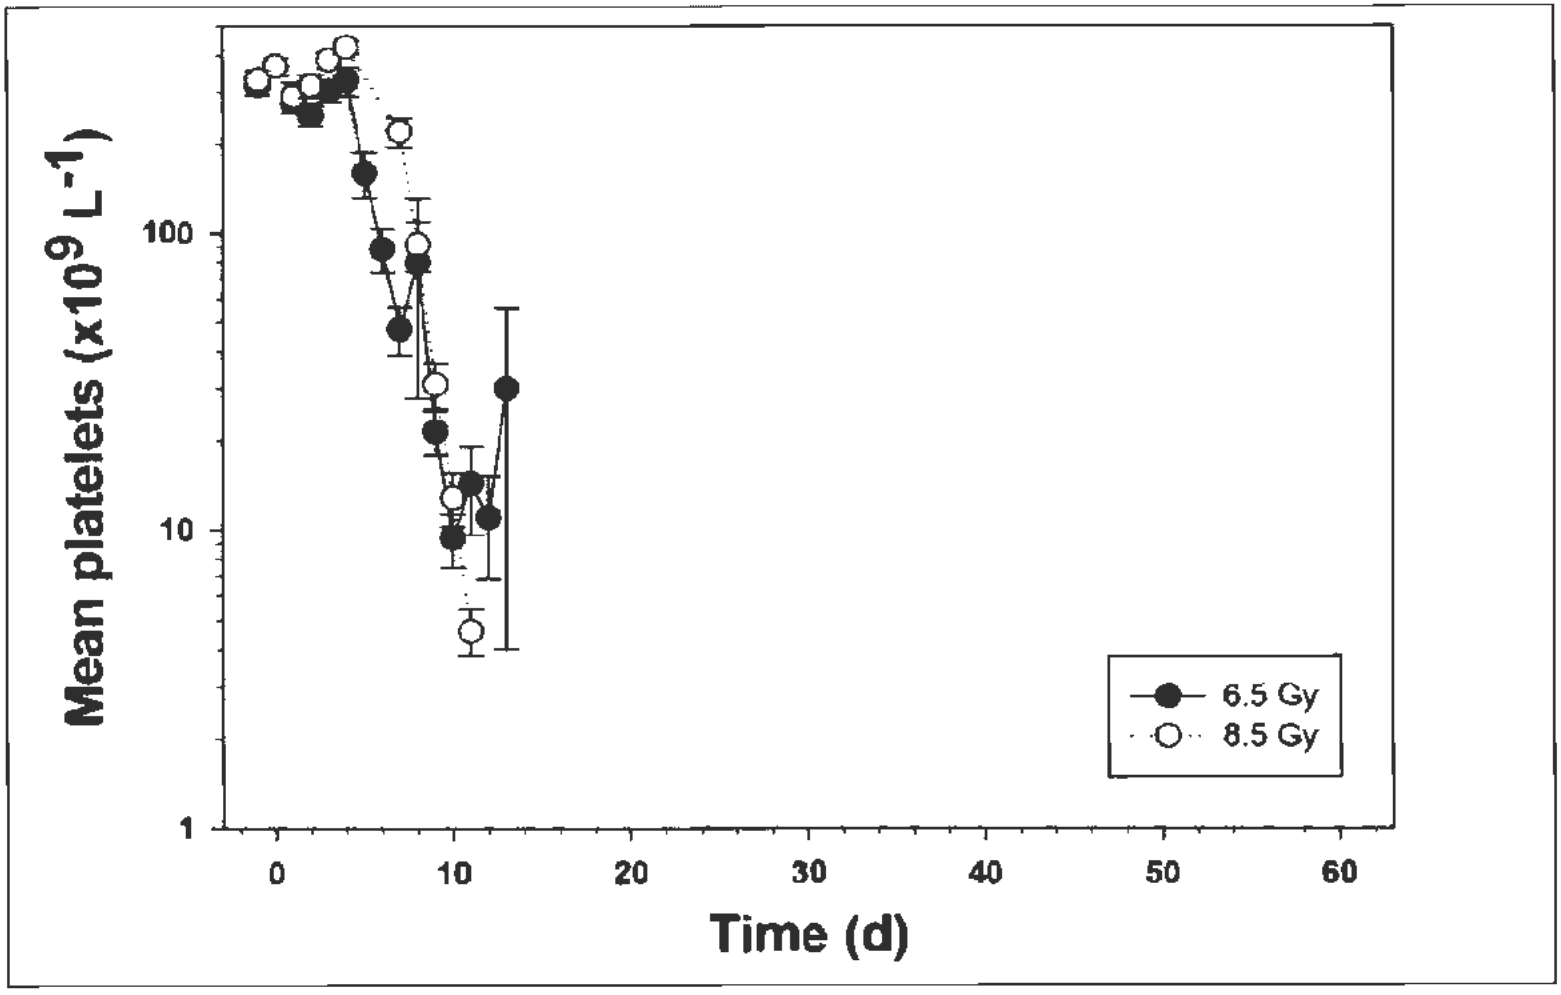
1. Xylazine
2. Ketamine
3. Medical grade lactated Ringers Solution
4. Sterile saline
5. Dexamethasone (corticosteroids)
6. Diphenhydramine (antihistamine)
7. Citrate-phosphate-dextrose with adenine (CPD-A) [Sigma]

Blood Collection Supplies

1. 19-25 Gauge needles
2. Winged catheter infusion set
3. EDTA tubes
4. Serum separator tubes
5. 1 mL syringes
6. 30 mL syringes
7. Syringe caps
8. 50 mL tubes
9. 250 mL tubes (secondary containers) [Denville Scientific C-3411. (http://www.denvillescientific.com/node/950]
10. Parafilm
11. 70 micron cell strainer [BD Biosciences]
12. 18 micron blood filter [Utah Medical Products]

Appendix H - Attachment B. NHP Donor Study Schedule: Blood draw schedule and blood volumes										
Time, wk/d/h	Blood volume in Micro SS Tube for chemistries, ml	Blood volume in an EDTA tube for CBC, ml Syringe containing Citrate Phosphate Dextrose, ml & Lactate Ringers Solution Replacement Volumes Required, ml (per 30 d period)								
NHP body weights, kg		3	3.5	4.0	4.5	5	5.5	6	6.5	7
Maximum daily blood draw volume, ml*		1.6	1.9	2.2	2.45	2.7	2.95	3.2	3.5	3.8
Maximum blood draw volume in 3-4 wk period#, ml		16	19	22	24.5	27	29.5	32	35	38
LRS fluid replacement, ml		8	10	11	12.5	14	15	16	18	19
At time of blood donation										
CBC	--	0.4	0.4	0.4	0.4	0.4	0.4	0.4	0.4	0.4
Blood donation maximum volume, ml		16	19	22	24.5	27	29.5	32	35	38
During periods of blood donation										
Once every 2 weeks	0.225	0.4	0.4	0.4	0.4	0.4	0.4	0.4	0.4	0.4
During periods when animal is not used for blood donation										
Blood for CBC and chemistries once every 6±2wk	0.225	0.4	0.4	0.4	0.4	0.4	0.4	0.4	0.4	0.4
*Note. For repeated daily blood draws the maximum daily amount of blood volume should be ≤1% of total blood volume, typically estimated based on the animal body weight. For Rhesus the blood volume per body weight is 54 ml/kg (Laboratory Animals 27:1-22, 1993). Sample calculation: Assume a 4.5 kg NHP this represents a daily blood draw of 2.4 ml (4.5 kg x 54 ml/kg x 0.01). #Whole blood transfusion volume based on 7-14 ml per kg.										

Appendix H – Attachment C. Platelet counts in NHPs TBI to 6.5 and 8.5 Gy with ^{60}Co γ-rays (DARPA study results)



Appendix I – Implantable Microchips

Microchips. The animals will be anesthetized at the beginning of the study for microchip implantation, see V.4.1.2.1. The microchip is located inside of a needle (12 Guage) and syringe like device (Figure 1).

Figure 1. Pre-sterilized, disposable, needle assemblies.

The animal skin between the shoulder blades is lifted up and the microchip is injected subcutaneously. A small amount of tissue glue may be applied to the exit area, in order to ensure that the microchip stays in the place as the animal begins to move around (Figure 2).

Figure 2. Implantable microchip - anchors securely to tissue.

These devices facilitate monitoring from a distance, the subcutaneous body temperature without having to anesthetize the primates (Figure 3).

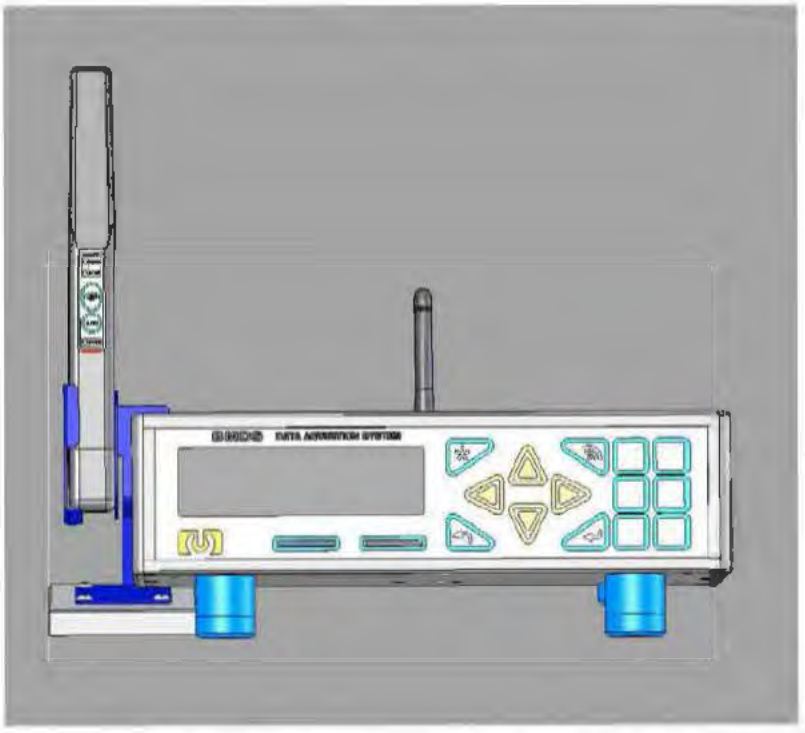


Figure 3. Bio Medic Data System DAS-6001 Data Acquisition System.

The use of microchip is a further refinement in that it does reduce stress and provides improvement diagnosis without the intervention of staff to handle the animals. IM injections will be administered in the cranial or caudal thigh muscles using a 25 – 22 gauge needle.

DOD ANIMAL CARE AND USE STANDARDIZED PROTOCOL FORMAT WITH EMBEDDED INSTRUCTIONS (October 2012)

Reference DOD Instruction 3216.01 & AFRRI Instruction 3216.2H

****

Information requested in the following animal use protocol template reflects the requirements of the Animal Welfare Act Regulations (AWAR), the Guide for the Care and Use of Laboratory Animals, and other applicable Federal regulations and DOD instructions.

****

This document is intended to be an aid in the preparation of DOD-sponsored animal use protocols. It is a companion document to an identical protocol template that does not have embedded instructions. Either template may be used to format DOD-sponsored animal research proposals; however, reference to the instructions during protocol preparation is highly recommended. If using the template with instructions, the instructions should be deleted prior to submitting the finished protocol for IACUC review. Please use Arial, regular, size 12, black font to prepare the protocol. With the exception of section headings, all paragraphs require a response. Paragraphs that do not apply should be marked N/A. There is no space limitation for responses to the information requested.

Approved standard operating procedures (SOPs) promulgated by the AFRRI Veterinary Sciences Department (VSD) or similar VSD-validated documents that describe specific procedures may be referenced by SOP number and title in lieu of repeating the details in the protocol. However, it is essential to include general descriptions of all animal manipulations to be carried out under the IACUC-approved protocol and to provide details where no approved references are cited. To do otherwise would constitute a breach of statutory regulations. Manipulations not covered in the originally approved protocol can be initiated only after IACUC approval of a formal amendment adding the new procedures. Additionally, Principal Investigators (PIs), or other delegated research personnel, should maintain accurate experimental records and be able to provide an audit trail of animal expenditures and use that correlates with their approved protocol. Protocol PIs will be required to provide this and other information during annual protocol reviews.

Any supporting information that may be of use to the IACUC during its review may be attached to the completed protocol. Adding subparagraphs within the body of the protocol template is permissible, *provided that the numbering sequence of paragraphs in the original standard format is maintained.* In other words, all of the labeled paragraphs and subparagraphs in this template must be retained, with additional information being presented as sub-numbered paragraphs containing information that supports or complements what is requested.

INTELLECTUAL PROPERTY STATEMENT

Research protocols drafted by Government scientists include intellectual property (e.g., concepts, ideas, experimental approaches, etc.), some of which is innovative or original and therefore considered proprietary to the investigators and/or the sponsoring agency. All Government and non-Government personnel handling this protocol shall exercise EXTREME CARE, to ensure that the information contained herein is NOT DUPLICATED OR DISCLOSED, in whole or part, for any purpose other than to evaluate the protocol, without the written permission of the principal investigator or the sponsoring agency.

I. NON-TECHNICAL SYNOPSIS

Mortality after exposure to radiation from nuclear devices or dirty bombs results to a large extent from failure of blood-forming tissue to produce sufficient quantities of platelets and white blood cells, causing hemorrhage and infection. This is referred to as the hematopoietic subsyndrome of the Acute Radiation Syndrome (ARS). There is a vital need for effective treatment against radiation targeting blood-forming tissue, both in response to potential nuclear attacks and in the clinical setting. Precursors of blood cells and platelets are termed hematopoietic stem and progenitor cells (HSPC). In bone marrow (BM), HSPC are in close association with cells that form blood vessels, i.e., endothelial cells (EC). There is evidence that the maintenance and healthy functioning of HSPC require interaction with EC; however, the mechanisms by which EC support HSPC are little-investigated and poorly understood. Our hypothesis is that EC signals are important in promoting recovery of HSPC after radiation injury. Our long-term goal is to identify important EC signals that support HSPC in injured hematopoietic tissue, with a view toward developing radiation countermeasures. The roles of EC and their signals are being tested in an in vitro model system comprising coculture of EC and HSPC. We showed that EC stimulate functional recovery of HSPC after radiation injury. Specific signaling pathways are being investigated to determine which signals might be modulated in EC to improve their ability to promote HSPC production and function. In this project, we will test the hypothesis that signals in EC prolong animal survival after ionizing radiation in mice by injecting EC into mice exposed to irradiation. This has been demonstrated in one report from 2007 using brain EC, but we hypothesize that BM EC will be superior in this regard. After irradiation of mice and subsequent injection of EC, mice will be monitored for 30-day survival (hematopoietic syndrome), and BM functions will be analyzed. The work is preparatory to future work where specific signaling pathways will be altered in EC by genetic engineering before administration to mice.

II. BACKGROUND

II.1. Background

Radiation Injury and Radiation Countermeasures

There is an increasing threat of nuclear attacks.[1-3] No ARS countermeasures have

been approved by the FDA, partly due to the fact that the mechanisms of radiation injury and recovery are poorly understood. Although elements of the hematopoietic lineage have been studied in isolation,[5] another approach is to study hematopoietic signals expressed by other cell types; this resulted in a successful FDA IND application for CBLB502, based on a protein made by microorganisms.[6] The approach of identifying potential drug targets based on signals in non-hematopoietic cells can be applied to cells making up the BM microenvironment, which regulates survival, proliferation, and differentiation of HSPC.[7] Hematopoietic factors are induced in BM in response to radiation injury,[8] and one of these, G-CSF, is now the standard treatment for radiation casualties.[9] We examined interactions between irradiated HSPC and osteoblasts and discovered radiation induces hematopoietic factors, including G-CSF, in these cells. Another important component of the microenvironment is the microvasculature, because of hematopoietic signals expressed by EC.[7,11-14] These are important in normal hematopoiesis, and EC enhance recovery of HSPC from radiation,[15,16] but the specific signals are not known. The overall goal of our research program is to understand the signals expressed in EC, before and after radiation, and to determine which ones promote recovery of hematopoiesis.

(b)(4),(b)(6)

(b)(4),(b)(6)

HSPC and EC in the Perivascular Niche

HSPC comprise self-renewing, relatively quiescent stem cells that give rise to progenitors of all blood lineages, and progenitor cells, which are more rapidly dividing, and lose self-renewal capacity as they become more differentiated along specific lineages.[17] They reside within specific BM niches that support maintenance, differentiation, and proliferation:[7] the osteoblastic or "bone" niche, and the perivascular niche. The perivascular niche comprises mesenchymal progenitor cells, reticular cells, megakaryocytes, and EC. These cells regulate HSPC survival by secreting factors, and/or expressing receptors and/or ligands that signal upon cell-cell contact.[18] In addition to osteoblasts,[19-21] recent work suggests that EC[7,18,22,23] play critical roles.[24] The perivascular niche is characterized by discrete areas of endothelium that express high levels of EC adhesion molecules (CAMs) such as E-selectin, as well as growth factors and chemokines, such as SCF, TGF-β, IL-8, IL-11, CXCL12, FGF-4, and Ang1/2 (see Appendix 1 for list of acronyms).[25] Mice deficient in CXCL12 display a defect in the hematopoietic colonization of the BM during embryogenesis,[26] a defect that could be rescued by enforced expression of SDF-1 in vascular EC, suggesting EC in BM are essential for colonization of fetal BM by HSPC.[27] Isolated BMEC contribute to hematopoiesis and support the proliferation and differentiation of HSPC via cytokines and possibly by physical contact.[28-30] BM sinusoidal EC provide a platform for differentiation of progenitors, such as megakaryocytic progenitor cells.[31] Recent work showed the activation state of EC upregulates factors which support HSPC expansion via Akt or maintenance and differentiation via p44/42.[32] HSPC may also exert direct effects on EC. This is supported by the observation that HSPC VEGF-A stimulates EC proliferation.[33]

Effects of EC on hematopoiesis after radiation injury

Radiation exposure leads to myelosuppression via apoptosis of hematopoietic cells as well as effects on the BM vasculature. There is no hematopoietic regeneration without

vascular reconstitution of BM.[7,34] Damage to EC within BM is followed by incomplete repair and cell death.[35] In addition to endothelial apoptosis, radiation induces endothelial NF-κB activation, alters chemokines and adhesion molecules, tissue factor, and thrombomodulin,[36] and induces release of von Willebrand factor, promoting a pro-inflammatory response. Radiation upregulates PDGF (A-D) in EC.[37] VCAM-1 upregulation and P-selectin downregulation in BM microvessels were observed after TBI, and this led to increases in hematopoietic progenitors adhering to vessels.[38] Damage to EC causes an increase in circulating EC after irradiation.[39] Reestablishment of EC activity improves hematopoietic recovery and survival of irradiated mice.[25] Transplantation of primary vascular EC enhanced survival of irradiated mice, and resulted in increased numbers of BM HSPC and recovery of circulating white blood cells and platelets.[15] Pleiotrophin expressed in human brain EC is a hematopoietic factor and its administration results in expansion of HSPC in vivo in mice.[40] Endogenous pleiotrophin in BM EC regulated retention and self-renewal of HSPC in BM.[12] We believe identifying roles of EC-derived factors that enhance survival of a functional hematopoietic niche will facilitate identification of drug targets and lead to development of safe, effective radiation countermeasures.

II.2. Literature Search for Duplication
II.2.1. Literature Sources Searched: BRD, NIH Reporter, PubMed
II.2.2. Date of Search: January 18-20, 2013

II.2.3. Period of Search All available years:
BRD: FY2005-FY2009
NIH Reporter: 1988-2013 (Projects and Publications)
PubMed: includes MEDLINE (1966-present) and OLDMEDLINE (1950-1965).

II.2.4. Key Words of Search Hematopoietic AND Endothelial AND Radiation AND Transplantation

Subsets of these key words produce many projects and papers with which we are familiar, and which are relevant to our program. However, all keywords together are necessary to find possible projects and papers that are duplicative of the proposed work.
II.2.5. Results of Search

Most of the projects revealed in the searches of the three databases did not deal with transplantation of EC for addressing ARS. They addressed use of EC to expand HSPC in vitro for subsequent transplantation of HSPC, other types of transplants, and radiation injury to EC.
BRD: 220 references were found. None were relevant to the issue of duplication.

NIH Reporter: 70 results were found. Two relevant funded programs were found. They are parts of NIAID-funded Centers for Medical Countermeasures against Radiation (CMCRs) at:

1) Duke University, where a project headed by John Chute is exploring transplantation of EC as a radiation countermeasure. Papers from this program are cited in the Background section.[12,15,40] Endothelial progenitor cells (EPC) were shown previously by this group to promote hematopoietic reconstitution in vivo after total-body irradiation.[41]

2) Albert Einstein College of Medicine of Yeshiva University, where a project headed by Chandan Guha is testing transplantation of EPC as a radiation countermeasure. EPC were shown by this group to mitigate gastrointestinal radiation injury.[42]

Our proposed protocol is not duplicative of the two cited projects because:

1. The project at Duke is using EC from tissues other than BM. EC from different tissues are known to have widely different properties. In fact, it is known that some types of EC from tissues other than BM have no effect on hematopoiesis, while others do.[15] Therefore, it is important to test EC from the tissue being affected by radiation injury during the hematopoietic syndrome: BM. These are the endogenous EC that can potentially mediate recovery from hematopoietic injury.

2. The Guha project is not using EC, but EPC, as was done previously by the Chute group.[41] Although these may have some beneficial effect, it is important to test the ability of mature, differentiated EC to promote hematopoiesis and survival after radiation injury, as our hypothesis, supported by the literature, is that it is the EC that have these beneficial effects.

3. The Guha group is studying gastrointestinal injury, whereas we propose to study the hematopoietic syndrome.

4. In addition to the previous three issues, the current project is part of a long-term research program at AFRRI that aims to identify important signaling molecules in EC and to genetically engineer EC to produce a radiation countermeasure superior to native EC. It is important for us to establish EC transplantation in our laboratory, and to verify their beneficial effects, as part of this larger program.

5. To date, only one publication showed administration of EC (from brain) mitigates the hematopoietic syndrome.[15] This needs to be confirmed by an independent group, as we propose here. This needs to be confirmed not only for EC in general, but for EC from BM. This confirmation is required to set the stage for our subsequent work.

PubMed: 111 papers were found. In addition to the work cited above, a recent relevant study on EPC transplantation by Zeng et al.[43] was discovered in this search. Our proposal is not duplicative of the Zeng project because we are using EC, not EPC. Moreover, the Zeng paper only tracked migration of injected EPC rather than studying functions or effects of the transplanted cells, as we propose here. Other papers in the search results used EPC to treat nonradiation injuries.

III. OBJECTIVE / HYPOTHESIS 1. The primary hypothesis to be tested in this protocol is that postexposure administration of mouse BM EC will enhance survival of mice irradiated at doses that cause the hematopoietic syndrome.
2. A secondary, related hypothesis is that postexposure administration of mouse BM EC will improve bone marrow function as assessed by peripheral blood counts and clonogenic quantification of hematopoietic progenitors in BM.

IV. MILITARY RELEVANCE Currently, there is no safe and non-toxic radiation countermeasure available. Military personnel are potentially exposed to radiation in various scenarios, some of which include exposure to neutrons. Both early and late health effects of radiation exposure are major concerns for the military. Thus there is an urgent need to develop clinically safe, potent and non-toxic radiation countermeasures. Developing countermeasures to radiation exposure is a top priority for the US Department of Defense.

With the deployment of radiation countermeasures, forces exposed to moderate doses of ionizing radiation will exhibit enhanced survivability, expanding the range of operable threat environments. The options available to field commanders will increase, and the morale of personnel at risk of exposure to ionizing radiation will improve. DoD Defense Technology Objective MD.18 listed the military payoffs of radiation countermeasure deployment as follows: "Effective mitigation of health consequences will (1) reduce casualty load at medical treatment facilities, (2) sustain a more effective operational force after a radiation exposure event, (3) allow commanders to conduct operations in radiation field environments without undue risk of decremented performance of personnel due to acute tissue injury ..., and (4) reduce the negative psychological impact on personnel tasked to operate in contaminated environments."

V. MATERIALS AND METHODS
V.1. Experimental Design and General Procedures
General:
Male CD2F1 mice will be obtained from an approved vendor (Harlan preferred), quarantined upon arrival, and representative animals screened for evidence of disease before irradiation and experimentation. Total-body irradiations of 280 mice (64 from Expt. 1, 120 from Expt. 2, and 96 from Expt. 3) at 0.6 Gy/min in the high-level Cobalt-60 facility will be performed according to previously published methods, following AFRRI (b)(4),(b)(6) standard operating procedures [redacted] Animals will be placed into well-ventilated Plexiglas boxes and irradiated bilaterally. All irradiations will be performed before 12 noon. 112 mice (64 from Expt.1, 96 from Expt. 3) will be sham-irradiated. Sham-irradiated mice will undergo the same procedures as the irradiated mice (transport to radiation facility, placement into Plexiglas box), minus the radiation exposure.

Isolation of BM EC from donor mice

BM aspirates from femurs of male CD2F1 mice will be washed and seeded in gelatin-coated flasks containing EC media, and cells in suspension will be separated 4-6 h later. This time allows adherent cells to stick and any cells in suspension, including cells that may express the EC marker CD31, to be removed with the

medium. After adherent cells are near confluence, they will be trypsinized, and incubated with Dynabeads® (Invitrogen, Inc.) CD31 EC isolation beads following the manufacturer's protocol. The identify of the CD31-enriched cells will be verified, cells expanded and tested for possible *Mycoplasma* contamination in-house using a commercially available kit (MycoAlert, Lonza, Inc.), and used in *in vivo* experiments.

V.1.1. Experiment 1 Determine the maximum number of BMEC efficiently administered intravenously via tail vein injection.

This experiment will involve technical training to gain competence in IV injections, and to specifically determine the maximum dose and injection schedule of BMEC. Three different doses of BMEC ($2.5X10^5$, $4X10^5$, $5X10^5$ cells/mouse) diluted in Hanks Balanced Salt Solution (HBSS) + 1% BSA , along with HBSS/BSA as a vehicle control will be infused iv 5 times (1 time/day) into male CD2F1 mice (8 mice per group) that are non-irradiated or irradiated at an LD 70/30 (currently 9.25 Gy) to ensure the technical accuracy of injecting cells and the effect of irradiation on cell infusion. Mice will be monitored for 10 days to ensure that there is no reaction to the cell injection. Based on the results of this study, the highest dose efficiently administered will be selected for remaining studies.

Number of mice required for Experiment 1:
Radiation doses: 2 (0 Gy, 9.25 Gy)
Treatment groups: 4 (1=HBSS, 2=$2.5X10^5$ BMEC, 3=$4X10^5$ BMEC, 4=$5X10^5$ BMEC)
Mice/Group: 8
Iterations: 2
Training mice (for perfecting iv injections): 50
Note: training mice will also be used for donor mice.
Total number calculated by multiplying cells:

Radiation Doses	Treatment Groups	Mice/ Group	Iterations	Total
2	4	8	2	**128**

Total mice for Experiment 1: 128 + 50 = **178**

V.1.1. Experiment 2 Effect of administered EC on survival (moribundity)

All mice (except donor mice) will be exposed to radiation at a dose that causes 70% mortality in our laboratory, currently 9.25 Gy. There will be three experimental groups (b)(4),(b)(6) differing by what will be administered after irradiation: 1) nothing, 2) HBSS+ 1% bovine serum albumen, and 3) BM EC. After irradiation, mice will be given BM EC with a preliminary injection schedule based on results from Experiment 1, but not to exceed 5x105 cells daily for five days by iv tail vein injection, with the first injection at 2 h post-irradiation. The HBSS group will receive injections with the same schedule. This initial dosing schedule and administration route is based on the work of Chute at al.[15] but may be altered based on preliminary results. Following Chute et al, [15] EC will be used after

no more than 5 passages, and washed twice and resuspended in HBSS + BSA just before injection.
The experimental endpoint will be 30-day mouse survival (number of mice reaching 30 days without dying or displaying signs of moribundity requiring euthanasia).

Number of mice required for Experiment 2:
Radiation doses: 1
Treatment groups (1. no treatment, 2. HBSS, 3. EC): 3
Mice/Group: 20
Iterations: 2

Total number calculated by multiplying cells:

Radiation Doses	Treatment Groups	Mice/ Group	Iterations	Total
1	3	20	2	120

Donor mice for EC for Group 3 (2 iterations): 40
Total mice for Experiment 1 = 120 + 40 = 160

V.1.2. Experiment 3 Effect of administered EC on hematology (peripheral blood elements and BM HSPC)
Mice (except donor mice) will be exposed to a sublethal dose of radiation low enough to allow sufficient cells in circulation and BM for analysis during the first two weeks after exposure: 3 Gy[redacted] To assess the effect of injections on unirradiated mice, other mice will be subjected to sham-irradiation. Treatment groups will be as in Experiment 1, differing by what will be administered after irradiation: 1) nothing, 2) HBSS, and 3) BM EC. After irradiation, mice will be given BM EC or HBSS (or nothing) as described for Experiment 2.
The experimental endpoints will be 1) quantitation of peripheral blood elements using CBC-diffs, and 2) quantitation of BM progenitors using clonogenic assays standard in our laboratory.[44] Mice will be euthanized on days 7 and 14 (8 mice/group) after radiation to perform these procedures.

(b)(4),(b)(6)

Number of mice required for Experiment 3:
Radiation doses (1. sham-irradiation, 2. 3 Gy): 2
Treatment groups (1. no treatment, 2. HBSS, 3. EC): 3
Mice/Group: 16
Iterations: 2
Total number calculated by multiplying cells:

Radiation Doses	Treatment Groups	Mice/ Group	Iterations	Total
2	3	16	2	192

Donor mice for EC for Group 3 (2 iterations): 40

Total mice for Experiment 3 = 192 + 40 = 232

Grand Total of mice needed for Experiments 1, 2, and 3: 178 + 160 + 232 = 570

V.2. Data Analysis Means with standard errors, or percentages, will be reported if applicable. The significance level will be set at 5% for each test. All statistical tests will be two-sided. Multiple comparison tests will be used when appropriate. Drugs will be compared to vehicle injections, and irradiation will be compared to sham irradiation where appropriate. Statistical software, PC SAS, will be used for statistical analyses.

Experiment 2: Log-rank tests will be used in comparing survival curves for each experiment. If those are significant, pair-wise comparisons will be done by Fisher's exact tests.

Experiment 3:
Analysis of variance (ANOVA) will be used to detect significant differences among groups. If significant, then Tukey-Kramer pair-wise comparisons will be used to identify which groups are different from each other.

Sample size justification for Experiment 2:
The 20 mice per group could have 80% power to detect a significant difference between two groups, given type I error of 5% and a treatment group survival rate of at least 73%, if the control group is 25%. Similar statements would apply, provided the treatment groups display survival of at least 86%, 83%, or 78%, if the respective control groups would be 40%, 35%, and 30% respectively. Note: power analysis may suggest smaller groups are adequate. However, radiobiologists at AFRRI and elsewhere observe considerable variability from experiment to experiment in mouse survival protocols that is not reflected in the power analysis. In fact, some institutions have gone to a group size of 30 in these types of experiments for this reason (b)(6) (b)(6). We have found over the last six years that 20 mice per group are sufficient to obtain results that are interpretable and repeatable.

Sample size justification for Experiment 3:
The sample size per group (N=8) would have 80% power to detect a significant difference between two groups, given type I error of 5% and delta/sigma of at least 1.4, where the delta is the estimated mean differences between the two groups and sigma is the standard deviation of the ANOVA model.[47]

Note on requirement to repeat experiments: It is a generally accepted principle of the scientific method that results must be repeated to evaluate a hypothesis.[48] Scientific journals (e.g., Endocrinology) state that experiments must be repeated to qualify for publication.

V.3. Laboratory Animals Required and Justification

V.3.1. Non-animal Alternatives Considered

V.3.2. Animal Model and Species Justification We considered computer models and tissue culture as alternatives to animals. Both alternatives lack the knowledge base and complexity needed to evaluate the effects of radiation and countermeasures on the hematological and immune systems. The phenomena under study involve complex information-processing networks comprising hundreds of cell types and biological signaling molecules. Responses to irradiation and drugs involve interactions between the central nervous system, the peripheral nervous system including the enteric nervous system, endocrine glands, the immune and inflammatory systems, hematopoietic organs, etc. We do not know all of the cell types and tissues involved and many of the signaling molecules have not been discovered yet. Even if all of the tissues, cell types and signaling molecules were known, the present state of the art of tissue culture would be incapable of reproducing their in vivo relationships. One would have to reproduce much of an entire mammalian organism in culture to study these phenomena in vitro, a scenario that would have its own ethical issues and would blur the distinction between "in vitro" and "in vivo." As for computer models, the most powerful supercomputers available in the foreseeable future would be incapable of analyzing interactions between so many elements in the network. These drugs and formulations will have to be evaluated in whole animal models. The purpose of the proposed research is to begin to identify the cells and signaling molecules necessary to construct a model of radiation injury and countermeasure mechanisms. It is also important to understand that it is a fallacy to assume that high level "emergent" phenomena can be understood by the reductionist approach of studying each basic component in isolation, and then synthesizing the results.

V.3.3. Laboratory Animals

V.3.3.1. Genus / Species: Mice (Mus musculus)

V.3.3.2. Strain / Stock: CD2F1. Origin: female BALB/c x male DBA/2

V.3.3.3. Source / Vendor: VSD approved vendor (Harlan preferred)

V.3.3.4. Age: 10-14 weeks

V.3.3.5. Weight: 24-32 g

V.3.3.6. Sex Male. To avoid influences of hormonal cycles in these proof-of-principle experiments, females are not included. Effects of sex differences will be explored in the future if funding is obtained.

V.3.3.7. Special Considerations The vendor's animal husbandry, breeding, and shipping practices should be in accordance with the Animal Welfare Act P.L. 89-544 and The Guide For The Care and Use of Laboratory Animals.

The animals must be adventitious disease-free. All animals should be raised with restricted access and strict entry and exit policy in caging that reduces the exposure to

pathogens such as in barrier condition, microisolation caging or isolators. They must be free of pathological lesions as assessed by gross exam.

Health surveillance monitoring must be performed regularly on the colonies and verified by an outside source. Health Surveillance reports should be sent with the animal shipments and must be current as well as accurate.

The mice must be pathogen-free, specifically for the following agents: *Pseudomonas aeruginosa*, *Klebsiella pneumoniae*, *Proteus morgani* and *Pasteurella*. In addition, all mice need to be free of the following viral agents: Sendai, Pneumonia Virus of Mice (PVM), Reovirus-3 (Reo 3), Mouse Adenovirus (MAD-1, MAD-2), Mouse Cytomegalovirus Virus (MCMV), Ectromelia, K virus, Lymphocytic Choriomeningitis Virus (LCM), Epizootic Diarrhea of Infant Mice (EDIM), Hantaan virus, Rotavirus, Mouse Parvovirus (MPV), Polyoma Virus, Mouse Minute Virus (MMV), Mouse Thymic Virus (MTV), Theiler's Mouse Encephalomyelitis Virus (TMEV/GDVII), *Encephalitozoon cuniculi*, CAR bacillus, *Mycoplasma pulmonis*, and *Clostridium piliforme*. Endoparasite- and ectoparasite-free.

Genetic monitoring should be used to detect possible contamination and policies and procedures must be in place to reduce genetic drift.

Diet and Bedding Monitoring:
Standard laboratory animal diet should be used, Teklad preferred. Diet should be manufactured under ISO 9000 procedures with careful ingredient sourcing and monitoring. High quality bedding and bedding enrichment products should be manufactured following appropriate quality standards and screened periodically for contaminants, with certification available.

V.3.4. Number of Animals Required (by species) Mice: 570

V.3.5. Refinement, Reduction, Replacement (3 R's)
V.3.5.1. Refinement The radiation dose for Experiment 2 is sublethal, minimizing discomfort due to ARS. In the mortality studies, in order to minimize discomfort when animals become morbid, investigators and animal care staff will examine the mice at least twice daily, including in the early morning and late afternoon. Moribund animals will be considered to have arrived at the study endpoint and will be euthanized. Analgesics were considered as a way of minimizing discomfort during the onset of opportunistic infections, which will occur during the survival experiments. However, analgesics and anesthetics are well-known to alter the functional properties of the immune system and resistance to infection,[49-73] which would defeat the purpose of the study.

V.3.5.2. Reduction We will use training animals in Experiment 1 as donor animals for BM EC. We will use the same mice for peripheral blood counts and clonogenic studies of BM progenitors. We will use only one dose of radiation for the survival experiment, and one for the hematology experiment, to avoid gathering data that does not add

substantially to the main points being tested. We considered reducing the number of mice per group, but decided we could not in light of previous results [redacted] (b)(4),(b)(6) Although some institutions have gone to a group size of 30 in these types of experiments because of variability [redacted] we have found over the last six years that 20 mice per group is sufficient to obtain results that are interpretable and repeatable.

V.3.5.3. Replacement None (see section V.3.2 for explanation)

V.4. Technical Methods

V.4.1. Pain / Distress Assessment

V.4.1.1. APHIS Form 7023 Information

V.4.1.1.1. Number of Animals

V.4.1.1.1.1. Column C 290 (# of animals)

V.4.1.1.1.2. Column D 0 (# of animals)

V.4.1.1.1.3. Column E 400 (# of animals)

V.4.1.1.1.4. Pain Category Assignments

Exp. #	Experimental/Control Group	C	D	E	Totals
1	Training/Donor animals (for BM EC)	50			50
1	All groups (non-irradiated and irradiated at 9.25 Gy)	64		64	128
2	Donor animals (for BM EC)	40			40
2	All groups (irradiated at 9.25 Gy)			120	120
3	Donor animals (for BM EC)	40			40
3	All groups (non-irradiated and irradiated at 3.0 Gy)*	96		96	192
Totals:		290	0	280	570

* The 3.0 Gy dose of total-body gamma radiation in CD2F1 mice (LD50 ~8.75 Gy) corresponds to a dose of approximately 1.3 Gy in humans (LD50 ~3.75 Gy). ARS is not clinically significant below 2.0 Gy in humans (corresponding to 4.7 Gy in CD2F1 mice) [redacted] (b)(4)

V.4.1.2. Pain Relief / Prevention

V.4.1.2.1. Anesthesia / Analgesia / Tranquilization Mice will be anesthetized as part of euthanasia (in cases of moribundity or for sample collection) using a portable metered Isoflurane system. There will be no recovery from anesthesia in this case, and no prolonged period of anesthesia, hence hypothermia is not a concern. All euthanasia will be according to AVMA guidelines and performed by trained and technically proficient personnel.[80] For injection of EC into the tail vein, the same Isoflurane system will be used, but animals will revive after the procedure. Body temperature will be maintained using a heated stage or heating lamp.

V.4.1.2.2. Pre- and Post-procedural Provisions: N/A

V.4.1.2.3. Paralytics: N/A

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures

V.4.1.3.1. Sources Searched: Agricola and PubMed
V.4.1.3.2. Date of Search: January 22, 2013

V.4.1.3.3. Period of Search: All available years:
Agricola: 1600s to present (according to Wikipedia)
PubMed: includes MEDLINE (1966-present) and OLDMEDLINE (1950-1965).

V.4.1.3.4. Key Words of Search: The aspects of the study relevant to alternatives to painful or distressful procedures are exposure to 9.25 Gy total-body ionizing irradiation causing ARS, and iv injections of EC. Therefore, the following key words were used: ionizing radiation AND pain, ionizing radiation AND alternatives, cell transplants AND pain, cell transplants AND alternatives.

V.4.1.3.5. Results of Search: Agricola: no hits.
PubMed:
ionizing radiation AND pain: 170 hits
ionizing radiation AND alternatives: 27 hits
cell transplants AND pain: 145 hits
cell transplants AND alternatives: 61 hits

The only relevant reference found was the work by Teskey et al. showing that total-body irradiation can produce analgesic effects.[81] For a discussion of alternatives considered, please see section V.3.2.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification Irradiated animals die due to compromised immune responses and opportunistic infections. The percentage of surviving animals is the indicator of the efficacy of a countermeasure. As discussed above, we cannot give anesthetic and/or analgesic agents to animals since they are known to interact with the immune system, and would confound the interpretation, resulting in a waste of animals. See references in section V.3.5.1.

V.4.2. Prolonged Restraint N/A

V.4.3. Surgery N/A

V.4.3.1. Pre-surgical Provisions N/A

V.4.3.2. Procedure(s) N/A

V.4.3.3. Post-surgical Provisions N/A

V.4.3.4. Location N/A

V.4.3.5. Surgeon N/A

V.4.3.6. Multiple Major Survival Operative Procedures

V.4.3.6.1. Procedures N/A

V.4.3.6.2 Scientific Justification N/A

V.4.4. Animal Manipulations

V.4.4.1. Injections Personnel will be trained in tail vein injections by VSD. Guidance on injections of cell suspensions into mouse tail veins from the Animal Care and Use Committee of NCI in Frederick[82] and AAALAS[83] will also be followed. For injections of EC (or equivalent volume of HBSS) into tail veins, animals will be anesthetized as described in section V.4.1.2.1. An alcohol swab will be used to remove the scale from the animal's tail. This will increase the visibility of the vein, as well as make entry into the tail easier. If the vein is not easily visualized, the tail will be warmed by placing it in warm water (about 40 °C) for several minutes and/or placing the mouse at least 12 inches from a heat lamp for no longer than 3 minutes[84]. Preparation, dosages of cells and frequency will be as described in section V.1.1. Experiment 1. A 1.0 cc syringe will be loaded by drawing cells up with a 20 gauge needle. The needle will then be replaced with a 27 gauge needle for injection. A different injection needle will be used for each mouse. All syringes and needles will be sterile. Cell suspensions will be agitated just prior to withdrawal from the vial and injection, to avoid cell clumping. The 1% bovine serum albumen added to the HBSS will also help to reduce clumping. The cell suspension will be at room temperature. The tail will be held so that the lateral tail vein is uppermost. The tail will be held taut with one hand, near the tip of the tail, and the needle inserted into the vein at a minimal angle, in the proximal 1/3 of the tail. The needle will be advanced to approximately ½ (~5 mm) the length, feeding the needle into the vein, being careful not to perforate the vein. The syringe will be drawn back slightly to detect traces of blood flow into the needle hub, which will indicates the needle was successfully inserted into the vein. The plunger will be pushed in slowly, to inject all material into the vein. The cell suspension injected will be 200 µL in volume or less and will be delivered at a rate of less than 6 µL/sec. There should be minimal resistance when injecting, and the dark vein should turn clear as the HBSS or cell suspension displaces the venous blood. The needle will be removed and gentle pressure using sterile gauze will be applied directly to the injection site (approximately 5-10 seconds) to stop any bleeding.

In most cases an injection volume of 0.2-0.5 ml can be safely given to an adult mouse.[82] Most users try to limit the injection to 0.25 ml, a standard veterinary recommendation, but for cell injections, over-concentration may lead to embolism in lung capillaries and death of the recipient.[82] If moderate to severe dyspnea is observed immediately following injection (uncommon), the animals will be euthanized. Most mice show only reduced activity levels. Animals will be segregated and observed for the first hour following injection. If no problems are observed other than reduced activity, the mice will be returned to standard housing; normal behavior should be evident the next morning.

V.4.4.1.1. Pharmaceutical Grade Drugs No pharmaceutical grade drugs are used in this protocol.

V.4.4.1.2. Non-Pharmaceutical Grade Drugs
The cells will be grown in endothelial growth medium (Lonza, Inc.) supplemented with 5% FBS, EGF, and VEGF to support EC growth. The medium is not FDA-approved but it has been used to grow cells for implantation in *in vivo* models[85]. The recombinant cytokines (mouse) will be purchased from R&D systems and Invitrogen. We will wash cells with HBSS and inject cells suspended in HBSS + 1% BSA. The pH of the HBSS is 7.4. Sterile solutions of culture grade will be used and handled under aseptic procedures.

V.4.4.2. Biosamples Blood will be drawn from the caudal vena cava or by cardiac puncture in mice anesthetized by Isoflurane inhalation as a terminal procedure. After Isoflurane anesthesia and blood collection, animals immediately will be euthanized by cervical dislocation. Femur marrow for clonogenic assays or EC preparation, or bodies for disposal, will be collected after euthanasia as described under Euthanasia (V.4.6). All euthanasia will be according to AVMA guidelines by trained and technically proficient personnel.[80]

V.4.4.3. Adjuvants: N/A

V.4.4.4. Monoclonal Antibody (MAb) Production: N/A

V.4.4.5. Animal Identification: Cage cards. Mice will be held in groups of 4 per cage. Each card states the investigator's name, protocol number, experiment number, cage number, start date, end date, species, item number (animal lot), birthdate, gender, strain, number of animals in the cage, vendor, arrival date, treatments, and dates of death, including the initials of the staff person who found and removed the dead animals.

V.4.4.6. Behavioral Studies: N/A

V.4.4.7. Other Procedures: mice will be weighed prior to radiation. This weight will provide a baseline for monitoring weight loss. Mice will only be weighed after radiation if weight loss is suspected by visual inspection. Weight loss (up to 10%) is a concern that will be reported to VSD.

V.4.4.8. Tissue Sharing: N/A

V.4.4.9. Animal By-Products: Culture-derived mouse BM EC will be used in this study. BM samples will be taken from CD2F1 donor mice post-mortem while in VSD and brought to our culture laboratory (b)(6) for isolation and expansion of EC. These cells will be washed in HBSS + 1% BSA and injected into mice through the tail vein. Testing for infectious adventitious agents is not required as the cells will be from the same lot of mice (VSD "item") as the recipient mice.

V.4.5. Study Endpoint In Experiment 2, the endpoint is euthanasia of moribund animals. In Experiment 3, the endpoints are peripheral blood counts (CBC/diffs) and clonogenic quantification of hematopoietic progenitors in femur. A score sheet is now provided for criteria for euthanasia in the 30-day survival experiments, according to IACUC Policy #10 (see Table 1, next page).

V.4.6. Euthanasia For sample collection, mice first will be anesthetized with Isoflurane and then cervical dislocation will be performed to cause death under a portable fume hood with charcoal filter. Mice to be euthanized at the end of the experiment will be exposed to CO2 by investigative or VSD staff followed by cervical dislocation.

V.5. Veterinary Care

V.5.1. Husbandry Considerations
No more than 4 mice will be placed in a cage during experiments. Animals will receive Harlan Teklad Rodent Diet and water *ad libitum*. Acidified water (pH 2.5 – 3.0) is routinely provided to AFRRI mice. Cages will be regularly changed and cleaned by VSD staff in accordance with Standard Operating Procedures and the most recent edition of the *Guide for the Care and Use of Laboratory Animals*. Animal rooms will be maintained under a 12 h light/dark cycle.

V.5.1.1. Study Room
As assigned by VSD within the vivarium.

V.5.1.2. Special Husbandry Provisions N/A
Table 1: Score Sheet for Euthanasia Criteria (taken from IACUC Policy Letter #10)

Appearance:		
	Normal (smooth coat, clear eyes/nose)	0
	Hunched and/or fluffed	1
	Ocular discharge, and/or edema	3
	Emaciated, dehydrated (skin tent) **	5
	Soft stools (fecal matter around anus)	5
	Bloody diarrhea	9
Respiratory rate:		
	Normal breathing	0
	Increased breathing (double normal rate, rapid, shallow)	6
	Abdominal breathing (gasping +/- open mouth breathing)*	12
General Behavior:		
	Normal (based on baseline observations)	0
	Stretching of hind limbs with abdominal motion (writhe) or grimace (App. B and C)	1
	Decreased mobility	2
	Ataxia, wobbly, weak**	6
	Inability to stand*	12
Provoked Behavior:		
	Normal (moves when cage is disturbed, runs from hand (mice) or investigates (rat))	0
	Subdued; responds to stimulation (moves away briskly)	1
	Subdued even to stimulation (moves away slowly)	3
	Unresponsive to gentle prodding **	6
	Does not right when placed gently on side within 5 seconds*	12
TOTAL		_____

Definitive criteria for morbidity:
Weight Loss up to 10% baseline (if available)**
Pale, white mucous membranes/ skin * *
Fever >104F/40C (if available)**

Definitive criteria for moribundity:
Weight Loss > 20% OR <15g (adult mouse)*
Blue mucous membranes/ skin (cyanosis)*
Cool to the touch or <86F/30C (if available)*

**** Regardless of score, notify appropriate person immediately.**

*** Regardless of score, immediately euthanize (death is imminent)**

Score:
< 6 Normal
6 - 9 Morbid: Monitor at least 3 times per day; notify appropriate personnel immediately
> 10 Moribund: Notify responsible personnel immediately for euthanasia (if no single criteria is 12*)
Any single criteria of 12* euthanize immediately; consider as 'found dead'

(Note: This form does not have to filled out for every individual at every observation, so long as the criteria are used in informing decisions on increased monitoring and/or euthanasia. This form may be used to make a spreadsheet for greater ease of multiple animal observations, as long as the criteria and numbering system are exactly copied.)

V.5.1.3. Exceptions

Mice will be socially (group-) housed. There is a possibility that during survival studies cagemates may be lost through attrition and for a period of time the sole surviving mouse may remain singly housed until the end of the 30-day study. In addition, fighting among cagemates may require removal and single housing of the aggressor(s).

V.5.2. Veterinary Medical Care

V.5.2.1. Routine Veterinary Medical Care The animals will be observed daily by research staff of this protocol. Morbid mice will be observed twice a day (early morning

and late afternoon). Any moribund mice will be euthanized as soon as possible. If needed, a VSD veterinarian will be contacted for decision to euthanize.

V.5.2.2. Emergency Veterinary Medical Care
Emergency veterinary medical care is available 24 hours a day, seven days a week by VSD veterinarians and technicians and will include immediate euthanasia of any moribund mice.

V.5.3. Environmental EnrichmentV.5.3.1. Enrichment Strategy The animals will be housed in standard/conventional rodent caging. Mice will be group-housed, 4 mice per cage, with cotton bedding nestlets. Plastic tubes, hutches etc. will be introduced once mice have been declared non-radioactive by Safety.

V.5.3.2. Enrichment Restrictions: N/A

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING

NAME	DEGREE	TRAINING	DATE	PROCEDURES	YRS/MOS EXPERIENCE
(b)(6)				3	(b)(6)

X. ASSURANCES

Protocol Title: Endothelial Cell Regulation of Hematopoiesis after Radiation Injury in the Laboratory Mouse (Mus musculus)

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made every effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with a qualified individual who evaluated the experimental design with respect to the statistical analysis, and that the minimum number of animals needed for scientific validity will be used.

D. Biohazard / Safety: I have taken into consideration and made the proper coordinations regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R", namely, "Responsibility," which the DOD has embraced for implementing animal use alternatives where feasible and conducting humane and lawful research.

G. Scientific Review: This proposed animal use protocol has received appropriate peer scientific review and is consistent with good scientific research practice.

H. Painful Procedure(s): I **AM** / **AM NOT** conducting biomedical experiments, which may potentially cause more than momentary or slight pain or distress to animals. If applicable, potential pain and/or distress **WILL** / **WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

PROTOCOL TITLE: Radioprotective efficacy of a novel formulation of GT3-Lipid nanoparticle in a mouse (*Mus musculus*) model

PRINCIPAL INVESTIGATOR: (b)(6) **Ph. D**
CO-INVESTIGATOR(S): (b)(6) **Ph. D**

AFRRI SCIENTIFIC RESEARCH PROTOCOL NUMBER: (b)(6)

I. NON-TECHNICAL SYNOPSIS Gamma-tocotrienol (GT3), one of the eight vitamin E isoforms that is not a pharmaceutical grade drug and is known for its robust antioxidant capabilities with little to no known toxicity (Berbee *et al.*, 2009). We have shown previously that (1) GT3 is a radiation prophylactic drug with a dose reduction factor (DRF) of 1.28-1.32, (2) GT3 ameliorates radiation-induced pancytopenia (reduction in all types of blood cells) in peripheral blood and protects bone marrow cells suggesting the sustenance of innate and adaptive immunity, and (3) GT3 protects crypt cells from injury and accelerates post-radiation regeneration of the gastro-intestinal (GI) mucosa when GT3 was administered via SC route. These results indicate that GT3 prevents lethality due to radiation-induced infection, hemorrhage and opportunistic infection by translocation of intestinal bacterial flora into systemic circulation, and provides medical options against acute radiation syndrome (ARS). Technological advantages of lipid based nanoparticle formulations include biodegradability, no or little toxicity, high stability at ambient temperature, and significantly high cellular uptake following administration. (b)(4)

(b)(4)

Additionally, we will assess the efficacy of the nano-GT3 formulation via two different administration routes (SC and Oral) to determine if it is effective, regardless of administration route. A mouse model was selected because we are going to compare the efficacy of the nano-GT3 formulation compared to the parent compound (IACUC Protocol (b)(6) in the same strain of CD2F1 mice after whole body gamma radiation.

II. BACKGROUND

II.1. Background Overview of the subject, issue, and/or problem.

The issue and/or the problem that we will address in this proposal is the urgent need to protect first responders deployed in a radiation field for rescue and recovery military operations resulting from accidental or intentional nuclear/radiological detonations. Currently there is no FDA approved drug to protect first responders deployed in a radiation field for military operations. This is a serious gap in medical capabilities that needs to be addressed. Drugs under various stages of development in small and large animals are only effective in large doses or are toxic at effective doses. Therefore, there is an immediate need for non-toxic radioprotectants (prophylactic

agents that can prevent radiation induced tissue injuries) useful for military personnel and civilians who may be exposed to a nuclear/radiological scenario. The present proposal directly addresses this need by moving forward with the development of a promising drug delivery approach to increase radioprotective efficacy of subcutaneous (SC) or oral (PO) delivery of the gamma-tocotrienol (GT3).

In an effort to identify suitable radioprotectants, a number of compounds of diverse chemical structures were considered. These compounds include thiols (Davidson *et al.*,1980), cytokines (Waddick *et al.*, 1991), steroids (b)(4) prostaglandin analogs (Hanson *et al.*, 1988), antioxidants (b)(4) (b)(4) and nutraceuticals (b)(4) (b)(4) The search for radioprotectants has been dominated by the study of sulphydryl compounds such as Amifostine (Davidson *et al.*, 1980). Amifostine has been approved for clinical use in conjunction with cisplatin for patients undergoing radiotherapy for head and neck cancer (Capizzi and Oster, 1995). Despite its effectiveness, Amifostine has not been accepted and approved as a suitable radioprotectant for military personnel. Moreover, it may not be useful for first responders in response to nuclear threat due to its performance- degrading toxicity (b)(4) and resultant hypocalcaemia (Glover *et al.*,1983).

Available Information for GT3

We reported that subcutaneously (SC) administered microsuspension formulation of gamma-tocotrienol (GT3) in 5% Tween-80, can prevent pancytopenia and reduce lethality in the short-term period following the adminstration of a lethal radiation dose in mice (b)(4),(b)(6) oral GT3 was minimally effective (preliminary study by us). GT3 and other potential drugs for radiation countermeasures being developed are used subcutaneously. This proposal directly addresses the need to develop an oral formulation of GT3 that is equally effective. We propose to accomplish this by using recently developed advanced concepts of nanotechnology for drug delivery to enhance the bioavailability of GT3 by oral administration, which is the preferred route of drug administration for emergency personnel involved in rescue operations. We also propose to increase radioprotective efficacy of GT3 by SC administration using this advanced formulation in nanoparticles.

Lipid Nanoparticles: For the GT3 radioprotectant, a series of formulations will be prepared by incorporating varying amounts of the drug and lipid modifier by our collaborators (b)(4)

(b)(4)

II.2.4. Key Words of Search
Gamma-tocotrienol, radiation, radioprotection, mice, toxicity, nanoformulation, microsuspension formulations, free radicals, oral, subcutaneous

II.2.5. Results of Search Table 1 includes a summary of the keywords and keyword combinations used for searching the RePORTer, BRD, and PubMed databases.

Table 1: Summary of Database Keyword Searches			
keywords	RePORTer (CRISP)	BRD	PubMed
GT3	1	9	252
GT3 and radiation	1	9	21
GT3 and radioprotection	0	4	3
GT3 and toxicity	1	2	25
GT3 and toxicity and oral	0	0	2
GT3 and toxicity and subcutaneous	1	0	0
GT3 and mice and radiation	1	7	12
GT3 and mice and radioprotection	0	4	1
GT3 and nanoformulation	0	0	0
GT3 and free radicals	1	0	20
GT3 and hematopoietic cytokines	0	0	3
GT3 and G-CSF	0	0	4
Microsuspension formulation	0	0	15
Microsuspension formulation and radioprotection	0	0	0

Although there have been several studies performed using GT3 as a radioprotectant, the searches indicated that there have been no previous performed utilizing a nanoformulation of GT3 as a radioprotectant. Therefore, the proposed study to determine the optimal method of drug delivery (SC or PO) and the dose required for effective radioprotection is not a duplication of a previous experiment. Several groups have explored GT3 for its anti-inflammatory properties, however only our colleagues have explored the efficacy of GT3 as a radioprotectant (b)(4) For example, *in vitro* studies using a murine macrophage cell line (RAW264.7) determined that treatment with GT3 has anti-inflammatory properties by inhibiting NF-κB and C/EBP activation (Wang and Jiang, 2012). Reporter database revealed only one ongoing project with GT3 as a radioprotectant, but this study was not utilizing the novel nanoformulation of GT3 that we have proposed.

III. OBJECTIVE / HYPOTHESIS

In this proposal, we hypothesize that (b)(4) (b)(4) administered via SC or PO will provide (b)(4) (b)(4) Our specific aim for this pilot project is to assess the radioprotective efficacy of nano-GT3 administered via oral and SC routes.

IV. MILITARY RELEVANCE

Military operations are seriously impaired by radiation exposures depending on the dose and dose rate. Currently, there is no FDA approved preventive measure available for military men and women to protect them from the hazards of radiation exposure. The problem is more acute in recent times due to the unpredictable nature of terrorist attacks. Recognizing this urgent need, the United States Department of Defense has assigned top priority in "Defense Technology Objectives (DTO)" to the "development of medical countermeasures to radiation exposure" against both early effects and late

arising health effects. These concerns address the urgent need to develop an appropriate radiation protective agent (prophylactic or therapeutic) to sustain immediate warfighter capabilities and to enable the commanders to make judicious decisions in troop deployment. Currently, there are several drugs at various stages of development. This study will focus on revealing the mechanism of action of a prophylactic radiation countermeasure, gamma tocotrienol (GT3) using a promising new lipid based nanoparticle formulation to increase the radioprotective efficacy of GT3 following SC or PO administration.

V. MATERIALS AND METHODS

V.1. Experimental Design and General Procedures

We propose to do the following experiments to assess the improved radioprotective efficacy of nano-GT3 given both orally and subcutaneously over microsuspension formulations of GT3.

Animals.

Male CD2F1 mice will be used throughout this study. Mice between the ages of 8 and 10 weeks, weighing approximately 22 to 25 g, will be purchased from Harlan Laboratories, IN, held in quarantine for a minimum of 10 days, tested for *Pseudomonas*, and maintained in an AAALACi (Association for Assessment and Accreditation of Laboratory Animal Care)-International accredited facility at the Armed Forces Radiobiology Research Institute (AFRRI) before use in the experiment. Animals will be kept in polycarbonate micro-isolator cages (eight per cage) on sani-chip contact bedding with free access to food and acidified water in an environmentally controlled room.

Irradiation.

All irradiations of mice will be carried out in well-ventilated plexiglass boxes that are compartmentalized to accommodate eight un-anaesthetized mice per box. Radiation administration will occur via bilateral irradiation in the cobalt-60 facility of AFRRI at a dose rate of 0.6 Gy/minute. All mice with drug administered SC will be irradiated at doses of 11, 11.5 and 12 Gy while mice with drug administered PO will be irradiated at doses of 9 and 9.5 Gy.

Administration of drug or vehicle :

The microsuspension formulation of GT3 or vehicle (5% Tween-80) will be supplied by (b)(4) We are using the same formulation for three other protocols at AFRRI. 100 mg/kg GT3 (optimum dose) or vehicle will be injected subcutaneously (SC) 24 h prior to radiation (0.1 ml per mouse) at the nape of the neck with a 23-25 G needle. The nanoformulation of GT3 will be supplied by (b)(4) (b)(4) Two drug doses of the nanoformulation of GT3 (dose1 and dose 2), with dose 1 being 1/4 of the maximum tolerated dose (as determined by ODDS method, please see experimental design V.1.1) and dose 2 being 2 times of dose 1, will be used for the initial screening. Thirty day survival will be determined in drug treated and control

mice after exposure to radiation (Cobalt-60 gamma at 0.6 Gy/min). Drug-treated mice will be compared to a vehicle-treated control group. V.1.1.

V.1.1. Experiment 1. Determination of the maximum tolerated dose of nano-GT3 (SC and PO). We will use the general guidelines adopted in our screening protocols (# (b)(6) . We will adopt the modified toxicity protocol Optimal (non-toxic) Drug Dose for screening (ODDs) which has been used in evaluating several drugs in other IACUC protocols at AFRRI. The purpose of using the ODDs method is that it allows testing in one gender (males in the present protocol) and requires fewer animals when compared to the FDA protocol. Drugs will be administered by two routes, subcutaneously (SC) and orally (PO).

We will start with 300 mg/kg as starting dose (a single administration) which is the maximum tolerated dose (MTD) for GT3 parent microsuspension formulation for SC administration as we have determined from our previous study. A maximum of six animals per drug dose (maximum 5 doses per drug) will be used to evaluate toxicity. Animals will be monitored daily for acute (1 to 4 h) and chronic (up to 14 days) signs of toxicity. Signs of acute toxicity include: decreased activity, squinting eyes, hunching, labored breathing or injection site swelling. If animals display any signs/symptoms of being adversely effected by the drug (i.e. toxicity symptoms previously described) they will be euthanized CO_2 overdose from a compressed gas cylinder followed by cervical dislocation in accordance with the current American Veterinary Medical Association (AVMA) Guidelines for Euthanasia. Death will be confirmed by cessation of heart function. All observations will be done by a trained technician including PI and Investigators. Animals will be observed twice daily for 14 days for morbidity (chronic sign of toxicity such as weight loss (>10%), decreased activity, hunched posture, labored breathing or any other abnormal clinical signs of toxicity). Moribund mice will be euthanized and necropsy will be performed (see section V.4.5), and all surviving mice will be transferred to another protocol. If a drug dose shows no initial toxicity in mice with a test dose of the drug, then the dose will be escalated approximately 3-fold and evaluated. If there is still no toxicity, we will continue the 3-fold increase until either maximum tolerated dose is reached or issues with solubility of drug become apparent. Conversely, if toxicity is found, the dose will be stepped down approximately 3-fold until no adverse effect is found.

For PO formulation, we will start with 600 mg/kg dose (a single gavage, 0.2 mL dose) as an estimated safe dose (300 mg/kg was found to be the MTD for SC administration for the parent GT3 formulation, (b)(6) Again, a maximum of six animals per drug dose (maximum 5 doses per drug) will be used to evaluate toxicity. Animals will be monitored daily for acute (1 to 4 h) and chronic (up to 14 days) signs of toxicity using the same signs/symptoms mentioned in the previous paragraph for the SC administration. If a drug dose shows no initial toxicity in mice with a test dose of the drug, then the dose will be escalated approximately 3-fold and evaluated. If there is still no toxicity, we will continue the 3-fold increase until either maximum tolerated dose is reached or issues with solubility of drug become apparent. Conversely, if toxicity is found, the dose will be stepped down approximately 3-fold until no adverse effect is found. The mice will be restrained by hand to insure minimal head movement. The drug

will be administered according to AAALAC guidelines (WRAIR Investigators' Handbook – Section 1; Injection routes, sites and needle sizes for common laboratory animals) for mice: 20 gauge needle and disposable syringe with a curved shaft that is 1.5 inches in length and contains a 2.25 mm ball to minimize trauma to oral and esophageal tissue.

In conclusion, if a drug dose shows no initial toxicity in mice with a test dose of the drug, then the dose will be escalated approximately 3-fold and evaluated. Conversely, if toxicity is found, the dose will be stepped down approximately 3-fold until no adverse effect is found. This experiment will only be used to determine the MTD that does not result in overt toxicity in mice. If we have to use more drug doses to achieve MTD, we will use fewer animals to do a pilot study until we achieve a dose with no observed adverse effect in animals.

Mice needed:
No of groups: 7 (1 vehicle/ blank nanoparticle and 3 drug doses each for both SC and PO) No of mice per group: 6
Total mice for this experiment: 7x6 = 42

V.1.2. Experiment 2. Compare the survival efficacy of nano-GT3 with the microsuspension formulation of GT3 administered SC 24 h prior to radiation.
CD2F1 mice will be irradiated at doses of 11, 11.5 and 12 Gy and monitored for 30 days for any observed weight loss, ruffled fur, behavioral changes and any other signs of morbidity or moribundity. If animals show signs or symptoms of morbidity/moribundity, they will be euthanized either by (1) cervical dislocation under isoflurane anesthesia or (2) CO_2 overdose from a compressed gas cylinder followed by cervical dislocation in accordance with the current American Veterinary Medical Association (AVMA) Guidelines for Euthanasia. At the end of experiments, surviving unused animals will be transferred to other protocols. Death will be confirmed by cessation of heart function. Two doses of nano-GT3 will be used; one is ¼ of MTD as determined from expt 1 and one dose higher (i.e. ½ of MTD).

Mice needed:
No of groups: 4 (vehicle/ blank nanoparticle, nano-GT3 dose 1, nano-GT3 dose 2, and microsuspension formulation of GT3, 100 mg/kg)
Radiation doses: 3 (11, 11.5 and 12 Gy)
No of mice per each exposure: 16
Number of repeats: 2
Total mice for this experiment: 3x4x16x2 = 384

V.1.3. Experiment 3. Compare the survival efficacy of nano-GT3 with the microsuspension formulation of GT3 administered PO pre- and post-radiation.
CD2F1 mice will be irradiated at doses of 9 and 9.5 Gy and monitored for 30 days for any observed weight loss, ruffled fur, behavioral changes and any other signs of morbidity or moribundity. Two doses of nano-GT3 will be used; one is ¼ of MTD as determined from expt 1 and one dose higher (i.e. ½ of MTD).

Mice needed:
No of groups: 4 (vehicle/ blank nanoparticle, nano-GT3 dose 1, nano-GT3 dose 2, and microsuspension formulation of GT3, 100 mg/kg)
Radiation doses: 2 (9 and 9.5 Gy)
Time of administration: 4 (-24, -12, +6, and +12
h) No of mice per each exposure: 16
No. of repeats = 2
Total mice for this experiment: 4x2x4x16x2 = 1024

V.2. Data Analysis
Toxicity Study: We will follow the same guideline as we used in our Intramural screening protocol to find the optimal drug dose for screening (ODDS) (Protocol# (b)(6) In this method, six mice per group will be used per drug dose. Since we will be using fewer mice, this procedure will be strictly observational and no statistical significance will be derived from this study.

For the survival data, Fisher's exact test will be used to compare survival at 30 days and a log-rank test will be used to compare survival curves. Analysis of variance (ANOVA) will be used to determine if significant differences exists among different groups. For a given day, if a significant difference among groups will be detected, a pair wise comparison will be performed using the Turkey-Kramer method. A significance level will be set at 5% for each test. All statistical analyses described in this protocol will be approved by a qualified statistician.

V.3. Laboratory Animals Required and Justification

V.3.1. Non-animal Alternatives Considered
Our ultimate goal is to find a suitable radioprotectant for human use. We have already established that the microsuspension formulation GT3 is a good prophylactic radiation countermeasure in male CD2F1 mice, protecting both the hematopoietic and GI systems from radiation injury when injected SC. In order to increase the radioprotective efficacy of GT3 and reduce the dose required, the nano-GT3 drugs must be tested in an animal model. Additionally, we hope to improve the efficacy of GT3 as an oral prophylactic which we hope to demonstrate with our nano-GT3 formulation. Structure based drug design employing computer modeling and *in vitro* screening in cell cultures are used by drug manufacturers during the development of candidate drugs. However, this method cannot tell us whether a given regimen, prophylactic or therapeutic, is effective in promoting survival or not. No *in vivo* data are currently available that can address the questions we are addressing in this protocol.

V.3.2. Animal Model and Species Justification
As discussed in the previous section, animals must be used to study the radioprotective efficacy of a drug *in vivo*. We want to use the mouse as the animal model because we share 97.5 - 99% of our DNA with mice, and mouse models are well characterized to study the mechanism of action of a radioprotectant in a whole body system (b)(4)

(b)(4) Zebrafish and Drosophila are not considered for this study because their physiology is largely different from mammalian systems.
The use of the mouse model is necessary to determine if a prophylactic or therapeutic agent can protect against acute radiation effects and prevent lethality. It is not an option to use non-animal systems in place of animal models to address the research questions in this proposal (please see section V.3.1 for justification).

V.3.3. Laboratory Animals

V.3.3.1. Genus / Species
Mus musculus

V.3.3.2. Strain / Stock
CD2F1

V.3.3.3. Source / Vendor
Harlan Labs, Indianapolis, IN or similar approved vendors.

V.3.3.4. Age
8-10 wks old

V.3.3.5. Weight
22-25 g

V.3.3.6. Sex
Male

Justification of using only male mice: Previous studies have been conducted with male mice, so male mice are needed for data comparison. Although, it is important to confirm observations in females, such studies may be carried out at a later time.

V.3.3.7. Special Considerations
Commercially procured animals must be adventitious, disease free, and pathogen-free—including *Pseudomonas aeruginosa*, and *Pasteurella*. All mice need to be free of the following agents: Sendai, Pneumonia Virus of Mice (PVM), Reovirus-3 (Reo 3), Mouse Adenovirus (MAD-1, MAD-2), Mouse Cytomegalovirus Virus (MCMV), Ectromelia, K virus, Lymphocytic Choriomeningitis Virus (LCM), Epidemic Diarrhea of Infant Mice (EDIM), Hantan virus, Rotavirus, Mouse Parvovirus (MPV), Polyoma Virus, Mouse Minute Virus (MMV), Mouse Thymic Virus (MTV), Theiler's Mouse Encephalomyelitis Virus (TMEV/GDVII), *Encephalitozoon cuniculi*, CAR bacillus, *Mycoplasma pulmonis*, and *Clostridium piliforme*. They must also be endoparasite and ectoparasite-free.

V.3.4. Number of Animals Required (by species): 1450

V.3.5. Refinement, Reduction, Replacement (3 R's)

V.3.5.1. Refinement
Moribund animals (as discussed in V.4.1) will be euthanized to minimize the magnitude and duration of suffering these animals might experience when they are subjected to toxic effects of ionizing radiation and/or high doses of the test drug. In such cases moribundity (please see V.4.1) will be used as a surrogate for death in animals and will be considered to have arrived at an early endpoint.

V.3.5.2. Reduction
Previously published and unpublished data have established which radiation doses are required for each method of drug delivery to accurately assess radioprotective efficacy. Results from the toxicity study will allow us to utilize 2 doses of the drug to minimize the number of animals required. Based on our previous experiments on survival study, we will use the minimum required number of animals for statistical validity. This will reduce the number of animals to be used in this protocol.

V.3.5.3. Replacement
N/A

V.4. Technical Methods

V.4.1. Pain / Distress Assessment
According to the IACUC Operating Policy Letter #10 "Guidelines for establishment of early endpoints in experiments with expected mortality", examples of clinical signs of morbidity and moribundity are listed below in Appendix A: Clinical Observations with Criteria for Euthanasia (Rodent):

VIII. Appendix A: Clinical Observations with Criteria for Euthanasia (Rodent)

DATE:	Time:	Animal ID#	Score
Appearance:			
	Normal (smooth coat, clear eyes/nose)		0
	Hunched and/or fluffed		1
	Ocular discharge, and/or edema		3
	Emaciated, dehydrated (skin tent) **		5
	Soft stools (fecal matter around anus)		5
	Bloody diarrhea		9
Respiratory rate:			
	Normal breathing		0
	Increased breathing (double normal rate, rapid, shallow)		6
	Abdominal breathing (gasping +/- open mouth breathing)*		12
General Behavior:			
	Normal (based on baseline observations)		0
	Stretching of hind limbs with abdominal motion (writhe) or grimace (App. B and C)		1
	Decreased mobility		2
	Ataxia, wobbly, weak**		6
	Inability to stand*		12
Provoked Behavior:			
	Normal (moves when cage is disturbed, runs from hand (mice) or investigates (rat))		0
	Subdued; responds to stimulation (moves away briskly)		1
	Subdued even to stimulation (moves away slowly)		3
	Unresponsive to gentle prodding **		6
	Does not right when placed gently on side within 5 seconds*		12
TOTAL			_____

Definitive criteria for morbidity:	**Definitive criteria for moribundity:**
Weight Loss up to 10% baseline (if available)**	Weight Loss > 20% OR <15g (adult mouse)*
Pale, white mucous membranes/ skin * *	Blue mucous membranes/ skin (cyanosis)*
Fever >104F/40C (if available)**	Cool to the touch or <86F/30C (if available)*
**** Regardless of score, notify appropriate person immediately.**	***Regardless of score, immediately euthanize (death is imminent)**

Score:
< 6 Normal
6 - 9 Morbid: Monitor at least 3 times per day; notify appropriate personnel immediately
> 10 Moribund: Notify responsible personnel immediately for euthanasia (if no single criteria is 12*)
Any single criteria of 12* euthanize immediately; consider as 'found dead'

(Note: This form does not have to filled out for every individual at every observation, so long as the criteria are used in informing decisions on increased monitoring and/or euthanasia. This form may be used to make a spreadsheet for greater ease of multiple animal observations, as long as the criteria and numbering system are exactly copied.)

The moribund condition is defined as a clinically irreversible condition leading inevitably to death. Animals involved in experiments that may lead to moribundity or death will be monitored daily by personnel experienced in recognizing signs of moribundity (Tomasivic, 1988, Montgomery, 1990). Experimental mice that are found morbid (affected with disease or illness), but not moribund, will be allowed to continue in the experimental protocol, but no supportive care is proposed. The morbid mice will be examined at least twice daily, in the early morning and late afternoon, by the research

staff (including weekends and holidays) in addition to the regular VSD health checks. VSD veterinarians will be consulted for all matters regarding animal welfare. Animals receiving a score ranging from 6-9 on the IACUC Policy Letter #10, Appendix A: Clinical Observations with Criteria for Euthanasia (Rodent) will be considered morbid and subjected to 3 health checks per day. Any animals receiving a score of >10 will be considered morbid and immediately euthanized.

V.4.1.1. APHIS Form 7023 Information

V.4.1.1.1. Number of Animals

V.4.1.1.1.1. Column C ___42__ (# of animals)

V.4.1.1.1.2. Column D ___0__ (# of animals)

V.4.1.1.1.3. Column E ___*1408__ (# of animals)*

V.4.1.1.1.4. Pain Category Assignments

Exp. #	Experimental/Control Group	C	D	E	Totals
V.1.1	Experiment 1	42			42
V.1.2	Experiment 2			384	384
V.1.3	Experiment 3			1024	1024
Totals:		42		1408	1450

V.4.1.2. Pain Relief / Prevention

V.4.1.2.1. Anesthesia / Analgesia / Tranquilization
Radiation might cause momentary pain in animals. We placed the animals which will be irradiated or drug treated in the E category. We will not be using any anesthesia/analgesia in this protocol as a measure of pain relief.

V.4.1.2.2. Pre- and Post-procedural Provisions
Mice will be housed and monitored in accordance with VSD standard operating procedures both before and after irradiation (see Section V.5."Veterinary Care")

V.4.1.2.3. Paralytics
No paralytic agents will be administered

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures

V.4.1.3.1. Sources Searched
Altweb
AGRICOLA
PubMed

V.4.1.3.2. Date of Search
Altweb – 02/13/2012
AGRICOLA – 02/13/2013
PubMed – 02/13/2013

V.4.1.3.3. Period of Search
1970-2013

V.4.1.3.4. Key Words of Search
Pain, toxicity, analgesia, anesthesia, radiation, radioprotection, mouse, humane, alternative, gamma-tocotrienol, nano-GT3, micro-GT3.

V.4.1.3.5. Results of Search
We are studying a new formulation of GT3 in this protocol. We will be using lethal doses of radiation (9, 9.5, 11, 11.5, and 12 Gy) in this study based on results from our previous studies to assess the improved radioprotective efficacy of nano-GT3 given both orally and subcutaneously over microsuspension formulations of GT3. Radiation sickness is an acute illness caused by high doses of penetrating ionizing radiation to most or all of the body in a relatively short time period which can be painful. Literature search verifies that developing symptoms due to hematopoietic and gastrointestinal damage appears to be painful and distressful to humans and animals. Table 2 includes a summary of the keyword combinations used for searching and the results of the search. We are using nanoparticles to minimize the dose of drug that we must administer to the animals prior to radiation exposure. The literature suggests that nanoparticles are now commonly used to treat many forms of cancer. Although they are not toxic to the animals' system, the drug preparations in this formulation are highly toxic to cancer cells and therefore very effective. A nanoparticle formulation of GT3 was highly efficacious in increasing intestinal permeability of GT3 and therefore enhancing its oral bioavailability (Abuasal *et al.*, 2012). While the literature indicates that cell models have been used to study radiation damage, such models cannot alone predict mechanism of radioprotection of a specific drug. Although radiation-induced pain was alleviated during some studies (Ciezki and Macklis, 1995, Desai *et al.*, 1997, Sonoo *et al.*, 1995), such pain relief was the aim of the studies in question, which focused on patients receiving radiotherapy for cancer treatment. We do not have the option of using alternatives such as a cell culture model. We do expect to see clinical signs of pain in mice since we are using a lethal doses of 9, 9.5, 11, 11.5, and 12 Gy. Therefore, if animals show signs of pain or distress (please see section V.4.1), all moribund animals will be euthanized immediately to minimize potential pain or distress.

Table 2: Summary of Database Keyword Searches			
keywords	Hits		
	AGRICOLA (NAL catalog)	AltWeb	PubMed
Nanoparticles and toxicity	23	30	5819
Gammatocotrienol AND toxicity	11	0	25

Pain AND radiation	93	7	9503
Pain AND analgesia AND radiation	23	4	335
Gammatocotrienol AND pain	0	0	0
Nano-GT3	0	0	0
Micro-GT3	0	0	0
Radioprotection AND pain	0	0	5
Radiation AND humane	0	28	8
Pain AND analgesia AND mice	0	21	1656
Radiation AND mouse AND pain	0	6	207
Radiation AND mouse AND pain AND alternative	0	5	3

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification
Since the purpose of these studies is to determine the radioprotective efficacy of nano-GT3, we will be unable to use analgesics and anesthetics because they may interfere with the innate system (Galley *et al.*, 1998, Galley and Webster, 1997). However, if we see any morbidity or moribundity (as described in section V.4.1) frequency of examination will increase. All moribund (see section V.4.1) animals will be euthanized by overdose of CO_2 inhalation and cervical dislocation as described in section V.4.6 rather than allowing them to progress to death.

V.4.2. Prolonged Restraint
N/A

V.4.3. Surgery
N/A

V.4.3.1. Pre-surgical Provisions N/A

V.4.3.2. Procedure(s) N/A

V.4.3.3. Post-surgical Provisions N/A

V.4.3.4. Location
N/A

V.4.3.5. Surgeon
N/A

V.4.3.6. Multiple Major Survival Operative Procedures N/A

V.4.3.6.1. Procedures
N/A

V.4.3.6.2 Scientific Justification
N/A

V.4.4. Animal Manipulations

V.4.4.1. Injections
Microsuspension formulation of GT3 (200 mg/kg) will be injected subcutaneously (SC) (0.1 ml) using a sterile 23-25 G needle and syringe at the nape of the neck (b)(4) (b)(4) Nanoparticle formulations of GT3 will be injected (dose to be determined following toxicity study) SC (0.1 ml, maximum volume 0.25 ml is approximately equal to 1% body weight for 25 g mouse) using a sterile 23-25 G needle and syringe at the nape of the neck. Oral gavage will be performed using 20 G disposable gavage feeding syringes, with an approximate gavage volume of 0.2 ml (maximum volume 0.3 ml/mouse). Mice will be restrained with hand restraint for both the SC injection as well as the oral gavage.

V.4.4.1.1. Pharmaceutical Grade Drugs N/A

V.4.4.1.2. Non-Pharmaceutical Grade Drugs
GT3 is a non-pharmaceutical grade drug. It had been tested endotoxin free for another protocol (Protocol# (b)(6) , and was found to have no adverse reactions. GT3 will be tested for endotoxin by Charles River Laboratory before using in the animals. We will be using the same excipient (5% Tween-80 in saline, pH 6.8, osmolality 290 mOsm) as we used for GT3 in the other protocol (b)(6) as a SC injection in a volume of 0.1 ml per mouse. (b)(4)

(b)(4)

(b)(4) So, we are not expecting any toxic effects in animals.

V.4.4.2. Biosamples
N/A

V.4.4.3. Adjuvants
N/A

V.4.4.4. Monoclonal Antibody (MAb) Production
N/A

V.4.4.5. Animal Identification
Different groups of mice for a particular treatment group will be identified in cage cards. However, for toxicology experiments, ear punching will be used to identify individual animals in a cage. Three animals (in a cage) will be identified as L (as left ear punched), R (as right ear punched) and N (as no ear punched). This will help us monitor each animal for drug toxicity. The individuals who have the training and are responsible for ear punching have been indicated in the table on qualification and animal handling experience described in section VI. Animals will be restrained (hand restraint) during the ear punching procedure, ears will be cleaned with alcohol swabs prior to performing the punch, and the instrument will be cleaned with an alcohol swab in between animals. The punch will be placed on the pinna of the ear in a standard location (outermost point). After firmly pressing on the punch device and verifying that the procedure left a circular hole through the ear, the ear will be gently separated from the punch device to avoid additional injury to the ear.

V.4.4.6. Behavioral Studies
None

V.4.4.7. Other Procedures
None

V.4.4.8. Tissue Sharing
At present there are no plans for tissue sharing.

V.4.4.9. Animal By-Products
N/A

V.4.5. Study Endpoint

For the toxicity study, the endpoint will be a 14-day survival with any surviving animals euthanized. For the radioprotective efficacy study, the endpoint will be 30-day post-irradiation survival and the surviving mice will be transferred to another protocol.

If we see any moribund animals beyond access to food and water, we will humanly euthanize the animals. It is critical to define criteria for euthanizing mice humanely without compromising the study objective and complying with the IACUC recommendations stipulated in The IACUC Operating Policy Letter #10 "Guidelines for establishment of early endpoints in experiments with expected mortality" (please see V.4.1).

Experimental mice that are found morbid, but not moribund, will be allowed to continue in the experimental protocol, but no supportive care is proposed. The morbid mice will be examined at least twice daily, in the early morning and late afternoon, by the research staff (including weekends and holidays) in addition to the regular VSD health checks. VSD veterinarians will be consulted for all matters regarding animal welfare. However, an extra arm involving histopathology of animals that survive 14 days using the "pluck" method for collection of tissues will be used. For this purpose, animals

will be euthanized by CO2 inhalation and cervical dislocation prior to harvesting the following tissues: (Heart; tongue; lung; esophagus; trachea; kidney; thymus; liver; spleen; stomach; colon; cecum; duodenum; jejunum; pancreas; ileum; seminal vesicle; testis; epididymus; urinary bladder; haired skin; skeletal muscle; eye; cerebrum; cerebellum; bone marrow; tibia; femur) will be collected. Tissues such as those described above will also be collected in animals that are euthanized due to a moribund condition (as described in section V.4.1). Histopathology will include evaluation of all major organ systems and the data will be used to characterize tissue-specific responses.

V.4.6. Euthanasia All moribund animals (see section V.4.5) as well as surviving animals at the end of the study will be euthanized by overdose of CO_2 inhalation and cervical dislocation as described by VSD SOP, by trained investigators or technicians in accordance with current AVMA Guidelines on Euthanasia. Compressed CO_2 gas in a cylinder with a regulator will be used for euthanasia in a euthanasia chamber.

V.5. Veterinary Care

V.5.1. Husbandry Considerations
Animal husbandry procedures will be followed according to the VSD SOPs.
Mice will be group housed in polycarbonate micro-isolator cages (eight per cage) on sanichip contact bedding with free access to food and acidified water in an environmentally controlled room.

V.5.1.1. Study Room
Mice after quarantine will be housed in designated rooms and used when they are ready. For brief periods, mice will be transported (slowly to minimize vibration and/or bumpiness) to the cobalt irradiation facility in well ventilated Plexiglas boxes that are completely covered by an opaque lab coat to minimize transportation stress.

V.5.1.2. Special Husbandry Provisions
None

V.5.1.3. Exceptions
None

V.5.2. Veterinary Medical Care

V.5.2.1. Routine Veterinary Medical Care
Experimental animals will be observed at least once a day by one of the investigators or technicians. As described in section V.4.1, morbid animals will be monitored at least twice daily, early morning and late afternoon by the research staff. In addition, VSD personnel will also monitor the experimental animals during their routine twice daily rounds. The experimental design does not contemplate supportive therapy.

V.5.2.2. Emergency Veterinary Medical Care

Emergency veterinary medical care is available 24 hrs and 7 days a week. Veterinary staff will be contacted as needed.

V.5.3. Environmental Enrichment

V.5.3.1. Enrichment Strategy

The enrichment strategy for mice will be according to VSD Standard Operating Procedure, which involves socially grouped housing and providing nestlets and huts/igloos in the cage.

V.5.3.2. Enrichment Restrictions N/A

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING

NAME	DEGREE	TRAINING	DATE	PROCEDURES	YRS/MOS EXPERIENCE
(b)(6)				1,3,4,5	(b)(6)
				1,3,4,5	
				1,3b,4	
				1, 3b, 4, 5	

Procedure and manipulation codes:
Code 1= Animal handling and euthanasia
Code 2= Surgery (aseptic technique) pre- and post-operative care
Code 3= Injections (3a-ip, 3b-sc, 3c-gavage) - can say 3 if trained in all manipulations or add 3d-iv
Code 4= Blood collection under anesthesia (4a-cardiac, 4b-posterior vena cava)
Code 5= Tissue collection (after euthanasia) - doesn't need to be specific
Code 6 = Implantation (provide details)
Code 7 = Others - (provide protocol specific manipulations or procedures for e.g., retro-orbital bleeding, tail vein injection, or drug delivery)

VII. BIOHAZARDS/SAFETY

An AFRRI Safety and Health Department protocol Hazard Analysis was approved on January 2, 1997 for the general research program of the Radiation Casualty Management team (now Radiation Countermeasures Program). All personnel listed in the present IACUC protocol have been trained either as radioactive users or as general radiation users on a regular basis. All investigators and technicians while in the vivarium will use appropriate procedures as described by VSD. This will include wearing of mask and gloves during observation of mice. All investigators and technicians are current in safety training and medical surveillance.

X. ASSURANCES

Protocol Title: Radioprotective efficacy of a novel formulation of GT3-Lipid nanoparticle in a mouse model

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made every effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with a qualified individual who evaluated the experimental design with respect to the statistical analysis, and that the minimum number of animals needed for scientific validity will be used.

D. Biohazard / Safety: I have taken into consideration and made the proper coordinations regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R", namely, "Responsibility," which the DOD has embraced for implementing animal use alternatives where feasible and conducting humane and lawful research.

G. Scientific Review: This proposed animal use protocol has received appropriate peer scientific review and is consistent with good scientific research practice.

H. Painful Procedure(s): I **AM / AM NOT** conducting biomedical experiments, which may potentially cause more than momentary or slight pain or distress to animals. If applicable, potential pain and/or distress **WILL / WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

DOD ANIMAL CARE AND USE STANDARDIZED PROTOCOL FORMAT WITH EMBEDDED INSTRUCTIONS (October 2012)

Reference DOD Instruction 3216.01 & AFRRI Instruction 3216.2H

****

Information requested in the following animal use protocol template reflects the requirements of the Animal Welfare Act Regulations (AWAR), the Guide for the Care and Use of Laboratory Animals, and other applicable Federal regulations and DOD instructions.

****

This document is intended to be an aid in the preparation of DOD-sponsored animal use protocols. It is a companion document to an identical protocol template that does not have embedded instructions. Either template may be used to format DOD-sponsored animal research proposals; however, reference to the instructions during protocol preparation is highly recommended. If using the template with instructions, the instructions should be deleted prior to submitting the finished protocol for IACUC review. Please use Arial, regular, size 12, black font to prepare the protocol. With the exception of section headings, all paragraphs require a response. Paragraphs that do not apply should be marked N/A. There is no space limitation for responses to the information requested.

Approved standard operating procedures (SOPs) promulgated by the AFRRI Veterinary Sciences Department (VSD) or similar VSD-validated documents that describe specific procedures may be referenced by SOP number and title in lieu of repeating the details in the protocol. However, it is essential to include general descriptions of all animal manipulations to be carried out under the IACUC-approved protocol and to provide details where no approved references are cited. To do otherwise would constitute a breach of statutory regulations. Manipulations not covered in the originally approved protocol can be initiated only after IACUC approval of a formal amendment adding the new procedures. Additionally, Principal Investigators (PIs), or other delegated research personnel, should maintain accurate experimental records and be able to provide an audit trail of animal expenditures and use that correlates with their approved protocol. Protocol PIs will be required to provide this and other information during annual protocol reviews.

Any supporting information that may be of use to the IACUC during its review may be attached to the completed protocol. Adding subparagraphs within the body of the protocol template is permissible, *provided that the numbering sequence of paragraphs in the original standard format is maintained.* In other words, all of the labeled paragraphs and subparagraphs in this template must be retained, with additional information being presented as sub-numbered paragraphs containing information that supports or complements what is requested.

INTELLECTUAL PROPERTY STATEMENT

Research protocols drafted by Government scientists include intellectual property (e.g., concepts, ideas, experimental approaches, etc.), some of which is innovative or original and therefore considered proprietary to the investigators and/or the sponsoring agency. All Government and non-Government personnel handling this protocol shall exercise EXTREME CARE, to ensure that the information contained herein is NOT DUPLICATED OR DISCLOSED, in whole or part, for any purpose other than to evaluate the protocol, without the written permission of the principal investigator or the sponsoring agency.

I. NON-TECHNICAL SYNOPSIS

The Acute Radiation Syndrome (ARS) develops over time, depending on the amount of radiation absorbed. The ARS is classically divided into 4 sub-syndromes, based on the organ with the most severe damage: hematopoietic (H), gastrointestinal (GI), cutaneous (C) and neurovascular (N). Evidence suggests that these syndromes have some overlap in time and dose range. Efficacy of clinical management should therefore be assessed on multiple organs involved in concurrent sub-sequelae.

The GI syndrome progresses at the same time as the hematopoietic syndrome starts to develop. The GI-ARS is expected to be affected by H-ARS bone marrow aplasia; similarly, changes in the intestinal tract may influence development of H-ARS. Lethality from the GI develops fast (days), and involves desquamation of epithelial mucosa in the intestine, leading to loss of fluids and electrolytes, decreased absorption of nutrients and bacterial translocation. Lethality from H-ARS happens within months, and it is speculated to be due mainly to bone marrow aplasia, susceptibility to sepsis and low platelets count. Some delayed GI damage may be expected. Because of the difference in the mechanism of lethality, recovery from GI-ARS does not guarantee survival from H-ARS. Development of animal models to study the natural history of ARS and test radiation countermeasures remains one of the main bottlenecks for drug development. So far, a very limited number of large animal models are available for countermeasures testing (NHP, dogs and swine); understanding of the natural history of radiation sickness and development of multi-organ failure is still largely incomplete.

We are developing a minipig model of ARS. So far we have optimized implantation and patency of a vascular access port for blood sampling, characterized the H-ARS, and tested the efficacy of G-CSF on survival and bone marrow recovery in the irradiated Gottingen minipig. Signs and symptoms, kinetics of blood cell depletion and recovery, multi-organ dysfunction and histological findings resembled closely what observed in human victims of radiation accidents and in other large animal models (b)(4)

In the G. minipig, the H-ARS occurs between 1.6 and 2.0 Gy. (b)(4)
(b)(4)

Supportive care has been shown to profoundly alter and extend the survival period of human victims and animal models irradiated at hematopoietic doses (4). Standard of care consist of antibiotics, analgesics, antipyretics, fluids/ nutritional support and blood products (5). Because of the integrity of the GI tract at (b)(4) doses, we expect that administration of antibiotics, analgesics and fluids/ nutritional support will greatly improve survival at these doses, although blood products may still be necessary.

The purpose of the current study is to (i) use supportive care to extend the survival to a period of time sufficient to study the potential effects of countermeasures on recovery of bone marrow and the GI

system; (ii) characterize the natural history (NHx) of ARS at those doses; and (iii) to establish a probit curve to allow for future countermeasure drug testing.

The primary data points of the study will be mortality; secondary data points will be standard biomarkers of CBC counts, histology of the GI tract (primarily the small bowel) and bone marrow, and blood and tissue microbiology for broad cultures of suspected infections at necropsy.

II. BACKGROUND

II.1. Military personnel are potentially exposed to radiation during their duty (assembling, disassembling, stockpiling of nuclear weapons, cleanup of facilities, disposal of radioactive materials, civilian defense, etc). So far, only four drugs specifically designated for use in radiation emergency are present in the Strategic National Stockpile. Limited availability of a sufficient number of well-characterized animal models to test radiation countermeasures had been indicated as one of the main bottlenecks for advanced drug development. Developing large animal models for testing of countermeasures to radiation exposure and identification of the patho-physiological mechanisms underlying the development of the acute radiation syndrome (ARS) are fundamental to clinical management and one of the primary objectives of the Department of Defense.

Development of the acute radiation syndrome is dose and time dependent. A continuum in the development of symptoms and pathologies has been proposed over the years, and covers bone marrow (BM), gastrointestinal (GI), cutaneous and CNS syndrome. Although developing concomitantly, GI- and H-ARS have different mechanisms of action and time course. It is expected that mitigation of the GI syndrome will NOT waive the treatment for the hematopoietic syndrome if left untreated. Effects of standard drug treatment for the H-ARS must therefore be determined on the irradiated GI tract.

We recently developed a minipig model for the hematopoietic syndrome, characterized by signs and symptoms, bone marrow aplasia, kinetics of blood cell depletion and recovery similar to what observed in humans, canines and NHPs (b)(4) Sequence of signs and symptoms development, dynamics of hematological cell loss, susceptibility to infection and occurrence of multi-organ dysfunction leading to death, all confirm the validity of this model to study the ARS. Implantation of a subcutaneous vascular access port (VAP) (b)(4) allows for longitudinal sampling of large amounts of blood for CBC/diff counts, clinical chemistry parameters and in vitro assays that could be correlated to survival, gross and histo-pathology and vital signs.

(b)(4)

(b)(4)

The primary data point of the study will be mortality; secondary data-points will be standard biomarkers of CBC counts, histology of the GI tract (primarily the small bowel) and bone marrow (sternum, L1 vertebrae and femur or humerus, and blood and tissue microbiology.

III. OBJECTIVE / HYPOTHESIS

Our preliminary data show that doses ≥ 2 Gy are 100% lethal and that morbidity was reached ≤14 days after exposure to radiation. In the GI tract, villar blunting and fusion are observed, but no loss of crypts or decline in plasma citrulline levels are observed at doses 2.0-3.0 Gy.

Our hypothesis is that use of supportive care at doses 2.0 – 3.0 Gy will increase the survival of irradiated minipigs and that a 30-day survival probit curve in the presence of supportive care can be generated for estimation of lethality and for medical countermeasure (MCM) testing.

We plan to investigate the effect of additive elements of supportive care on 30-day survival starting with doses in the 2.0 - 3.0 Gy range, and to build a probit curve in the presence of an optimized supportive care regimen that will encompass the LD0/30 to the LD100/30.

IV. MILITARY RELEVANCE

According to the DoD Chemical and Biological Defense Program 2009 Annual Report to Congress (6): "Although the overall number of nuclear weapons continues to decline because of Russian and U.S. treaty commitments, the United States anticipates an increase in weapon numbers in China, India, and Pakistan. Motivated by economic and strategic interests, Russia and China (or political entities in each) and North Korea continue to supply technologies and components that are dual use and could support weapons of mass destruction and missile programs, especially in the Middle East and South Asia. Iran continues to develop its enrichment program in defiance of United Nations (U.N.) Security Council resolutions and also continues to build a heavy water reactor in Arak, which will be capable of producing plutonium that could be weaponized. While North Korea has halted portions of its nuclear program, it is possible that it has stockpiled several nuclear weapons from plutonium produced at Yongbyon. Non-nuclear radiological dispersal devices (RDD) and radiological exposure devices (RED) pose a significant potential threat especially in the hands of non-state groups ... Contamination and recovery issues associated with operating in a radiological environment remain significant concerns for military operations and underscore the need for robust detection, protection, and decontamination systems."

Currently, there is no safe and non-toxic radiation countermeasure available. Military personnel are potentially exposed to radiation in various scenarios. Both early and late health effects of radiation exposure are major concerns for the military. Developing countermeasures to radiation exposure is a top priority for the US Department of Defense. Effective countermeasures would expand the options available to field commanders operating Ionizing Radiation (here defined as IR) threat environments, and improve the morale of personnel at risk of exposure to IR. DoD Defense Technology Objective MD.18 states: "Effective mitigation of health consequences [of IR] will (1) reduce casualty load at medical treatment facilities, (2) sustain a more effective operational force after a radiation exposure event, (3) allow commanders to conduct operations in radiation field environments without undue risk of decremented performance of personnel due to acute tissue injury, and (4) reduce the negative psychological impact on personnel tasked to operate in contaminated environments."

An important barrier to advanced development of radiation countermeasures is the paucity of large, long-lived, non-rodent animal models of radiation injury. The only choices at present are NHPs and canines. The advanced evolutionary stage of NHPs, and the expense and danger of working with NHPs, are also disadvantages. The addition of miniature swine to available large animal radiation injury models would facilitate development of promising countermeasures.

V. MATERIALS AND METHODS

V.1. Experimental Design and General Procedures

The purpose of this study is to determine the ability of levels of supportive care to extend the survival of minipigs irradiated at doses 2.0-3.0 Gy to 30 days. Primary data-points of the study will be mortality;

secondary data-points will be CBC counts, histology of the GI tract and bone marrow, tissues and blood microbiology at necropsy.
Male Gottingen minipigs will be obtained from Marshall BioResources, North Rose, NY, at age of 4 months, and at a weight appropriate for healthy animals of that age range. Minipigs will be single-housed but kept in visual contact with each other, and fed twice a day according to their weight, following recommendations from the vendor (Marshall Bioresources), and IAW VSD SOP 2019, Care and Maintenance of Minipigs. Minipigs may be group-housed during quarantine. Age and weight will be strictly controlled, which will avoid possible complications related to increasing weight and fatty mass.

Animal care and use procedures will only be pertormed by trained and certified personnel. Secondary data-points will be standard hematology measurements in peripheral blood (numbers of neutrophils, platelets, erythrocytes, lymphocytes, mean corpuscular hemoglobin, etc.), body temperature, body weight, and occurrence of bloody stools. On day 30-33, each surviving minipig will be euthanized, blood taken for CBC/differentials, and tissues collected for histopathology and tissue repository.

An implantable Micro Identification transponder with programmable Temperature Transponder (Bio Med Data System) will be implanted subcutaneously to monitor body temperature (see section **V.4.3.1. Pre-surgical Provisions).** A Vascular Access Port (VAP) PMID or MID model (Instech Solomon, PA), will be used to improve ease of blood draws and facilitate administration of supportive care (fluids and blood products) (see section **V.4.3.2. Procedure(s)**). In all experiments listed below, VAPs will be implanted 7-14 days after arrival of animals at AFRRI. In case of VAP malfunction, we will access alternative veins (see list of potential sites under section V.4.4.2.Biosamples "Collection of blood samples").

Health of animals will be monitored twice-daily, CBC/differential will be monitored on the days indicated below (except in emergency cases, where blood for CBC counts will be taken by VSD request). These experiments will utilize the husbandry, irradiation, and VAP procedures perfected in the studies performed under previously approved protocols. Animals will be euthanized on day 30-33. Tissues and blood samples may be taken at the time of euthanasia and shared with other investigators for biodosimetric and mechanistic studies.

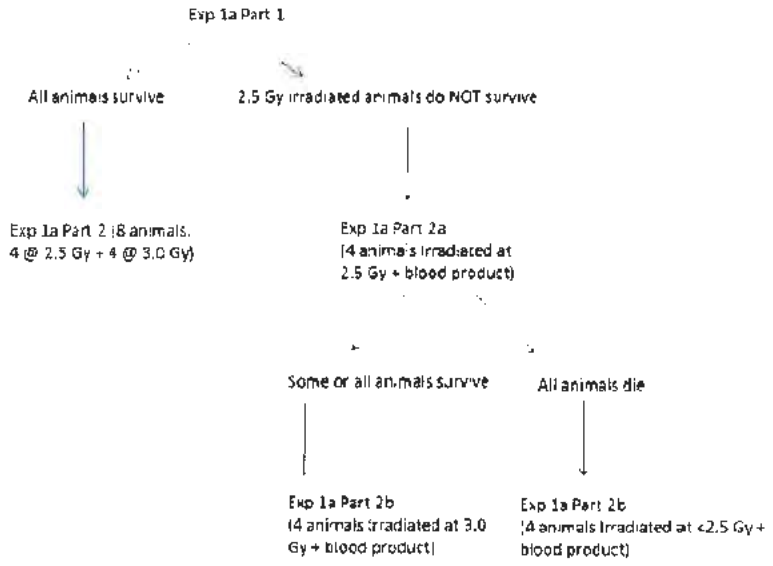
V.1.1. Experiment 1a - Pilot study: preliminary estimate of dose-survival relationship for whole-body gamma-irradiation at GI-light doses (2.0 – 3.0 Gy) in the presence of supportive care (n=16 animals).

Radiation doses of 2 Gy and higher are 100% lethal in the absence of supportive care. This experiment will allow us to obtain data on 30-d survival in the dose range 2.0 – 3.0 Gy in the presence of two levels of supportive care.

We will implant VAPs in male Gottingen minipigs to facilitate blood sampling and administration of supportive care. Three weeks after VAP implantation, we will expose minipigs to irradiation (Cobalt-60, total body, bilateral, 0.6 Gy/min). Two cohorts of 8 animals each will be used for Experiment 1; animals will be irradiated and administered supportive care, as described in Table 1. Survival will be followed for 30 days.

Table 1: study design	Supportive care	Radiation levels			Total no. animals
		2.0 Gy	2.5 Gy	3.0 Gy	
Exp 1a. Part 1	Per harmonized protocol, including VAPs with antibiotics, IV fluids.	4	4		8
Exp 1a. Part 2	As in Part 1, with blood products added		4	4	8
			Total no. of animals Exp 1a		16

Experiment 1a Part 2 is contingent upon results from Experiment 1a Part 1.
We expect that the use of supportive care will extend the survival of all 2.0 Gy irradiated animals to >14 days. If animals irradiated with 2.5 Gy (Experiment 1a Part 1) do not survive >14 days, we will break down to Exp 1a Part 2 into 2 sequential experiments (Exp 1a Part 2a and Exp 1a Part 2b). We will first irradiated 4 animals at 2.5 Gy and we will administered supportive care PLUS blood products added. If these animals survive >14 days, we will proceed to irradiating at 3.0 Gy (Exp 1a. Part 2); if the 2.5 Gy irradiated animals, receiving supportive care and blood, do not survive more than 14 days, the remaining 4 animals in the study will be irradiated at a dose lower than 2.5 Gy and will still be given supportive care WITH blood (see scheme below).



The regimen of supportive care is described in Table 2 (see section **V.4.4. Animal Manipulations**); it follows (b)(4) harmonized minipig protocol guidelines. Whole, anti-coagulated (ADC), blood will be purchased from commercial companies, shipped overnight on wet ice, irradiated, and filtered again prior to administration (see section **V.4.4.9. Animal By-Products**). ADC blood will be infused at a rate of 100 ml/hour, unless otherwise directed by VSD veterinarians.

TABLE 2: Regimen for supportive care

Treatment		Regimen	Admin route	Start/end
Antibiotics	Enrofloxacin (Baytril)	5-7 mg/kg *SID*	*PO* (or *IM* or *IV* if *PO* not possible)	3-30 d
	Amoxicillin	10 mg/kg *BID*	*PO* (or *IM* or *IV* if *PO* not possible)	3-30 d
Antipyretic/anti-inflammatory	Carprofen (Rimadyl)	2.2–4.4 mg/kg *BID*	*IV*, (or *PO* or *IM* if *PO* not possible	3-30 d
Dietary Supplementation	Moistened/liquid food, Metamucil, pumpkin mash			3-30 d
IV fluids	Lactate Ringers Solution	10-30 mL/kg	slow *IV* push (10-20 min)	Start day 3, every 1-3 days*

Blood product support	Whole blood	Up to 7-14 ml/kg, IV**		Once a week, starting on day 7-8.
* Depending on the hydration state of the animal, in consultation with VSD ** Total volume will depend upon HCT and platelets count, in consultation with VSD				

Multiple blood draws may be performed, with the following schedule (with day of irradiation or sham irradiation as "day 0"): blood will be collected -14, -7, -1 day (before irradiation) and on days 0, 1, 2, 3, 7, 10, 14, 17, 20, 23, and 30 (after irradiation). Shifts in blood draw days and reduction in the number of bleeds may be made as contingencies arise. Time points for single blood draws after day 17 after IR may be subject to changes of up to +/-48 hours. Volume of blood taken will not exceed 1% of total blood volume (65ml/kg in case of swine) or 6 ml, whichever is less.

ANIMALS FOR EXPERIMENT 1: 16 animals

V.1.2. Experiment 2 – Mortality probit curve study.

Based on results in Experiment 1, AFRRI will perform a 30-day survival probit study over several radiation levels in the presence of supportive care, as suggested by results from Experiment 1a and in consultation with (b)(4)

The probit curve will be constructed from 7 separate groups of 8 animals each (56 animals), at doses (TBI, 0.6 Gy/min) to be determined based on results of experiment 1a, in the AFRRI cobalt facility. The primary data-points of the study will be 30-day survival; secondary data-points will be CBC counts, histology of the GI tract (small bowel representative areas) and bone marrow (sites noted above), and tissue and blood microbiology at necropsy. The blood draw schedule and supportive care regimen will be those established in pilot study 1.

TOTAL ANIMALS FOR EXPERIMENT 2: 7 doses x 8 animals/dose = 56

TOTAL ANIMALS FOR EXPERIMENT 1+2: 56+16 = 72

V.2. Data Analysis

Survival in Exp 1a Part 1 with supportive care at 2.0 Gy will be compared against historical controls with no supportive care.
Survival in Part 1a with supportive care at 2.5 Gy will be compared against supportive care at 2.0 Gy.
Survival in Part 2 with supportive care and blood products at 2.5 Gy will be compared against supportive care only at 2.5 Gy.
Dose-survival relationship in Part 2 (supportive care and blood products) will be compared across a dose range to be determined based on results of Exp1a Part 1. We will compare groups using the ANOVA test and we will obtain preliminary information on the effect of supportive care and blood products on survival. This information will be used to establish the regimen for the generation of the survival curve.

For the generation of the survival curve, the LD30, 50 and 70 will be estimated using the probit method. This method allows for construction of confidence intervals to describe the precision of the estimated lethal doses. The width of the confidence interval depends on the number of doses, number of animals per dose, and the slope of the dose-response curve, and a narrow interval indicates a more reliable estimate. We propose to use seven doses that are equally spaced, and eight animals per dose. For a dose-response curve with mortality rates of 5, 20, 35, 50, 65, 80 and 95 percent for the seven doses, the expected width of the 95% confidence interval for the LD50 will be 0.57 Gy, and the expected width of the 95% confidence interval for the LD30 and LD70 will be .72 Gy. We anticipate that most dose-response curves will be steeper and therefore will yield even more precise estimates of the LD30, 50 and

70. Expected confidence interval widths are based on the average of 1,000 simulated data sets using the study design and mortality parameters indicated.

V.3. Laboratory Animals Required and Justification

V.3.1. Non-animal Alternatives Considered.

The purpose of this project is to determine the effect of supportive care on survival. There is no computer model or tissue culture that can mimic the effect of radiation on the whole organism and predict lethality. Survival depends on an intricate network of organ cross-talks and cellular microenvironment that cannot be recreated *in vitro*. Consequently, administration of supportive care to cellular components grown *in vitro* will not allow any assessment on survival.

We do not know all of the cell types and tissues involved in radiation injury or how radiation injury causes lethality. The concept of multi-organ failure has been suggested, but how the injured organs affect each other's vital functions is unknown. The present state of the art of tissue culture is still incapable of reproducing the *in vivo* relationships. Computer modeling is similarly limited by lack of full characterization of the biological elements and interactions under study.

These considerations are consistent with the FDA requirement for preclinical research in both small and large mammals before granting approval for drug testing in humans.

V.3.2. Animal Model and Species Justification
We have been developing the Gottingen minipig as an additional large animal model for the study of the ARS and advanced development of radiation countermeasures. Large, long-lived, non-rodent animal models are required for drug studies submitted to the FDA for licensure applications. The current study will help characterize the model in terms of natural history of ARS. The close similarity to humans in anatomy and physiology of organs such as the liver, pancreas, kidney and heart has made the pig the primary species of interest as organ donors for xenographic procedures. Minipigs are routinely used for toxicity testing. As such, further and rapid characterization at physiological, molecular and genetic level of the minipig is likely to occur, thus increasing acceptance of this model and facilitating advanced drug development. Our previous studies have employed male Gottingen minipigs to develop a probit curve; female minipigs of a corresponding age (approximately 4 months old) are more sensitive to irradiation, based on data from other laboratories. Since we are testing the effect of supportive care on survival and we are using our own historical data as one of the terms of comparison, we will continue to use male minipigs for this study.

V.3.3. Laboratory Animals

V.3.3.1. Genus / Species *Sus scrofa domestica*

V.3.3.6. Sex Male

V.3.3.7. Special Considerations NA

V.3.4. Number of Animals Required (by species)

Exp 1+2: 72 animals

V.3.5. Refinement, Reduction, Replacement (3 R's)

V.3.5.1. Refinement
The study data-points currently mandated by the FDA for approval of radiation countermeasures under the Animal Efficacy Rule is mortality. Hence the primary study data-point in our development of Gottingen minipigs as a model for ARS is survival. Moribundity will be used as a surrogate for mortality, and euthanasia will be used in order to minimize pain and distress, using an extensive set of criteria (see animal endpoints, paragraph V.4.5 – Lethargy, weight loss, temperature, respiratory distress, food intake, bleeding etc). Animal care and use procedures will only be performed by trained personnel. We have considerable experience in the care and handling of minipigs. Extensive human interaction every weekday will reduce stress in the animals. Use of slings, topical anesthetics, and the VAPs will minimize distress during blood collections and the animals will be gradually acclimated to the slings for these procedures. VAP design and the blood collection have been refined during multiple iterations of previous studies to minimize discomfort to the animals.

V.3.5.2. Reduction Blood samples obtained from minipigs before irradiation will serve as controls, thus reducing the number of animals required for this study. Use of historical controls will reduce the number of animals needed for this study.

SURGERY
To prepare animals for intubation and VAP implantation, pigs will be sedated with intramuscular tiletamine/zolazepam (Telazol®, 6-8 mg/kg IM; 100 mg/ml, Fort Dodge Laboratories, IA) or ketamine (20 mg/kg *IM*)/xylazine (2 mg/kg *IM*) will be considered as an additional anesthetic option for sedation prior to intubation. Atropine (0.05 mg/kg *IM, SC, IV*; atropine sulfate, Butler, Columbus, OH) may be given to reduce mucosal secretions. Cetacain topical spray will be used to enhance tracheal intubation success

rate. Following tracheal intubation, pigs will be maintained under general anesthesia using isoflurane gas (Abbott Laboratories, North Chicago, *IL*) at a maintenance rate of 1% to 3% and oxygen flow rate of 1 to 2 l/min.

IRRADIATION
Prior to irradiation, animals will be sedated with Telazol® (Telazol, 6-8 mg/kg *IM*; 100 mg/ml, Fort Dodge Laboratories, IA). Alternatively, Telazol® (4.4 mg/kg *IM*), in combination with dexmedtomidine (0.05-0.1 mg/kg *IM*) or ketamine (20 mg/kg *IM*)/xylazine (2 mg/kg *IM*) can also be used for sedation. Atropine (0.05 mg/kg *SC*, *IM* or *IV*; atropine sulfate, Butler, Columbus, OH) or glycopyrrolate (0.01 mg.kg) may be given to reduce mucosal secretions. At the end of the irradiation procedure, once the animals are back in their quarters, dexmedetomidine can be reversed by atipamezole *IM* (same volume as dexmedotmidine) to facilitate recovery.

V.4.1.2.2. Pre- and Post-procedural Provisions

Body weights will be determined at least once prior to treatment, on the first day of treatment, and on days of blood collection. Body temperature will be determined daily between 8 am and 12 noon. The time of each temperature collection will be recorded for each minipig.

IRRADIATION

Pre-Irradiation: Animals will be fasted overnight (approximately 16 – 18 h) and sedated as described above. Once sedated in the VSD animal facility, minipigs will be transported to the AFRRI cobalt facility in an approved, covered transport cage. Heart rate and temperature will be measured prior to irradiation. At least one vet tech or one veterinarian will be present at the time of irradiation. Immediately before irradiation, the vet or vet tech will determine whether or not to administer additional sedative to keep the animal asleep during irradiation.

Irradiation procedure: animals will be strapped in place into slings in polyvinylchloride PVC frames for irradiation. Effect of anesthesia will be monitored in real time through video cameras positioned in the Cobalt waiting area. Minipigs will be removed from the slings once irradiation is completed. Temperature and heart rate will be taken before returning the minipigs to their home cages.

Post-Irradiation: After irradiation, animals will be transported back to their cages, where they will be allowed to recover from sedation under the careful surveillance of VSD and/or research staff who will monitor vital signs and provide thermal support (e.g. Bair Hugger blanket) if necessary. Atipamezole *IM* (same volume as dexmedotmidine) may be used to reverse the anesthetic effect of dexmedetomidine.

BLOOD SAMPLING

Preparation of the animals: for blood draws, lidocain (5%) will be applied topically to the VAP site to minimize discomfort to the animals about 15 minutes before starting the procedure. Animal may be sedated at the time of blood sampling and administration of supportive care with Midazolam (0.1-0.5 mg/kg s.c.or *IM*), or acepromazine (1.1 mg/kg *IM*),10 minutes prior to venous access

After blood draw, animals will be returned to their cages and checked to ensure that the needle puncture wound is closed and the blood has clotted.

V.4.1.2.3. Paralytics N/A

Swine AND radiation sequelae AND alternatives:.....47 results found, not related to this work (mainly related to swine flu, medical imaging, mice models, ablation techniques, medical surgeries, bone marrow transplantation, cancer treatment

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification
Depending upon the irradiation dose irradiated animals die due to compromised immune responses and opportunistic infections. The percentage of surviving animals is the indicator of the efficacy of a countermeasure. We cannot give systemic anesthetic agents to animals after the irradiation procedures, since they are known to interact with the immune system (see references in Jacobsen, K. O., V. Villa, V. L. Miner, and M. H. Whitnall. 2004. Effects of anesthesia and vehicle injection on circulating blood elements in C3H/HeN male mice. *Contemp Top Lab Anim Sci* 43:8-12.), and would confound the correlation of radiation dose with incidence of moribundity, resulting in a waste of animals. However, we are providing supportive care in terms of antibiotics, analgesics, antipyretics, fluids/ nutritional support and blood products to increase survival. Use of supportive care is expected to mitigate the pain associated to the sequelae of irradiation.

V.4.2. Prolonged Restraint
Only short periods of restraint in the sling (<30 minutes) will be necessary for blood collections and the irradiation procedure. To minimize discomfort, we have designed a new type of sling that uses softer, elastic material to support the animal, and utilizes a more efficient restraint design that maintains the animal in place while reducing manipulation by technicians and consequently stress to the animals. After the quarantine period, animals are acclimated to the sling for 5-10 minutes, 2-3 times before initiating blood draws. Acclimation to the sling is very rapid and non-stressful; animals are petted and gently spoken to while restrained. It has been our experience that resting on the sling does not agitate the animal at all.
Animals are anesthetized and transported to the Cobalt Facility holding area before being put into slings for irradiation (<20 minutes). Animals will be kept under continuous observation while in the sling. Slings will be cleaned with a towel after each use, and washed weekly and sanitized.

V.4.3. Surgery

V.4.3.1. Pre-surgical Provisions
Animals will be cared for according to section V.5.1 and IAW VSD SOP 2019, Care and Maintenance of Minipigs. They will be fasted overnight (approximately 16 – 18 h) prior to VAP implantation surgery.
For antibiotic, Cefazolin sodium 20 mg/kg *IV* or ampicillin sodium 10-20 mg/kg *IV* will be given just prior to the surgery, or intra-operatively, for prophylaxis. At the time of surgery, a temperature microtransponder (Implantable Electronic ID Transponder IPPT-300, Bio Medic Data Systems, Seaford, DE) will be

implanted subcutaneously behind the neck, over the shoulder opposite to the site of VAP surgery, to facilitate body temperature measurements.

V.4.3.2. Procedure(s)

VAP SURGERY

VAP catheters (SoloPort subcutaneous access port, either PMID or MID model; Instech Solomon, PA) will be surgically implanted in the right external jugular veins under general anesthesia according to the principles of aseptic surgery. Animals will be lying on their back; vital signs will be taken at regular intervals by vet techs. The catheter tip will be introduced through an 2-3 mm incision in the right jugular vein and advanced to the junction of the external jugular vein and vena cava. Prior to insertion of the VAP catheter, it will be flushed with locking solution (heparin lock flush solution, 100 IU/ml). Prior to securing the VAP catheter within the vein, 1 preplaced 3-0 polydioxanone (PDS) suture (Ethicon, Somerville, NJ) will be used to ligate the vessel just cranial to the insertion point of the catheter tip. A second and third PDS ligature will be placed around the caudal portion of the vessel containing the VAP catheter and retention bead, with 1 ligature on either side of the bead. The port will be secured within the scapular incision site to the underlying musculature by use of 3-0 PDS (Ethicon) at a minimum of 2 of the 5 anchor holes on the port. Catheter function will be confirmed intraoperatively through aspiration of locking solution and withdrawal of a blood sample via the septum. The port reservoir and catheter will be flushed again with 6 ml saline and locked with 3 ml of a heparin lock flush solution (100 IU/ml) all subsequent lock solutions will be heparin (100 IU/ml).

During closure of the surgical sites, special attention will be given to eliminating dead space around the port and around the catheter loop on the neck. The muscle and subcutaneous layers will be closed with 3-0 PDS II (polydioxanone suture; Ethicon). Skin incisions will be closed with 2-0 PDS II (Ethicon) in a continuous intradermal pattern. Tissue glue (VetBond, 3M, St Paul, MN) may be used to help seal surgical sites as necessary to help prevent contamination. Cefazolin sodium 20 mg/kg *IV* or ampicillin sodium 10-20 mg/kg *IV* will be given just prior to the surgery, or intra-operatively, for prophylaxis.

V.4.3.3. Post-surgical Provisions

VAP SURGERY

Postoperative intramuscular buprenorphine (0.01 to 0.02 mg/kg; Buprenex, Reckitt Benckiser, Richmond, VA) or Carprofen (2.2 mg/kg) will be provided foranalgesia before full recovery from anesthesia (12). Additional post-operative analgesia will be given as Carprofen (2.2 mg/kg *PO* BID) for three days starting the day after surgery, or as recommended by an AFRRI veterinarian in consultation with the PI. Alternatively, fentanyl transdermal patch at 5mcg/kg/hr or buprenorphine sustained release 0.12 – 0.27 mg/kg SC for analgesia can be used as determined by the veterinarian. The fentanyl patch, if used, will be applied to a shaved portion of skin and secured. It takes approximately 12 hrs for the fentanyl patch to take effect. Animals will continue to be monitored until fully recovered from anesthesia; they will be returned to their home cage when ambulatory. Supplemental heat may be provided in the home cage post-operatively (e.g. Bair Hugger warm air blanket

After surgery, 25-50 mg/kg trimethoprim-sulfa *PO* (500 mg *PO* for 10 kg pig or 5mg/hg *IM*), *SID*, will be given for 5 days or more as determined by veterinarian to lessen the risk of post-op infection. Alternatively, enrofloxacin 5-10 mg/kg *IV/PO* can be given every 24 hrs for 3-5 days or more if needed as determined by the veterinarian. Convenia 5-10 mg/kg SC may be used as an antibiotic as determined by the veterinarian. The advantage of this antibiotic is that the single injection provides protection against the bacterial infection for several days.
Postsurgical recovery and pain will be monitored twice daily by visual examination of the incisions and overall conditions of the animals. Parameters monitored will be food and water intake, activity, alertness, vocalization, guarding, and response to human contact.

V.4.3.4. Location VSD surgical suite

V.4.3.5. Surgeon
Surgeons will be AFRRI veterinarians.

V.4.3.6. Multiple Major Survival Operative Procedures

V.4.3.6.1. Procedures NA

V.4.3.6.2 Scientific Justification NA

V.4.4. Animal Manipulations

V.4.4.1. Injections
All injections listed in section V.4.1.2.1 will be administered *IM*, sc, using sterile needles (23 – 21 gauge) and syringes, or IV through the VAP using Huber needles or *PO*.

V.4.4.1.1. Pharmaceutical Grade Drugs

Lidocain (5%), topical
Telazol®
Ketamine/xylazine
Atropine atropine sulfate
Cefazolin sodium
Ampicillin sodium
Heparin lock, IV
Saline
Ibuprenorphine
Carprofen
Fentanyl transdermal patch, topical
Metamucil
Enroflaxacin
Baytril
Amoxicillin
Carprofen
Rimadyl
Midazolam
Acepromazine
Cetacain topical spray
All the drugs listed above are ordered from veterinary product distributors by VSD and they all are pharmaceutical grade drugs.
Atipamezole (Antisedan, Pfizer)
Dexmedtomidine (Dexdomitor, Pfizer)
Convenia (Cefovecin sodium, Pfizer)

V.4.4.1.2. Non-Pharmaceutical Grade Drugs NA

V.4.4.2. Biosamples

Collection of blood samples. This has been done routinely in the previous minipig protocols. Each sample will be a maximum of 6 ml in volume or less than 1% total blood volume (whichever is less) and will be collected from the VAP if the device is available and functional. Mean blood volume for pigs is 65-67 ml/kg. At the time of blood draws, our animals are about 10-14 kg in weight. Up to 1% of total blood will be drawn per time point, depending upon the frequency of previous bleeds ((Walter Reed Army Institute

of Research. 1997. Investigators' Handbook. Section I: Handling Techniques and Noninvasive Procedures). We will obtain blood samples using Solomon Instech VAPs; sedation may be used. Collection of samples will be performed with the minipig restrained in a sling; at the same time, we will take vitals. The entire procedure takes less than 30 min. Two types of non-coring Huber needles will be used to access the port through the skin: straight or a right-angled (the needles will be of appropriate length to facilitate uncomplicated blood withdrawal from the VAP reservoir).

Before accessing the VAP site, 5% lidocaine ointment USP will be applied topically 15 min prior to sampling, to minimize animal discomfort Before placement of a non-coring needle, the port injection site will be scrubbed with povidone iodine and 70% isopropyl alcohol until all gross debris is removed (3 to 5 scrubs). To collect a sample, approximately 1 ml fluid will be withdrawn from the catheter and port until blood no longer appears to be mixed with saline. This fluid will be discarded. The blood sample will be collected into a new syringe and placed in appropriate vials for analysis. Next, 3 ml heparin lock flush solution (100 IU/ml) will be infused into the port and catheter as a locking solution. A standard protocol will be followed for obtaining a sample from a problematic catheter. First, external pressure will be applied to the non-coring needle where it entered the port to ensure the tip of the needle is all the way through the septum and into the reservoir. Second, high-pressure turbulent flushing will be attempted with a change in the animal's position. A second person will be needed to extend the neck of the animal by raising it or flexing it away from the side that contains the VAP. Third, the non-coring needle will be replaced; at times the needle may be clotted. Fourth, if the described series of interventions fails to return the VAP to functioning, the sample will be collected from accessible peripheral vessels (e.g., the jugular, saphenous, femoral or ear vein). If required during collection from alternate vessels (peripheral vessels, marginal ear veins, possibly femoral if animals have recovered from irradiation), the animals may be anesthetized for restraint following the recommendations of an AFRRI veterinarian. All procedures will be entered into the experimental record. The next team would repeat the procedures at the next time point in hopes of restoring the VAP to use. Three sequential attempts will be made to rescue the VAP before it is considered nonfunctional. In the previous pilot protocol, collections from the VAPs have been 99% successful.

Animal may be sedated at the time of blood sampling and administration of supportive care with Midazolam (0.1-0.5 mg/kg s.c.or *IM*), or acepromazine (1.1 mg/kg *IM*),10 minutes prior to venous access, or Telazol if necessary

Tissue and histological samples:
Tissue samples, to include organs, blood and hairs, may be taken at the time of euthanasia for slide preparation as well as for frozen tissue repository, and may be shared with other investigators. The cadaver of a few animals may be kept intact and used to establish dosimetry for LINAC for future experiments requiring the use of the LINAC to irradiate minipigs.

V.4.4.3. Adjuvants NA

V.4.4.4. Monoclonal Antibody (MAb) Production NA

V.4.4.5. Animal Identification
Tattoos or ear tags and cage cards/tags

V.4.4.6. Behavioral Studies NA

V.4.4.7. Other Procedures

V.4.4.8. Tissue Sharing Blood, tissues, plasma or urine samples may be provided to other investigators for assays, as experiments permit

V.4.4.9. Animal By-Products

Anticoagulated whole blood will be obtained from Gottingen Minipigs from Marshall Bioresources and shipped overnight to AFRRI on wet ice. When available, blood from siblings of animals that have been irradiated at AFRRI will be provided by Marshall Bioresources. Donors will be tested for the pathogens listed in the Report shown below. These are the same organisms for which the minipigs that enter AFRRI VSD vivarium are being tested. Blood will be irradiated and filtered before transfusion.

Health Monitoring Report According to FELASA Recommendations

NE=not examined

The VAP be used as the primary access for blood support. If the VAP fails, it will be to the discretion of the veterinarians how to best proceed, given the fact that the animals are thrombocytopenic and the superficial veins are not easily accessible. If blood products cannot be administered, animal will still be maintained in the study and will serve as control for survival in the absence of blood products.

V.4.5. Study Endpoint The data-point currently mandated by the FDA for approval of radiation countermeasures under the Animal Efficacy Rule is moribundity or mortality. Moribundity will be used as a surrogate for mortality, and euthanasia will be used in order to minimize pain and distress. Euthanasia will be carried out when any one or combination of the following signs of moribundity are observed and in consultation with AFRRI veterinarians.

Absolute

1. Non responsive, assuming the animal has recovered from anesthesia.
2. Dyspnea
3. Loss of 20% of expected weight (based on Marshall Bio-resources growth chart –weight vs age- and day 0 baseline percentile).

Non-absolute

1. Hyper/hypothermia
2. Anorexia (skip 3 consecutive BID meals)
3. Anemia/pallor, CRT >2 seconds. CRT will be performed behind the ears.
4. Petechiae/ecchymosis
5. Vomiting/diarrhea
6. Lethargy
7. Seizures or vestibular signs (falling, circling or head tilt)
8. Uncontrollable hemorrhage

V.4.6. Euthanasia

Animals will be euthanized according to current American Veterinary Medical Association (AVMA) guidelines. Animals will be anesthetized with Telazol® (6-8 mg/kg *IM*) or ketamine (20 mg/kg *IM*)/xylazine (2 mg/kg *IM*). Animals will then be euthanized with and injected IV Euthasol® (sodium pentobarbital, (1 ml/4.5 kg IV or IC) with Euthasol® (sodium pentobarbital) or another commercial euthanasia solution. Death will be confirmed by VSD veterinarian or veterinary technician via auscultation of the heart, with cessation of sounds for at least 2 minutes or longer as per current SOP. See item V.4.5 for euthanasia criteria before the end of the study

V.5. Veterinary Care

V.5.1. Husbandry Considerations

Minipigs will be housed in stainless steel cages/runs, in tactile, visual and olfactory contact with adjacent animals. During quarantine/acclimation period, up to day of surgery, minipigs may be group-housed. After surgery, they will be singly housed to prevent damage to the VAPs and to allow individual assessment of feed consumption and fecal/urine/blood production. Rooms will be maintained on a 12:12 h light (0600 to 1800) dark cycle with the temperature set to 27 to 29°C and 30% to 70% relative humidity. Commercial diet (Mini-Swine Diet 8753, Harlan Teklad Diets, Madison, WI) will be provided. Water will be provided ad libitum.

V.5.1.1. Study Room

Minipigs will be located at AFRRI for the duration of the study. They will either be in a VSD surgical suite for VAP implantation, in transit to and from the cobalt facility in a covered transport cage, in slings for irradiation in the cobalt facility, or in their housing cage or a VSD prep room for blood collections or euthanasia. They will be housed in stainless-steel cages in an environmentally controlled and continuously monitored animal room as described in Section V.5.1

V.5.1.2. Special Husbandry Provisions
Tap water will be provided ad libitum. Diet will be controlled in accordance with vendor's recommendations so as to prevent excessive weight gain. Metamucil and pumpkin mash will be provided starting at day 7 after irradiation to all animals. Liquid food (i.e. ProMod Liquid Protein) and/or moistened pellet will be offered if observed that the sick animal prefers it to dry food. No treats in the form of marshmallow, peanut butter, crackers will be offered to this animal, since they are on a calorie-restricted diet. Instead, fresh fruits, vegetables, and/or yogurt will be offered daily.

V.5.1.3. Exceptions NA

V.5.2. Veterinary Medical Care

V.5.2.1. Routine Veterinary Medical Care
Animals will be acclimated for approximately 1-2 weeks prior to VAP implantation. Each animal will be observed at least twice daily for evidence of pain or distress. Body weights will be determined at least once prior to implantation, on the day of implantation, and on days of blood collection. The time of each daily temperature collection will be recorded for each animal. Animals will be qualitatively assessed at least twice daily (a.m. and p.m.) for general behavioral status and food consumption by VSD techs and/or research techs. The heart rate will be measured at the time of each blood collection. Stools consistency, left-over food, demeanor and overall animal appearance. If animals look dehydrated, supplemental oral fluids (Pedialyte, etc.) will be provided. Diarrhea has not been observed in minipigs irradiated at doses <8 Gy. Appropriate standard operating procedures will be followed by staff veterinarians in the event of pain or distress.

V.5.2.2. Emergency Veterinary Medical Care Emergency veterinary medical care is available 24/7 and will be provided based on the restrictions approved in earlier sections of this protocol

V.5.3. Environmental Enrichment

V.5.3.1. Enrichment Strategy
Toys and balls will be provided to the minipigs and they will be housed in the same room as conspecifics as per VSD SOPs on enrichment of minipigs. Single housing justifications are filed under IACUC memo regarding animals undergoing surgery and irradiation.

V.5.3.2. Enrichment Restrictions
Minipigs will be single-housed after surgery and after irradiation until completion of the study, to avoid mechanical and infectious complications related to implanted VAPs, but they will be in visual, olfactory and auditory contact with other minipigs in the same room.

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING

Trained personnel are certified by VSD.

NAME	DEGREE	TRAINING	DATE	PROCEDURES	YRS/MOS EXPERIENCE

X. ASSURANCES

Protocol Title: Effect of supportive care on irradiated Gottingen minipigs (*Sus scrofa domestica*)

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made every effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with a qualified individual who evaluated the experimental design with respect to the statistical analysis, and that the minimum number of animals needed for scientific validity will be used.

D. Biohazard / Safety: I have taken into consideration and made the proper coordinations regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R", namely, "Responsibility," which the DOD has embraced for implementing animal use alternatives where feasible and conducting humane and lawful research.

G. Scientific Review: This proposed animal use protocol has received appropriate peer scientific review and is consistent with good scientific research practice.

H. Painful Procedure(s): I **AM / AM NOT** conducting biomedical experiments, which may potentially cause more than momentary or slight pain or distress to animals. If applicable, potential pain and/or distress **WILL / WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

(b)(6)

DOD ANIMAL CARE AND USE STANDARDIZED PROTOCOL FORMAT WITH EMBEDDED INSTRUCTIONS (October 2012)

Reference DOD Instruction 3216.01 & AFRRI Instruction 3216.2H

****

Information requested in the following animal use protocol template reflects the requirements of the Animal Welfare Act Regulations (AWAR), the Guide for the Care and Use of Laboratory Animals, and other applicable Federal regulations and DOD Instructions.

****

This document is intended to be an aid in the preparation of DOD-sponsored animal use protocols. It is a companion document to an identical protocol template that does not have embedded instructions. Either template may be used to format DOD-sponsored animal research proposals; however, reference to the instructions during protocol preparation is highly recommended. If using the template with instructions, the instructions should be deleted prior to submitting the finished protocol for IACUC review. Please use Arial, regular, size 12, black font to prepare the protocol. With the exception of section headings, all paragraphs require a response. Paragraphs that do not apply should be marked N/A. There is no space limitation for responses to the information requested.

Approved standard operating procedures (SOPs) promulgated by the AFRRI Veterinary Sciences Department (VSD) or similar VSD-validated documents that describe specific procedures may be referenced by SOP number and title in lieu of repeating the details in the protocol. However, it is essential to include general descriptions of all animal manipulations to be carried out under the IACUC-approved protocol and to provide details where no approved references are cited. To do otherwise would constitute a breach of statutory regulations. Manipulations not covered in the originally approved protocol can be initiated only after IACUC approval of a formal amendment adding the new procedures. Additionally, Principal Investigators (PIs), or other delegated research personnel, should maintain accurate experimental records and be able to provide an audit trail of animal expenditures and use that correlates with their approved protocol. Protocol PIs will be required to provide this and other information during annual protocol reviews.

Any supporting information that may be of use to the IACUC during its review may be attached to the completed protocol. Adding subparagraphs within the body of the protocol template is permissible, *provided that the numbering sequence of paragraphs in the original standard format is maintained.* In other words, all of the labeled paragraphs and subparagraphs in this template must be retained, with additional information being presented as sub-numbered paragraphs containing information that supports or complements what is requested.

INTELLECTUAL PROPERTY STATEMENT

Research protocols drafted by Government scientists include intellectual property (e.g., concepts, ideas, experimental approaches, etc.), some of which is innovative or original and therefore considered proprietary to the investigators and/or the sponsoring agency. All Government and non-Government personnel handling this protocol shall exercise EXTREME CARE, to ensure that the information contained herein is NOT DUPLICATED OR DISCLOSED, in whole or part, for any purpose other than to evaluate the protocol, without the written permission of the principal investigator or the sponsoring agency.

I. NON-TECHNICAL SYNOPSIS

The Acute Radiation Syndrome (ARS) develops over time, depending on the amount of radiation absorbed. The ARS is classically divided into 4 sub-syndromes, based on the organ with the most severe damage: hematopoietic (H), gastrointestinal (GI), cutaneous (C) and neurovascular (N). Evidence suggests that these syndromes have some overlap in time and dose range. Efficacy of clinical management should therefore be assessed on multiple organs involved in concurrent sub-sequelae.

The GI syndrome progresses at the same time as the hematopoietic syndrome starts to develop. The GI-ARS is expected to be affected by H-ARS bone marrow aplasia; similarly, changes in the intestinal tract may influence development of H-ARS. Lethality from the GI develops fast (days), and involves desquamation of epithelial mucosa in the intestine, leading to loss of fluids and electrolytes, decreased absorption of nutrients and bacterial translocation. Lethality from H-ARS happens within months, and it is speculated to be due mainly to bone marrow aplasia, susceptibility to sepsis and low platelets count. Some delayed GI damage may be expected. Because of the difference in the mechanism of lethality, recovery from GI-ARS does not guarantee survival from H-ARS. Development of animal models to study the natural history of ARS and test radiation countermeasures remains one of the main bottlenecks for drug development. So far, a very limited number of large animal models are available for countermeasures testing (NHP, dogs and swine); understanding of the natural history of radiation sickness and development of multi-organ failure is still largely incomplete.

We are developing a minipig model of ARS. So far we have optimized implantation and patency of a vascular access port for blood sampling, characterized the H-ARS, and tested the efficacy of G-CSF on survival and bone marrow recovery in the irradiated Gottingen minipig. Signs and symptoms, kinetics of blood cell depletion and recovery, multi-organ dysfunction and histological findings resembled closely what observed in human victims of radiation accidents and in other large animal models (b)(4)

In the G. minipig, the H-ARS occurs between 1.6 and 2.0 Gy (b)(4)
(b)(4)

Supportive care has been shown to profoundly alter and extend the survival period of human victims and animal models irradiated at hematopoietic doses (4). Standard of care consist of antibiotics, analgesics, antipyretics, fluids/ nutritional support and blood products (5). Because of the integrity of the GI tract at (b)(4) doses, we expect that administration of antibiotics, analgesics and fluids/ nutritional support will greatly improve survival at these doses, although blood products may still be necessary.

The purpose of the current study is to (i) use supportive care to extend the survival to a period of time sufficient to study the potential effects of countermeasures on recovery of bone marrow and the GI

system; (ii) characterize the natural history (NHx) of ARS at those doses; and (iii) to establish a probit curve to allow for future countermeasure drug testing.

The primary data points of the study will be mortality; secondary data points will be standard biomarkers of CBC counts, histology of the GI tract (primarily the small bowel) and bone marrow, and blood and tissue microbiology for broad cultures of suspected infections at necropsy.

II. BACKGROUND

II.1. Military personnel are potentially exposed to radiation during their duty (assembling, disassembling, stockpiling of nuclear weapons, cleanup of facilities, disposal of radioactive materials, civilian defense, etc). So far, only four drugs specifically designated for use in radiation emergency are present in the Strategic National Stockpile. Limited availability of a sufficient number of well-characterized animal models to test radiation countermeasures had been indicated as one of the main bottlenecks for advanced drug development. Developing large animal models for testing of countermeasures to radiation exposure and identification of the patho-physiological mechanisms underlying the development of the acute radiation syndrome (ARS) are fundamental to clinical management and one of the primary objectives of the Department of Defense.

Development of the acute radiation syndrome is dose and time dependent. A continuum in the development of symptoms and pathologies has been proposed over the years, and covers bone marrow (BM), gastrointestinal (GI), cutaneous and CNS syndrome. Although developing concomitantly, GI- and H-ARS have different mechanisms of action and time course. It is expected that mitigation of the GI syndrome will NOT waive the treatment for the hematopoietic syndrome if left untreated. Effects of standard drug treatment for the H-ARS must therefore be determined on the irradiated GI tract.

We recently developed a minipig model for the hematopoietic syndrome, characterized by signs and symptoms, bone marrow aplasia, kinetics of blood cell depletion and recovery similar to what observed in humans, canines and NHPs (b)(4) Sequence of signs and symptoms development, dynamics of hematological cell loss, susceptibility to infection and occurrence of multi-organ dysfunction leading to death, all confirm the validity of this model to study the ARS. Implantation of a subcutaneous vascular (b)(4) access port (VAP) allows for longitudinal sampling of large amounts of blood for CBC/diff counts, clinical chemistry parameters and in vitro assays that could be correlated to survival, gross and histo-pathology and vital signs.

(b)(4)

The primary data point of the study will be mortality; secondary data-points will be standard biomarkers of CBC counts, histology of the GI tract (primarily the small bowel) and bone marrow (sternum, L1 vertebrae and femur or humerus, and blood and tissue microbiology.

III. OBJECTIVE / HYPOTHESIS

Our preliminary data show that doses ≥ 2 Gy are 100% lethal and that morbidity was reached ≤14 days after exposure to radiation. In the GI tract, villar blunting and fusion are observed, but no loss of crypts or decline in plasma citrulline levels are observed at doses 2.0-3.0 Gy.

Our hypothesis is that use of supportive care at doses 2.0 – 3.0 Gy will increase the survival of irradiated minipigs and that a 30-day survival probit curve in the presence of supportive care can be generated for estimation of lethality and for medical countermeasure (MCM) testing.

We plan to investigate the effect of additive elements of supportive care on 30-day survival starting with doses in the 2.0 - 3.0 Gy range, and to build a probit curve in the presence of an optimized supportive care regimen that will encompass the LD0/30 to the LD100/30.

IV. MILITARY RELEVANCE

According to the DoD Chemical and Biological Defense Program 2009 Annual Report to Congress (6): "Although the overall number of nuclear weapons continues to decline because of Russian and U.S. treaty commitments, the United States anticipates an increase in weapon numbers in China, India, and Pakistan. Motivated by economic and strategic interests, Russia and China (or political entities in each) and North Korea continue to supply technologies and components that are dual use and could support weapons of mass destruction and missile programs, especially in the Middle East and South Asia. Iran continues to develop its enrichment program in defiance of United Nations (U.N.) Security Council resolutions and also continues to build a heavy water reactor in Arak, which will be capable of producing plutonium that could be weaponized. While North Korea has halted portions of its nuclear program, it is possible that it has stockpiled several nuclear weapons from plutonium produced at Yongbyon. Non-nuclear radiological dispersal devices (RDD) and radiological exposure devices (RED) pose a significant potential threat especially in the hands of non-state groups ... Contamination and recovery issues associated with operating in a radiological environment remain significant concerns for military operations and underscore the need for robust detection, protection, and decontamination systems."

Currently, there is no safe and non-toxic radiation countermeasure available. Military personnel are potentially exposed to radiation in various scenarios. Both early and late health effects of radiation exposure are major concerns for the military. Developing countermeasures to radiation exposure is a top priority for the US Department of Defense. Effective countermeasures would expand the options available to field commanders operating Ionizing Radiation (here defined as IR) threat environments, and improve the morale of personnel at risk of exposure to IR. DoD Defense Technology Objective MD.18 states: "Effective mitigation of health consequences [of IR] will (1) reduce casualty load at medical treatment facilities, (2) sustain a more effective operational force after a radiation exposure event, (3) allow commanders to conduct operations in radiation field environments without undue risk of decremented performance of personnel due to acute tissue injury, and (4) reduce the negative psychological impact on personnel tasked to operate in contaminated environments."

An important barrier to advanced development of radiation countermeasures is the paucity of large, long-lived, non-rodent animal models of radiation injury. The only choices at present are NHPs and canines. The advanced evolutionary stage of NHPs, and the expense and danger of working with NHPs, are also disadvantages. The addition of miniature swine to available large animal radiation injury models would facilitate development of promising countermeasures.

V. MATERIALS AND METHODS

V.1. Experimental Design and General Procedures

The purpose of this study is to determine the ability of levels of supportive care to extend the survival of minipigs irradiated at doses 2.0-3.0 Gy to 30 days. Primary data-points of the study will be mortality;

secondary data-points will be CBC counts, histology of the GI tract and bone marrow, tissues and blood microbiology at necropsy.
Male Gottingen minipigs will be obtained from Marshall BioResources, North Rose, NY, at age of 4 months, and at a weight appropriate for healthy animals of that age range. Minipigs will be single-housed but kept in visual contact with each other, and fed twice a day according to their weight, following recommendations from the vendor (Marshall Bioresources), and IAW VSD SOP 2019, Care and Maintenance of Minipigs. Minipigs may be group-housed during quarantine. Age and weight will be strictly controlled, which will avoid possible complications related to increasing weight and fatty mass.

Animal care and use procedures will only be pertormed by trained and certified personnel. Secondary data-points will be standard hematology measurements in peripheral blood (numbers of neutrophils, platelets, erythrocytes, lymphocytes, mean corpuscular hemoglobin, etc.), body temperature, body weight, and occurrence of bloody stools. On day 30-33, each surviving minipig will be euthanized, blood taken for CBC/differentials, and tissues collected for histopathology and tissue repository.

An implantable Micro Identification transponder with programmable Temperature Transponder (Bio Med Data System) will be implanted subcutaneously to monitor body temperature (see section **V.4.3.1. Pre-surgical Provisions).** A Vascular Access Port (VAP) PMID or MID model (Instech Solomon, PA), will be used to improve ease of blood draws and facilitate administration of supportive care (fluids and blood products) (see section **V.4.3.2. Procedure(s)**). In all experiments listed below, VAPs will be implanted 7-14 days after arrival of animals at AFRRI. In case of VAP malfunction, we will access alternative veins (see list of potential sites under section V.4.4.2.Biosamples "Collection of blood samples").

Health of animals will be monitored twice-daily, CBC/differential will be monitored on the days indicated below (except in emergency cases, where blood for CBC counts will be taken by VSD request). These experiments will utilize the husbandry, irradiation, and VAP procedures perfected in the studies performed under previously approved protocols. Animals will be euthanized on day 30-33. Tissues and blood samples may be taken at the time of euthanasia and shared with other investigators for biodosimetric and mechanistic studies.

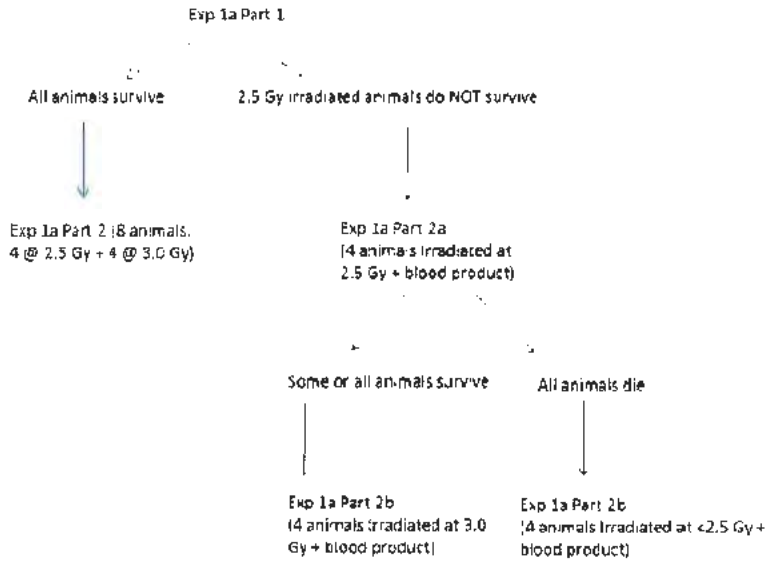
V.1.1. Experiment 1a - Pilot study: preliminary estimate of dose-survival relationship for whole-body gamma-irradiation at GI-light doses (2.0 – 3.0 Gy) in the presence of supportive care (n=16 animals).

Radiation doses of 2 Gy and higher are 100% lethal in the absence of supportive care. This experiment will allow us to obtain data on 30-d survival in the dose range 2.0 – 3.0 Gy in the presence of two levels of supportive care.

We will implant VAPs in male Gottingen minipigs to facilitate blood sampling and administration of supportive care. Three weeks after VAP implantation, we will expose minipigs to irradiation (Cobalt-60, total body, bilateral, 0.6 Gy/min). Two cohorts of 8 animals each will be used for Experiment 1; animals will be irradiated and administered supportive care, as described in Table 1. Survival will be followed for 30 days.

Table 1: study design	Supportive care	Radiation levels			Total no. animals
		2.0 Gy	2.5 Gy	3.0 Gy	
Exp 1a. Part 1	Per harmonized protocol, including VAPs with antibiotics, IV fluids.	4	4		8
Exp 1a. Part 2	As in Part 1, with blood products added		4	4	8
			Total no. of animals Exp 1a		16

Experiment 1a Part 2 is contingent upon results from Experiment 1a Part 1.
We expect that the use of supportive care will extend the survival of all 2.0 Gy irradiated animals to >14 days. If animals irradiated with 2.5 Gy (Experiment 1a Part 1) do not survive >14 days, we will break down to Exp 1a Part 2 into 2 sequential experiments (Exp 1a Part 2a and Exp 1a Part 2b). We will first irradiated 4 animals at 2.5 Gy and we will administered supportive care PLUS blood products added. If these animals survive >14 days, we will proceed to irradiating at 3.0 Gy (Exp 1a. Part 2); if the 2.5 Gy irradiated animals, receiving supportive care and blood, do not survive more than 14 days, the remaining 4 animals in the study will be irradiated at a dose lower than 2.5 Gy and will still be given supportive care WITH blood (see scheme below).



The regimen of supportive care is described in Table 2 (see section **V.4.4. Animal Manipulations**); it follows (b)(4) harmonized minipig protocol guidelines. Whole, anti-coagulated (ADC), blood will be purchased from commercial companies, shipped overnight on wet ice, irradiated, and filtered again prior to administration (see section **V.4.4.9. Animal By-Products**). ADC blood will be infused at a rate of 100 ml/hour, unless otherwise directed by VSD veterinarians.

TABLE 2: Regimen for supportive care

Treatment		Regimen	Admin route	Start/end
Antibiotics	Enrofloxacin (Baytril)	5-7 mg/kg *SID*	*PO* (or *IM* or *IV* if *PO* not possible)	3-30 d
	Amoxicillin	10 mg/kg *BID*	*PO* (or *IM* or *IV* if *PO* not possible)	3-30 d
Antipyretic/anti-inflammatory	Carprofen (Rimadyl)	2.2–4.4 mg/kg *BID*	*IV*, (or *PO* or *IM* if *PO* not possible	3-30 d
Dietary Supplementation	Moistened/liquid food, Metamucil, pumpkin mash			3-30 d
IV fluids	Lactate Ringers Solution	10-30 mL/kg	slow *IV* push (10-20 min)	Start day 3, every 1-3 days*

Blood product support	Whole blood	Up to 7-14 ml/kg, IV**		Once a week, starting on day 7-8.
* Depending on the hydration state of the animal, in consultation with VSD ** Total volume will depend upon HCT and platelets count, in consultation with VSD				

Multiple blood draws may be performed, with the following schedule (with day of irradiation or sham irradiation as "day 0"): blood will be collected -14, -7, -1 day (before irradiation) and on days 0, 1, 2, 3, 7, 10, 14, 17, 20, 23, and 30 (after irradiation). Shifts in blood draw days and reduction in the number of bleeds may be made as contingencies arise. Time points for single blood draws after day 17 after IR may be subject to changes of up to +/-48 hours. Volume of blood taken will not exceed 1% of total blood volume (65ml/kg in case of swine) or 6 ml, whichever is less.

ANIMALS FOR EXPERIMENT 1: 16 animals

V.1.2. Experiment 2 – Mortality probit curve study.

Based on results in Experiment 1, AFRRI will perform a 30-day survival probit study over several radiation levels in the presence of supportive care, as suggested by results from Experiment 1a and in consultation with (b)(4)

The probit curve will be constructed from 7 separate groups of 8 animals each (56 animals), at doses (TBI, 0.6 Gy/min) to be determined based on results of experiment 1a, in the AFRRI cobalt facility. The primary data-points of the study will be 30-day survival; secondary data-points will be CBC counts, histology of the GI tract (small bowel representative areas) and bone marrow (sites noted above), and tissue and blood microbiology at necropsy. The blood draw schedule and supportive care regimen will be those established in pilot study 1.

TOTAL ANIMALS FOR EXPERIMENT 2: 7 doses x 8 animals/dose = 56

TOTAL ANIMALS FOR EXPERIMENT 1+2: 56+16 = 72

V.2. Data Analysis

Survival in Exp 1a Part 1 with supportive care at 2.0 Gy will be compared against historical controls with no supportive care.
Survival in Part 1a with supportive care at 2.5 Gy will be compared against supportive care at 2.0 Gy.
Survival in Part 2 with supportive care and blood products at 2.5 Gy will be compared against supportive care only at 2.5 Gy.
Dose-survival relationship in Part 2 (supportive care and blood products) will be compared across a dose range to be determined based on results of Exp1a Part 1. We will compare groups using the ANOVA test and we will obtain preliminary information on the effect of supportive care and blood products on survival. This information will be used to establish the regimen for the generation of the survival curve.

For the generation of the survival curve, the LD30, 50 and 70 will be estimated using the probit method. This method allows for construction of confidence intervals to describe the precision of the estimated lethal doses. The width of the confidence interval depends on the number of doses, number of animals per dose, and the slope of the dose-response curve, and a narrow interval indicates a more reliable estimate. We propose to use seven doses that are equally spaced, and eight animals per dose. For a dose-response curve with mortality rates of 5, 20, 35, 50, 65, 80 and 95 percent for the seven doses, the expected width of the 95% confidence interval for the LD50 will be 0.57 Gy, and the expected width of the 95% confidence interval for the LD30 and LD70 will be .72 Gy. We anticipate that most dose-response curves will be steeper and therefore will yield even more precise estimates of the LD30, 50 and

70. Expected confidence interval widths are based on the average of 1,000 simulated data sets using the study design and mortality parameters indicated.

V.3. Laboratory Animals Required and Justification

V.3.1. Non-animal Alternatives Considered.

The purpose of this project is to determine the effect of supportive care on survival. There is no computer model or tissue culture that can mimic the effect of radiation on the whole organism and predict lethality. Survival depends on an intricate network of organ cross-talks and cellular microenvironment that cannot be recreated *in vitro*. Consequently, administration of supportive care to cellular components grown *in vitro* will not allow any assessment on survival.

We do not know all of the cell types and tissues involved in radiation injury or how radiation injury causes lethality. The concept of multi-organ failure has been suggested, but how the injured organs affect each other's vital functions is unknown. The present state of the art of tissue culture is still incapable of reproducing the *in vivo* relationships. Computer modeling is similarly limited by lack of full characterization of the biological elements and interactions under study.

These considerations are consistent with the FDA requirement for preclinical research in both small and large mammals before granting approval for drug testing in humans.

V.3.2. Animal Model and Species Justification
We have been developing the Gottingen minipig as an additional large animal model for the study of the ARS and advanced development of radiation countermeasures. Large, long-lived, non-rodent animal models are required for drug studies submitted to the FDA for licensure applications. The current study will help characterize the model in terms of natural history of ARS. The close similarity to humans in anatomy and physiology of organs such as the liver, pancreas, kidney and heart has made the pig the primary species of interest as organ donors for xenographic procedures. Minipigs are routinely used for toxicity testing. As such, further and rapid characterization at physiological, molecular and genetic level of the minipig is likely to occur, thus increasing acceptance of this model and facilitating advanced drug development. Our previous studies have employed male Gottingen minipigs to develop a probit curve; female minipigs of a corresponding age (approximately 4 months old) are more sensitive to irradiation, based on data from other laboratories. Since we are testing the effect of supportive care on survival and we are using our own historical data as one of the terms of comparison, we will continue to use male minipigs for this study.

V.3.3.6. Sex Male

V.3.3.7. Special Considerations NA

V.3.4. Number of Animals Required (by species)

Exp 1+2: 72 animals

V.3.5. Refinement, Reduction, Replacement (3 R's)

V.3.5.1. Refinement
The study data-points currently mandated by the FDA for approval of radiation countermeasures under the Animal Efficacy Rule is mortality. Hence the primary study data-point in our development of Gottingen minipigs as a model for ARS is survival. Moribundity will be used as a surrogate for mortality, and euthanasia will be used in order to minimize pain and distress, using an extensive set of criteria (see animal endpoints, paragraph V.4.5 – Lethargy, weight loss, temperature, respiratory distress, food intake, bleeding etc). Animal care and use procedures will only be performed by trained personnel. We have considerable experience in the care and handling of minipigs. Extensive human interaction every weekday will reduce stress in the animals. Use of slings, topical anesthetics, and the VAPs will minimize distress during blood collections and the animals will be gradually acclimated to the slings for these procedures. VAP design and the blood collection have been refined during multiple iterations of previous studies to minimize discomfort to the animals.

V.3.5.2. Reduction Blood samples obtained from minipigs before irradiation will serve as controls, thus reducing the number of animals required for this study. Use of historical controls will reduce the number of animals needed for this study.

2	Mortality probit curve study with supportive care			56	56
Totals:				72	72

V.4.1.2. Pain Relief / Prevention

V.4.1.2.1. Anesthesia / Analgesia / Tranquilization

SURGERY
To prepare animals for intubation and VAP implantation, pigs will be sedated with intramuscular tiletamine/zolazepam (Telazol®, 6-8 mg/kg IM; 100 mg/ml, Fort Dodge Laboratories, IA) or ketamine (20 mg/kg *IM*)/xylazine (2 mg/kg *IM*) will be considered as an additional anesthetic option for sedation prior to intubation. Atropine (0.05 mg/kg *IM, SC, IV*; atropine sulfate, Butler, Columbus, OH) may be given to reduce mucosal secretions. Cetacain topical spray will be used to enhance tracheal intubation success

rate. Following tracheal intubation, pigs will be maintained under general anesthesia using isoflurane gas (Abbott Laboratories, North Chicago, *IL*) at a maintenance rate of 1% to 3% and oxygen flow rate of 1 to 2 l/min.

IRRADIATION
Prior to irradiation, animals will be sedated with Telazol® (Telazol, 6-8 mg/kg *IM*; 100 mg/ml, Fort Dodge Laboratories, IA). Alternatively, Telazol® (4.4 mg/kg *IM*), in combination with dexmedtomidine (0.05-0.1 mg/kg *IM*) or ketamine (20 mg/kg *IM*)/xylazine (2 mg/kg *IM*) can also be used for sedation. Atropine (0.05 mg/kg *SC*, *IM* or *IV*; atropine sulfate, Butler, Columbus, OH) or glycopyrrolate (0.01 mg.kg) may be given to reduce mucosal secretions. At the end of the irradiation procedure, once the animals are back in their quarters, dexmedetomidine can be reversed by atipamezole *IM* (same volume as dexmedotmidine) to facilitate recovery.

V.4.1.2.2. Pre- and Post-procedural Provisions

Body weights will be determined at least once prior to treatment, on the first day of treatment, and on days of blood collection. Body temperature will be determined daily between 8 am and 12 noon. The time of each temperature collection will be recorded for each minipig.

IRRADIATION

Pre-Irradiation: Animals will be fasted overnight (approximately 16 – 18 h) and sedated as described above. Once sedated in the VSD animal facility, minipigs will be transported to the AFRRI cobalt facility in an approved, covered transport cage. Heart rate and temperature will be measured prior to irradiation. At least one vet tech or one veterinarian will be present at the time of irradiation. Immediately before irradiation, the vet or vet tech will determine whether or not to administer additional sedative to keep the animal asleep during irradiation.

Irradiation procedure: animals will be strapped in place into slings in polyvinylchloride PVC frames for irradiation. Effect of anesthesia will be monitored in real time through video cameras positioned in the Cobalt waiting area. Minipigs will be removed from the slings once irradiation is completed. Temperature and heart rate will be taken before returning the minipigs to their home cages.

Post-Irradiation: After irradiation, animals will be transported back to their cages, where they will be allowed to recover from sedation under the careful surveillance of VSD and/or research staff who will monitor vital signs and provide thermal support (e.g. Bair Hugger blanket) if necessary. Atipamezole *IM* (same volume as dexmedotmidine) may be used to reverse the anesthetic effect of dexmedetomidine.

BLOOD SAMPLING

Preparation of the animals: for blood draws, lidocain (5%) will be applied topically to the VAP site to minimize discomfort to the animals about 15 minutes before starting the procedure. Animal may be sedated at the time of blood sampling and administration of supportive care with Midazolam (0.1-0.5 mg/kg s.c.or *IM*), or acepromazine (1.1 mg/kg *IM*),10 minutes prior to venous access

After blood draw, animals will be returned to their cages and checked to ensure that the needle puncture wound is closed and the blood has clotted.

Swine AND radiation sequelae AND alternatives:.....47 results found, not related to this work (mainly related to swine flu, medical imaging, mice models, ablation techniques, medical surgeries, bone marrow transplantation, cancer treatment

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification
Depending upon the irradiation dose irradiated animals die due to compromised immune responses and opportunistic infections. The percentage of surviving animals is the indicator of the efficacy of a countermeasure. We cannot give systemic anesthetic agents to animals after the irradiation procedures, since they are known to interact with the immune system (see references in Jacobsen, K. O., V. Villa, V. L. Miner, and M. H. Whitnall. 2004. Effects of anesthesia and vehicle injection on circulating blood elements in C3H/HeN male mice. *Contemp Top Lab Anim Sci* 43:8-12.), and would confound the correlation of radiation dose with incidence of moribundity, resulting in a waste of animals. However, we are providing supportive care in terms of antibiotics, analgesics, antipyretics, fluids/ nutritional support and blood products to increase survival. Use of supportive care is expected to mitigate the pain associated to the sequelae of irradiation.

V.4.2. Prolonged Restraint
Only short periods of restraint in the sling (<30 minutes) will be necessary for blood collections and the irradiation procedure. To minimize discomfort, we have designed a new type of sling that uses softer, elastic material to support the animal, and utilizes a more efficient restraint design that maintains the animal in place while reducing manipulation by technicians and consequently stress to the animals. After the quarantine period, animals are acclimated to the sling for 5-10 minutes, 2-3 times before initiating blood draws. Acclimation to the sling is very rapid and non-stressful; animals are petted and gently spoken to while restrained. It has been our experience that resting on the sling does not agitate the animal at all.
Animals are anesthetized and transported to the Cobalt Facility holding area before being put into slings for irradiation (<20 minutes). Animals will be kept under continuous observation while in the sling. Slings will be cleaned with a towel after each use, and washed weekly and sanitized.

V.4.3. Surgery

V.4.3.1. Pre-surgical Provisions
Animals will be cared for according to section V.5.1 and IAW VSD SOP 2019, Care and Maintenance of Minipigs. They will be fasted overnight (approximately 16 – 18 h) prior to VAP implantation surgery.
For antibiotic, Cefazolin sodium 20 mg/kg *IV* or ampicillin sodium 10-20 mg/kg *IV* will be given just prior to the surgery, or intra-operatively, for prophylaxis. At the time of surgery, a temperature microtransponder (Implantable Electronic ID Transponder IPPT-300, Bio Medic Data Systems, Seaford, DE) will be

implanted subcutaneously behind the neck, over the shoulder opposite to the site of VAP surgery, to facilitate body temperature measurements.

V.4.3.2. Procedure(s)

VAP SURGERY

VAP catheters (SoloPort subcutaneous access port, either PMID or MID model; Instech Solomon, PA) will be surgically implanted in the right external jugular veins under general anesthesia according to the principles of aseptic surgery. Animals will be lying on their back; vital signs will be taken at regular intervals by vet techs. The catheter tip will be introduced through an 2-3 mm incision in the right jugular vein and advanced to the junction of the external jugular vein and vena cava. Prior to insertion of the VAP catheter, it will be flushed with locking solution (heparin lock flush solution, 100 IU/ml). Prior to securing the VAP catheter within the vein, 1 preplaced 3-0 polydioxanone (PDS) suture (Ethicon, Somerville, NJ) will be used to ligate the vessel just cranial to the insertion point of the catheter tip. A second and third PDS ligature will be placed around the caudal portion of the vessel containing the VAP catheter and retention bead, with 1 ligature on either side of the bead. The port will be secured within the scapular incision site to the underlying musculature by use of 3-0 PDS (Ethicon) at a minimum of 2 of the 5 anchor holes on the port. Catheter function will be confirmed intraoperatively through aspiration of locking solution and withdrawal of a blood sample via the septum. The port reservoir and catheter will be flushed again with 6 ml saline and locked with 3 ml of a heparin lock flush solution (100 IU/ml) all subsequent lock solutions will be heparin (100 IU/ml).

During closure of the surgical sites, special attention will be given to eliminating dead space around the port and around the catheter loop on the neck. The muscle and subcutaneous layers will be closed with 3-0 PDS II (polydioxanone suture; Ethicon). Skin incisions will be closed with 2-0 PDS II (Ethicon) in a continuous intradermal pattern. Tissue glue (VetBond, 3M, St Paul, MN) may be used to help seal surgical sites as necessary to help prevent contamination. Cefazolin sodium 20 mg/kg *IV* or ampicillin sodium 10-20 mg/kg *IV* will be given just prior to the surgery, or intra-operatively, for prophylaxis.

V.4.3.3. Post-surgical Provisions

VAP SURGERY

Postoperative intramuscular buprenorphine (0.01 to 0.02 mg/kg; Buprenex, Reckitt Benckiser, Richmond, VA) or Carprofen (2.2 mg/kg) will be provided foranalgesia before full recovery from anesthesia (12). Additional post-operative analgesia will be given as Carprofen (2.2 mg/kg *PO* BID) for three days starting the day after surgery, or as recommended by an AFRRI veterinarian in consultation with the PI. Alternatively, fentanyl transdermal patch at 5mcg/kg/hr or buprenorphine sustained release 0.12 – 0.27 mg/kg SC for analgesia can be used as determined by the veterinarian. The fentanyl patch, if used, will be applied to a shaved portion of skin and secured. It takes approximately 12 hrs for the fentanyl patch to take effect. Animals will continue to be monitored until fully recovered from anesthesia; they will be returned to their home cage when ambulatory. Supplemental heat may be provided in the home cage post-operatively (e.g. Bair Hugger warm air blanket

After surgery, 25-50 mg/kg trimethoprim-sulfa *PO* (500 mg *PO* for 10 kg pig or 5mg/hg *IM*), *SID*, will be given for 5 days or more as determined by veterinarian to lessen the risk of post-op infection. Alternatively, enrofloxacin 5-10 mg/kg *IV/PO* can be given every 24 hrs for 3-5 days or more if needed as determined by the veterinarian. Convenia 5-10 mg/kg SC may be used as an antibiotic as determined by the veterinarian. The advantage of this antibiotic is that the single injection provides protection against the bacterial infection for several days.
Postsurgical recovery and pain will be monitored twice daily by visual examination of the incisions and overall conditions of the animals. Parameters monitored will be food and water intake, activity, alertness, vocalization, guarding, and response to human contact.

V.4.3.4. Location VSD surgical suite

V.4.3.5. Surgeon
Surgeons will be AFRRI veterinarians.

V.4.3.6. Multiple Major Survival Operative Procedures

V.4.3.6.1. Procedures NA

V.4.3.6.2 Scientific Justification NA

V.4.4. Animal Manipulations

V.4.4.1. Injections
All injections listed in section V.4.1.2.1 will be administered *IM*, sc, using sterile needles (23 – 21 gauge) and syringes, or IV through the VAP using Huber needles or *PO*.

V.4.4.1.1. Pharmaceutical Grade Drugs

Lidocain (5%), topical
Telazol®
Ketamine/xylazine
Atropine atropine sulfate
Cefazolin sodium
Ampicillin sodium
Heparin lock, IV
Saline
Ibuprenorphine
Carprofen
Fentanyl transdermal patch, topical
Metamucil
Enroflaxacin
Baytril
Amoxicillin
Carprofen
Rimadyl
Midazolam
Acepromazine
Cetacain topical spray
All the drugs listed above are ordered from veterinary product distributors by VSD and they all are pharmaceutical grade drugs.
Atipamezole (Antisedan, Pfizer)
Dexmedtomidine (Dexdomitor, Pfizer)
Convenia (Cefovecin sodium, Pfizer)

V.4.4.1.2. Non-Pharmaceutical Grade Drugs NA

V.4.4.2. Biosamples

Collection of blood samples. This has been done routinely in the previous minipig protocols. Each sample will be a maximum of 6 ml in volume or less than 1% total blood volume (whichever is less) and will be collected from the VAP if the device is available and functional. Mean blood volume for pigs is 65-67 ml/kg. At the time of blood draws, our animals are about 10-14 kg in weight. Up to 1% of total blood will be drawn per time point, depending upon the frequency of previous bleeds ((Walter Reed Army Institute

of Research. 1997. Investigators' Handbook. Section I: Handling Techniques and Noninvasive Procedures). We will obtain blood samples using Solomon Instech VAPs; sedation may be used. Collection of samples will be performed with the minipig restrained in a sling; at the same time, we will take vitals. The entire procedure takes less than 30 min. Two types of non-coring Huber needles will be used to access the port through the skin: straight or a right-angled (the needles will be of appropriate length to facilitate uncomplicated blood withdrawal from the VAP reservoir).

Before accessing the VAP site, 5% lidocaine ointment USP will be applied topically 15 min prior to sampling, to minimize animal discomfort Before placement of a non-coring needle, the port injection site will be scrubbed with povidone iodine and 70% isopropyl alcohol until all gross debris is removed (3 to 5 scrubs). To collect a sample, approximately 1 ml fluid will be withdrawn from the catheter and port until blood no longer appears to be mixed with saline. This fluid will be discarded. The blood sample will be collected into a new syringe and placed in appropriate vials for analysis. Next, 3 ml heparin lock flush solution (100 IU/ml) will be infused into the port and catheter as a locking solution. A standard protocol will be followed for obtaining a sample from a problematic catheter. First, external pressure will be applied to the non-coring needle where it entered the port to ensure the tip of the needle is all the way through the septum and into the reservoir. Second, high-pressure turbulent flushing will be attempted with a change in the animal's position. A second person will be needed to extend the neck of the animal by raising it or flexing it away from the side that contains the VAP. Third, the non-coring needle will be replaced; at times the needle may be clotted. Fourth, if the described series of interventions fails to return the VAP to functioning, the sample will be collected from accessible peripheral vessels (e.g., the jugular, saphenous, femoral or ear vein). If required during collection from alternate vessels (peripheral vessels, marginal ear veins, possibly femoral if animals have recovered from irradiation), the animals may be anesthetized for restraint following the recommendations of an AFRRI veterinarian. All procedures will be entered into the experimental record. The next team would repeat the procedures at the next time point in hopes of restoring the VAP to use. Three sequential attempts will be made to rescue the VAP before it is considered nonfunctional. In the previous pilot protocol, collections from the VAPs have been 99% successful.

Animal may be sedated at the time of blood sampling and administration of supportive care with Midazolam (0.1-0.5 mg/kg s.c.or *IM*), or acepromazine (1.1 mg/kg *IM*),10 minutes prior to venous access, or Telazol if necessary

Tissue and histological samples:
Tissue samples, to include organs, blood and hairs, may be taken at the time of euthanasia for slide preparation as well as for frozen tissue repository, and may be shared with other investigators. The cadaver of a few animals may be kept intact and used to establish dosimetry for LINAC for future experiments requiring the use of the LINAC to irradiate minipigs.

V.4.4.3. Adjuvants NA

V.4.4.4. Monoclonal Antibody (MAb) Production NA

V.4.4.5. Animal Identification
Tattoos or ear tags and cage cards/tags

V.4.4.6. Behavioral Studies NA

V.4.4.7. Other Procedures

V.4.4.8. Tissue Sharing Blood, tissues, plasma or urine samples may be provided to other investigators for assays, as experiments permit

V.4.4.9. Animal By-Products

Anticoagulated whole blood will be obtained from Gottingen Minipigs from Marshall Bioresources and shipped overnight to AFRRI on wet ice. When available, blood from siblings of animals that have been irradiated at AFRRI will be provided by Marshall Bioresources. Donors will be tested for the pathogens listed in the Report shown below. These are the same organisms for which the minipigs that enter AFRRI VSD vivarium are being tested. Blood will be irradiated and filtered before transfusion.

The VAP be used as the primary access for blood support. If the VAP fails, it will be to the discretion of the veterinarians how to best proceed, given the fact that the animals are thrombocytopenic and the superficial veins are not easily accessible. If blood products cannot be administered, animal will still be maintained in the study and will serve as control for survival in the absence of blood products.

V.4.5. Study Endpoint The data-point currently mandated by the FDA for approval of radiation countermeasures under the Animal Efficacy Rule is moribundity or mortality. Moribundity will be used as a surrogate for mortality, and euthanasia will be used in order to minimize pain and distress. Euthanasia will be carried out when any one or combination of the following signs of moribundity are observed and in consultation with AFRRI veterinarians.

Absolute

1. Non responsive, assuming the animal has recovered from anesthesia.
2. Dyspnea
3. Loss of 20% of expected weight (based on Marshall Bio-resources growth chart –weight vs age- and day 0 baseline percentile).

Non-absolute

1. Hyper/hypothermia
2. Anorexia (skip 3 consecutive BID meals)
3. Anemia/pallor, CRT >2 seconds. CRT will be performed behind the ears.
4. Petechiae/ecchymosis
5. Vomiting/diarrhea
6. Lethargy
7. Seizures or vestibular signs (falling, circling or head tilt)
8. Uncontrollable hemorrhage

V.4.6. Euthanasia

Animals will be euthanized according to current American Veterinary Medical Association (AVMA) guidelines. Animals will be anesthetized with Telazol® (6-8 mg/kg *IM*) or ketamine (20 mg/kg *IM*)/xylazine (2 mg/kg *IM*). Animals will then be euthanized with and injected IV Euthasol® (sodium pentobarbital, (1 ml/4.5 kg IV or IC) with Euthasol® (sodium pentobarbital) or another commercial euthanasia solution. Death will be confirmed by VSD veterinarian or veterinary technician via auscultation of the heart, with cessation of sounds for at least 2 minutes or longer as per current SOP. See item V.4.5 for euthanasia criteria before the end of the study

V.5. Veterinary Care

V.5.1. Husbandry Considerations

Minipigs will be housed in stainless steel cages/runs, in tactile, visual and olfactory contact with adjacent animals. During quarantine/acclimation period, up to day of surgery, minipigs may be group-housed. After surgery, they will be singly housed to prevent damage to the VAPs and to allow individual assessment of feed consumption and fecal/urine/blood production. Rooms will be maintained on a 12:12 h light (0600 to 1800) dark cycle with the temperature set to 27 to 29°C and 30% to 70% relative humidity. Commercial diet (Mini-Swine Diet 8753, Harlan Teklad Diets, Madison, WI) will be provided. Water will be provided ad libitum.

V.5.1.1. Study Room

Minipigs will be located at AFRRI for the duration of the study. They will either be in a VSD surgical suite for VAP implantation, in transit to and from the cobalt facility in a covered transport cage, in slings for irradiation in the cobalt facility, or in their housing cage or a VSD prep room for blood collections or euthanasia. They will be housed in stainless-steel cages in an environmentally controlled and continuously monitored animal room as described in Section V.5.1

V.5.1.2. Special Husbandry Provisions
Tap water will be provided ad libitum. Diet will be controlled in accordance with vendor's recommendations so as to prevent excessive weight gain. Metamucil and pumpkin mash will be provided starting at day 7 after irradiation to all animals. Liquid food (i.e. ProMod Liquid Protein) and/or moistened pellet will be offered if observed that the sick animal prefers it to dry food. No treats in the form of marshmallow, peanut butter, crackers will be offered to this animal, since they are on a calorie-restricted diet. Instead, fresh fruits, vegetables, and/or yogurt will be offered daily.

V.5.1.3. Exceptions NA

V.5.2. Veterinary Medical Care

V.5.2.1. Routine Veterinary Medical Care
Animals will be acclimated for approximately 1-2 weeks prior to VAP implantation. Each animal will be observed at least twice daily for evidence of pain or distress. Body weights will be determined at least once prior to implantation, on the day of implantation, and on days of blood collection. The time of each daily temperature collection will be recorded for each animal. Animals will be qualitatively assessed at least twice daily (a.m. and p.m.) for general behavioral status and food consumption by VSD techs and/or research techs. The heart rate will be measured at the time of each blood collection. Stools consistency, left-over food, demeanor and overall animal appearance. If animals look dehydrated, supplemental oral fluids (Pedialyte, etc.) will be provided. Diarrhea has not been observed in minipigs irradiated at doses <8 Gy. Appropriate standard operating procedures will be followed by staff veterinarians in the event of pain or distress.

V.5.2.2. Emergency Veterinary Medical Care Emergency veterinary medical care is available 24/7 and will be provided based on the restrictions approved in earlier sections of this protocol

V.5.3. Environmental Enrichment

V.5.3.1. Enrichment Strategy
Toys and balls will be provided to the minipigs and they will be housed in the same room as conspecifics as per VSD SOPs on enrichment of minipigs. Single housing justifications are filed under IACUC memo regarding animals undergoing surgery and irradiation.

V.5.3.2. Enrichment Restrictions
Minipigs will be single-housed after surgery and after irradiation until completion of the study, to avoid mechanical and infectious complications related to implanted VAPs, but they will be in visual, olfactory and auditory contact with other minipigs in the same room.

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING

Trained personnel are certified by VSD.

NAME	DEGREE	TRAINING	DATE	PROCEDURES	YRS/MOS EXPERIENCE
(b)(6)				1, 3b, 4, 5, 7 (drug delivery)	(b)(6)
				1 through 5

X. ASSURANCES

Protocol Title: Effect of supportive care on irradiated Gottingen minipigs (*Sus scrofa domestica*)

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made every effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with a qualified individual who evaluated the experimental design with respect to the statistical analysis, and that the minimum number of animals needed for scientific validity will be used.

D. Biohazard / Safety: I have taken into consideration and made the proper coordinations regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R", namely, "Responsibility," which the DOD has embraced for implementing animal use alternatives where feasible and conducting humane and lawful research.

G. Scientific Review: This proposed animal use protocol has received appropriate peer scientific review and is consistent with good scientific research practice.

H. Painful Procedure(s): I **AM / AM NOT** conducting biomedical experiments, which may potentially cause more than momentary or slight pain or distress to animals. If applicable, potential pain and/or distress **WILL / WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

DOD ANIMAL CARE AND USE STANDARDIZED PROTOCOL FORMAT WITH EMBEDDED INSTRUCTIONS (October 2012)

Reference DOD Instruction 3216.01 & AFRRI Instruction 3216.2H

****

Information requested in the following animal use protocol template reflects the requirements of the Animal Welfare Act Regulations (AWAR), the Guide for the Care and Use of Laboratory Animals, and other applicable Federal regulations and DOD Instructions.

****

This document is intended to be an aid in the preparation of DOD-sponsored animal use protocols. It is a companion document to an identical protocol template that does not have embedded instructions. Either template may be used to format DOD-sponsored animal research proposals; however, reference to the instructions during protocol preparation is highly recommended. If using the template with instructions, the instructions should be deleted prior to submitting the finished protocol for IACUC review. Please use Arial, regular, size 12, black font to prepare the protocol. With the exception of section headings, all paragraphs require a response. Paragraphs that do not apply should be marked N/A. There is no space limitation for responses to the information requested.

Approved standard operating procedures (SOPs) promulgated by the AFRRI Veterinary Sciences Department (VSD) or similar VSD-validated documents that describe specific procedures may be referenced by SOP number and title in lieu of repeating the details in the protocol. However, it is essential to include general descriptions of all animal manipulations to be carried out under the IACUC-approved protocol and to provide details where no approved references are cited. To do otherwise would constitute a breach of statutory regulations. Manipulations not covered in the originally approved protocol can be initiated only after IACUC approval of a formal amendment adding the new procedures. Additionally, Principal Investigators (PIs), or other delegated research personnel, should maintain accurate experimental records and be able to provide an audit trail of animal expenditures and use that correlates with their approved protocol. Protocol PIs will be required to provide this and other information during annual protocol reviews.

Any supporting information that may be of use to the IACUC during its review may be attached to the completed protocol. Adding subparagraphs within the body of the protocol template is permissible, *provided that the numbering sequence of paragraphs in the original standard format is maintained.* In other words, all of the labeled paragraphs and subparagraphs in this template must be retained, with additional information being presented as sub-numbered paragraphs containing information that supports or complements what is requested.

INTELLECTUAL PROPERTY STATEMENT

Research protocols drafted by Government scientists include intellectual property (e.g., concepts, ideas, experimental approaches, etc.), some of which is innovative or original and therefore considered proprietary to the investigators and/or the sponsoring agency. All Government and non-Government personnel handling this protocol shall exercise EXTREME CARE to ensure that the information contained herein is NOT DUPLICATED OR DISCLOSED, in whole or part, for any purpose other than to evaluate the protocol, without the written permission of the principal investigator or the sponsoring agency.

AFRRI SCIENTIFIC RESEARCH PROTOCOL NUMBER: (b)(6)

I. NON-TECHNICAL SYNOPSIS: Hematopoietic syndrome resulting from exposure to ionizing radiation is characterized by loss of neutrophils, an important white blood cell component, as well as significant suppression to overall immunity and increased susceptibility to opportunistic infection with high potential for mortality. Failure to recover from infection can be attributed to a lack of circulating white blood cells and reduced proliferative capacity of the bone marrow to compensate this loss by increasing progenitors. In addition, thrombocytopenia (decreased platelet counts) resulting from radiation exposure may lead to uncontrolled internal bleeding. Recently, (b)(4) (b)(4) (b)(4) that specifically increased platelets five-fold compared to normal untreated mice. Further, the drug significantly increased 30-day survival in mice exposed to a lethal dose of ionizing radiation. We have an ongoing IACUC protocol (b)(6) that evaluates the drug (b)(4) as a radiation countermeasure in a large mammal model, specifically, nonhuman primates (NHP). We have shown that various drug doses (b)(4) injected subcutaneously increased platelet levels in NHPs and caused no drug-related deleterious effects. Finally, in a recent ongoing experiment a dose of (b)(4) of the drug injected as a single subcutaneous administration significantly increased platelets by two-fold in unirradiated animals without causing any obvious toxicity. Therefore, survival studies at this highest dose are in progress.

The present protocol involves evaluating this drug (b)(4) in lethally irradiated NHPs that are provided supportive care such as antibiotics and blood transfusions in order to increase post-irradiation survival. We hypothesize that administration of the drug (b)(4) being specific to control of thrombocytopenia will enhance survival significantly. For example, if without supportive care animals survive 7 Gy, then with support the survivable dose may increase to 8 Gy and with support care plus (b)(4) it may increase to 9 Gy.

II. BACKGROUND

II.1. Background

Increased mortality due to bone marrow failure: Because of increasing terrorist activity and dissemination of nuclear materials, the chances of military or civilian personnel being exposed to dirty bombs or improvised nuclear devices have risen dramatically in recent years. The prevailing sentiment of U.S. government officials is that it is a matter of when, not if, an attack with radiological or nuclear weapons will take place. The nation needs to be prepared for this eventuality. Acute radiation syndrome results when whole-body ionizing radiation causes defective hematopoiesis as a function of the radiation dose, dose-rate, and radiation quality. Defective hematopoiesis due to ionizing radiation exposure results in a decline in all blood cell counts for several weeks postirradiation. The primary cause of death during the early phase of the radiation-induced hematopoietic syndrome is multi-organ failure (MoF) resulting from opportunistic infection due to a decline in the numbers of neutrophils (neutropenia) and increased translocation of bacteria across the damaged gastrointestinal mucosa. Sepsis and shock result in eventual multiple organ failure and death. Acute radiation syndrome is often complicated by hemorrhage as a consequence of thrombocytopenia resulting in reduced circulating platelets (Stickney et al., 2007).

Current treatment strategies: The current treatment practice for radiation victims is the off-label administration of marrow growth factors such as G-CSF, which are not yet approved for this purpose by the Food and Drug Administration (FDA), and must be used under the constant supervision of physicians because of possible adverse effects. Other agents that may be used for radiation victims, like potassium iodide (KI), Prussian Blue, Calcium DTPA, and Zinc DTPA, address the internalization of specific radioactive isotopes, not the general injury caused by external exposure to ionizing radiation. For example, KI is used to prevent thyroid cancers by competing with internalized radioactive iodine for binding sites. Other potential radiation countermeasures still are in the pre-clinical research stage. There is a pressing need to develop countermeasures to ionizing radiation that will have a general beneficial effect on blood-forming tissues and immune competence. In order to expedite such studies that cannot be undertaken in humans due to ethical reasons, the FDA has established "the animal efficacy rule" (FDA 2002). Under this rule, pivotal efficacy studies in large-animal models, such as use of rhesus macaques exposed to lethal doses of ionizing radiation, are appropriate to supportive approval of novel radiation countermeasure agents for human use.

Role of Thrombocytopenia: The effectiveness of drugs to reduce or eliminate deleterious biological effects of ionizing radiation depends on their effectiveness in controlling neutropenia, thrombocytopenia, and possibly anemia. Off-label drugs such as growth factors (GFs), G-CSF, and GM-CSF are available to treat neutropenia but no such treatment exists for thrombocytopenia (although thrombopoietic GFs interleukin 11 (IL-11) and thrombopoietin (TPO) have been studied). However, administration of (b)(4) (b)(4) formulations resulted in adverse effects in clinical trials (Kuter 2002, 2007, 2008) although they were effective in increasing circulating platelets. (b)(4) (b)(4) have been successful in clinics for treating idiopathic thrombocytopenia purpura (ITP).

Brief background information on (b)(4) as a radiation countermeasure agent:

The drug for the present study will be synthesized by incorporation of a 14-amino-acid peptide into a fully human antibody (PA83) scaffold at both the end region of the light chains and the hinge region of the heavy chain. Therefore, control antibody without the 14-amino-acid ligand will be used as vehicle or PBS vehicle used for suspending (b)(4) in the present experiment.

We evaluated (b)(4) (b)(4) as a radiation countermeasure in mice. (b)(4) (b)(4) (b)(4),(b)(6) Briefly, thrombopoietin (TPO) receptor agonists lacking sequence homology to TPO were designed by grafting a known peptide sequence into the hinge and/or kappa constant regions of a human anti-anthrax antibody. Some of these proteins were equipotent to TPO in stimulating cMpl-r activity *in vitro*, and in increasing platelet levels *in vivo*. (b)(4) (b)(4) (b)(4) (2 mg/kg, SC) administered once either 24 h pre- or 6 h post-TBI showed superior protection to five once daily doses given pre- or post-TBI. Prophylactic administration (69 to 94% 30-day survival) was superior to therapeutic schedules (60% 30-day survival). (b)(4) conferred significant survival benefit ($p<0.01$) when administered 4 days before or even 12 h after exposure, and across a dose range of 0.1 to 8 mg/kg. The dose reduction factors (DRFs) with a single dose of 1 mg/kg (b)(4) 24 h pre- or 12 h post-TBI were 1.32 and 1.11, respectively ($p<0.0001$). Furthermore, (b)(4) increased bone marrow cellularity, megakaryocytic development, and accelerated multi-lineage hematopoietic recovery in irradiated mice demonstrating the potential of (b)(4) as both protectant and mitigator in the event of a radiological incident.

Ongoing nonhuman primate studies using (b)(4) Currently, we are evaluating the (b)(4) as a radiation countermeasure in the rhesus macaque. This project is different from the current protocol because approved protocol animals are provided minimal supportive care. They are not provided antibiotics or blood products for enhancing their postirradiation survival; instead, they will be humanely euthanized on meeting appropriate observational criteria after irradiation. Preliminary results show that the drug (b)(4) is effective in enhancing platelets although to a lesser degree than seen in mice (see figures in preliminary section).

Impact of the present protocol: The use of antibiotics, fluids, blood products, analgesics, and nutrition is the "standard of care" for patients exposed to cytotoxic chemotherapy and cytotoxic "conditioning" for stem cell transplant (Smith, et al. 2006, Timmer-Bonte et al. 2005). These measures will be similar for personnel exposed to myelosuppressive and potentially lethal doses of radiation (as reviewed in Farese 2013). It is known that medical management alone can significantly enhance survival of animals exposed to lethal doses of uniform total-body irradiation (TBI) (Jackson et al. 1959; MacVittie et al. 2005).

(b)(4) proposed a pilot 60-day efficacy study of subcutaneous administration of a radiation countermeasure agent (b)(4) to treat hematopoietic syndrome of the Acute Radiation Syndrome (H-ARS) following a lethal dose (70/60) of ionizing radiation in rhesus macaques. The relationship between

supportive care and lethality under H-ARS has been shown previously in canines (MacVittie et al. 1991; MacVittie et al. 2005). Recently, Farese et al. (2012) have established a NHP model with supportive care. The model defines radiation dose- and time-dependent relationships for mortality and major signs of morbidity to include other organ damage that may contribute to morbidity and mortality in nonhuman primate exposed to total-body radiation and with supportive care, which has also been defined as medical management.

Drug to be tested in the current protocol: (b)(4) (b)(4),(b)(6)

Broad scope of the current protocol: The current protocol will use both males and females and the proportion will be dependent on availability. The design will consist of exposure of both control- (vehicle-PBS) and (b)(4) PBS) treated groups to a LD70/60 dose of cobalt-60 gamma radiation with supportive care, including blood transfusion and standard care for neutropenic and thrombocytopenic events in irradiated NHPs. We will be using PBS vehicle instead of the control antibody because in our ongoing NHP project we have shown that control antibody has no effect on circulating platelets and the fact that the (b)(4) formulation is in PBS.

Sixty (60) day post-irradiation survival will be the primary endpoint, with several secondary end points: Neutrophil-related parameters: absolute neutrophil counts (ANC) nadir, duration of neutropenia (days), ANC <500/μL and <100/μL, and time to recovery to ANC ≥500/μL and ≥1,000/μL, for three consecutive days. It also will include platelet (PLT)-related parameters such as PLT nadir, duration of thrombocytopenia (days), PLT <20,000/μL, time to recovery to PLT count ≥20,000/μL, for three consecutive days. Additional parameters that will be evaluated but not restricted to are: a. Number of whole-blood transfusions; b. Number of days with fever (temp ≥103 °F); c. Incidence of documented infection (confirmed by aerobic culture of blood or tissues or histopathology); and d. Incidence of febrile neutropenia (FN).

Summary: Results reveal that although there are specific hits in certain combinations, there is no duplication in terms of the work that is being proposed. References such as those from Farese, McVittie as well as Graham and others have been incorporated in specific sections of the present protocol.

III. OBJECTIVE/HYPOTHESIS: The primary objective of the present study is to evaluate the beneficial effects radiation countermeasures (such as [(b)(4)] as measured by significant increase in 60-day post-irradiation survival with the drug being administered post-irradiation (as a mitigator) in conjunction with supportive care (such as intravenous fluids, blood products, nutrition and antibiotics). A significant increase is considered 30% higher than the control treatment modality.
Secondary objective(s) include studying hematopoietic recovery including neutrophil and platelet profiles, mean survival time (MST), incidence of febrile neutropenia (FN), and infection, number of blood transfusions, and incidence and severity of diarrhea in the rhesus macaque.

We hypothesize that [(b)(4)] will be an effective radiation countermeasure in NHPs and that drug administration postirradiation will enhance survival over and above the protection provided by standard supportive care for immunosuppression (such as antibiotics and blood product administration).

IV. MILITARY RELEVANCE: Nuclear proliferation, terrorist activity, and the distribution of nuclear and radioactive materials through underground networks make incidents involving radiation injuries increasingly likely. As explained in a recent Department of Defense (DOD) Report to Congress (www.acq.osd.mil/cp), Al-Qaeda is known to have ambitious plans to acquire or develop nuclear weapons and is receptive to outside nuclear assistance. That group has attempted to purchase enriched uranium. Nuclear fuel-cycle and weapons-related technologies have spread to the point that additional states may be able to produce sufficient fissile material to develop radiological weapons. In view of the increasing likelihood of radiation exposure and bioterrorism, the need for field-able radiation countermeasures has been recognized as a high priority by the DOD.

Advances in radiation countermeasure strategies may enable military forces to operate, when required, in nuclear or radioactive combat environments while minimizing both short- and long-term consequences of exposure to ionizing radiation. Accurate casualty-prediction models promote effective command decisions and force structure planning. Advanced biological dosimetry methodology is used in triage, treatment decisions, and risk assessment. Together, the results of the three research thrusts improve therapeutic strategies for the treatment and prevention of early and long-term health effects and mitigate the risks to our personnel (AFRRI mission statement).

V. MATERIALS AND METHODS

V.1. Experimental Design and General Procedures

The experimental design for the proposed nonhuman primate (NHP) studies will include:

1) Specific aim 1: Establish LD70/30 radiation dose with supportive care
Fliedner TM et al. (2001) describe various categories of supportive care for patients exposed to accidental irradiation or in their acute phase of treatment. Four response categories (RC) have been identified. In RC1, outpatient care is recommended and patients are allowed to recover on their own and no supportive care is deemed necessary. In RC2, patients are provided supportive care and substitution (blood component therapy). The present protocol and this specific experiment are compatible with the "RC2" clinical supportive care regimen. The RC3 group would require stimulation with growth factors in addition to whatever is applicable to be RC2 supportive. Thus, "RC3" clinical supportive could be equated to the next specific aim, which involves treatment with medical countermeasure agents (in this case, (b)(4) . In the fourth category, RC4, patients would require stem cell transplantation in addition to supportive care.

In a recent publication (Farese et al. 2012), supportive care for NHPs subjected to ionizing radiation has been reviewed extensively. The article indicates that supportive care studies such as the one being proposed here have been studied only to a limited extent. There have been no studies with cobalt-60 gamma radiation exposure and supportive care. However, based on historical data and that of Farese, et al. (2012), a dose modifying factor of 1.13 is suggested for supportive care studies. For example, if the LD70/60 dose is 7.0 Gy, then with supportive care the LD70/60 dose will be 8.0 Gy."

Farese et al. (2012) have provided LD50/60 and probit curve for supportive care in animals exposed to radiation from a 6 MV linear accelerator (LINAC). However, because the source and type of exposure differ from AFRRI's cobalt-60 pool type facility, the current protocol will test 3 radiation doses between 7.2 Gy and 8.5 Gy for establishing preliminary data on survival with supportive care. Although large numbers of animals are required to establish dose response relationship (DRR), the observations from these sets will be used to identify an initial radiation dose for studying the effect of (b)(4)

Animals required: 3 radiation doses × 3 animals per radiation = 9 animals

2) Specific aim 2: Study the effect of postirradiation drug treatment on 60-day survival in animals receiving LD70/60 gamma radiation @ 0.6 Gy/min and supportive care.

Preliminary Dose Escalation Study (DES) data with (b)(4) in NHPs at AFRRI:
The research strategy for the present study is to extend our significant observations in (b)(4) irradiated mice to a large-animal model. Use of a large-animal model is essential as per the FDA's "animal efficacy rule" for advancement of radiation countermeasures to humans. We showed recently (ongoing research at AFRRI supported by (b)(4) (b)(4) that the proposed drug (b)(4) is safe for use with NHPs. Figure 1 shows preliminary data on enhancement of platelet (1A) in unirradiated animals administered a single sc injection of 8 mg/kg (b)(4) as well as changes in neutrophil counts (1B).

Figure 2 shows that a single sc injection of (b)(4) administered either pre-irradiation (-24 h) or post-irradiation (+24 h) resulted in survival and recovery of circulating platelets by day 18. The non-drug treated animal, the control, although survived had a prolonged recovery (day 29). It is important to note that animals in these experiments received minimal supportive care which is different from the current protocol under review.

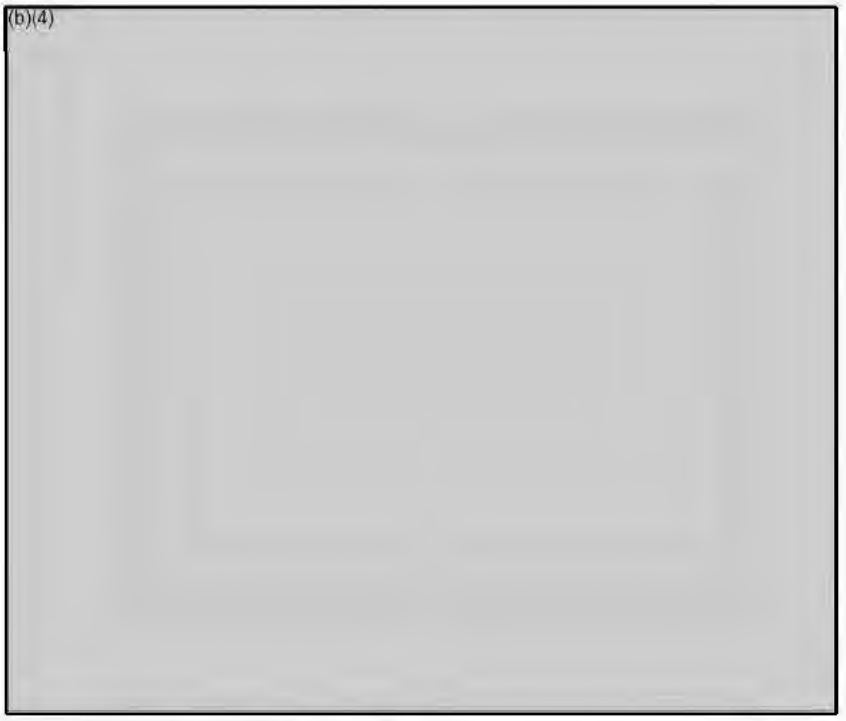

Figure 3 shows that a single sc injection of (b)(4) administered either pre-irradiation (-24 h) or post-irradiation (+24 h) resulted in recovery of circulating platelets (Figure 3A) and neutrophils (Figure 3B) in irradiated (7 Gy). The control animal did not survive.

Note: The proposed IACUC protocol differs significantly from the ongoing NHP study (Figures 1–3) because all animals other than blood donor animals in this proposed protocol will receive supportive care.

Therefore, the following survival experiments will be conducted:
Specific aim 2, Experiment 1: In this preliminary experiment, we will evaluate two time points for drug administration. The drug will be administered either +6 h or +24 h postirradiation.

PBS vehicle (used to dilute/suspend (b)(4)	3 animals
(b)(4) administered sc 6 h postirradiation	3 animals
administered sc 24 h postirradiation	3 animals

Total: 9 animals

Specific aim 2, experiment 2: Because this is a confirmatory experiment, only one time point that is optimum in response will be used (for example, either +6 h or +24 h) for drug administration.

PBS vehicle (used to dilute/suspend (b)(4)	3 animals
(b)(4) administered sc either 6 h or 24 h	6 animals

Total: 9 animals

3) Specific aim 3: Multiple-dose regimen for (b)(4)

(b)(4)
(b)(4) is effective when administered as a once-weekly injection for 8 weeks to idiopathic thrombocytopenia purpura (ITP). Our drug has not been tested as a multiple regimen although experiments are in progress at AFRRI (ongoing NHP protocol), we propose a three-dose regimen for (b)(4) Three doses to be used are based on the potential benefit to animals recovering from radiation damage. We hypothesize that the drug will be effective in enhancing postirradiation survival of irradiated NHPs in a three-drug regimen, as shown below.

Specific aim 3, experiment 1: Two-dosing regimens with three injections will be tested to evaluate improved drug efficacy using the multiple injection modality. The drug for these studies will be a nontoxic drug dose of 8 mg/kg.

The experimental groups for this experiment are as follows:

Control:	PBS vehicle administered +6 h, +4 d, and +10 d	3 animals
Regimen 1:	(b)(4) administered +6 h, +4 d, and +10 d	3 animals
Regimen 2:	administered +24 h, +4 d, and +10 d	3 animals
		Total: 9 animals

Specific aim 3, experiment 2: This is a confirmatory experiment in which one of the two regimens described above will be used.
The experimental groups are:

1. PBS vehicle administered as per one of the schedules: 3 animals
2. (b)(4) administered as regimen 1 or Regimen 2: 6 animals

(Regimen 1 = +6 h, +96 h, and +240 h. Regimen 2 = +24 h, +96 h, and +240 h)

Total: 9 animals

4) Blood donor program: There will be 10 donor animals that will provide whole blood for transfusion. Total: 10 animals

Total number of animals for all studies: specific aim 1 (9) + specific aim 2 (18) + specific aim 3 (18) + donor (10) = 55. Male donor animals will be preferred due to their larger size. Therefore, total number of males = 33 and females = 22.

Drug procurement:

(b)(4)

(b)(4) The drug has been well characterized by the company.

Irradiation

Animals will not be fed in the morning of radiation in order to control potential radiation-induced vomiting. Animals will be anesthetized with ketamine (10–15 mg/kg IM) prior to transferring them to NHP-specific radiation plexiglass boxes. Additional anesthetic will be administered at the discretion of the veterinarian or veterinary technician to keep the primates sedated during irradiation and transport. Animals will be transported to the radiation facility in covered carriers. For all radiation studies, a radiation dose rate of 0.6 Gy/min will be used. Radiation dose used will be 7.2–8.5 Gy (LD70/60), a dose that will result in mortality of 70% of the irradiated NHP over a 60-day period with supportive care (described elsewhere). It should be noted that specific LD70/60 dose for NHPs using AFRRI's cobalt-60 gamma radiation facility with supportive care as described elsewhere in the protocol has not been determined. Farese et al. (2012) have demonstrated that supportive care itself provides a certain

degree of protection and increased survival. Therefore, PI has projected a wide range of radiation doses for dose-determination studies.

Description of supportive care:

The supportive care can be divided into 4 major categories: 1) intravenous (parenteral) fluids, 2) blood products, 3) nutrition, and 4) antibiotics. Details on the indication/criteria for specific supportive care are provided in Section V-4: technical methods. A brief description of each supportive care category is described below:

Nutrition: This will consist of Bio-Serv-certified Rhesus Liquidiets or similar products and will be administered to control weight loss or anorexia.

Parenteral fluids: Ringer's lactate and Ringer's lactate with 5% dextrose in equal volumes or other products such as hetastarch will be administered to control dehydration.

Blood products: Whole blood or packed red blood cells will be obtained via a commercial source (see appendix), obtained from donor animals and irradiated at 2500 cGy with a source in USUHS prior to transfusion and will be administered when thrombocytopenia and anemia are observed.

Antibiotic(s) administration: Based on evidence of infection (neutropenia, and febrile neutronpenia), various antibiotics (a broad spectrum or those specific to Gram positive or Gram negative organisms) may be used. Blood samples will be collected prior to antibiotic treatment and 10 days after ceasing antibiotic treatment to assess bacterial load.

General: In addition to these supports, animals may receive analgesics and non-steroidal anti-inflammatory drugs as well as antidiarrheal agents.
See Table 1 for details concerning supportive care.

V.2. Data Analysis

Survival study:

For this protocol we will use the criteria of declaring a countermeasure or test agent as promising if a 30 percent increase in survival is observed over the vehicle-treated group exposed to a radiation dose producing approximately 70% (±10%) mortality over 60 days postirradiation. This criterion is based on discussions with AFRRI and (b)(4) in terms of assessing a drug for use in mass-casualty scenarios involving civilian populations, and has been used extensively in mouse studies to evaluate potential radiation countermeasures. The Exact Log Rank test (one-tailed) and the generalized Savage (Mantel-Cox) procedure (BMDP Statistical Software Inc., CA, available with an institutional statistician) will be used to compare survival of drug-treated and control groups in the radiation-survival experiments. In order to obtain the number of animals, data on human volunteers using a similar class of compound (b)(4) in terms of enhancement of platelets and variation between subjects also was considered (b)(4) (b)(4) Further, multiple blood draws from the same animal over a 60-day period also was considered. Experiments with nine NHPs per group have 80% of power to detect significant differences between the drug-treated and vehicle controls. For these calculations, we assumed that type-1 error is controlled at 5%, type-2 error is 20% and sample sizes are equal between the different groups.

Demographic, hematology, vital signs, blood counts, chemistry, antibody levels, and cytokine estimations will be compiled as summarized using mean, standard deviation, minimum, median and maximum values.

Vital signs will be summarized using descriptive statistics at each assessment time for each treatment group.

V.3. Laboratory Animals Required and Justification

V.3.1. Non-animal Alternatives Considered: The effectiveness of drugs such as (b)(4) against radiation cannot be adequately assessed using current *in vitro* technologies. The U.S. FDA recognizes the ethical considerations involved in testing the efficacy of radioprotective drugs in humans. Therefore, the FDA requires preclinical drug assessments (safety and efficacy) to be performed using both small and large animal models (FDA 2002) prior to granting approval for safety testing in humans. The proposed experiments will provide efficacy data with NHPs, one of the preferred large-animal models. If these studies are successful, full-fledged GLP studies will be conducted for safety and efficacy. GLP studies are very expensive and cannot be done with the grant for this study.

V.3.2. Animal Model and Species Justification: Nonhuman primates (NHP) are necessary for the pre-clinical development of a drug candidate intended for use in humans, because drug metabolism and physiology are very similar between humans and nonhuman primates. Testing a drug with potential for human application in NHPs ensures safety and specificity prior to the drug entering into clinics. This is true especially because of safety risks and the chance of unexpected autoimmune or hyper-immune reactions. Due to the species-specific nature of immune reactions, the drugs can only be studied *in vivo* in hosts whose immune systems are very closely related to that of humans. Rhesus macaques are the model of choice for investigations of radiation injury and countermeasures because of the large database available from the existing literature that allows for robust comparison. The FDA has accepted rhesus macaques as the appropriate animal model for pilot and pivotal efficacy testing of radiation countermeasures under the Animal Efficacy Rule, where efficacy testing cannot be performed in humans. The safety and efficacy of (b)(4) was demonstrated in mice. (b)(4) (b)(4) and hence, it is appropriate to conduct the present set of experiments to advance the drug for human use.

V.3.3. Laboratory Animals: *Macaca mulatta* (rhesus macaque) will be obtained from vendors registered with the USDA.

V.3.3.1. Genus/Species: *Macaca mulatta*

V.3.3.2. Strain/Stock: Preference will be given to animals of Chinese origin so that comparisons can be made with existing data on NHPs from AFRRI. Male and female *M. mulatta* are required that have been chair-trained, have normal cardiovascular parameters, no infections or wounds or surgical traumas, and which have normal liver and kidney enzyme functions.

V.3.3.3. Source/Vendor: In general, the sources for these animals are commercial vendors registered with USDA. However, attempts will be made to obtain suitable animals from the DOD pool that would meet specifications stated in V.3.3.7.

V.3.3.4. Age: Animals of 3 to 8 years of age are requested for the present study.

V.3.3.5. Weight: Animals must weigh in the range of 4–8 kg.
V.3.3.6. Gender: Male and female

V.3.3.7. Special Considerations: In addition to the requirements listed in sections V.3.3.2 and V.3.3.3 above, nonhuman primates shall test negative for Herpes B Virus (aka, *Macacine herpesvirus*), simian T-cell leukemia virus type 1 (STLV-1), simian immunodeficiency virus (SIV), and simian retrovirus (SRV) Types 1, 2, 3, and 5. Animals shall also test negative by means of virus isolation or polymerase chain reaction (PCR) for SRV Type 2. NHPs will either be vaccinated for measles or, in the case of previously measles-vaccinated NHPs, tested for the presence of measles antibodies.

Nonhuman primates coming from the vendor colony must test negative for *Salmonella*, *Shigella* and *Campylobacter*. The animals also must test negative for *Klebsiella pneumoniae*. On the advice of the attending veterinarian, in consultation with the PI, the exclusion criteria for certain viral and bacterial pathogens may be waived.

CBC and blood chemistry will be obtained from vendors for each primate and screened for abnormalities by an AFRRI veterinarian. Any abnormal findings will be discussed with the PI and a determination of the fitness of the animal for use on the protocol will be made. Individual medical records will be maintained during the entire length of the study. Tuberculosis testing will be performed in accordance with VSD SOPs and results must be negative or the NHP will be removed from the study.

V.3.4. Number of Animals Required (by species): 55 (total), 33 males and 22 females

V.3.5. Refinement, Reduction, Replacement (3 R's)

V.3.5.1. Refinement:
One of the most significant refinements in the reduction of distress and hemorrhage would be the use of a vascular access port (VAP) for blood withdrawal. Graham et al. (2009) have demonstrated that VAP implants were successful and safe for use with primates.

Chairing devices will be used as positional aids during the irradiation procedure as well as brief (<1 hour) restraint for phlebotomy procedures.

The use of chair-trained rhesus primates (preferably from vendor) will reduce stress on the animals during blood draw and injections. Acclimatization to bottle for oral supplementation such as drinking water, juices, Gatorade and electrolytes will be used to relieve discomfort from radiation-induced vomiting or diarrhea. Prior to placement of the animals within radiation-restraining chairs, they will receive light immobilizing doses of ketamine or Telazol (as determined by veterinarian) to reduce anxiety caused by movement. Time in the chair will be kept to a maximum of 1 h. In addition, the animals will be transported to the radiation facility in a covered cart to reduce the excitement of

being moved from their home cages to the radiation area. Over-the-counter medications will be provided in case of fever, diarrhea, vomiting, and bloating.

To minimize animal suffering, pain, or distress, moribund animals (section V.4.) will be considered to have arrived at the study endpoint. Such animals will be euthanized and recorded as "mortality".

Animals will be considered morbid when they display symptoms listed in V.4.5. Experimental animals that are morbid but not moribund will be allowed to continue in the experimental protocol with supportive care in order to evaluate effect of irradiation and the drug accurately.

Animals will be considered moribund when showing some or all signs of morbidity, or appear severely debilitated and in terminal distress. Animals will be monitored a minimum of twice daily, no sooner than 8 h apart, and appropriate actions taken when animals show signs of morbidity. Early endpoints (see 4.5, Study Endpoint) will be used in determining euthanasia.

V.3.5.2. Reduction: Information obtained in the dose-escalation study will allow us to determine the dose of (b)(4) to be used in radiation studies and, because we plan to conduct studies with only a limited number of animals (control/drug treated), we will halt these studies if adverse effects are seen during an experiment. Further, we propose to use multiple sampling points for blood collection and use individual animals as their own control that will lead to use of fewer animals in the protocol, in addition to appropriate study controls described in section 4.1.1.1.4)

V.3.5.3. Replacement: None

V.4. Technical Methods

Animal procedures: Rhesus macaques (*Macaca mulatta*) will be pair-housed as much as possible after observing compatibility. Animals will be quarantined for a minimum of 37 days prior to the inception of the experiment.

Surgical procedure will install vascular access port (VAP) in all experimental animals including donor animals based on veterinarian recommendation (see surgical section-V.4.3.2).

Chair training: The vendor will provide basic chair training involving the pole-and-collar technique. This will be reinforced at AFRRI with additional training by VSD staff.

General procedures:

Drug formulation: (b)(4) (Endotoxin, tested by Charles River laboratories) and the drug will be diluted appropriately in sterile PBS prior to injection (within 1–2 h after preparation). The drug will be maintained undiluted at 4 °C until injection. PBS will be used as control. Endotoxin testing results will be reported to the IACUC office.

Details on medical management of infection, thrombocytopenia, and anemia are provided below. See table 1 in section 4.3.2 for greater details on the criteria for initiating medical management procedures.

Evidence of Infection: Animals will be administered antibiotics as recommended by

the attending veterinarian or when a diagnosis of infection has been determined by blood culture or when there is evidence of neutropenia or FN that may be associated with infection. The Infectious Disease Society of America guidelines for treatment of humans are being followed for antibiotic administration in the case of neutropenia [i.e., antibiotics are recommended when prolonged and severe neutropenia (<100 cells/μL) is expected for 7 or more days]. Antibiotics will be selected by the attending veterinarian based on:

1) Institutional knowledge of potentially infecting organisms,
2) antibiotic susceptibility of pathogens isolated locally,
3) importance of broad-spectrum antibacterial activity, and
4) the animal's infection risk assessment.

Baytril® will be administered when the ANC (absolute neutrophil count) becomes <500/μL and will be continued until the ANC is ≥500/μL for two consecutive days. Blood collection will occur every day after Baytril is administered. Gentamicin will be initiated and administered for two days only, if FN (ANC <500/μL and body temperature ≥103 °F) is observed and is persistent during Baytril treatment. Gentamicin is effective against bacteremia partially because it stays in the bloodstream due to poor tissue absorption. Other possible antibiotics that will be used if resistance to Baytril has been demonstrated are third-generation cephalosporins such as Clavamox. Rectal swabs will be obtained for culture and sensitivity prior to irradiation to determine antibiotic sensitivity of normal gastrointestinal flora.

For microbial evidence of infection, blood (at least 1.0 mL) will be collected aseptically and inoculated into a BACTEC® culture vials and submitted to the testing facility. Blood culture will be performed on the first-day of FN to determine if antibiotic resistance has occurred. Blood cultures will be collected if FN (ANC <500/μL and body temperature ≥ 103 °F) is observed or any day the body temperature is ≥103 °F. Additional blood cultures will be collected 24 h after the first blood culture if FN persists and the preliminary bacteriology report of the first culture is either Gram negative or a Gram positive organism is identified.

Preparation of Blood Products to Treat Thrombocytopenia and Anemia: Whole blood for transfusions will be obtained from a pool of approximately 10 healthy adult donor rhesus macaques. Whole blood aliquots will be exposed to 2,500 cGy of ionizing radiation prior to transfusion in order to minimize rH factor complications although this is minimal in NHPs. Packed RBC will be obtained from a commercial source and kept for a minimum period based on blood bank procedures and will be administered in preference to whole blood when PLT counts are satisfactory (≥100,000/μL with no clinical bleeding) but the Hgb or Hct remain low (Hgb <7 g/dL or Hct <20%).

Blood collection: Blood samples will be collected according to appropriate VSD SOPs. See Table 3 for tentative blood collection scheme in the biosampling section. Blood (0.5 ml to 1.5 ml/day) will be collected from a peripheral vessel or femoral vein or through VAP using a 22–25 G needle attached to a 3 ml (generally) syringe to reduce the chances of bleeding after blood collection in irradiated animals. A small aliquot (0.25 ml) from each sample will be taken immediately for CBC/differential. Further, 0.35 ml will be used to prepare serum that will be frozen at –70 °C for clinical chemistry and antibody measurements.

The area for the blood draw will be swabbed with providone-iodine (left in place for 3 minutes) or isopropyl alcohol before inserting the needle. Providone-iodine will be swabbed off to reduce irritation to the tissue. The blood sample will be drawn as described above. While withdrawing needle, pressure will be applied at the same time with a clean gauze to reduce bleeding from the blood-draw site. While making routine observation of animals, the blood-draw site will be checked for bleeding. If the site becomes infected, topical antibiotics may be applied, under supervision by VSD.

Study endpoints: Experimental animals will be euthanized based on a moribundity scale and in consultation with the attending veterinarian. Euthanasia will be carried out when any one of the following signs and symptoms of moribundity are observed as determined by protocol technicians, the PI or by AFRRI veterinarians. Early end points will be used and are described in section V.4.5.

Body weights will be determined at least once prior to treatment, on the first day of treatment, and twice weekly except when inappetence sets in (daily measurements). Body temperature (implanted chip, see section V.4.1.2.1 for chip implantation) will be determined daily beginning approximately one week prior to the first treatment. The time of temperature collection will be recorded for each monkey. On day 60, after the last blood collection, all surviving monkeys may be transferred to AFRRI's NHP pool.

Identification of pain: NHPs demonstrate remarkably little reaction to surgical procedures and injury. An NHP in pain has a general appearance of misery and dejection. We will observe all irradiated animals for grimacing and glassy eyes, loud and persistent vocalization, avoidance of social interaction, and grooming. Gastrointestinal injury may be associated with abdominal pain displayed as facial contortions, teeth clenching, and restlessness. Headaches manifest by pressing the head against the enclosure surface. Self-directed injurious behavior may be a sign of more intense pain. Because most primates in pain will refuse food and water, daily food and water intake will be monitored closely. Further, response to familiar personnel and changes in willingness to cooperate may also indicate pain, which will be closely monitored and recorded.

Euthanasia: Animals will be euthanized according to current American Veterinary Medical Association (AVMA) guidelines. See sections V.4.5 and V.4.6.

Estimation of hematological indices: Blood (0.5–1.5 ml/day) will be obtained from a VAP or peripheral vessel using a heparinized 3 ml (mostly) syringe and a 22-25 G needle, generally from non-anesthetized NHP, and transferred immediately into pre-coated ethylenediaminetetra-acetic acid (EDTA, Sigma-Aldrich, St. Louis, MO, USA) tubes and mixed gently on a rotary shaker until analysis. The coded tubes will be analyzed for white blood cell (WBC), absolute neutrophil counts, monocytes, lymphocytes, reticulocytes, hemoglobin and platelet counts.

Concomitant medication and medical management will be given if clinically indicated. Table 1 summarizes the conditions under which concomitant medications and medical management will be given as well as the procedure for providing care.

Table 1. Summary of Plan for Medical Management and Medication Use

Drug class	Allowed medication or supportive care agents	Indication and/or criterion for administration
Anesthetics	Ketamine 10 ± 5 mg/kg, IM	**Anesthesia during procedures:** • Administered before animal manipulations to minimize stress and anxiety.
Sedatives	Xylazine (Rompum®) 1 ± 0.5 mg/kg, either IM or SC Diazepam 1 ± 0.25 mg/kg, IM,	**Sedation during procedures:** When animals are restrained a mild sedative may be administered as required.
Analgesics and non-steroidal anti-inflammatory drugs	Buprenorphine 0.01 mg/kg/dose BID, IM, IV, or SC Marcaine (0.25% bupivacaine), topical Carprofen (Rimadyl®) 2.04.0SID or BID, IM or IV Acetaminophen (Tylenol) 5–10 mg/kg PO BID-QID	**Pain Management:** • Rimadyl® (Carprofen) can be administered as an alternative to buprenorphine when evidence of pain is present. **Fever (temperature ≥ 104 °F):** • Carprofen or acetaminophen will be administered until the temperature remains below <104 °F for 2 consecutive days.
Parenteral fluids	Equal volume of Ringer's lactate and Ringer's lactate with 5% Dextrose; each at 5 ± 2.5 mL/kg body weight via slow IV push; twice daily depending on extent of dehydration; or Ringer's lactate at 40 ± 5 mL/kg body weight by IV drip over 2 hrs. Pedialyte® or Gastrolyte® orally 15 ± 5 mL/kg of body weight	**Dehydration:** • Mild to moderate dehydration (Grade 1). Ringer's lactate and Ringer's lactate with 5% dextrose eight via slow IV push. • Severe dehydration (Grade 2). Ringer's lactate by IV drip. • Pedialyte® or Gastrolyte® or similar commercial solutions containing sodium, potassium, and glucose may also be used if IV access is difficult or precluded. See Table footnote for definitions of severity grade. **Fever (temperature ≥103 °F):**
Anti-diarrheal	Loperamide hydrochloride (Imodium), Initial dose 0.04 mg/kg PIOID Diphenoxylate HCl/atropine sulfate (Lomotil), 0.1 mg/kg, (2.5 mg/tablet) will be administered BID, PO. The 2.5 mg tablet first will be dissolved in 5 mL of tap water. Then, 1 mL of the Lomotil solution (0.5 mg/mL) will be added to 5–10 mL tap water, with Oral Ringer's solution or liquid nutrition for 3 days.	**Diarrhea:** • At the first sign of soft to loose stools: Imodium will be administered up to twice daily and should continue for 3 days. It may be stopped earlier than 3 days if the diarrhea resolves. • Severe diarrhea or if Imodium has been administered for 3 days, Lomotil, up to BID, PO for 3 days. It may be stopped earlier than 3 days if the diarrhea resolves. If the diarrhea does not resolve the Imodium treatment will be repeated.
Anti-ulcer	Carafate 1g/day. (0.5 g BID) daily from days 5–30, PO	For treatment of possible ulcers of the stomach or proximal small intestine

Antibiotics	Enrofloxacin (Baytril®) 5 ± 2 mg/kg, IM or IV or PO, SID Gentamicin, 3 ± 1.5 mg/kg, IM or IV BID Clavamox, 6.5-13.5 mg/kg, PO, QID or 15 mg/kg, PO, BID Imipenem-cilastatin (Primaxin®) 10 ± 1 mg/kg, IV or IM, BID Cefepime hydrochloride (Maxipime®) 40 mg/kg IV QID	**Evidence of infection (microbial culture, neutropenia, and FN): Antibiotics will be administered when:** • Pre-nadir febrile neutropenia (FN) (ANC <500/µL, body temperature ≥103 °F) is observed. • When ANC <500/µL with the expectation of the development of a prolonged, severe neutropenia (ANC <100/µL). • Standard veterinary practice warrants administration, e.g., open wound. • Body temperature ≥ 103 °F following a positive blood culture. • Pending blood culture results, regardless of the ANC. **Antibiotics will cease when:** • No fever is observed and ANC increases ≥500/µL for two consecutive days • Fever is observed, blood culture for aerobic microorganism is negative and ANC increases ≥1,000/µL for two consecutive days.
Anti-emetics	Ondansetron (1-2 mg/kg), IM, IV or PO 25-90 minutes prior to irradiation and 30-45 minutes following irradiation to suppress emesis or Granisetron (0.25 mg/kg), PO or IV	• Administered pre-and post-radiation to suppress emesis
Blood products	Whole blood or packed red blood cells will be obtained from a commercial source or obtained from donor animals and blood product irradiated @ 2500 cGy with a source in USUHS prior to transfusion Whole blood at 7 – 14 mL/kg or Packed red blood cells (RBC). Fluid replacement policy: Volume replacement with fluids will be subject to clinical decision. <u>Note:</u> Repeat blood collection from donor animals will be defined on the total volume collected each time, recovery period and other criteria as described by Diehl et al 2001	Whole blood will be transfused if: • PLT counts are <20,000/□L and hemoglobin (Hgb) <7 g/dL or hematocrit (Hct) <20; • An animal experiences a 5-unit decrease in Hct in a 24-hour period that results in an Hct of ≤ 25%; • An animal that has previously received a transfusion demonstrates continued evidence of bleeding, such as bloody stools and/or any decrease in Hct relative to the most recent result obtained; or • If there is obvious evidence of uncontrolled hemorrhage. • An animal experiences a 7-10 unit decrease in Hct in a 24-hour period; or • An animal's Hct is ≤ 25% for 2 consecutive days and PLT counts are <3,000/□L. Packed RBCs will be administered in preference to whole blood when PLT counts are satisfactory (≥100,000/□L with no clinical bleeding) but the Hgb or Hct remain low (Hgb <7 g/dL or Hct <20 g/dL). • PLT counts are satisfactory (≥100,000/□L with no clinical bleeding) but the Hgb or Hct remain low (Hgb <7 g/dL or Hc <20 g/dL).

Barbiturates	0.4% pentobarbital sodium (Euthanasia III), 0.27 mL/kg IV or similar pentobarbital solution	**Euthanasia.**
Nutritional Support	BIO-SERV certified Rhesus Liquidiets	**Weight Loss (Anorexia):** Nutritional support will be administered via oral gastric tube when body weight is <85% of baseline and will be continued as long as the body weigh remains <85% of baseline, and the animal is not eating. In the case where an animal loses its ability to regain weight following irradiation despite actively eating and drinking, nutritional supplementation via oral gastric tube may be foregone in order to avoid daily anesthesia.

Definitions of severity grade of dehydration: Grade 1 and 2, mild to moderate dehydration. Symptoms include diminished skin turgor, dry mucous membranes, dry nose, increased hematocrit, and sunken eyes. Grade 3, severe dehydration. Symptoms include all of the above plus rapid and weak pulse, cold extremities, cyanosis, lethargy, rapid breathing, and comatose.

V.4.1. Pain/Distress Assessment:

V.4.1.1. APHIS Form 7023 Information:

Exp #2	Drug +6 or +24 h			18	18
Exp #3	Drug multiple regimen			18	18
	Donor animals		10		10
Totals:			10	45	55

V.4.1.2. Pain Relief/Prevention

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization microchips will be implanted under ketamine sedation (10–15 mg/kg, IM). Bone marrow biopsy will be done only for surviving animals subjected to ionizing radiation and only at the end of the experiment (60 days). It may be obtained under the same dose of ketamine or another suitable anesthetic determined by the veterinarian. Anesthetic and analgesics required for VAP surgery also will be procured by PI. Microchips may be placed during the initial physical

examination. If necessary, a drop of surgical glue will be placed at the chip-insertion site to ensure that the chip stays in place.

Bone marrow collection is expected to be a painful procedure. As such, the primates will be under general anesthesia at the time of marrow cell harvesting. NHPs will be sedated with ketamine IM in order to facilitate placement of an IV catheter or mask (as recommended by the veterinarian), and the animal is intubated and maintained on isoflurane at a surgical plane of anesthesia. Additional local anesthesia with Lidocaine (approximately 1 ml) will be provided at the marrow-harvesting site on recommendation of the staff veterinarian. Bone marrow sampling will be performed in the VSD surgical suites under aseptic conditions. Primates also will be administered opioids such as Buprenorphine at a dose of 0.01–0.03 mg/kg IM twice daily or more frequently if needed to relieve the stress and pain. Because bone marrow aspirates and/or core biopsy will be obtained at the end of the experiment (60 days), pain relief provided at that time will not interfere with the overall outcome of the experiment (see additional information on bone marrow collection under Surgery).

V.4.1.2.2. Pre- and Post-procedural Provisions Animals will be assessed for signs of pain and distress by either the veterinary or research staff at least twice daily or more often as needed according to appropriate VSD SOPs. Before procedures that require general anesthesia, NHPs will be fasted for 12 h prior to administration of anesthetic. Clinical signs of acute radiation sickness (e.g. diarrhea, vomiting, and fever) can be treated with over-the-counter medications on the advice of a VSD veterinarian. For any NHP not taking in sufficient food and/or water, additional foods can be offered to entice them to eat. In addition, NHPs will be prior-acclimated to feeding syringes and sipper bottles by vet techs and lab techs associated with the project to allow for the use of supplemental oral fluids if dehydration is noted. Criteria for euthanasia are listed in Section V.4.5.

V.4.1.2.3. Paralytics: No paralytics will be used in this study

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures

V.4.1.3.1. Sources Searched: Agricola (1974 to present), Pubmed (1946 to present), and Altweb

V.4.1.3.2. Date of Search: April 8, 2013

V.4.1.3.3. Period of Search: See above (v.4.1.3.1)

V.4.1.3.4. Key Words of Search: See table below

V.4.1.3.5. Results of Search: See table below

Keywords	AGRICOLA 1974-present	PubMed 1946-present	Altweb
alternatives to painful procedures	2	119*	148
primates + bone marrow harvesting	0	79*	7

primates + radiation	7	39117*	6
primates + blood draw	0	697*	53

supportive care + pain + primate	0	41*	3
blood transfusion + pain	0	52*	0
blood transfusion + pain + primate	0	37*	0

*Includes data from other species

The literature search did not indicate specific alternatives to pain other than what is described below.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification There are no alternative procedures for irradiation because it is a unique stimulus/stress that cannot be otherwise duplicated. Radiation does not cause pain or distress. Nevertheless, the sequelae of nausea, vomiting, and diarrhea cause pain and distress in humans in the early post-irradiation period, when high doses (8 Gy and above) are used. Although radiation does not induce pain, animals in these experiments might experience pain and distress prior to death because of hematological and gastro-intestinal damage. Therapeutic guidelines to address pain and distress are addressed in section V.4.1.2.2.

Bacteria translocated from the alimentary canal may cause infections that result in discomfort either locally or systemically. Many opportunistic pathogenic bacteria have unusual or even unique virulent characteristics but they have common attributes, including binary multiplication and penetration of tissues, and cause common responses and disease process in animals, which cannot be mimicked readily by substitutes. The investigators and animal-care staff will provide as much comfort and well-being to the animals as is consistent with the scientific integrity of the work plan. The principle purpose of these studies is to evaluate the efficacy of (b)(4) in enhancing survival of irradiated NHPs. As stated, bone marrow, peripheral blood, liver and kidney (liver and kidney analysis done by blood chemistry with the hematological studies) analyses also will be performed after (b)(4) administration. Moribund animals will be euthanized in consultation with VSD's veterinarian.

We expect that (b)(4) will provide some relief from pain and or discomfort due to the sequelae of irradiation by its protective effect and by the possibility that it will advance hematopoietic recovery in some or all of the (b)(4) treated and irradiated primates.

V.4.2. Prolonged Restraint The *Guide for the Care and Use of Laboratory Animals* and the AFRRI IACUC Policy Letter discuss "prolonged restraint" guidelines. The devices used during irradiation (chairs) are for positioning the animal, not for restraint. Primates will be sedated during irradiation and transport. The restraint devices will not be used as the normal method of housing.

V.4.3. Vascular access port (VAP) surgical procedure

General anesthesia:

- Premedication: Ketamine (10–15mg/kg IM + Atropine: 0.05 mg/kg IM), or Glycopyrrolate (0.005–0.01 mg/kg IM)
- Induction: 3–5% Isoflurane in 100% oxygen by mask
- Maintenance: 1–3% Isoflurane in 100% oxygen via endotracheal tube or mask
- Anesthesia monitoring: At least SpO2, heart rate, respiration rate, and temperature will be monitored and recorded throughout the procedure.
- Antibacterial prophylaxis: Cefazolin IV 20–25 mg/kg one time or Ampicillin 15–20 mg/kg IV one time.
- IV fluids: During the procedure, animals should be maintained on isotonic fluids at 5–10 ml/kg/hr via an IV catheter. If the catheter cannot be placed after 4 attempts, this step will be skipped as VAP placement is a quick procedure and involves accessing a vein so VAP should be available for intraoperative fluid administration once it is in place.
- Site of VAP catheter placement: Jugular vein or femoral vein or saphenous vein. No more than 1 site will be used per animal.
- Site of VAP port placement: Subcutaneously adjacent to vein or tunnel the port to the site that will be safe and easily accessible in a restrained animal (such as in between the shoulder blades on the back or caudal thigh or caudal lateral part of the chest).
- Preparation of the site: Hair will be clipped using a surgical #40 blade or equivalent. The site will be scrubbed at least 3 times using either betadine or chlorhexidine and 70% alcohol.
- Procedure: VAP catheters will be implanted surgically in the vein under general anesthesia according to the principles of aseptic surgery. A 5–7 cm incision will be made on the skin at the site of catheter placement. Vein will be isolated by doing a blunt dissection. The catheter tip will be introduced through a 2–3 mm incision in the vein and secured properly using absorbable or nonabsorbable sutures. Prior to insertion of the VAP catheter, it will be flushed with heparinized saline solution (100 IU of heparin/ml). VAP port will be placed subcutaneously and connected to the catheter tunneled through the subcutaneous tissue. The VAP will be checked for patency before securing it to the subcutaneous tissue. The VAP port will be flushed and locked with heparin lock solution (100IU of heparin/ml). The surgical site will be closed using the standard technique using the layer suture technique with absorbable or non-absorbable suture. Special attention will be given to eliminate any dead space.
- Post Op care: Baytril 5–10 mg/kg IM or PO bid for at least 5 days or longer as needed. Buprenorphine 0.01 mg/kg IM immediately after the procedure. Carprofen: 2.2 mg/kg IM or PO bid for at least 3 days or longer as needed.
- Restraint used to access the VAP: Either chemical (Ketamine 5–10 mg/kg IM) or chair restraint.
- Please note: Alternative anesthetics, analgesics and antibiotics may be used as deemed necessary by the veterinarian.
- Animals will be used only once for this purpose or any other survival surgical procedure unless the subsequent use is a terminal procedure.

Note: VAP installation in minipigs subjected to irradiation has been well documented (Ege et al 2006). According this article, VAP will be functional 2 weeks after surgery. The following general precautions and procedure will be followed: VAPs need to be

flushed at least weekly- blood could be drawn at this first flush but would have abnormal blood parameters and post-operative drugs (pain meds, antibiotics, etc.). The minimum time before return to normal would be 2 weeks, which would be the day -7 blood draw, so minimum 3 weeks between VAP implantation and irradiation will be the norms.

Bone marrow surgical procedure:

- General anesthesia
  - Premedication-ketamine: 5–15 mg/kg IM
  - Induction: 3–5% isoflurane in 100% oxygen by mask
  - Maintenance: 1–3 % Isoflurane in 100% oxygen by endotracheal tube or mask
- Anesthesia monitoring: At least SpO2, heart rate, respiration rate, and temperature will be monitored and recorded throughout the procedure.
- Site of bone marrow: iliac crest
- Procedure: Animal will be positioned appropriately (dorsal or ventral, or lateral recumbency). A sterile drape will be used to cover the site (survival study).
  - Biopsy: A stab incision (1-2 cm) will be made. A 13–16ga bone marrow biopsy needle will be advanced through the incision into the cortex of the bone. The stylet will be removed and the needle advanced 1–2 cm with gentle rotation and rocking of the needle. The needle is then retracted and advanced, slightly before being gently removed from the bone. The included expeller is used to remove the sample from the needle and placed in a cassette with foam insert, if necessary, which is then put in 10% formalin for fixation and processing.
- The incision will be closed with tissue glue or a suture after bone marrow collection. Either a non-absorbable nylon or absorbable monocryl suture will be used to close the skin.
- Additional precautions will include:
  - Antibacterial prophylaxis—Cefazolin intravenous (IV) or subcutaneous (SC) 20–25 mg/kg one time or Ampicillin 15–20 mg/kg IV or IM one time.
  - Animals will be used only once for this purpose.
  - Preparation of the site of bone marrow collection—The site will be prepared as a surgical procedure: hair will be clipped, the site area scrubbed 3 times with either betadine or chlorhexidine and 70% alcohol.

V.4.3.1. Pre-surgical Provisions Prior to general anesthesia for all surgical and procedures, all NHPs will be fasted for 12–18 h.

V.4.3.2. Procedure(s)

Microchips are inserted under ketamine anesthetic after animals clear quarantine. The chips are used to monitor body temperature and are pre-loaded in a specially designed needle/syringe device that is inserted subcutaneously between the shoulder blades. Once the chip is deposited, the needle is withdrawn and the skin is pinched between 2 fingers for about 10–20 seconds to ensure that the chip itself (about the size of a grain of rice) does not dislodge out through the puncture site. If a chip fails, a second chip will be inserted. If necessary, a drop of surgical glue will be placed at the puncture site to ensure that the chip stays in place.

Bone marrow collection: Described under general surgery section

VAP installation: Described under general surgery section

V.4.3.3. Post-surgical Provisions Incision monitoring, antibiotics and pain relief will be provided at the discretion of the staff veterinarian for bone marrow collection and VAP surgery.

V.4.3.4. Location All surgical procedures will take place in the VSD surgical suite.

V.4.3.5. Surgeon AFRRI veterinarians will perform all surgical procedures.

V.4.3.6. Multiple Major Survival Operative Procedures No major multiple surgical procedures will be performed on animals used in this protocol.

V.4.3.6.1. Procedures N/A

V.4.3.6.2 Scientific Justification N/A

V.4.4. Animal Manipulations

V.4.4.1. Injections Trained personnel will carry out Injections (subcutaneous, Intramuscular) within the scope of VSD SOPs.

Drug injection: The drug in sterile PBS will be freshly prepared from a liquid formulation on the day of injection. Depending on the drug concentration and dilution, injection volume may vary 1 to 5 ml animal/injection.

Needle: Drug will be administered to restrained animals using 22–25G needle and 2-5 ml syringes.

V.4.4.2. Biosamples Chair restraint of rhesus primates for the purposes of phlebotomies was previously discussed as a technique to obtain blood samples over a short period of time that would reduce stress to the animals. Should technical issues with chairing and blood collection arise, sedation with ketamine may be used as an alternative at PI's discretion.

Blood will be collected on days as shown in Table 2. This will include 3 pre-irradiation time points. The hematological data from these points will be averaged and used as the control data for the specific animal. Additional blood collections will provide experiment specific data on hematology, blood chemistry, cytokine profile and CFU as indicated in Table 2.

Table 2: Blood collection; time-points and volumes (SA:2)

Time of blood draw	PK (0.5 ml)	CBC (0.5 ml)	CFU/chemistry/ cytokine (0.5 ml)	Culture (1.0 ml)	Total blood, ml
–7d	+	+	+		1.5
–3d		+			0.5
–2d	+	+	+		1.5
Day –1 (pre-TBI injection)					
Irradiation (Day 0)					
Day 1 (post-TBI injection)					

Day 2	+	+	+		1.5
Day 4	+	+	+		1.5
Day 6		+		+	1.5
Day 8	+	+	+		1.5

Day 42	+	+			1.0
Day 49		+			0.5
Day 60	+	+			1.0
				TOTAL	**33.0 mls**

V.4.4.3. Adjuvants N/A

V.4.4.4. Monoclonal Antibody (MAb) Production N/A

V.4.4.5. Animal Identification The animals are identified by indelible markings on their chest area and or inner thighs. If the primate is not tattooed upon arrival, a VSD colony number will be assigned and tattooed onto the chest or inner thigh.

V.4.4.6. Behavioral Studies No behavioral studies will be performed in this experimental protocol.

V.4.4.7. Other Procedures None

V.4.4.8. Tissue Sharing: None

V.4.4.9. Animal By-Products: Blood products such as irradiated blood or packed RBCs

V.4.5. Study Endpoint

Primary endpoint: The primary study endpoint is 60-day overall survival.

Study endpoints (primary)

1. Weight loss: Loss of more than 20% body weight over baseline. Normally animals will be weighed twice a week; however, if inappetence sets in then we will monitor weight at frequent intervals (daily if required).
2. Inappetence: Complete anorexia for 2 days with deteriorating conditions based on clinical examination.

3. Weakness/inability to obtain food or water: Inability or extreme reluctance to stand that persists for 4–6 h, assuming the animal has recovered from anesthesia.
4. Minimal or absence of response to stimuli (animal does not move when prodded), assuming the animal has recovered from anesthesia.
5. Core body temperature: below 35.9 °C following a period of febrile neutropenia ($\leq 500 \times 10^3$ cells/µl), monitoring by way of microchip will be done on a daily basis.
6. Severe acute anemia: (<40 g/L hemoglobin, <13% hematocrit).
7. Infection documented by blood culture (septicemia) and accompanied by severe systemic signs of illness.
8. Other signs of severe organ system dysfunction with a poor prognosis as determined by a veterinarian that may need additional diagnostic tests:
   - 8.1 Respiratory: severe dyspnea, severe cyanosis.
   - 8.2 Gastrointestinal: severe vomiting or diarrhea, evisceration (immediate euthanasia required). **Note:** Transient vomiting and diarrhea are expected results of total-body irradiation (TBI). Therefore, as criteria for euthanasia, these symptoms should be severe and life-threatening i.e., hemorrhagic diarrhea to the point of causing anemia as listed above or severe uncompensated dehydration.
   - 8.3 Urogenital: renal failure characterized by elevated BUN, and creatinine.
   - 8.4 Neuronal: CNS depression, seizures, paralysis of one or more extremities.
   - 8.5 Integumentary: Non-healing wounds, repeated self-trauma, severe skin infections, indicating severe organ system dysfunction with a poor prognosis.

Technical note: One or more criteria will be used to euthanize animals in consultation with a veterinarian.

V.4.6. Euthanasia Animals will be euthanized according to current American Veterinary Medical Association (AVMA) guidelines. All animals first will be anesthetized with ketamine (IM, 5–10 mg/kg). Animals will be euthanized with sodium pentobarbital (IV, 100 mg/kg), under the guidance and supervision of a staff veterinarian. After euthanasia solution has been administered, the animals will be examined by VSD veterinarian or technician to confirm death. A full-body necropsy and histopathologic analysis will be performed after death has been confirmed.

V.5. Veterinary Care Animal procedures performed at AFRRI will be in compliance with the *Animal Welfare Act* and the *Guide for the Care and Use of Laboratory Animals*. The AFRRI facility is accredited by Association for Assessment and Accreditation of Laboratory of Animal Care (AAALAC) International.

V.5.1. Husbandry Considerations All NHPs will be housed according to IAW VSD SOPs.

V.5.1.1. Study Room All animals will be assigned room(s) designated by VSD staff.

V.5.1.2. Special Husbandry Provisions Routine and emergency veterinary medical care: Animals will be quarantined for 4–6 weeks on arrival and chair-trained during the quarantine period. Each animal will be observed twice daily for evidence of pain or distress. Body weights will be determined at least once prior to treatment, on the first day of treatment, and at periodical intervals or when chaired for blood collection. Body

temperature will be determined using a microchip installed in irradiated animals. Regular temperature will be measured during blood collection schedule when the animals are chaired. Animals will be qualitatively assessed twice daily (a.m. and p.m.) for general behavioral status and food consumption. Additional observation points will be added based on recommendation from attending veterinarian and will depend on the health of experimental animals. Appropriate standard operating procedures will be followed by staff veterinarians in the event of pain or distress.

V.5.1.3. Exceptions N/A

V.5.2. Veterinary Medical Care

V.5.2.1. Routine Veterinary Medical Care All primates will be quarantined for 4–6 weeks prior to any experiment. Animals will be tested for TB. Also, note the requirements given under V.3.3.2 and V.3.3.3 above.

All NHPs will be observed at least twice per day by veterinary staff (IAW VSDM SOP 2002, Animal Health Rounds). A veterinarian and a veterinary technician will provide 24 h emergency care to the animals if needed (IAW VSD SOPs). When animals become ill or debilitated, a veterinarian will be contacted immediately to assess the animal and provide adequate/emergency care. If the animal becomes moribund, it will be euthanized according to current American Veterinary Medical Association (AVMA) guidelines.

V.5.2.2. Emergency Veterinary Medical Care The on-call veterinary officer will be available via telephone 24 h daily. The on-call roster is located outside the VSD conference room (b)(6) on the bulletin board and at the security watch desk. These procedures are in accordance with VSD SOPs.

V.5.3. Environmental Enrichment

V.5.3.1. Enrichment Strategy In these studies, all primates will receive regular enrichment (IAW VSDM SOPs).

V.5.3.2. Enrichment Restrictions None

VI. Study Personnel Qualifications and Training

NAME	DEGREE	TRAINING	DATE	PROCEDURES	YRS/MOS EXPERIENCE
(b)(6)				1	(b)(6)
				1	
				1	
				1	
				1,2,3, 4, 5, 6,	
				1,2,3, 4, 5, 6,	

Procedure and manipulation codes:
Code 1 = Animal handling and euthanasia
Code 2 = Surgery (aseptic technique) pre- and post-operative care
Code 3 = Injections (3a–ip, 3b-sc, 3c-gavage)—Can say 3 if trained in all manipulations or add 3d-iv
Code 4 = Blood collection under anesthesia (4a-cardiac, 4b-posterior vena cava)
Code 5 = Tissue collection (after euthanasia)—Need not be specific

Code 6 = Implantation (provide details)
Code 7 = Others—Provide protocol specific manipulations or procedures for e.g., retro-orbital bleeding, tail vein injection, or drug delivery

X. ASSURANCES

Protocol Title:

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made every effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with a qualified individual who evaluated the experimental design with respect to the statistical analysis, and that the minimum number of animals needed for scientific validity will be used.

D. Biohazard/Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R", namely, "Responsibility," which the DOD has embraced for implementing animal-use alternatives where feasible and conducting humane and lawful research.

G. Scientific Review: This proposed animal use protocol has received appropriate peer scientific review and is consistent with good scientific research practice.

H. Painful Procedure(s): **I AM / AM NOT** conducting biomedical experiments, which may potentially cause more than momentary or slight pain or distress to animals. If applicable, potential pain and/or distress **WILL / WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

DOD ANIMAL CARE AND USE STANDARDIZED PROTOCOL FORMAT WITH EMBEDDED INSTRUCTIONS (AUGUST 2011)

Reference DOD Instruction 3216.01 & AFRRI Instruction 3216.2H

****

Information requested in the following animal use protocol template reflects the requirements of the Animal Welfare Act Regulations (AWAR), the Guide for the Care and Use of Laboratory Animals, and other applicable Federal regulations and DOD instructions.

****

This document is intended to be an aid in the preparation of DOD-sponsored animal use protocols. It is a companion document to an identical protocol template that does not have embedded instructions. Either template may be used to format DOD-sponsored animal research proposals; however, reference to the instructions during protocol preparation is highly recommended. If using the template with instructions, the instructions should be deleted prior to submitting the finished protocol for IACUC review. Please use Arial, regular, size 12, black font to prepare the protocol. With the exception of section headings, all paragraphs require a response. Paragraphs that do not apply should be marked N/A. There is no space limitation for responses to the information requested.

Approved standard operating procedures (SOPs) promulgated by the AFRRI Veterinary Sciences Department (VSD) or similar VSD-validated documents that describe specific procedures may be referenced by SOP number and title in lieu of repeating the details in the protocol. However, it is essential to include general descriptions of all animal manipulations to be carried out under the IACUC-approved protocol and to provide details where no approved references are cited. To do otherwise would constitute a breach of statutory regulations. Manipulations not covered in the originally approved protocol can be initiated only after IACUC approval of a formal amendment adding the new procedures. Additionally, Principal Investigators (PIs), or other delegated research personnel, should maintain accurate experimental records and be able to provide an audit trail of animal expenditures and use that correlates with their approved protocol. Protocol PIs will be required to provide this and other information during annual protocol reviews.

Any supporting information that may be of use to the IACUC during its review may be attached to the completed protocol. Adding subparagraphs within the body of the protocol template is permissible, *provided that the numbering sequence of paragraphs in the original standard format is maintained.* In other words, all of the labeled paragraphs and subparagraphs in this template must be retained, with additional information being presented as sub-numbered paragraphs containing information that supports or complements what is requested.

INTELLECTUAL PROPERTY STATEMENT

Research protocols drafted by Government scientists include intellectual property (e.g., concepts, ideas, experimental approaches, etc.), some of which is innovative or original and therefore considered proprietary to the investigators and/or the sponsoring agency. All Government and non-Government personnel handling this protocol shall exercise EXTREME CARE, to ensure that the information contained herein is NOT DUPLICATED OR DISCLOSED, in whole or part, for any purpose other than to evaluate the protocol, without the written permission of the principal investigator or the sponsoring agency.

AFRRI SCIENTIFIC RESEARCH PROTOCOL NUMBER:

I. NON-TECHNICAL SYNOPSIS Exposure to ionizing radiation causes rapid hematopoietic cell damage and bone marrow suppression. Radiation also induces damage of the gastrointestinal (GI) system. This multiple organ failure can result in human and animal death (b)(6),(b)(4) Over several decades, many candidate drugs have been tested. However, highly effective countermeasures are still lacking. Because radiation injuries are heterogeneous disorders that influence many pathophysiological pathways, a broader approach may increase the likelihood that we can prevent damage or sustain repair in mass casualty scenarios. We propose to explore the protective and mitigative/therapeutic effects of small molecule tilorone dihydrochloride (tilorone), on mouse hematopoietic and GI system after different doses of total-body γ-irradiation (TBI).

II. BACKGROUND

II.1. Background

Introduction: Nuclear proliferation, terrorist activity, and the distribution of nuclear and radioactive materials increase the risk of radiation injury incidents. Injury after prompt radiation of hematopoietic and GI tissue occurs over a period of hours to days (2, 3). No countermeasures for acute radiation syndrome (ARS) have been approved by the FDA, partly due to the fact that the mechanisms of radiation-induced multiple organ cellular and molecule damage and mortality are extremely complex and poorly understood (4).

(b)(4)

(b)(4) Small-molecule tilorone dihydrochloride (tilorone) is one of several compounds that have been tested in a drug screening program, according to previous reports (5, 6). Preliminary data from the screening program demonstrated that tilorone at very low dosage (7.5 mg/kg) significantly enhanced 30-day survival in lethally γ-irradiated mice. Administration of tilorone as a single subcutaneous (SC) injection 24 h before or 6 h after irradiation rescued 69% and 56% of mice from 9.0 Gy irradiation-induced death compared with 25% survival for vehicle-treated mice. In addition, (b)(4)

(b)(4)

(b)(4) Consistent with AFRRI studies, Kim and colleagues recently reported a radiation-mitigation function by tilorone after high throughput screening of small molecule libraries for modifiers of radiation responses in murine T lymphocytes (7). However, the underlying mechanisms of tilorone aiding the survival of irradiated mice are unclear.

Tilorone is the first to be recognized as an orally active interferon (IFN) inducer, developed in the 1970s by Richardson Merrell, Inc. (US Patent 3592819, filed Dec. 30, 1968, Ser. No. 788,038) (8). Tilorone is a broad-spectrum antiviral agent active *in vivo* (9, 10) for viral infection therapeutics and prophylaxis (flu, hepatitis A, B, herpes simplex). Although it has been widely used in the Ukraine since March 2005, tilorone is not available in the USA as a pharmaceutical-grade drug.

Drug-toxicity assays showed that the LD_{50} for a single dose, oral administration in mice is 959 mg/kg, and intraperitoneal administration is 145 mg/kg (Krueger, Mayer). Although the drug has a high capacity to induce interferon *in vivo*, no antiviral effects were seen in cell cultures, even at high concentration, suggesting an indirect stimulation *in vivo* (8).

AFRRI toxicity studies: Limited toxicity studies were conducted at AFRRI using the up-and-down method for evaluating drug toxicity. CD2F1 mice (6/group) were SC injected with a single dose of 30–150 mg/kg tilorone in PBS and observed for adverse effects. All mice injected with 150 mg/kg of tilorone died within 5 minutes of drug administration; our Veterinary Sciences Department pathologist concluded that death was due to CNS (central nervous system) effects rather than systemic toxicity. When the tilorone dose was reduced to 50 mg/kg, no adverse effects were monitored and tilorone was considered safe for single administration.

Hypothesis of the mechanisms of increased survival in radiated animals by tilorone: It was well known that exposure to ionizing radiation leads to rapid hematopoietic cell damage and bone marrow suppression. Radiation also induces damage of the GI system, such as loss of intestinal crypts, damage of crypt stem cells, and breakdown of the GI mucosal barrier. Failure of these organs can result in human and animal death (b)(6),(b)(4) As a countermeasure candidate, tilorone significantly enhanced 30-day survival in lethally γ-irradiated mice. It may reverse the effect of radiation on these organs and protect them. In our study, the mechanisms of the effect of tilorone on these hematopoietic and GI systems will be addressed.

Studies at the molecular biological level showed that tilorone is an effective activator of the hypoxia inducible factor-1 (HIF-1) that provides prophylaxis against stroke and spinal cord injury (11). Interestingly, (b)(4)

(b)(4)

(b)(6),(b)(4) REDD1 is a target of HIF-1, which is induced strongly under hypoxic conditions (13, 14) and subsequently inhibits a downstream protein kinase, mTOR, to regulate cell growth (15). We hypothesize that tilorone-induced HIF-1 activation is associated with its radio-protective and/or mitigative effects.

In this study, we propose to evaluate the protective and mitigation/therapeutic effects of tilorone on mouse hematopoietic and GI system after different doses of γ-radiation. We expect that the preliminary data from our study could provide sufficient information to support our hypotheses that tilorone is a valuable radiation countermeasure candidate,

and guide us to further characterize the effects and mechanisms of tilorone-induced survival in γ-irradiated mice.

II.2. Literature Search for Duplication
II.2.1. Literature Sources Searched: BRD, NIH Reporter, PubMed, FEDRIP
II.2.2. Date of Search: June 20–August 27, 2013
II.2.3. Period of Search
All available years. BRD: FY1998–FY2011; NIH Reporter and PubMed: includes MEDLINE (1966–present) and OLDMEDLINE (1950–1965); FEDRIP (up to August 27, 2013)
II.2.4. Key Words of Search: tilorone and ionizing radiation
tilorone and hematopoietic cells and radiation damage
tilorone and gastrointestinal tissue and radiation damage
tilorone and radiation countermeasures
tilorone and stress signaling
II.2.5. Results of Search: Articles for all tilorone studies = 407
Articles for tilorone and radiation studies = 9
Articles for tilorone and ionizing radiation studies = 4
Articles for tilorone and hematopoietic cells studies = 10
Articles for tilorone and gastrointestinal cells studies = 2
Articles for tilorone and radiation and hematopoietic cells studies = 1
Articles for tilorone and radiation and gastrointestinal cells studies = 0
Articles for tilorone and stress signaling = 0

Most of the articles suggested that tilorone is an inducer of interferon-1 (IFN-alpha), which induces natural killer (NK) cells and lymphocyte activity. Orally administrated tilorone can induce IFN-α production in the intestine and systemically (Munakata et al. 2008). Ratan, RR et al. (11) reported that tilorone or its analogs are novel potent activators of hypoxia-inducible factor-1 (HIF-1), which provides prophylaxis against stroke and spinal cord injury. Four articles (one *in vivo* and three *in vitro* studies) reported the effects of tilorone on ionizing radiation (including 90Sr, gamma- and helium-alpha irradiation), and the *in vivo* study was focused on helium-alpha irradiation (5). Recently, Kim, K et al. (7) reviewed the data from a drug discovery high-throughput screening (HTS) *in vitro* program (assay system endpoints included radiation-induced genotoxicity and DNA damage in yeast and apoptosis in murine lymphocytes) and suggested that tilorone has radioprotection and moderate mitigating activity. Their conclusion is that in *vitro* study has limitations and is unable to fully recapitulate all aspects of the complex *in vivo* acute radiation response.

The proposed study has no overlapping with published data.

III. OBJECTIVE/HYPOTHESIS: In the present study, we propose to evaluate the radiation-protective (before irradiation) and mitigative (post-irradiation) effects and mechanisms of tilorone on survival of γ-irradiated mice.

IV. MILITARY RELEVANCE: Currently, there is no safe and non-toxic radioprotective agent available. Military personnel potentially are exposed to ionizing radiation in various scenarios. Thus, there is an urgent need to develop clinically safe, potent and non-toxic radioprotective agents. Developing countermeasures to radiation exposure is

a top priority for the U.S. Department of Defense. We propose to conduct a study to further explore the protective and mitigative/therapeutic effects of this very promising candidate of countermeasure, tilorone, on survival of mice after exposure to different doses of γ-radiation.

V. MATERIALS AND METHODS

V.1. Experimental Design and General Procedures

Mice: Twelve- to 14-week-old male CD2F1 mice (Harlan Laboratories, Indianapolis, IN) will be used in all experiments.

Animals will be housed in plastic micro-isolator cages on autoclaved hardwood-chip contact bedding with free access to food and acidified water (pH: 2.5–3.0) in a facility accredited by the Association for Assessment and Accreditation of Laboratory Animal Care, International (AAALAC-I). Animals will be grouped randomly (criteria-weight within 10%, etc.) for different treatments prior to each experiment and re-housed (6–8 to animals per cage).

Tilorone drug preparation and administration in mice model: Mice will be weighed before drug administration. Tilorone dihydrochloride (tilorone) is a water-soluble, small molecule compound and will be purchased from Sigma-Aldrich (St. Louis, MO). It will be freshly prepared and administered at a single dose of 40 mg/kg subcutaneous (SC) injection in 0.1–0.25 ml volume based on data from AFRRI's screening program. Phosphate buffered saline (PBS) will be used as solvent and vehicle control in animal studies.

Radiation: Mice will be placed in ventilated Plexiglas containers and exposed bilaterally to γ-radiation in the AFRRI cobalt-60 facility at doses of 0 (sham-irradiation), 7, 9, 10, or 12 Gy at a dose-rate of 0.6 Gy/min. Sham-irradiated mice will be treated exactly the same way as the γ-irradiated animals, except the cobalt-60 sources will not be raised from the shielding water pool. After irradiation, mice will be returned to their specific cages, thereafter animals will be monitored for 30 days after 7, 9 or 10 Gy, and for 20 days after 12 Gy irradiation. For survival studies there will be 20 mice/group. To evaluate the effects of tilorone on survival of mouse hematopoietic and GI tissues, each treatment group will include 6 mice and two separate experiments will be conducted.

V.1.1. Experiment 1

Survival study

This study will consist of 5 treatment groups, naïve, vehicle, and tilorone-treatment at 24 h before (–24 h), or 6 or 24 h postirradiation (+6 h or +24 h). A single dose of tilorone (40 mg/kg) or PBS vehicle will be injected subcutaneously into mice. Drug-treated mice weighing 25 ± 2 g will receive 0.1 ml of tilorone; injection volume will be adjusted for mice weighing more than 28 g. Control mice will receive 0.1 ml of vehicle (PBS). All SC injections of tilorone and vehicle will be performed aseptically in the nape of the neck with a 23G needle. Each treatment group will receive four doses (7, 9, 10 or 12 Gy) of radiation at a dose rate of 0.6 Gy/min in the AFRRI cobalt-60 radiation facility. Animals will be irradiated in Plexiglas boxes (8 animals/box). After irradiation, the mice will be returned to their specific cages, thereafter animals will be monitored for 20–30 days.

V.1.2. Experiment 2

Evaluate the effects of tilorone on survival of mouse hematopoietic tissues after γ-irradiation

CD2F1 mice (6/group) will be given 7 or 9 Gy irradiation or sham-irradiation as control. A single SC dose of tilorone (40 mg/kg) or vehicle control will be administrated to mice 24 h before or 6, or 24 h after irradiation. At different time points (1, 7, 14, 21 and 28 days after radiation), blood and bone marrow (BM) from femurs and humerus, sternum, and spleen tissue will be collected from the sham-irradiated and γ -irradiated mice for various experimental assays. Animals will be anaesthetized prior to blood collection via cardiac puncture and then a confirmatory cervical dislocation will be performed before tissue collection. The collected blood will be analyzed for hematological study. The total myeloid cell numbers and the viability from individual mouse BM will be counted at indicated time points and the BM cell clonogenicity will be determined by colony-forming assay (16) to evaluate the effects of tilorone on survival of mouse hematopoietic stem and progenitor cells (HSPC). Cell death and apoptosis markers and cell surface phenotypes will be analyzed by flow cytometry on freshly collected BM tissue. Immuno-fluorescence staining, immunoblotting (western blot) assay for γ-H2AX, TUNEL assay and neutral comet assay will be used to evaluate radiation-induced DNA damage.

BM pathological changes will be evaluated in HE-stained mouse sternum longitudinal sections. BM structure, BM hemorrhage and cellularity (especially megakaryocyte restoration) (17) will be examined.

The production of cytokines and chemokines in mouse serum and HSPC and spleen cell lysates will be evaluated using cytokine array and ELISA assays. Levels of hematopoietic cytokines and inflammatory cytokines including G-CSF, Flt-3 ligand, IL-1, IL-4, IL-6, IL-8, IL-10, and interferon will be measured.

V.1.3. Experiment 3

Examine the radioprotective and mitigative/therapeutic effects of tilorone on mouse gastrointestinal (GI) tract

At different time points (12 h, 3.5 days, or 10 days after radiation), blood and jejunum tissue will be collected from tilorone-treated and vehicle-treated mice after sham- or γ-irradiation (10 or 12 Gy) for mechanism studies. Animals will be anaesthetized prior to blood collection via cardiac puncture and then a confirmatory cervical dislocation will be performed before tissue collection.

HE-stained mouse intestinal tissue slides will be examined for intestinal mucosal surface area, crypt cell apoptosis, intestinal crypt colony generation, and villi. We will collect segments of proximal jejunum 12 h, 3.5 days or 10–12 days after TBI (0, 10 or 12 Gy) to study the effects of tilorone on mouse intestinal crypts and GI mucosal barrier protection.

Plasma citrulline concentrations will be determined. The plasma level of citrulline is a well-validated biomarker for functional enterocyte mass. A decrease in citrulline levels is a characteristic of radiation injury. The correlation between plasma citrulline levels and more conventional markers of intestine radiation injury will be addressed (18).

Cytokine release from jejunum mucosal will be measured and compared in different treatment groups. The effects of tilorone on radiation-induced inflammatory cytokine production in mouse jejunum mucosa will be evaluated.

Radiation-induced intestinal bacterial translocation in the liver, heart blood and spleen, and radiation-induced sepsis will be quantified by bacterial translocation assay (19). Radiation-induced bacterial translocation starts around day 7 and peaks around 2 weeks after TBI. Analysis of bacterial translocation will be performed on days 10–12 after exposure to 10 or 12 Gy TBI. The samples collected from heart blood, liver, and spleen will be applied to a special medium and cultured for bacteria growth. Single colonies of isolated microorganisms will be observed for their morphological characteristics. Gramstain characteristics will be determined by Gram staining. They will be subcultured and a pure culture will be analyzed by a Vitek 2 Compact automated system to determine the type of bacteria.

Total number of animals: 1696 male CD2F1 mice will be used.

Experiment 1 Survival study:
Naïve, vehicle- and tilorone-treated (24 h before, 6 h and 24 h after TBI) = 5 groups × 7, 9, 10 or 12 Gy TBI (4 radiation doses) × 20 mice/group = 400 mice

Experiments 2 and 3: Sham-irradiated mice will be shared between Experiments 2 and 3. Experiment 3 will need to use an extra 3.5-day post-radiation group.

Sham-irradiated section = 2 groups (vehicle and drug) × 6 animals/group × 6 time points after drug treatment = 72 animals

Irradiated section for Experiment 2 = 2 groups (vehicle, drug) × 6 animals/group × 3 drug-giving times × 5 sample collection time points after irradiation × 2 radiation doses (7 and 9 Gy) = 360 animals

Irradiated section for Experiment 3 = 2 groups (vehicle and drug) × 6 animals/group × 3 drug-giving times × 3 sample collection time points after irradiation × 2 radiation doses = 216

Sum of 72 + 360 + 216 animals = 648 animals × two experiments (statistically required) = 1296

Total animals required = 400 + 1296 = 1696

V.2. Data Analysis
The differences in 20- and 30-day survival of mice will be analyzed by Kaplan-Meier analysis. Differences between means will be compared by ANOVA and by Student's *t* tests. $P<0.05$ will be considered statistically significant. Results will be presented as means ± standard deviations.

V.3. Laboratory Animals Required and Justification
V.3.1. Non-animal Alternatives Considered: In AFRRI's drug-screening program, the preliminary data of the effect of tilorone on animal survival after irradiation are based on *in vivo* studies. As a start, we would like to conduct *in vivo* study first because the

responses of various tissues and organs to the radiation and the radio-protective effect of tilorone are linked directly to that in the previous survival study. Radiation-induced adjustment in cellular tissue homeostasis triggered by various molecular responses related to inter- and intracellular signaling causes both acute and late effects depending upon the interactions in different organs and tissues in animal models. The morphological changes in tissues can be seen only in tissues obtained from the animals. The hematological analysis and cytokine and chemokine measurements can be performed only from blood collected from the animals. Therefore, the observation of changes in hematopoietic and GI systems after exposure to radiation will be more meaningful using an *in vivo* model for the proposed study.

V.3.2. Animal Model and Species Justification
The murine model is the most well-defined animal model for research. The mouse was chosen over other animal models because of extensive published data that is readily available for comparison, review and analysis. The mouse model has significant hematological and immunological similarities to higher animals and humans. AFRRI's staff has extensive experience with mice, including male CD2F1 in radiation injury and countermeasure research.

V.3.3. Laboratory Animals

V.3.3.1. Genus/Species
Mice (*Mus musculus)*

V.3.3.2. Strain/Stock
CD2F1

V.3.3.3. Source/Vendor
CD2F1 from vendor approved by VSD (Harlan-Indianapolis, IN, preferred)

V.3.3.4. Age
12–14 weeks

V.3.3.5. Weight
24–30 g

V.3.3.6. Sex
Male

V.3.3.7. Special Considerations The mice must be pathogen-free, specifically for the following agents: Pseudomonas aeruginosa, Klebsiella pneumoniae, Proteus morgani and Pasteurella. In addition, all mice need to be free of the following viral agents: Sendai, Pneumonia Virus of Mice (PVM), Reovirus-3 (Reo 3), Mouse Adenovirus (MAD-1, MAD-2), Mouse Cytomegalovirus Virus (MCMV), Ectromelia, K virus, Lymphocytic Choriomeningitis Virus (LCM), Epizootic Diarrhea of Infant Mice (EDIM), Hantaan virus, Rotavirus, Mouse Parvovirus (MPV), Polyoma Virus, Mouse Minute Virus (MMV), Mouse Thymic Virus (MTV), Theiler's Mouse Encephalomyelitis Virus (TMEV/GDVII), Encephalitozoon cuniculi, CAR bacillus, Mycoplasma pulmonis, and Clostridium piliforme. Endoparasite- and ectoparasite-free.

V.3.4. Number of Animals required (by species)

Animal (genus, species and common names)	Original	All previous amendments	This amendment
CD2F1mice	1696		

V.3.5. Refinement, Reduction, Replacement (3 R's)

V.3.5.1. Refinement
None.
V.3.5.2. Reduction
We shall make every effort to minimize the use of non-necessary animals. Control groups will be shared between experimental groups. At every stage of the research, plans will be reevaluated in light of incoming data in an attempt to reduce the numbers of experiments and groups.

V.3.5.3. Replacement
None.

V.4. Technical Methods

V.4.1. Pain / Distress Assessment

V.4.1.1. APHIS Form 7023 Information
V.4.1.1.1. Number of Animals
V.4.1.1.1.1. Column C: 0 (# of animals)
V.4.1.1.1.2. Column D: Vehicle- or drug-injected and sham-irradiated mice 144 (# of animals)
V.4.1.1.1.3. Column E: All irradiated mice 1552 (# of animals)

2	IR-induced GI syndrome		72	432	504
Totals:			144	1552	1696

Mice in pain category D (144) will be anesthetized for blood collection by cardiac stick, which causes more than momentary pain and distress. Mice in pain category E (1552) will be irradiated and they will not receive any anesthesia or analgesia to relieve them from radiation-induced pain/distress.

V.4.1.2. Pain Relief/Prevention
V.4.1.2.1. Anesthesia/Analgesia/Tranquilization
For blood sample collection, animals will be anaesthetized with isoflurane 1–3% in

100% oxygen using the anesthesia machine in the AFRRI IACUC-approved rodent procedure room. Blood will be drawn by cardiac puncture (or from the inferior vena cava if the "cardiac stick" method is unsuccessful) in mice anesthetized by isoflurane inhalation. Animals will be euthanized by cervical dislocation immediately after blood collection and then tissue samples will be taken.

V.4.1.2.2. Pre- and Post-procedural Provisions N/A
V.4.1.2.3. Paralytics: No paralytic agent will be administered.

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures

V.4.1.3.1. Sources Searched
AGRICOLA, PubMed

V.4.1.3.2. Date of Search
June 20–July 30, 2013

V.4.1.3.3. Period of Search: List AGRICOLA–1976–present
PubMed: includes MEDLINE (1966–present) and OLDMEDLINE (1950–1965)

V.4.1.3.4. Key Words of Search
Irradiation or Pain and Distress or Alternatives or Animal Model; Mouse or Irradiation or Pain or Alternatives; Tilorone or Treatment or Irradiation or Mouse; Blood Collection or Mouse or Cardiac Puncture or Alternative.

V.4.1.3.5. Results of Search
Irradiation with ionizing radiation is not a painful process but it induces various changes in the body and kills hematopoietic cells and gastrointestinal epithelium. In irradiated animals, the immune response is compromised and opportunistic infections may ensue. There is no less painful or distressful alternative found that can be used to develop protective and mitigating agents for irradiation. No references were found suggesting any effect of tilorone, or PBS on pain or distress. There are alternatives for blood collection by cardiac puncture in a mouse, such as tail vein and facial vein blood draw, etc. However, none of these alternatives can provide more than 0.1–0.2 ml of blood. We will need about 1 ml of blood sample to run all the tests for our experiments. Therefore, we will be using cardiac puncture for blood collection. Blood also may be drawn from the inferior vena cava if the "cardiac stick" method is unsuccessful. However, we will do so while the animal is anesthetized and as a terminal procedure. Therefore, it will not cause more than momentary pain or distress.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification
There is no alternative to the *in vitro* system and no less painful/distressful *in vivo* system is available to test new therapies against acute irradiation syndrome. Thus, we have to use this mouse model to test the protective and mitigative/therapeutic effects of tilorone on mouse hematopoietic and gastrointestinal systems after different doses of gamma-irradiation.

Furthermore, we will need to collect about 1 ml of blood sample to run all the tests for our experiments in the proposed study. However, there is no other alternative available

to obtain 1 ml of blood from a mouse other than via use of a cardiac stick. Therefore, we will be using cardiac puncture for blood collection, while the animal is anesthetized. Therefore, it will not cause more than momentary pain or distress.

V.4.2. Prolonged Restraint N/A

V.4.3. Surgery
V.4.3.1. Pre-surgical Provisions N/A

V.4.3.2. Procedure(s) N/A

V.4.3.3. Post-surgical Provisions N/A

V.4.3.4. Location N/A

V.4.3.5. Surgeon N/A

V.4.3.6. Multiple Major Survival Operative Procedures

V.4.3.6.1. Procedures N/A

V.4.3.6.2 Scientific Justification N/A

V.4.4. Animal Manipulations
Mice will be anesthetized by isoflurane. Anesthesia will be induced in a properly scavenged chamber using 2–3% Isoflurane in 100% oxygen. Once they are recumbent and start to take slow and deep breaths, they will be maintained on 1–2% isoflurane via nose cone. Mice will be placed in dorsal recumbence. Toe pinch will be used to make sure they are deeply anesthetized before doing the procedure. A 23–27G needle with bevel up will be inserted through the diaphragm lateral to the xiphoid process and will direct the needle forward and medially toward the heart. Approximately 1 ml of blood will be collected by gentle pulling of the plunger. At the end of blood collection, mice will be immediately euthanized by cervical dislocation while deeply sedated.

V.4.4.1. Injections We will use 25- to 30-gauge needles for SC injections of 0.1 ml PBS or tilorone in the nape of the neck. PBS will be used as control. Injections will be carried out in AFRRI IACUC-approved procedure rooms.

V.4.4.1.1. Pharmaceutical Grade Drugs N/A

V.4.4.1.2. Non-Pharmaceutical Grade Drugs
Tilorone is not available in the USA as a pharmaceutical-grade drug. It will be purchased from Sigma-Aldrich Inc., St. Louis, MO. Tilorone is water soluble and can be dissolved in PBS (using PBS will allow for an acceptable pH level for SC injection) for injection solution. According to standard practice in approved AFRRI protocols, there have been no injection site reactions in these mice using the proposed volume (0.1 ml) and route (SC) for tilorone in PBS.

The drug is supplied as sterile and will be dissolved in sterile filtered PBS under aseptic

conditions. A solution of 40 mg/ml tilorone in PBS has a pH of 6.6, which is well within the acceptable range for SC injections as stipulated by IACUC (pH 6–8). The endotoxin titer for the Sigma-Aldrich research grade drug was <0.068 EU/mg; the FDA limit is 0.15 EU for a 30 g mouse^{-1}. Tilorone will be freshly prepared using PBS.

V.4.4.2. Biosamples

Blood, bone marrow, spleen, and jejunum tissue will be collected from the sham-irradiated and gamma-irradiated mice. Mechanism studies will be performed using these tissue samples. Heart, liver, and jejunum will be collected for bacterial translocation study.

V.4.4.3. Adjuvants N/A
V.4.4.4. Monoclonal Antibody (MAb) Production N/A
V.4.4.5. Animal Identification N/A
V.4.4.6. Behavioral Studies N/A
V.4.4.7. Other Procedures N/A
V.4.4.8. Tissue Sharing N/A
V.4.4.9. Animal By-Products N/A

V.4.5. Study Endpoint

In the proposed study, the animals will be euthanized by a maximum of 20–30 days. We will follow the IACUC policy letter (Operating Policy #10) on early end points. We do anticipate that the animals will become morbid during this study. However, we will not consider death as an endpoint in this study. If the animals become morbid as described in the policy letter on early end points, we will increase monitoring and will euthanize the animals immediately if they are found to be in moribund condition. Our staff is experienced in evaluating the health status of mice. However, we will consult the VSD veterinary staff if we have any questions evaluating the health status of our animals. We will use the clinical signs as described in the IACUC policy letter on early end points to categorize the animal as morbid or moribund.

[1] Limit for endotoxin is 5.0 Endotoxin Units (EU) per kg for the maximum dose to be administered in a one hour period. Center for Drug Evaluation and Research, "Guideline on Validation of the Limulus Amebocyte Lysate Test as an end product Endotoxin test for human and animal parenteral drugs, biological products and medical devices", p10.

VIII. Appendix A: Clinical Observations with Criteria for Euthanasia (Rodent)

DATE:	Time:	Animal ID#	Score
Appearance:			
	Normal (smooth coat, clear eyes/nose)		0
	Hunched and/or fluffed		1
	Ocular discharge, and/or edema		3
	Emaciated, dehydrated (skin tent) **		5
	Soft stools (fecal matter around anus)		5
	Bloody diarrhea		9
Respiratory rate:			
	Normal breathing		0
	Increased breathing (double normal rate, rapid, shallow)		6
	Abdominal breathing (gasping +/- open mouth breathing)*		12
General Behavior:			
	Normal (based on baseline observations)		0
	Stretching of hind limbs with abdominal motion (writhe) or grimace (App. B and C)		1
	Decreased mobility		2
	Ataxia, wobbly, weak**		6
	Inability to stand*		12
Provoked Behavior:			
	Normal (moves when cage is disturbed, runs from hand (mice) or investigates (rat))		0
	Subdued; responds to stimulation (moves away briskly)		1
	Subdued even to stimulation (moves away slowly)		3
	Unresponsive to gentle prodding **		6
	Does not right when placed gently on side within 5 seconds*		12
TOTAL			_____

Definitive criteria for morbidity:
Weight Loss up to 10% baseline (if available)**
Pale, white mucous membranes/ skin * *
Fever >104F/40C (if available)**

Definitive criteria for moribundity:
Weight Loss > 20% OR <15g (adult mouse)*
Blue mucous membranes/ skin (cyanosis)*
Cool to the touch or <86F/30C (if available)*

**** Regardless of score, notify appropriate person immediately.**

*** Regardless of score, immediately euthanize (death is imminent)**

Score:
< 6 Normal
6 - 9 Morbid: Monitor at least 3 times per day; notify appropriate personnel immediately
> 10 Moribund: Notify responsible personnel immediately for euthanasia (if no single criteria is 12*)
Any single criteria of 12* euthanize immediately; consider as 'found dead'

V.4.6. Euthanasia: Animals in experiments involving blood collection will be anesthetized with isoflurane before blood collection. After blood collection, confirmatory cervical dislocation will be performed while the animal is still anesthetized.

For the non-blood collection groups, before tissue collection animals will be euthanized by CO_2 inhalation as per the AVMA Guidelines on Euthanasia.

Time of euthanasia: For Experiment 1, time of euthanasia will be 30 days after animals receive 7, 9 or 10 Gy of irradiation, and 20 days after receiving 12 Gy irradiation; for Experiment 2 it will be 1, 7, 14, 21 and 28 days post-irradiation; and for Experiment 3 it will be 12 h, 3.5 and 10–12 days post-irradiation.

V.5. Veterinary Care

V.5.1. Husbandry Considerations: Husbandry care will be done as per VSD SOPs. Mice are social animals and will be housed together in groups. Nesting material/igloos/shelters will be provided in each cage. Animals will receive Harlan Teklad Rodent Diet (w) 8604 and water *ad libitum*. Acidified water (pH 2.5–3.0) will be provided. Cages will be regularly changed and cleaned by VSD staff. Animal rooms will be kept on a 12 h/12 h light/dark cycle.

V.5.1.1. Study Room As assigned by VSD

V.5.1.2. Special Husbandry Provisions N/A

V.5.1.3. Exceptions

V.5.2. Veterinary Medical Care

V.5.2.1. Routine Veterinary Medical Care
Routine veterinary care will be provided as per VSD SOPs. Experimental animals will be observed at least once daily by our staff. However, if the animals become morbid and more monitoring is needed, our staff will increase monitoring to 2–3 times daily. Our staff will monitor the animals outside normal VSD working hours (after 5 pm in the evening and before 7 am in the morning) to provide a wider range of monitoring for morbid animals.

V.5.2.2. Emergency Veterinary Medical Care
On weekends and holidays, morning rounds will be done by VSD animal caretakers and during evening rounds it will be done by VSD veterinary technicians. Animal caretakers and veterinary technicians can contact the on-call veterinarian if needed. Our (PI) staff will provide after-hours coverage (outside of the routine veterinary coverage provided by VSD staff) on an as-needed basis as determined by the VSD veterinarians. Our staff will contact the on-call veterinarian if needed.

V.5.3. Environmental Enrichment

V.5.3.1. Enrichment Strategy
Nestling pads, shelters, and/or igloos will be provided in each cage during bedding changes.

V.5.3.2. Enrichment Restrictions N/A

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING

Name	Degree	Training	Date	Procedures	Yrs/Mos Experience
(b)(6)				1, 3b, 4a, 5, and 7 (tail vein injection) anesthesia	(b)(6)
				1, 3b, 4a, and 5, anesthesia	
				1, 3b, 4a, and 5, anesthesia	
				1, 3b, 4a, and 5, anesthesia	

Procedure and manipulation codes:
Code 1 = Animal handling and euthanasia
Code 2 = Surgery (aseptic technique) pre- and post-operative care
Code 3 = Injections (3a-ip, 3b-sc, 3c-gavage)—Three if trained in all manipulations or add 3d-iv
Code 4 = Blood collection under anesthesia (4a-cardiac, 4b-posterior vena cava)
Code 5 = Tissue collection (after euthanasia)—doesn't need to be specific
Code 6 = Implantation (provide detail here)
Code 7 = Others — (provide protocol specific manipulations or procedures for e.g., retro-orbital bleeding, tail vein injection, or drug delivery)

VII. BIOHAZARDS/SAFETY

All investigators and personnel will use appropriate protective gear while in the vivarium, as described by the VSD. All listed personnel are current regarding safety training and medical surveillance. All listed personnel have completed the Animal Care and Use in Research and Education training (AALAS learning library) courses. Recently they took three refresher courses: Common Compliance Issues, 8th Edition of the Guide for the Care and Use of Laboratory Animals, Pain Recognition and Alleviation in Laboratory Animals and passed the exams.

X. ASSURANCES

Protocol Title: Evaluation of tilorone as a novel radiation countermeasure candidate: *In vivo* study using laboratory mouse model (*Mus musculus*).

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made every effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with a qualified individual who evaluated the experimental design with respect to the statistical analysis, and that the minimum number of animals needed for scientific validity will be used.

D. Biohazard / Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures/manipulations/observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures/manipulations.

F. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R", namely, "Responsibility," which the DOD has embraced for implementing animal use alternatives where feasible and conducting humane and lawful research.

G. Scientific Review: This proposed animal use protocol has received appropriate peer scientific review and is consistent with good scientific research practice.

H. Painful Procedure(s): I **AM/AM NOT** conducting biomedical experiments, which may potentially cause more than momentary or slight pain or distress to animals. If applicable, potential pain and/or distress **WILL/WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

DOD ANIMAL CARE AND USE STANDARDIZED PROTOCOL FORMAT WITH EMBEDDED INSTRUCTIONS (March 2013)

Reference DOD Instruction 3216.01 & AFRRI Instruction 3216.2H

****

Information requested in the following animal use protocol template reflects the requirements of the Animal Welfare Act Regulations (AWAR), the Guide for the Care and Use of Laboratory Animals, and other applicable Federal regulations and DOD instructions.

****

This document is intended to be an aid in the preparation of DOD-sponsored animal use protocols. It is a companion document to an identical protocol template that does not have embedded instructions. Either template may be used to format DOD-sponsored animal research proposals; however, reference to the instructions during protocol preparation is highly recommended. If using the template with instructions, the instructions should be deleted prior to submitting the finished protocol for IACUC review. Please use Arial, regular, size 12, black font to prepare the protocol. With the exception of section headings, all paragraphs require a response. Paragraphs that do not apply should be marked N/A. There is no space limitation for responses to the information requested.

Approved standard operating procedures (SOPs) promulgated by the AFRRI Veterinary Sciences Department (VSD) or similar VSD-validated documents that describe specific procedures may be referenced by SOP number and title in lieu of repeating the details in the protocol. However, it is essential to include general descriptions of all animal manipulations to be carried out under the IACUC-approved protocol and to provide details where no approved references are cited. To do otherwise would constitute a breach of statutory regulations. Manipulations not covered in the originally approved protocol can be initiated only after IACUC approval of a formal amendment adding the new procedures. Additionally, Principal Investigators (PIs), or other delegated research personnel, should maintain accurate experimental records and be able to provide an audit trail of animal expenditures and use that correlates with their approved protocol. Protocol PIs will be required to provide this and other information during annual protocol reviews.

Any supporting information that may be of use to the IACUC during its review may be attached to the completed protocol. Adding subparagraphs within the body of the protocol template is permissible, *provided that the numbering sequence of paragraphs in the original standard format is maintained.* In other words, all of the labeled paragraphs and subparagraphs in this template must be retained, with additional information being presented as sub-numbered paragraphs containing information that supports or complements what is requested.

INTELLECTUAL PROPERTY STATEMENT

Research protocols drafted by Government scientists include intellectual property (e.g., concepts, ideas, experimental approaches, etc.), some of which is innovative or original and therefore considered proprietary to the investigators and/or the sponsoring agency. All Government and non-Government personnel handling this protocol shall exercise EXTREME CARE, to ensure that the information contained herein is NOT DUPLICATED OR DISCLOSED, in whole or part, for any purpose other than to evaluate the protocol, without the written permission of the principal investigator or the sponsoring agency.

I. NON-TECHNICAL SYNOPSIS: The threat of a limited radiological attack on American cities (i.e. a "dirty" bomb), or a nuclear accident, requires the development of a radiation countermeasure capable of protecting the gastrointestinal (GI) tract of military personnel, who might have to enter a contaminated area, or capable of mitigating GI lethality in the general population. At present there is no effective treatment for the acute radiation GI syndrome. We aim to assess anti-ceramide monoclonal antibody (mAb) as a mechanism-based approach to protect against and mitigate this potentially-lethal pathophysiology. The drug we are going to use will mimic turning off a stress signal (the asmase gene) and thereby allow cells to heal when they would otherwise die. In preliminary studies, anti-ceramide antibody significantly protected murine GI tracts up to 15 Gy total body irradiation when delivered prior to radiation exposure, and mitigated crypt lethality when delivered up to 24 h following irradiation. In the current protocol, we propose to develop anti-ceramide antibody for preclinical testing for use as a radiation protecting/mitigating therapeutic.

II. BACKGROUND

II.1. Background: The laboratories of (b)(4) (b)(4) (b)(4) proposed a physicochemical mechanism for ceramide signaling involving ceramide-driven re-organization of microscopic membrane rafts into ceramide-rich macrodomains (b)(4) (b)(4) While initial studies focused on Fas and *Pseudomonas aeruginosa* infection (b)(4) (b)(4) more recently (b)(4) focused on ultraviolet-C (UV-C) light, ionizing radiation and T cells. Their findings, described below, indicate that ceramide-rich platforms (CRPs) play a fundamental structural role in transmembrane signaling of death signals.

Extensive literature supports ceramide as an evolutionarily-conserved second messenger for stress (14, 15). This system is usually in the "off" state under basal conditions, activated upon contacting stress, and calibrates the extent of cellular stress, evoking an adaptive or apoptotic cellular response depending on strength of signal. The most widely studied ceramide-generating mechanism involves the translocation of an acid form of the enzyme sphingomyelinase (ASMase) to the outer plasma membrane,

where it hydrolyses its substrate sphingomyelin, generating ceramide therein (b)(4) While the mechanism by which diverse stresses (UV-C, heat, mechanical stress etc.) are registered at the plasma membrane is uncertain, it has been shown that such stresses induce translocation of a non-lysosomal form of ASMase, termed secretory ASMase, to the exoplasmic leaflet of the plasma membrane to initiate stress signaling (b)(4) Ceramide, once generated, has a unique biophysical property, that of self-association, forming CRPs on the cell surface, 1-5 microns in diameter, which serve as sites for protein oligomerization and transmembrane signal transduction (b)(4) 25). The basis of this protocol is that CRP formation on the surface of endothelial cells of the GI tract mediates the pathology that leads to radiation-induced GI lethality after whole body irradiation, as a result of an acute vascular dysfunction which regulates stem cell clonogens (SCC) demise and is amenable to inhibition by anti-ceramide antibody under development for this purpose.

The ability to antagonize GI toxicity using genetic and pharmacologic inhibitors of endothelial apoptosis has revealed multiple layers of complexity concomitant with ionizing radiation damage to the GI tract. Whereas mice most commonly die from the GI syndrome within days 5-10 after whole body irradiation, death from the bone marrow (BM) syndrome occurs at day 14-17 after whole body irradiation, a 10-day cutoff for assigning lethality from the whole body irradiation-induced BM versus GI syndrome has become generally accepted(21, 28). Recent evidence from some investigators challenged this notion, demonstrating that genetic inhibition of GI death at whole body irradiation doses of ≥14 Gy resulted in mice death from an accelerated form of BM aplasia at 8.2±0.9 days (24). Hence the use of a 10-day cutoff to separate the GI from BM syndromes appears inappropriate. Studies examining the impact of autologous BM transplantation (BMT) on this accelerated mode of BM aplasia were also revealing. Whereas protection of the GI tract by genetic inhibition of endothelial cell apoptosis switched animal demise to accelerated BM aplasia as the cause of animal death, only 60-70% of mice could be rescued with BMT. The 30-40% that died from accelerated marrow aplasia despite receiving syngeneic BM appeared to succumb to BMT engraftment failure, apparently due to radiation-induced stromal damage and failure of BM "take" (unpublished observation from collaborator laboratory). Consistent with the notion that BM matrix has become refractory at high radiation doses to marrow take, increasing the delivered marrow to $1x10^7$ cells or multiple doses of $5x10^6$ cells could not save these mice. Thus, the capability to selectively inhibit the GI syndrome has allowed for redefinition of the mechanism of animal demise during the acute phase response to single high dose whole body irradiation, indicating that there are at least three syndromes that need to be treated to preserve animal survival: a HSC syndrome at low radiation doses treatable with BM transplant, a coupled endothelial cell apoptosis-crypt SCC damage-regulated GI syndrome that can be impacted by agents that prevent ceramide-mediated endothelial cell apoptosis, and a BM stromal syndrome that we know little about currently. Interrogation of the biological response to radiation exposure should address these three syndromes. *Our strategy for mitigating the GI syndrome selectively using anti-ceramide antibody is based on these principles.* Earlier, anti-ceramide antibody whole molecule has been tested against whole body irradiation. This protocol is for evaluating whole molecule of anti-ceramide antibody against partial body irradiation and its fragments against total-body irradiation (TBI). Whole antibody

molecule will be used as a control in experiments with antibody fragments for comparison

Full-length IgG monoclonal antibodies are large (150 kDa), multivalent proteins. Recombinant proteins consisting of only the antigen-binding portion of monoclonal antibodies (the variable heavy (V_H) and light (V_L) chain regions) have been generated that retain antigen binding compared to the parent monoclonal antibody, while displaying, in cases where Fc portions are not required for immunomodulatory function, equivalent biologic activity. These Fab and single-chain fusion proteins (referred to as scFv proteins), contain the parent antibody V_H and V_L domains, yet display several favorable characteristics compared to full-length monoclonal antibodies, most notably: 1) Antibody fragments display significantly faster diffusion rates into the blood stream (minutes compared to hours following im or sc administration) and higher tissue permeability than immunoglobulins, due to their small size and enhanced solubility; 2) Antibody fragments can be genetically manipulated to optimize antigen-binding, stability, and delivery (scFv forms deliverable orally to gut mucosa have been proposed); and 3) Product development costs can be considerably less than for a humanized immunoglobulins. For these reasons, antibody fragments appear ideally suited for development as medical radiation countermeasures for emergency scenarios, where an anti-ceramide reagent would be administered in triage to potentially large populations following a radiation disaster.

II.2. Literature Search for Duplication

II.2.1. Literature Sources Searched

Best effort has been made to find any possibility for duplication. The following data bases have been searched:

III. OBJECTIVE / HYPOTHESIS:

The objective of this protocol is to advance the pre-clinical development of anti-ceramide antibody as radioprotector (and radiomitigator) of the acute radiation GI syndrome. Here, we propose to evaluate the hypothesis that antagonism of CRP generation on endothelium within the small intestinal lamina propria with anti-ceramide

antibody will improve GI stem cell survival, protecting and mitigating GI tract damage, improving survival. (b)(4)

(b)(4)

and based on these investigations we propose that ceramide-neutralizing Abs represent a novel class of pharmacologic agents for radiological countermeasures. We propose several experiments with the intention of advancing technology development of anti-ceramide Abs as protectors and mitigators of tissue injury following acute radiation exposure.

IV. MILITARY RELEVANCE

Currently, there are no FDA approved pharmaceutical agents that can prevent or treat injury from external ionizing radiation. The problem has become more acute in recent times due to the unpredictable nature of terrorist attacks. Recognizing this urgent need, the U.S. Department of Defense has assigned top priority to the "development of medical countermeasures to radiation exposure" against both early and late arising health effects. These concerns imply the urgent need to develop an appropriate countermeasure for radiation injuries potentially sustained by war fighters during combat operations and enable commanders to make judicious decisions in troop deployment. There are several drugs at different stages of the development. This study will perform essential research and development of a promising new agent (anti-ceramide antibody) as a therapy for potential injuries sustained by military personnel who have been accidentally exposed to ionizing radiation.

V. MATERIALS AND METHODS

V.1. Experimental Design and General Procedures

We propose to do the following experiments to evaluate anti-ceramide antibody 2A2 as a radioprotector and a mitigator of the radiation. Experiment will be done in order shown below. Details of subsequent experiments will be based on results obtained in previous experiment. Any product found ineffective in initial experiment will be eliminated in subsequent experiments.

V.1.1. Experiment 1. Determination of the gastrointestinal (GI) lethal dose of partial body (subtotal) irradiation (X-Ray – Small Animal Radiation Research Platform – SARRP): The gastrointestinal lethal dose of subtotal body irradiation will be determined in C57BL/6 mice. Groups of 8 mice will be exposed to 13-16 Gy in 0.5 Gy (13.0, 13.5, 14.0, 14.5, 15.0, 15.5, 16.0 Gy) increments, with lead shielding of the animals' head and forelimbs (approximately 20% shielding). Anticipated GI lethal dose may be 14 Gy and mice may survive for 6 - 8 d. Animals will be monitored for survival. Expected results are that animals will survive >14 days (animals should survive indefinitely) at lower doses of subtotal body irradiation, but once a GI lethal dose is reached animals will succumb to the GI Syndrome. Animals will be observed for 30 d post-irradiation.

According to the suggestions from veterinary science department, a trial run (without irradiation) will be carried out to evaluate the best method (anesthesia etc) along with the VSD veterinarians. This will be accomplished using VSD training protocol (have consent from VSD veterinarian). Once the SARRP procedure is standardized, we will make necessary adjustments in the protocol by submitting appropriate amendment before proceeding further.

Group details and mice required for experiment 1:

Dose response of radiation: Seven radiation doses (13.0, 13.5, 14.0, 14.5, 15.0, 15.5, 16.0 Gy SAARP) x 8 mice/group x 2 experiments= 112

Total mice required for experiment 1 = 112

V.1.2. Experiment 2. Assessment of the efficacy of whole antibody molecule (H2A2) and recombinant antibody fragments (Fab and scFv) as radioprotector for the GI syndrome: H2A2 (1000 μg/ml) and recombinant antibody fragments of H2A2 (Fab or scFv, 100 μg/ml) will be administered intravenously (for additional details please see section **V.4.4.1. Injections**) to C57BL/6 mice 15 min prior to the GI lethal dose of subtotal body irradiation (100% lethal dose) to assess the efficacy of recombinant antibody fragments in comparison to whole molecule. Mice will be sacrificed 3.5 d after irradiation, and jejunum will be harvested after euthanasia for analysis by microcolony assay of Withers and Elkind as a quantifiable surrogate for GI damage following irradiation (31).

Details of treatment groups and mice required for experiment 2:

Evaluation of recombinant antibody fragments as radioprotector: Four groups (control, H2A2, Fab or scFv at -15 min) x 6 mice/group x 2 experiments (one with SARRP and other with Cobalt-60) = 48 mice

Total mice required for experiment 2 = 48

V.1.3. Experiment 3. Assessment of the efficacy of whole antibody molecule (H2A2) and recombinant antibody fragments (Fab and scFv) as radiomitigator of the GI syndrome: H2A2 and recombinant antibody fragments of H2A2 (Fab or scFv) will be administered intravenously (for details please see V.4.4.1. Injections) to C57BL/6 mice 12-48 h following GI lethal dose of subtotal body irradiation (100% lethal dose) (12, 24, and 48 h). Mice will be sacrificed 3.5 days following irradiation, and jejunum will be harvested after euthanasia for analysis in microcolony assay of Withers and Elkind as a quantifiable surrogate for GI damage following whole body irradiation.

Details of treatment groups and mice required for experiment 3:

Evaluation of recombinant antibody fragments as radiomitigator: Four groups (control, H2A2, Fab or scFv) x 6 mice/group x 3 time points (12, 24 and 48 h) x 2 experiments (one with SARRP and other with Cobalt-60) = 144 mice

Total mice required for experiment 3 = 144

V.1.4. Experiment 4. Investigation for optimal dose, schedule of treatment, and route of administration of H2A2, Fab, and scFv: Dosing, treatment schedule, and route of administration of H2A2 and recombinant antibody fragments of H2A2 (Fab or scFv) will be optimized. Antibody will be administered through various routes stated below. Mice will be sacrificed 3.5 days following, and jejunum will be harvested for analysis in Microcolony Assay of Withers and Elkind as a quantifiable surrogate for GI damage following whole body irradiation. First, optimal dose of antibody will be determined and with that dose, optimal route of administration will be determined.

Details of treatment groups and mice required for experiment 4:

Dose response: Four groups (0, 500, 750, and 1000 µg for H2A2 and 0, 25, 50 and 100 µg for Fab and scFv) x 2 experiments (one set for radioprotector and another for radiomitigator) x 3 products to be tested (H2A2, Fab, and scFv) x 6 mice/group = 144 mice

*Routes of administration: Two groups (ab and control) x 3 products to be tested (H2A2, Fab, and scFv) x 4 routes (iv, im, sc, ip) x 6 mice/group x 2 experiments (one with SARRP and other with Cobalt-60) = 288 mice

Schedule of ab administration: Two groups (control and ab) x 6 time points of ab administration x 2 sets of experiments for radioprotector and mitigator (-30 min, -1 h, -2 h, -4 h, -6 h, -12 h in relation to irradiation for protector, and 12 h, 18 h, 24 h, 30 h, 36 h, 48 h in relation to irradiation for mitigator) x 6 mice/group = 144 mice

Total mice required for experiment 4 = 144 + 288 + 144 = 576

*Preliminary data with anti-ceramide IgM Ab has been generated using iv route. Hence iv route is being used in initial experiment. Keeping in mind the limitation of iv route from drug administration point of view, other routes will be tried.

Route of administration of antibody for experiments 1.5, 1.6, and 1.7, will depend on the results of experiment 1.4 (most effective route for drug efficacy). Based on our experience, we expect retro-orbital injection will be most efficacious.

V.1.5. Experiment 5. Assessment of radioprotection by H2A2 and its fragments (Fab, and scFv) in mice (survival study): H2A2 or its fragment will be administered to C57BL/6 mice 15 min prior to the GI lethal dose of subtotal body irradiation. Radiation dose will be selected based on the success in above experiments (at least 50% higher crypt numbers compared to untreated control). Animals will be monitored for 30 d after radiation exposure for survival. Moribund mice (details discussed under section V.4.5. Study Endpoint, displaying clinical signs of imminent death from radiation gastrointestinal syndrome) will be euthanized. Jejunum and sternum will be harvested after euthanasia for hematoxylin and eosin staining and analysis.

Details of treatment groups and mice required for experiment 5:

Evaluation of recombinant antibody fragments as radioprotector: Four groups (control, H2A2, Fab or scFv at optimal time point based on above experiments) x 8 mice/group x 2 experiments (one with SARRP and other with Cobalt-60)= 64 mice

Total mice required for experiment 5 = 64

V.1.6. Experiment 6. Optimization of radiomitigation by H2A2 and its fragments (Fab, and scFv) in mice (survival study): H2A2 or its fragment will be administered to C57BL/6 mice after the GI lethal dose of subtotal body irradiation. Radiation dose will be selected from above experiments (at least 50% higher crypt numbers compared to untreated control) . Animals will be monitored for 30 d after radiation exposure for survival. Moribund mice (details discussed under section V.4.5. Study Endpoint, displaying clinical signs of imminent death from radiation gastrointestinal syndrome) will be sacrificed. Jejunum and sternum will be harvested for hematoxylin and eosin staining and analysis.

Details of treatment groups and mice required for experiment 6:

Evaluation of recombinant antibody fragments as radiomitigator: Four groups (control, H2A2, Fab or scFv) x 4 time points in relation to irradiation (12, 24, 36 and 48 h after irradiation) x 8 mice/group x 2 experiments (one with SARRP and other with Cobalt-60) = 256 mice

Total mice required for experiment 6 = 256

V.1.7. Experiment 7 Optimization of mitigation by addition of supportive care (antimicrobial therapy): Survival experiments will be performed comparing animals that receive supportive care (antimicrobial therapy) in addition to H2A2 to those receiving vehicle for antibiotics plus H2A2. H2A2 or fragments will be administered to C57BL/6 mice at the latest effective time in which H2A2 improves survival post the GI lethal dose of subtotal body irradiation. Effective supportive care is expected, in combination with H2A2, to confer 30 d survival to mice exposed to 15 Gy, while a majority of mice receiving sham antibiotic will die from sepsis. All mice with unprotected GI tracts that did not receive H2A2 will die from the radiation gastrointestinal syndrome.

Antimicrobial therapy: Antimicrobial agents from different classes, including 4-fluoroquinolones and aminopenicillins, will be selected for systemic administration based upon published recommendations for treatment of sepsis following irradiation (5) and recent experimental work in the laboratory of microbiology colleague (personal communication). Doses used to evaluate efficacy against sepsis in mice have been selected based on human pediatric doses together with consideration for the high metabolic rate of mice compared to humans and the published reports by others in non-irradiated mice. In general, doses of antimicrobial agents are three to five times greater in mice than in humans to achieve comparable efficacy and concentration in blood and tissues. Doses used in this study are based on pharmacokinetics and efficacy against sepsis determined in irradiated mice.

Systemic antimicrobial agents that will be evaluated in the classes (5):

4-Fluoroquinolone: Levofloxacin (LVX) [90-100 mg/kg *p.o.* (not gavage) *q.d.*]

(Giving drug by oral route is different from giving drug by gavage: gavage means forced feeding, specially a tube passed through the stomach (Dorland's Medical Dictionary, 28th edition, 1988), p.o. (*peros*) means by mouth, orally, commonly used in medical practice, in case of mouse – feeding needle will stay in mouth and fluid will be ejected slowly).

Aminopenicillin: Amoxicillin (AMX) [300-325 mg/kg *p.o. q.d.*].

When the combination of LVX and AMX is administered to mice, the LVX is delivered first with a 20- to 30-minute interval before AMX is delivered to allow time for LVX to be absorbed because AMX is a microencapsulated suspension, which coats the lining of the gastrointestinal tract (5).

In order to anticipate bacterial translocation and moribundity, we will start antibiotic therapy on d 3 post-irradiation and continue for 21 d (last dose on 23 d post-irradiation).

Details of treatment groups and mice required for experiment 7:

Mitigation by addition of antimicrobial therapy: Four groups (control, H2A2, Fab or scFv) x 4 antimicrobial therapy (control/sham, LVX, AMX, and combination of LVX and AMX) x 8 mice/group x 2 experiments (one with SARRP and other with Cobalt-60) = 256 mice

Total mice required for experiment 7 = 256

Total C57BL/6 mice needed for this Protocol:

Experiments	Total	C	D	E
Experiment 1	112	0	0	112
Experiment 2	48	0	0	48
Experiment 3	144	0	0	144
Experiment 4	576	0	0	576

Drugs and routes of administration:

Experiments	**Drugs**	**Route of administration**
Experiment 1	Anticeramide antibody (whole molecule- H2A2, fragments - Fab and scFv)	Retro-orbital (iv)
Experiment 2	Anticeramide antibody (whole molecule- H2A2, fragments - Fab and scFv)	Retro-orbital (iv)
Experiment 3	Anticeramide antibody (whole molecule- H2A2, fragments - Fab and scFv)	Retro-orbital (iv)
Experiment 4	Anticeramide antibody (whole molecule- H2A2, fragments - Fab and scFv)	sc, im, ip, retro-orbital (iv)
Experiment 5	Anticeramide antibody (whole molecule- H2A2, fragments - Fab and scFv)	Dependent on results of experiment 4
Experiment 6	Anticeramide antibody (whole molecule- H2A2, fragments - Fab and scFv)	Dependent on results of experiment 4

Experiment 7	Anticeramide antibody (whole molecule- H2A2, fragments - Fab and scFv)	Dependent on results of experiment 4
	Levofloxacin (LVX), Levofloxacin (LVX)	p.o.

V.2. Data Analysis

Mean with standard errors, or percentages, will be reported if applicable. The significance level will be set at 5% for each test. All statistical tests will be two-sided. Multiple comparison tests will be used when appropriate. Statistical software, PC SAS, will be used for statistical data analysis (6). Number of animals n = 6 - 8 per group (depending on dose, route, sampling time-point) will be used for the study to provide statistical power >90% for two-tailed Student's t test of less than 10% shifts in value.

Multivariate analysis of variance (MANOVA) Wilks' Lambda statistics will be used when comparing more than two groups and two-sided Student's *t* test will be used when comparing two groups to determine significant difference among sampling time and dose-points, efficacy, etc. Values of $P < 0.05$ will be considered statistically significant. Values will be expressed as means ± standard error (SE).

Comparison of survival curves will be made using the log-rank test. Fisher's exact test will be used to detect if there is a significant difference across the groups in survival rates by performing pair-wise comparisons. The 8 mice per group would provide 80% statistical power to detect a significant difference between two groups if any, given type I error of 5% and delta/sigma has at least 1.6 (where the delta is the estimated mean differences between the two groups and sigma is the pooled SD of the two groups) and a treatment group survival rate would be at least 74%, if the control group would be 20%. Similar statement would apply, provided the treatment group would be at least 88%, 85%, and 79%, if the vehicle group would be 35%, 30%, and 25% respectively (32).

V.3. Laboratory Animals Required and Justification

V.3.1. Non-animal Alternatives Considered

Both computer models and tissue culture have been considered as alternatives to animals. These alternatives lack the knowledge base and complexity needed to evaluate the effects of radiation and radiation countermeasures on the immune system. The phenomena under study involve complex information-processing networks comprising large number of cell types and biological signal transduction molecules. Responses to irradiation and radioprotective agents involve interactions between the central nervous system, the peripheral nervous system including the enteric nervous system, endocrine glands, the immune and inflammatory systems, hematopoietic system, gastrointestinal system etc. We do not know all of the cell types and tissues involved and many of the signal transduction molecules have not been discovered yet. Even if all of the tissues, cell types and signaling molecules were known, the present state of tissue culture would be incapable of reproducing their *in vivo* relationships. One would have to reproduce much of an entire mammalian organism in culture to study

these phenomena *in vitro*. As for computer models, the most powerful supercomputers available in the near future would be incapable of analyzing interactions between so many elements in the network. Thus these drugs necessitate investigation in whole animal models to see overall outcome.

V.3.2. Animal Model and Species Justification Evaluation of radiation countermeasures in *in vivo* model is the only option available for identifying clinically safe and non-toxic radiation countermeasures. The murine model is immunologically the most well defined animal model for research. The murine model is also the most studied animal model, and has significant immunological similarity to higher animals and humans. This model is also preferred over any other *in vivo* model due to readily available immunological and molecular biology research reagents. AFRRI staff has extensive experience with several strains of mice in radiation injury and radioprotection research. PI has extensive experience with C57BL/6 and CD2F1 mice. (b)(4) (b)(4) (b)(4) Thus, we need to stay with this strain of mice at this stage for the proposed study.**V.3.3. Laboratory Animals**

V.3.3.1. Genus / Species

Mus musculus, Laboratory mouse

V.3.3.2. Strain / Stock

C57BL/6

V.3.3.3. Source / Vendor

C57BL/6 mice will be purchased from a VSD approved vendor (the preferred vendor is Jackson Laboratory, 600 Main St., Bar Harbor, Maine 04609-1500; Tel: 207-288-5845; State of Maine animal welfare license is R012).

V.3.3.4. Age

6-12 weeks old

V.3.3.5. Weight

20 – 25 g

V.3.3.6. Sex

Male

Justification for using only male mice: Previous studies have been performed using male mice, so males are needed for data comparison. Also there is possibility that female hormone variation may interfere with our results. To see the effect of this drug in both sexes, we need to repeat such experiments in females. To minimize the number of animals, and to keep variables minimized, it was decided that the study will be performed only in one sex (male).

V.3.3.7. Special Considerations

Commercially procured animals must be adventitious disease free, including: *Pseudomonas aeruginosa*, and *Pasteurella*. All mice need to be free of the following agents: Sendai, Pneumonia Virus of Mice (PVM), Reovirus-3 (Reo 3), Mouse

Adenovirus (MAD-1, MAD-2), Mouse Cytomegalovirus Virus (MCMV), Ectromelia, K virus, Lymphocytic Choriomeningitis Virus (LCM), Epidemic Diarrhea of Infant Mice (EDIM), Hantaan virus, Rotavirus, Mouse Parvovirus (MPV), Polyoma Virus, Mouse Minute Virus (MMV), Mouse Thymic Virus (MTV), Theiler's Mouse Encephalomyelitis Virus (TMEV/GDVII), *Encephalitozoon cuniculi*, CAR bacillus, *Mycoplasma pulmonis*, *Clostridium piliforme*, *and C. difficile.* Mice should also be endoparasite- and ectoparasite-free.

V.3.4. Number of Animals Required (by species)

V.3.5. Refinement, Reduction, Replacement (3 R's)

V.3.5.1. Refinement

Moribund animals will be euthanized immediately to minimize the magnitude and duration of suffering those animals might experience when they are subjected to toxic effects of ionizing radiation. Under such situation moribundity will be used as a surrogate for death in animals and will be considered to have arrived at the endpoint. Pain experienced by retro-orbital injection will be minimized by the use of higher gauge needles and controlled isoflurane administration.

V.3.5.2. Reduction

As we move forward with experiments, plans will be reevaluated at every stage of the experiments, in light of incoming data in an attempt to reduce the numbers of experiments and groups, if possible. If deemed not necessary based on incoming data, some investigations may not be carried out to optimize the use of experimental animals.**V.3.5.3. Replacement**

It is not feasible to use non-animal systems in place of *in vivo* animal models to address the research questions proposed in this IACUC protocol.**V.4. Technical Methods**

Experiment 7	256	0	0	256
Ten mice for trial of anesthesia regimen – section **V.4.1.2.1**	10	0	10	0
Total mice required for this protocol	1466	0	10	1456

V.4.1.2. Pain Relief / Prevention

V.4.1.2.1. Anesthesia / Analgesia / Tranquilization

Since anesthesia, analgesia, and tranquilizers are known to affect functions of the immune system of animals, we do not plan to use analgesic agent during course of the experiment after irradiation (1, 9, 10). However, anesthesia will be used during partial body X-ray irradiation to prevent stress from the time the mice are placed in restraint.

The anesthesia protocol for the SARRP partial body irradiation will be developed under the oversight of VSD veterinarian/s. SARRP irradiation requires anesthesia for longer period of time (30-40 minutes). No one at AFFRI has used SARRP before. Therefore, we will need to try out the following anesthetic regimens along with VSD veterinarian to determine the best option. Ten mice have been requested for this purpose. If none of these anesthetic regimens are able to achieve our goal then we will submit an amendment to our protocol to add an alternate anesthetic as per the recommendation from VSD veterinarian.

1. Ketamine 75-150 mg/kg + Xylazine 5-10 mg/kg via ip administration. Total volume of injection will not exceed 0.5 ml/mouse.
2. Ketamine 50-100 mg/kg + Xylazine 5-10 mg/kg + Acepromazine 1-2 mg/kg. Total volume of injection will not exceed 0.5 ml/mouse.
3. Isoflurane 3-4% in 100% oxygen for induction in a chamber. 1 - 3% Isoflurane for maintenance via a nose cone.

Animals in experiments involving blood (collection/storage for future)/tissue collection (different organs) will be euthanized immediately before tissue collection by overdose of isoflurane followed by cervical dislocation. We will use isoflurane to anesthetize mice for retro-orbital injection. This allows more controlled and precise delivery of the anesthetic. We regularly use these procedures in different ongoing protocols. We will also use 0.5% proparacaine HCL ophthalmic solution in addition to the inhalant anesthetic, prior to retro-orbital injections, as an additional form of procedural and post-procedural analgesia.

V.4.1.2.2. Pre- and Post-procedural Provisions

Mice will be housed under standard conditions both before and after radiation procedures in accordance with VSD mouse Standard Operating Procedure (see section V.5).

V.4.1.2.3. Paralytics

No paralytic agent will be administered.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification

As stated above, irradiated animals finally die due to a compromised immune response and microbial infections. In the event that there is pain and distress for animals, as we have already discussed under above headings, we cannot give anesthetic/analgesic agents to the animals (except at the time of ocular injection or wounds procedures which can't be performed without anesthesia) since these agents interact with the immune system, and in turn will affect experimental results.

There are conflicting reports regarding effects of buprenorphine on the immune system (7, 11, 16, 17, 19, 20, 23, 29). A majority of reports suggest that buprenorphine influences immune response. Since buprenorphine has been shown to influence various arms of cellular and humoral immune response (7, 17, 23, 29), we have decided not to use it in our study. Non-steroidal anti-inflammatory drugs are not suitable for use in such experiments (18).

V.4.2. Prolonged Restraint: N/A

V.4.3. Surgery

V.4.3.1. Pre-surgical Provisions: N/A

V.4.3.2. Procedure(s): N/A

V.4.3.3. Post-surgical Provisions: N/A

V.4.3.4. Location: N/A

V.4.3.5. Surgeon: N/A

V.4.3.6. Multiple Major Survival Operative Procedures

V.4.3.6.1. Procedures: N/A

V.4.3.6.2 Scientific Justification: N/A

V.4.4. Animal Manipulations

V.4.4.1. Injections

Mice will be injected with anti-ceramide antibody through the retro-orbital sinus (venous plexus behind the eye – for intravenous route) with 27 or 28 G needle with a 1 or 0.5 ml syringe (AFRRI IACUC Operating Policy # 4). This is a commonly used method (2-4, 22, 26, 30, 33). The animals will be temporarily anesthetized by inhalation of isoflurane. Both eyes can be used but PI will select one side and all animals will be injected at the same site for one administration. The eyelid area will be stretched gently to expose the eye and the needle will be inserted slowly into the orbita going beneath the eyeball. The needle is gently inserted bevel downwards until it hits the bone of the orbita. The antibody or bone marrow cell suspension will be injected slowly. If the needle is correctly inserted into the plexus, some resistance will be felt while injecting. After injection of the desired volume, the needle will be removed and the eyelid will be closed. No liquid or blood should leak out. In case, blood leaks out from the eye, sterile cotton gauze will be used to wipe/clean and animal will be carefully observed for 5-10

min. Animals will be returned to the cage and observed until they fully recover from the effects of the anesthesia.

Recently it has been demonstrated that retro-orbital venous sinus injection is less stressful compared to lateral tail vein (27). In mice we have found retro-orbital injection more reproducible than tail vein injection due to difficultly visualizing the tail vein. Since our radiation mitigating agent needs to be injected at a particular time post-irradiation, we have a limited time period to administer the agent to all mice in the study in order to insure post-irradiation time of injection. Because retro-orbital injection is more rapidly performed than tail vein injection, a single technician is able to inject large numbers of mice in a relatively short period of time. Study personnel assigned to this protocol have been trained in this procedure.

We have used such a method for cell, blood, and anti-ceramide antibody injection to mice in several protocols.

Injection volume will be 100 – 150 µl/mouse. In case, any preparation has a low solubility, we may need to inject 200 µl. There will be no need to go above this volume for any preparation. According to the policy from University of California, San Francisco, a maximum of 200 µl can safely be injected via the retro-orbital sinus (web reference: a copy of the UCSF policy can be found here: *www.iacuc.ucsf.edu/Policies/RetroOrbitalInjection.doc*). Under such situation, we will try two options:

1. in a minimum of 5 mice we would try the 100 µl in each eye and
2. in different mice (a minimum of 5), try 200 µl in one eye.

In both cases injection will be administered slowly and/or with rest periods (for the 100 µl) as necessary. Both options will be evaluated with a VSD veterinarian and the best will be used. We have received such approval earlier (Protocol #(b)(6) (b)(6)

Antibody will be also injected im, ip and sc as mentioned above under various experiments.

Antimicrobial therapeutic drugs will be prepared aseptically with sterile diluent including the control vehicles. They will be administered orally. Therapeutic drugs given p.o. will be administered in a 0.2-ml volume with a 1-ml syringe and a 20-gauge feeding canula, which has a ball tip, or a disposable feeding needle, which has a silicone rubber tip. One sterile syringe and needle will be used for mice in each cage. However, the feeding needle will be wiped and disinfected between inoculations with a gauze sponge that is moistened with 70% ethanol to reduce the microorganisms on the needle as an extra precaution even though the mice share the sipper tube in the water bottle and oral microorganisms as well.

The following doses will be used for administration of the therapeutic antimicrobial agents based on earlier studies with mice: amoxicillin (300 - 325 mg/kg PO sid), levofloxacin (90-100 mg/kg PO sid).

V.4.4.1.1. Pharmaceutical Grade Drugs

Vendors (or others as appropriate):

Amerisource-Bergen, Glen Allen, Virginia, Tel. 1-800-262-8470 ext. 4313, Acct. No. 74047 (USUHS)

Henry Schein, Inc., Henry Schein Veterinary Institutional Department, 135 Duryea Road Melville, NY 11747, Phone: 800-872-4346, Fax: 1-800-483-8329

Webster Veterinary Supply, 86 Leominster Road, Sterling, MA 01564, 978-422-8211 (Phone), 800-225-7911 (Toll Free in the U.S.), 978-422-8959 (Fax)

Pharmaceuticals:

0.5% Proparacaine HCL ophthalmic solution (will be procured from USUHS pharmacy).

Amoxicillin (AMX), generic e.g. 150 ml/bottle, Amoxicillin for Oral Suspension, USP (Sandoz, Broomfield, Colorado 80020, 250 mg/5 ml as trihydrate, NDC 0781-6041-55); or 100 ml / bottle, commercial oral suspension (IVAX Pharmaceuticals, Inc., Miami, Florida 33137-3227 by PENN Labs, Inc., Philadelphia, Pennsylvania 19102, amoxicillin for oral suspension USP, 250 mg per 5 ml as the trihydrate, 100 ml total volume when reconstituted with sterile water according to manufacturer's directions, NDC 0172-7418-21). Amoxicillin is a semisynthetic aminopenicillin antibiotic. Stored at 4°C. after reconstitution, durable for up to 14 days.

Levofloxacin (LVX), LEVAQUIN Oral Solution (25 mg/mL, 16 oz. [480 mL], Ortho-McNeil, NDC 0045-1515-01), is a 4-fluoroquinolone antimicrobial agent. It will be diluted to a concentration of 10.4 mg/ml in sterile water to deliver a dose of 90 mg/kg *q.d.* for in 0.2 ml given *p.o.* Oral and i.v. routes are considered interchangeable and achieve the same plasma concentration profile (Ortho-McNeil product information).

The corresponding vehicle is sterile water given to control mice.

V.4.4.1.2. Non-Pharmaceutical Grade Drugs

Anti-ceramide antibody, its fragments and isotype control (non-specific antibody) will be purchased from commercial vendors. Purity is assured because the antibodies are purified by the vendor by Protein G affinity chromatography. These reagents have been tested for endotoxin by the vendor, but have not undergone other tests for infectious agents. Before use in animals, the antibody reagents will be tested for infectious agents using a serological test (MAP test or equivalent) or PCR (MAP-IT test or equivalent). Stability will be ensured by storing the antibodies as lyophilized powder at -20 °C, in a manual defrost freezer, with no repeated thaw/freeze cycles, as recommended by the vendor. Microgram quantity of antibodies will be injected intravenously in pharmaceutical grade sterile phosphate-buffered saline, so osmolarity will not be an issue. Please also see section V.4.4.9. Animal By-Products.

V.4.4.2. Biosamples

Animals will be euthanized by overdose of isoflurane (for blood collection – blood will be stored for future reference), followed by cervical dislocation immediately before tissue (jejunum and femur bone) collection. GI tract and femur bone will be collected post-mortem for histopathology.

V.4.4.3. Adjuvants: N/A

V.4.4.4. Monoclonal Antibody (MAb) Production: N/A

V.4.4.5. Animal Identification

Each cage will have a cage card. In addition to cage card, another experimental card will be displayed before starting the experiment. One cage will have mice of only one treatment/control group. Each card will state the investigator's name, protocol number, experiment number, cage number, start date, end date, species, item number (animal lot), birth date, gender, strain, number of animals in the cage, vendor, arrival date, treatments, and dates of death or euthanasia of moribund mice, including the initials of the staff person who found and removed the dead animals or euthanized the moribund mice.

V.4.4.6. Behavioral Studies: N/A**V.4.4.7. Other Procedures:** None

V.4.4.8. Tissue Sharing: N/A

V.4.4.9. Animal By-Products

Commercially available antibody to ceramide, its fragments, and isotypic control will be used for injecting into mice. As stated above, these products will be tested for adventitious agents prior to use. Such testing will be done for mycoplasma and 18 viral agents by BioReliance, Rockville, MD prior to use (also mentioned under Non-Pharmaceutical Grade Drugs). We have carried out such testing for anti-ceramide antibody earlier for approved protocol # (b)(6) (b)(6) (b)(6) The results of testing will be given to the attending veterinarian or his/her designee for review prior to using these biologics in mice.

V.4.5. Study Endpoint

In all experiments where jejunum or bone marrow cells will be harvested, mice will be anesthetized and euthanized by an overdose of isoflurane followed by cervical dislocation immediately before tissue collection at a preset time as described under experimental design (V.1). All mice that have survived beyond experimental duration (30 day post-irradiation) or for moribund mice, if any, will be euthanized by CO_2 overdose followed by cervical dislocation. Naïve mice, if not used in the experiments, will be transferred to another approved protocol, if possible, or euthanized. Animals in these studies may become morbid and hence it is critical to define criteria for euthanizing mice humanely without compromising the study objective and complying with the IACUC recommendations stipulated in Policy Letter #10. Mice will be considered morbid based on criteria described in policy # 10. Experimental mice that are found morbid, but not moribund, will be allowed to continue in the experimental protocol. Once mice are considered morbid, we will monitor them at least twice daily, early morning and late afternoon.

Mice found moribund will be euthanized by trained and experienced personnel listed on this protocol or by trained/experienced VSD staff. Compressed CO_2 gas in a cylinder with a regulator will be used for euthanasia in accordance with the current American Veterinary Medical Association (AVMA) Guidelines on Euthanasia. Cervical dislocation will be done following CO_2 overdose as a secondary method of euthanasia. Mice will be considered moribund based on criteria described in policy # 10.

The table provided in AFRRI IACUC Operating Policy # 10 (Guidelines for establishment of early end points in experiments with expected mortality) has been included below because this study will involve a large degree of lethality.

VIII. Appendix A: Clinical Observations with Criteria for Euthanasia (Rodent)

DATE:	Time:	Animal ID#	Score
Appearance:			
	Normal (smooth coat, clear eyes/nose)		0
	Hunched and/or fluffed		1
	Ocular discharge, and/or edema		3
	Emaciated, dehydrated (skin tent) **		5
	Soft stools (fecal matter around anus)		5
	Bloody diarrhea		9
Respiratory rate:			
	Normal breathing		0
	Increased breathing (double normal rate, rapid, shallow)		6
	Abdominal breathing (gasping +/- open mouth breathing)*		12
General Behavior:			
	Normal (based on baseline observations)		0
	Stretching of hind limbs with abdominal motion (writhe) or grimace (App. B and C)		1
	Decreased mobility		2
	Ataxia, wobbly, weak**		6
	Inability to stand*		12
Provoked Behavior:			
	Normal (moves when cage is disturbed, runs from hand (mice) or investigates (rat))		0
	Subdued; responds to stimulation (moves away briskly)		1
	Subdued even to stimulation (moves away slowly)		3
	Unresponsive to gentle prodding **		6
	Does not right when placed gently on side within 5 seconds*		12
TOTAL			_____

Definitive criteria for morbidity:	**Definitive criteria for moribundity:**
Weight Loss up to 10% baseline (if available)**	Weight Loss > 20% OR <15g (adult mouse)*
Pale, white mucous membranes/ skin * *	Blue mucous membranes/ skin (cyanosis)*
Fever >104F/40C (if available)**	Cool to the touch or <86F/30C (if available)*
**** Regardless of score, notify appropriate person immediately.**	***** Regardless of score, immediately euthanize (death is imminent)**

Score:
< 6 Normal
6 - 9 Morbid: Monitor at least 3 times per day; notify appropriate personnel immediately
> 10 Moribund: Notify responsible personnel immediately for euthanasia (if no single criteria is 12*)
Any single criteria of 12* euthanize immediately; consider as 'found dead'

(Note: This form does not have to filled out for every individual at every observation, so long as the criteria are used in informing decisions on increased monitoring and/or euthanasia. This form may be used to make a spreadsheet for greater ease of multiple animal observations, as long as the criteria and numbering system are exactly copied.)

V.4.6. Euthanasia

As already mentioned above under various headings, mice will be euthanized by overdose of isoflurane and cervical dislocation just before tissue collection. Terminal CO_2 euthanasia will be used for mice that have survived beyond experimental duration (30 day post-irradiation) or for moribund mice, if any. Compressed CO_2 gas in a cylinder with a regulator will be used for euthanasia in accordance with the current American Veterinary Medical Association (AVMA) Guidelines on Euthanasia. Cervical dislocation will be done following CO_2 overdose as a secondary method of euthanasia.

V.5. Veterinary Care

V.5.1. Husbandry Considerations

No special husbandry consideration needed.

V.5.1.1. Study Room: As assigned by VSD.

V.5.1.2. Special Husbandry Provisions: None

V.5.1.3. Exceptions

Mice will be socially (group) housed, except where there is a possibility that during survival studies cage mates may be lost through attrition and for a period of time the sole surviving mouse may remain singly housed until the end of the 30-day study.

V.5.2. Veterinary Medical Care

V.5.2.1. Routine Veterinary Medical Care

As per Standard Operating Procedures, VSD staff will monitor all animals at least twice daily during morning and afternoon rounds. Any abnormalities will be reported immediately to the on-call veterinarian and PI. In addition, animals will be observed daily by this protocol's research staff. Any morbid mice will be observed twice a day (early morning and late afternoon) by the research staff. PI staff will be responsible for before and after working hours observations of morbid mice. Any moribund mice will be euthanized as soon as possible. If needed, VSD veterinarian will be contacted for decision.

V.5.2.2. Emergency Veterinary Medical Care

Emergency veterinary medical care will include immediate euthanasia of any moribund mice.

V.5.3. Environmental Enrichment

V.5.3.1. Enrichment Strategy

Mice will be group housed and enrichment will be provided as per the VSD rodent enrichment SOP.

V.5.3.2. Enrichment Restrictions: None

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING

NAME	DEGREE	TRAINING	DATE	PROCEDURES	YRS/MOS EXPERIENCE
(b)(6)				1,3,4,5,7	(b)(6)
				1,3,4,5	
				1,3,4,5	
				1,3,4,5	
				1,3,4,5	
				1,3,4,5,7	
				1,3,4,5,7	

Procedure and manipulation codes:
Code 1= Animal handling and euthanasia
Code 2= Surgery (aseptic technique) pre- and post-operative care
Code 3= Injections (3a-ip, 3b-sc, 3c-gavage) - can say 3 if trained in all manipulations or add 3d-iv
Code 4= Blood collection under anesthesia (4a-cardiac, 4b-posterior vena cava)
Code 5= Tissue collection (after euthanasia) - doesn't need to be specific

Code 6 = Implantation (provide details)
Code 7 = Others - (provide protocol specific manipulations or procedures for e.g., retro-orbital injection)

VII. BIOHAZARDS/SAFETY

There is no plan to use any potential biohazard. Standard laboratory safety precautions will be observed throughout this study

VIII. ENCLOSURES

Form 310

List of references

X. ASSURANCES

Protocol Title: Development of anti-ceramide reagent as mitigators of acute radiation gastrointestinal syndrome in mice (*Mus musculus*)

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made every effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with a qualified individual who evaluated the experimental design with respect to the statistical analysis, and that the minimum number of animals needed for scientific validity will be used.

D. Biohazard / Safety: I have taken into consideration and made the proper coordinations regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R", namely, "Responsibility," which the DOD has embraced for implementing animal use alternatives where feasible and conducting humane and lawful research.

G. Scientific Review: This proposed animal use protocol has received appropriate peer scientific review and is consistent with good scientific research practice.

H. Painful Procedure(s): I (**AM**) / **AM NOT** conducting biomedical experiments, which may potentially cause more than momentary or slight pain or distress to animals. If applicable, potential pain and/or distress **WILL** / (**WILL NOT**) be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

DOD ANIMAL CARE AND USE STANDARDIZED PROTOCOL FORMAT WITH EMBEDDED INSTRUCTIONS (October 2012)

Reference DOD Instruction 3216.01 & AFRRI Instruction 3216.2H

****

Information requested in the following animal use protocol template reflects the requirements of the Animal Welfare Act Regulations (AWAR), the Guide for the Care and Use of Laboratory Animals, and other applicable Federal regulations and DOD instructions.

****

This document is intended to be an aid in the preparation of DOD-sponsored animal use protocols. It is a companion document to an identical protocol template that does not have embedded instructions. Either template may be used to format DOD-sponsored animal research proposals; however, reference to the instructions during protocol preparation is highly recommended. If using the template with instructions, the instructions should be deleted prior to submitting the finished protocol for IACUC review. Please use Arial, regular, size 12, black font to prepare the protocol. With the exception of section headings, all paragraphs require a response. Paragraphs that do not apply should be marked N/A. There is no space limitation for responses to the information requested.

Approved standard operating procedures (SOPs) promulgated by the AFRRI Veterinary Sciences Department (VSD) or similar VSD-validated documents that describe specific procedures may be referenced by SOP number and title in lieu of repeating the details in the protocol. However, it is essential to include general descriptions of all animal manipulations to be carried out under the IACUC-approved protocol and to provide details where no approved references are cited. To do otherwise would constitute a breach of statutory regulations. Manipulations not covered in the originally approved protocol can be initiated only after IACUC approval of a formal amendment adding the new procedures. Additionally, Principal Investigators (PIs), or other delegated research personnel, should maintain accurate experimental records and be able to provide an audit trail of animal expenditures and use that correlates with their approved protocol. Protocol PIs will be required to provide this and other information during annual protocol reviews.

Any supporting information that may be of use to the IACUC during its review may be attached to the completed protocol. Adding subparagraphs within the body of the protocol template is permissible, *provided that the numbering sequence of paragraphs in the original standard format is maintained.* In other words, all of the labeled paragraphs and subparagraphs in this template must be retained, with additional information being presented as sub-numbered paragraphs containing information that supports or complements what is requested.

INTELLECTUAL PROPERTY STATEMENT

Research protocols drafted by Government scientists include intellectual property (e.g., concepts, ideas, experimental approaches, etc.), some of which is innovative or original and therefore considered proprietary to the investigators and/or the sponsoring agency. All Government and non-Government personnel handling this protocol shall exercise EXTREME CARE, to ensure that the information contained herein is NOT DUPLICATED OR DISCLOSED, in whole or part, for any purpose other than to evaluate the protocol, without the written permission of the principal investigator or the sponsoring agency.

I. NON-TECHNICAL SYNOPSIS

The relationship between radiation dose and the effect on health has been well established. However, in addition to the dose absorbed other parameters such as genetic background, co-morbidities and age are considered as important risk factors. Very little information is available on the ARS in children, except for the well-known increased risk for cancer development. Because children are still in an active growing phase, the effects of radiation are expected to be more severe than for adults. Furthermore, radiation countermeasures developed for adults cannot be assumed to be effective or safe for children without prior testing, due to the fact that organs of children are immature, and their physiological and metabolic features still developing. Consequences for administration of adult drugs to children include potential differences in drugs' PK/PD and mechanism of action, over- or under-medication and unanticipated adverse events.

Under the FDA Animal Rule, data for radiation countermeasure efficacy testing can be extrapolated from animal models. Development of a pediatric large animal model for characterization of the Acute Radiation Syndrome as well as drug development is critical. The minipig represents an ideal animal model to test the effects of radiation on the pediatric population. Benefits include short reproductive cycle, prolificacy, large litter size, ease of cross-fostering, similarities in organ development, maturation, physiology and anatomy to human pediatric population, multiple administration routes to test intact drug formulation for more immediate translation to humans, regulatory acceptance, large historical database and expertise available. Here, we propose to subject juvenile animals (< 3 mos of age) to irradiation and to determine dose-survival relationship.

II. BACKGROUND

II.1.

There is very limited information available on total body irradiation (TBI)-ARS for demographics of 0-12 years (children) or >75 years (elderly), and no treatment for age-specific radiation injuries are being developed. Limited data suggest accentuated vulnerability in the very young, likely due to the immature immune system (1). At an early age, tissue and organ systems are still developing and are not fully mature. Data from adult animal models cannot be directly translated to the pediatric population because of major differences in the organ anatomy, physiology and metabolism between adults and pediatrics. Examples are represented by the different clearance mechanisms of liver and kidney, the immature immune system, the developing CNS and the rapid growth of bones. Pharmacokinetics and pharmacodynamics are different in children. For the same reason, countermeasures shown to provide benefits to adults must be tested in animal models of age range appropriate to mimic the same developmental characteristics as the target population.

Pediatric animal models, for development and testing of pediatric-friendly drugs, are urgently required. The Gottingen minipig represents a suitable animal model to study the influence of age on susceptibility to radiation insult. Here we proposed to use the Gottingen minipig to study the Acute Radiation Syndrome in the pediatric population. Juvenile minipigs have been used as model for hemorrhagic hypovolemic shock, lung injury, kidney replacement therapy, hemodynamics, cardiovascular pathophysiology, and

asphyxia among others. A table summarizing the age comparison between humans and the G. minipig is reported below.

Table 1. Age comparison: human vs minipig

	Human	Minipig
Neonate	birth to 1 month	birth to 1 month
Infant	1 mo – 2 yr	4 – 8 wk
Child	2 – 12 yr	8 wk – 3 mo
Adolescent	12 – 16 yr	3 – 5 mo

Stages in a minipig life – from: Ellegaard Gottingen Minipigs

In previous years under (b)(4) we have established a basic minipig model for the hematopoietic acute radiation syndrome (H-ARS) (2-4), after total-body irradiation (TBI) and in the absence of supportive care. We characterized dose-response relationships at radiation doses spanning from H-ARS and the gastrointestinal (GI) ARS. Animals used were adults and of an age corresponding to humans >16years. Use of a vascular access port allowed us to obtain serial samples from the same animal. We were thus able to analyze hematological changes over time, hematopoietic progenitor stem cells, kinetics of DNA damage/repair and residual foci (gamma-H2AX), circulating citrulline levels and microbiological status. In addition, we monitored organ function, and isolated peripheral blood mononuclear cells (PBMCs) and platelets for phenotypic and functional studies. Primary cell lines were obtained from the lungs to study mechanisms of DNA repair in vitro.

Our data so far confirm that minipigs provide an ideal system to test drugs and to study the natural history of ARS. One of the many advantages of this large animal model is the opportunity to study different populations (pediatric, juvenile, adults, geriatrics) and both genders. Here, we propose to subject juvenile animals (<3 months of age) to irradiation and to determine dose-survival relationship. Survival studies will be done in the presence of minimum supportive care (antibiotics, antipyretic/anti-inflammatory, and dietary supplementation – no IV fluids or blood supplements), to address the potential issue represented by the proven sensitivity of the juvenile minipig and the expected increase in sensitivity in younger animals. To our knowledge, this is the first attempt to establish a pediatric model of ARS. The adult control group will be represented by animals irradiated at approximately 4-5 months of age, and subjected to identical treatment as the pediatric cohorts. During this project, we will (i) develop and assess basic operating protocols for animal housing, handling, blood collection in a pediatric minipig model, (ii) measure normal growth rate of pediatric minipigs model, and (iii) establish dose-survival relationship in irradiated pediatric minipigs.

III. OBJECTIVE / HYPOTHESIS

Hypothesis: it is possible to establish a pediatric minipig model of ARS (corresponding to humans 1-12 years)

Objectives:
(i) establish protocols and procedures for handling and housing of minipigs <3 months of age at AFRRI

(ii) safely obtain multiple blood samples from pediatric minipigs for CBC counts; and measure animal growth

(iii) irradiate minipigs of pediatric age, establish survival probit curves and monitor signs and symptoms of ARS.

IV. MILITARY RELEVANCE

According to the DoD Chemical and Biological Defense Program 2009 Annual Report to Congress (6): "Although the overall number of nuclear weapons continues to decline because of Russian and U.S. treaty commitments, the United States anticipates an increase in weapon numbers in China, India, and Pakistan. Motivated by economic and strategic interests, Russia and China (or political entities in each) and North Korea continue to supply technologies and components that are dual use and could support weapons of mass destruction and missile programs, especially in the Middle East and South Asia. Iran continues to develop its enrichment program in defiance of United Nations (U.N.) Security Council resolutions and also continues to build a heavy water reactor in Arak, which will be capable of producing plutonium that could be weaponized. While North Korea has halted portions of its nuclear program, it is possible that it has stockpiled several nuclear weapons from plutonium produced at Yongbyon. Non-nuclear radiological dispersal devices (RDD) and radiological exposure devices (RED) pose a significant potential threat especially in the hands of non-state groups ... Contamination and recovery issues associated with operating in a radiological environment remain significant concerns for military operations and underscore the need for robust detection, protection, and decontamination systems."

Although there is no direct military relevance in developing a pediatric animal model of radiation injury, terrorist attacks are renowned for involving also civilian populations, including children. The use of sarin gas on the civilian population in Damascus, Syria, on August 21 2013, left men, women and children injured or dead and it is just one of the testimonies of the type of atrocities perpetrated by extremist groups. Terrorist attacks may extend to military installations housing families with children. Currently, there is no safe and non-toxic radiation countermeasure available for adults or children. Both early and late health effects of radiation exposure are major concerns for the military. Developing countermeasures to radiation exposure is a top priority for the US Department of Defense. Effective countermeasures would expand the options available to field commanders operating Ionizing Radiation (here defined as IR) threat environments, and improve the morale of personnel at risk of exposure to IR. DoD Defense Technology Objective MD.18 states: "Effective mitigation of health consequences [of IR] will (1) reduce casualty load at medical treatment facilities, (2) sustain a more effective operational force after a radiation exposure event, (3) allow commanders to conduct operations in radiation field environments without undue risk of decremented performance of personnel due to acute tissue injury, and (4) reduce the negative psychological impact on personnel tasked to operate in contaminated environments."

An important barrier to advanced development of radiation countermeasures is the paucity of large, long-lived, non-rodent animal models of radiation injury. The only choices at present are NHPs and canines. The advanced evolutionary stage of NHPs, and the expense and danger of working with NHPs, are also disadvantages. Canines are notoriously sensitive to NSAID and vomiting. The addition of miniature swine to available large animal radiation injury models would facilitate development of promising countermeasures.

V. MATERIALS AND METHODS

V.1. Experimental Design and General Procedures

The purpose of this study is to establish: 1) Establish protocols and procedures for handling, housing, feeding of pediatric minipigs; 2) Establish protocols and procedures for taking multiple blood samples from pediatric minipig model; and 3) Establish a probit curve for dose-survival relationship.
Health of animals will be monitored at least twice-daily, CBC/differential will be measured on the days indicated below (except in emergency cases, where blood for CBC counts will be taken per VSD veterinarian request). An implantable Micro Identification transponder with programmable Temperature Transponder (Bio Med Data System) will be implanted subcutaneously to monitor body temperature (see section **V.4.4.7. Other Procedures**). We will determine if an externalized catheter will improve ease of blood draws (see section **V.4.4.7. Other Procedures**). In case of catheter malfunction or if the catheter needs to be removed, we will access alternative veins (see list of potential sites under section **V.4.4.2.Biosamples "Collection of blood samples"**). This experiment will utilize irradiation procedures perfected during the experiments performed under IACUC protocol 2008-04-003 and 2011-04-003. Sham-irradiated Gottingen minipigs and minipigs gamma-irradiated at various doses will be compared in studies of radiation/mortality dose response, and invasive and non-invasive biological markers indicating severity of injury.

Number of animals requested for Experiment 1+2 = 6 total (3 animals 5-weeks old + 3 animals 9-weeks old).

Number of animals requested for Experiment 3 = 72 animals = 30 (age 5 weeks) +30 (age 9 weeks) +12 (age 4-5 months).

V.1.1. Experiment 1: handling and housing of pediatric minipigs (5 weeks and older)

Up until now, we have been dealing with adult Gottingen minipigs; protocols and procedures for handling and housing of minipigs <3 months of age at AFRRI are not yet in place and need to be established. Guidelines from the breeder, Marshall Bioresources, will be followed as much as possible (see attached "**Housing and Care Recommendations for the Marshall Gottingen Piglets**" and excerpts below). However, if necessary, modification may be introduced to reflect institutional and project requirements, as described below.

Quarantine and housing (see **V.5.1. Husbandry Considerations**): animals will be quarantined for 7 days, after which an externalized catheter may be implanted in the jugular vein (for animals of age <4 months, use of a VAP for long period of time may not be feasible). During the time of quarantine, animals may be group-housed; however, after implantation of the catheter and/or irradiation, animals will be single housed. Parameters such as food intake need to be monitored on a single animal basis, as anorexia is one of the criteria used for euthanasia. This would not be possible under group-housing conditions. Furthermore, pushing and biting is a normal and expected behavior in social animals while establishing a hierarchy in each new group; because of the immunocompromised and thrombocytopenic status of the irradiated animals, the potential of wounding and infection must be reduced to the minimum.

Feeding, Water (see **V.5.1.2. Special Husbandry Provisions**): normal weaning age is at 4 weeks. When the piglets are weaned their diet is mixed with a milk supplement for the first 2-4 weeks after weaning. This procedure will be continued until 8 weeks of age, when the piglets will be gradually transitioned to a grower maintenance diet (only dry pellets). Milk/formula supplement will be continued after irradiation throughout the duration of the study in addition to the dry pellets. During the weaning time, we will also provide pedialyte as nutritional supplements, in view of the supportive care treatment that the animals will receive after irradiation.

Water is offered ad libitum to piglets from 5 days of birth and older via automatic watering. The proper height for automatic water nipples is about ½ - 1 inch above the top of the pig / piglets shoulder. It is very important to make routine adjustments (weekly) in the height of the water nipples as piglets grow.

V.1.2. Experiment 2: to establish procedures for catheter implantation, blood draw and measurement of animal growth in animals 5 weeks old and older.

Blood counts and the dose that cause 50% of lethality (LD50) are among the most useful terms for ARS comparison across categories (species, age, co-morbidities etc). Indication of blood counts after irradiation together with the determination of the LD50 will be critical in the characterization of a pediatric model of ARS. The minipig is emerging as a valid alternative to NHP and dogs as a large animal model for the ARS. We have optimized the implantation and patency of Vascular Access Port (VAPs) in animals >4 months old, in order to obtain serial blood samples. By this age, skeletal growth rate has slowed down and an internal catheter can be safely left in place for at least 3 months (4). For animals of age <4 months, use of a VAP for long period of time may not be feasible. Growth rate of minipigs is highest between birth and 4 months of age (Figure 1); use of an internal catheter may require frequent adjustments in the catheter length after just a few weeks after implantation. In the case of irradiated minipigs, where blood cytopenia and susceptibility to infection and bleeding are among the leading causes of death, any major surgical intervention is expected to negatively impact the outcome.

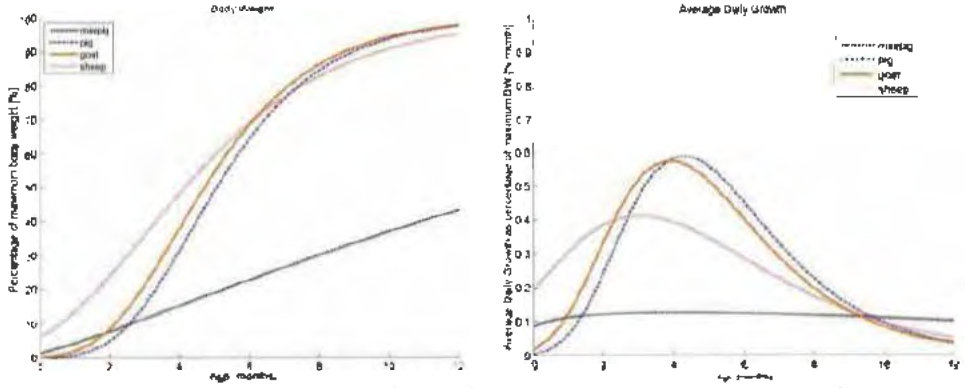

Fig. 1. Body weight (BW) and average daily growth curves expressed as percentage of the maximum BW for Gottingen minipig, Yorkshire pig, Young Hair goat, and Suffolk sheep. Growth curves acquired from Gompertz or Richards growth function as determined in the literature. From: Alex K. Roth, Rob Bogie, Eva Jacobs, , Jacobus J. Arts, Lodewijk W. van Rhijn, Large animal models in fusionless scoliosis correction research: a literature review. The Spine Journal 13 (2013) 675–688.

Our long term goal is to be able to collect sufficient amount of blood for CBC counts and other experiments from irradiated pediatric animals and age-matched sham-controls, within allowed limits, ("*All nonterminal blood collection without replacement of fluids is limited up to 10% of total circulating blood volume in healthy, normal, adult animals on a single occasion and collection may be repeated after 3 to 4 weeks. In case repeated blood samples are required at short intervals, a maximum of 0.6 ml/kg/day or 1.0% of an animal's total blood volume can be removed every 24 hour*"), up to three times a week and up to 60 days after irradiation and to establish basic preliminary, non-invasive assessment for future studies. See below calculated blood volumes per weight of animals. No more than 7% will be drawn in any one 7-day period, followed by a 7-day recovery period, and when performing serial bleeds, 24-hours of rest should be allowed for each 1% of body weight sampled up to a maximum of 21% of total blood volume within a 21-day period. A 7-day rest period must be observed whenever the maximum allowable 21-day volume has been attained.

Table 2: Relationship between age, weight and circulating blood volume.

Age	Weight (kg)	Total circulating blood volume (mL)	1% total circulating blood volume (mL)	10% total circulating blood volume (mL)
4-5 Weeks*	2-4	130-260	1.3 - 2.6	13-26
5-6 Weeks*	2-4	130-260	1.3 - 2.6	13-26
6-7 Weeks*	3-5	198-330	approx 2-3	approx 20-30
7-8 Weeks*	3-5	198-330	approx 2-3	approx 20-30
2 - 3 Months	5-7	330-462	approx 3-4.5	approx 30-45
3 - 4 Months	7-9	462-594	approx 4.5-6	approx 45-60
4 - 5 Months	9-11	594-726	approx 6-7	approx 60-70

On average, the total circulating blood volume is equal to 5.5 -7.0 % (~66 ml/kg) of the animal's body weight.

Blood sampling: blood may be used for CBC counts, and, if time and resource allow it, for in vitro/ex vivo studies (i.e. biodosimetry assays, mechanistic studies, immunophenotypic characterization of immune cell subsets etc).

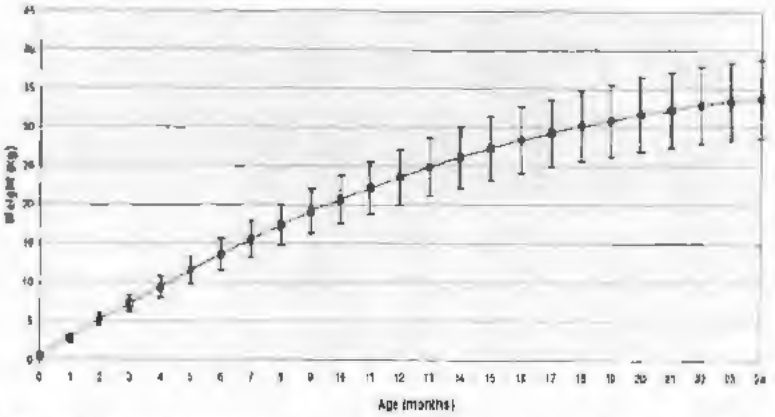
In Experiment 2, we propose to: (i) evaluate alternative ways to obtain serial blood samples, and (ii) assess growth of normal animals.

Experiment 2.1): Evaluate alternative ways to obtain serial blood samples, i.e. from externalized catheters and peripheral veins.

Using animals that will be sham irradiated, VSD personnel will attempt to sonographically guide the placement of an intravenous catheter in the jugular or femoral vein, for serial blood sampling, as described in (5) (see section **V.4.4.7. Other Procedures**). Ultrasound imaging is routinely used to facilitate safe, minimally invasive puncture of deep vessels; the described procedure is fast and results in no physiological complications. Ultrasound is used to visualize the jugular vein and the needle as it enters the vein, enhancing success (otherwise, this would be a blind technique in the pig). VSD has an ultrasound machine.VSD personnel will perform this technique- either a veterinarian or a properly trained technician. We would likely sedate with telazol the same as for irradiation, though it can be performed in the awake animal. Alternatively, if placement of the catheter fails and/or catheter loses patency, we will collect blood from peripheral veins such as auricular, femoral, cephalic, saphenous etc, with the animal under sedation (see section **V.4.4.7. Other Procedures**). Blood will be collected once before irradiation, and, with day 0 being the day of sham-irradiation, on days 0, 1, 3, and once a week after that, up to 60 days. Blood collected will not exceed 1% of total blood volume.

Experiment 2.2): Measurement of normal animal growth

-Body weight and skeletal development. At least once a week, we will measure body weight and take measurements of skeletal development such as: height (cm, from shoulder to floor) and length (cm, from snout to base of tail). As a guide, minipigs should gain roughly 0.5 kg per week, from 2 month of age until they are 12 months of age. We will also record vitals (T, HR and RR), and standard animal health check status (i.e. hydration status, hair coat, skin quality).



- Weight of the main organs. At the time of euthanasia we will take the weight of the main organs (i.e. heart, lungs, spleen, liver, kidney), for comparison with those of irradiated animals (second portion of this study).

Irradiated animals will be followed for at least 45 days after irradiation (45-day survival study); depending on availability of space and funds, animals may be observed up to 60 days from the day of irradiation, to obtain preliminary information about longer 60-day survival. Animals will be euthanized when they reach endpoint criteria or within 60 days from the day of irradiation, whichever comes first.

-Radiographs of the epiphyseal plates may be taken at the time of or prior to euthanasia, on sedated animals. Sedation will be the same as for irradiation (telazol), though dose may be on the lower side as duration of effect does not necessarily need to be so long.

Experiment 3: to determine age group-specific probit curves following irradiation with Co-60 (TBI, 0.6 Gy/min).

There is very limited information available on TBI-ARS for demographics of 0-12 years (children) or >75 years (elderly), and no treatment for age-specific radiation injuries are being developed. We propose to subject juvenile animals (<3 months of age) to irradiation and establish a dose-survival relationship. We will determine 2 probit curves, one for animal in the age range of 4-8 wks (representing 1 mo-2 yr humans) and the other one for animals in the range of 8 wks-3 mo (representing 2-12 yr humans). Animals will be administered minimum supportive care on a pre-fixed, standard regimen (see regimen for supportive care below). Probit curves will be compared to data obtained from young adult animals (5 months of age) administered the identical supportive care as the pediatric animals and irradiated at doses approaching the LD10 and LD90 (1.6 Gy and 2.0 Gy, respectively). This is not a repetition of our past minipig studies employing adult animals, since those studies were done in the absence of supportive care. Inclusion of adult animals is essential to establish preliminary observation regarding age-dependent dose-responses.

Irradiation: Irradiation will be total body, at the dose rate of 0.6 Gy/min (gamma photons, Co-60). Groups will be of 6 animals per dose (n=30 animal total). For each age group, we will begin with doses of 1.6 and 2.0 Gy, and will then choose 3 additional doses based on the results of the initial experiments and in consultation with a statistician. We do not expect to reach doses higher than 3.2 Gy. In order to determine if pediatrics are more sensitive to radiation-induced lethality, we will use a "control" age group, consisting of young adult animals (5 month old). For the control group, we will irradiated at 1.6 and 2.0 Gy, n=6 animals per dose); these doses represent the LD10 and LD100 for 5 month-old animals in the absence of supportive care (our historical data), and will provide a preliminary indication about the effect of supportive care on survival and the age-dependent difference in sensitivity. A complete dose response curve for 5-month old animals in the presence of supportive care is not the focus of this study. Below is reported the study protocol for this experiment.

Table 3: Study protocol

45-day survival study, 1 week quarantine, minimum supportive care	*Age 6 weeks*	*Age 10 weeks*	*Age 5 months*
Group 1 (survival+ blood draws)	6 animals (3x 1.6 Gy, + 3x 2.0)	6 animals (3x 1.6 Gy, + 3x 2.0)	
Group 2 (survival+ blood draws)	6 animals (3x 1.6 Gy, + 3x 2.0)	6 animals (3x 1.6 Gy, + 3x 2.0)	2 animals 1.6 Gy + 2 animals 2.0 Gy
Group 3 (survival+ blood draws)	6 animals (dose t.b.d)	6 animals (dose t.b.d)	2 animals 1.6 Gy + 2 animals 2.0 Gy
Group 4 (survival+ blood draws)	6 animals (dose t.b.d)	6 animals (dose t.b.d)	2 animals 1.6 Gy + 2 animals 2.0 Gy
Group 5 (survival+ blood draws)	6 animals (dose t.b.d)	6 animals (dose t.b.d)	
TOTAL (72)	30	30	12

Endpoints will be 45-day survival, CBC counts (if determined feasible from results of Experiment 2.1 and as per schedule described in **V.4.4.7. Other Procedures**), signs and symptoms, and measurement of animal growth.
Animals will be observed for a minimum of 45 days and up to 60 days after irradiation.
Signs and symptoms: vitals (T, HR and RR), body weight, and standard animal health check status (i.e. hydration status, hair coat, skin quality etc)
Measurement of animal growth will be taken as described in Experiment 1.2)

Supportive care: Animals will be administered minimum supportive care (defined here as antibiotics, antipyretic/anti-inflammatory, and dietary supplementation) on a standardized regimen. No IV fluids will be provided. Treatment schedule is chosen based on our historic dataset with TBI at doses 1.6 -12 Gy and reflects time to recovery of bone marrow after irradiation.

Table 4: Supportive care

Treatment		Regimen	Admin route	Start/end
Antibiotics	Enrofloxacin (Baytril)	For animals 3-10 kg, 3 ml of 0.5% oral solution *SID** For animals >10 kg, 5-7 mg/kg *SID*	*PO* (or *IM* or *IV* if *PO* not possible)	3-30 d
Antipyretic/anti-inflammatory	Carprofen (Rimadyl)	2.2–4.4 mg/kg *BID*	*PO* (or *IM* or *IV* if *PO* not possible)	3-30 d
Dietary Supplementation	Age-appropriate food, milk/formula, Pedialyte, Metamucil, canned fruits and vegetables. NO RAW FOOD			Throughout study, as necessary

* http://www.animalhealth.bayer.com/5293.0.html; if dosage is inadequate to cope with challenges from radiation damage, we will use the "adult" dosage of 5-7 mg/kd *SID*.

V.2. Data Analysis
The dose response relationship (DRR) will be plotted as probit percent mortality versus linear dose. Probit regression analysis will be used to generate the probit curves, using the PASW Statistic 18 software, SPSS Inc, IL, USA and preliminary values for LD30, LD50, and LD70will be obtained. Survival data from

the probit curve generated in Experiment 3 will be compared to our historical probit curve generated in the absence of supportive care (3).

For the generation of the dose-response curve, the LD30, 50 and 70 will be estimated using the probit method. This method allows for construction of confidence intervals to describe the precision of the estimated lethal doses. The width of the confidence interval depends on the number of doses, number of animals per dose, and the slope of the dose-response curve, and a narrow interval indicates a more reliable estimate. We propose to use five doses and six animals per dose. For a dose-response curve ranging from 1.6 to 2.0 Gy with mortality rates of .1, .3, .5, .7 and .9 percent for the five doses, the expected width of the 95% confidence interval for the LD50 will be 0.3 Gy, and the expected width of the 95% confidence interval for the LD30 and LD70 will be .5 Gy. Expected confidence interval widths are based on the average of 1,000 simulated data sets using the study design and mortality parameters indicated.

Survival data from young adult animals, administered identical supportive care as the pediatric population, will serve two purposes: to gain preliminary insight into the effect of age on sensitivity to radiation (group 1 vs group 2), and to gain preliminary insight into the efficacy of supportive care on survival (group 2 vs group 3).

Table 5: Group comparison for data analysis

Group 1	Pediatric animals + supportive care	This study
Group 2	Adult animals + supportive care	This study
Group 3	Adult animals - supportive care	Historical data

V.3. Laboratory Animals Required and Justification

V.3.1. Non-animal Alternatives Considered.

The purpose of this project is to determine the effect of age and supportive care on survival. There is no computer model or tissue culture that can mimic the effect of radiation on the whole organism and predict lethality. Survival depends on an intricate network of organ cross-talks and cellular microenvironment that cannot be recreated *in vitro*. Consequently, administration of supportive care to cellular components grown *in vitro* will not allow any assessment on survival. Development and aging also cannot be reproduced *in vitro*.

We do not know all of the cell types and tissues involved in radiation injury or how radiation injury causes lethality. The concept of multi-organ failure has been suggested, but how the injured organs affect each other's vital functions is unknown. The present state of the art of tissue culture is still incapable of reproducing the *in vivo* relationships. Computer modeling is similarly limited by lack of full characterization of the biological elements and interactions under study.

These considerations are consistent with the FDA requirement for preclinical research in both small and large mammals before granting approval for drug testing in humans.

V.3.2. Animal Model and Species Justification

We have been developing the adult Gottingen minipig as an additional large animal model for the study of the ARS and advanced development of radiation countermeasures. Currently, there is no pediatric animal model to study the ARS. Large, long-lived, and development-matched models are required for drug studies submitted to the FDA for licensure applications. Comparison between adult and pediatric Gottingen minipigs will help characterize the effect of radiation on the pediatric population, for countermeasure development and drug testing. The close similarity to humans in anatomy and physiology of organs such as the liver, pancreas, kidney and heart has made the pig the primary species of interest as organ donors for xenographic procedures. Minipigs are routinely used for toxicity testing. As such, further and rapid characterization at physiological, molecular and genetic level of the minipig is likely to occur, thus

increasing acceptance of this model and facilitating advanced drug development. Our previous studies have employed male Gottingen minipigs to develop a probit curve. Since we are testing the effect of supportive care and age on survival and we are using our own historical data as one of the terms of comparison, we will continue to use male minipigs for this study.

V.3.3.7. Special Considerations NA

V.3.4. Number of Animals Required (by species): 78

V.3.5. Refinement, Reduction, Replacement (3 R's)

V.3.5.1. Refinement
The study data-points currently mandated by the FDA for approval of radiation countermeasures under the Animal Efficacy Rule is mortality. Hence the primary study data-point in our development of Gottingen minipigs as a model for ARS is survival. Moribundity will be used as a surrogate for mortality, and euthanasia will be used in order to minimize pain and distress, using an extensive set of criteria (see animal endpoints, paragraph V.4.5 – Lethargy, weight loss, temperature, respiratory distress, food intake, bleeding etc). Animal care and use procedures will only be performed by trained personnel. We have considerable experience in the care and handling of minipigs. Extensive human interaction every weekday will reduce stress in the animals. Use of slings, topical anesthetics, and the catheters will minimize distress during blood collections and the animals will be gradually acclimated to the slings for these procedures.

V.3.5.2. Reduction
Control animals used to optimize protocols for animal handling, housing and blood draw will be used also to obtain data on growth of normal animals, and to set up dosimetry for future studies and to obtain baseline CBC data in pediatric animals. For irradiated animals, blood samples obtained from minipigs before irradiation will serve as controls, thus reducing the number of animals required for this study. Use of historical controls will also reduce the number of animals needed for this study.

V.3.5.3. Replacement NA

V.4. Technical Methods

3	Experiment 3: to determine age group-specific probit curves following irradiation with Co-60 (TBI, 0.6 Gy/min).			**72**	**78**
Totals:					**78**

V.4.1.2. Pain Relief / Prevention

V.4.1.2.1. Anesthesia / Analgesia / Tranquilization
Irradiation/Catheter placement
Prior to irradiation, animals will be sedated with Telazol® (Telazol, 6-8 mg/kg *IM*; 100 mg/ml, Fort Dodge Laboratories, IA). Alternatively, Telazol® (4.4 mg/kg *IM*), in combination with dexmedtomidine (0.05-0.1 mg/kg *IM*) or ketamine (20 mg/kg *IM*)/xylazine (2 mg/kg *IM*) can also be used for sedation. Atropine (0.05 mg/kg *SC, IM* or *IV*; atropine sulfate, Butler, Columbus, OH) or glycopyrrolate (0.01 mg.kg) may be given to reduce mucosal secretions. At the end of the irradiation procedure, once the animals are back in their quarters, dexmedetomidine can be reversed by atipamezole *IM* (same volume as dexmedotmidine) to facilitate recovery.
For catheter placement, Isoflurane 1-4% may be administered via face mask on as needed basis.

Blood sampling
Animal may be sedated at the time of blood sampling and administration of supportive care with Midazolam (0.1-0.5 mg/kg s.c.or *IM*), or acepromazine (1.1 mg/kg *IM*), 10 minutes prior to venous access. Telazol or Telazol +dexmedetomidine or Ketamine + Xylazine could be used as an option as well.

V.4.1.2.2. Pre- and Post-procedural Provisions
Irradiation
Pre-Irradiation: Animals will be fasted overnight (approximately 16–18 h) and sedated as described above. Once sedated in the VSD animal facility, minipigs will be transported to the AFRRI cobalt facility in an approved, covered transport cage. Heart rate and temperature will be measured prior to irradiation. At least one vet tech or one veterinarian will be present at the time of irradiation. Immediately before irradiation, the vet or vet tech will determine whether or not to administer additional sedative to keep the animal asleep during irradiation.
Irradiation procedure: To enable proper positioning, anesthetized animals will be strapped in place into slings in polyvinylchloride PVC frames for irradiation. Effect of anesthesia will be monitored in real time through video cameras positioned in the Cobalt waiting area. Minipigs will be removed from the slings once irradiation is completed. Temperature and heart rate will be taken before returning the minipigs to their home cages.
Post-Irradiation: After irradiation, animals will be transported back to their cages, where they will be allowed to recover from sedation under the careful surveillance of VSD and/or research staff who will

monitor vital signs and provide thermal support (e.g. Bair Hugger blanket) if necessary. Atipamezole *IM* (same volume as dexmedotmidine) may be used to reverse the anesthetic effect of dexmedetomidine.

Swine AND radiation sequelae AND alternatives:.....47 results found, not related to this work (mainly related to swine flu, medical imaging, mice models, ablation techniques, medical surgeries, bone marrow transplantation, cancer treatment

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification
Depending upon the irradiation dose irradiated animals die due to compromised immune responses and opportunistic infections. The percentage of surviving animals is the indicator of the efficacy of a countermeasure. We cannot give systemic anesthetic agents to animals after the irradiation procedures, since they are known to interact with the immune system (see references in Jacobsen, K. O., V. Villa, V. L. Miner, and M. H. Whitnall. 2004. Effects of anesthesia and vehicle injection on circulating blood elements in C3H/HeN male mice. *Contemp Top Lab Anim Sci* 43:8-12.), and would confound the correlation of radiation dose with incidence of moribundity, resulting in a waste of animals. However, we are providing supportive care in terms of antibiotics, analgesics, antipyretics, fluids/ nutritional support to increase survival. Use of supportive care is expected to mitigate the pain associated to the sequelae of irradiation.

V.4.2. Prolonged Restraint
Only short periods of restraint in the sling (<30 minutes) will be necessary for blood collections and the irradiation procedure. To minimize discomfort, we have designed a new type of sling that uses softer, elastic material to support the animal, and utilizes a more efficient restraint design that maintains the animal in place while reducing manipulation by technicians and consequently stress to the animals. After the quarantine period, animals are acclimated to the sling for 5-10 minutes, 2-3 times before initiating blood draws. Acclimation to the sling is very rapid and non-stressful; animals are petted and gently spoken to while restrained. It has been our experience that resting on the sling does not agitate the animal at all.
Animals are anesthetized and transported to the Cobalt Facility holding area before being put into slings for irradiation (<20 minutes). Animals will be kept under continuous observation while in the sling. Slings will be spot-cleaned between animals and will be sanitized at the conclusion of each irradiation day.

V.4.3. Surgery NA

V.4.3.1. Pre-surgical Provisions

V.4.3.2. Procedure(s)

V.4.3.3. Post-surgical Provisions

V.4.3.4. Location

V.4.3.5. Surgeon

V.4.3.6. Multiple Major Survival Operative Procedures NA

V.4.3.6.1. Procedures

V.4.3.6.2 Scientific Justification

V.4.4. Animal Manipulations

V.4.4.1. Injections

All injections listed in section V.4.1.2.1 will be administered *IM*, SC, using sterile needles (23 – 21 gauge) and syringes, or IV through the catheter or *PO*.

V.4.4.1.1. Pharmaceutical Grade Drugs

Lidocain (5%), topical
Telazol®
Ketamine/xylazine
Atropine atropine sulfate
Heparin lock, IV
Saline
Carprofen
Metamucil
Enroflaxacin or baytril
Rimadyl
Midazolam
Acepromazine
All the drugs listed above are ordered from veterinary product distributors by VSD and they all are pharmaceutical grade drugs.
Atipamezole (Antisedan, Pfizer)
Dexmedtomidine (Dexdomitor, Pfizer)

V.4.4.1.2. Non-Pharmaceutical Grade Drugs NA

V.4.4.2. Biosamples
Collection of blood samples. We will obtain blood samples from the externalized catheter or from peripheral veins. If the catheter fails or needs to be removed, the sample will be collected from accessible peripheral vessels (see section **V.4.4.7. Other Procedures**). Mean blood volume for pigs is 65-67 ml/kg. Up to 1% of total blood will be drawn per time point, depending upon the frequency of previous bleeds (Walter Reed Army Institute of Research. 1997. Investigators' Handbook. Section I: Handling Techniques and Noninvasive Procedures).

Tissue and histological samples. Tissue samples, to include organs, blood and hair may be taken at the time of euthanasia for tissue blocks and for frozen tissue repository.

V.4.4.3. Adjuvants NA

V.4.4.4. Monoclonal Antibody (MAb) Production NA

V.4.4.5. Animal Identification Tattoos or ear tags and cage cards/tags

V.4.4.6. Behavioral Studies NA

V.4.4.7. Other Procedures
Catheter implantation
Catheter implantation will be done following the Seldinger technique. Briefly, the procedure is described as follows:
(http://www.dechra.co.uk/Critical-Care-Tips/Central-Venous-Set---Using-the-Seldinger-Technique.aspx)

Placement

1 Clip and aseptically prepare site. Right Jugular vein in the neck area or the right/left femoral vein in the inner thigh may be used for catheter placement.
2. Insert the introducer needle into the vessel (gauge needle: 18-24).
3. Whilst steadying the needle use the adaptor to straighten the j-wire and insert it into the needle.
4. Advance the wire into the vessel.
5. Remove the needle and the wire cover making sure the wire does not advance any further into the vessel.
6 Whilst holding the wire steady advance the dilator over the wire 1 to 1.5 inches into the insertion point and rotate back and forth. A small nick incision (1-2 mm) may be needed in the skin prior to inserting dilator.
7. Remove the dilator.
8. Advance the catheter over the wire into the vessel.
9. Remove the wire.
10 Flush the catheter and secure the catheter to the patient with sutures
11. Attach fluid delivery equipment to the catheter.
12. Cover with sterile dressing and a light bandage.

Care and maintenance
1. Ensure the catheter site is kept clean and treated aseptically throughout use
2. Check suture integrity at regular intervals

Catheter to be used will be single lumen indwelling catheter in Polyurethane material which provides strength during insertion and also softens at body temperature to conform to the body tissues. The complete set of central venous catheter kit for catheter implantation consists of:

- Indwelling catheter
- Catheter holder
- Catheter holder clamp
- Extension line clamp
- Injection cap
- Introducer needle
- J-Tip guide wire
- Luer lock syringe
- Scalpel
- Vessel dilator

The soft Flexible J-Tip Guide wire provides good torque to ensure firm insertion and also prevents vessel perforation. The tip is specialty designed for smooth and easy insertion of catheter. Clear and definite marking facilitates correct placement of catheter tip. The catheter is radio-opaque for proper placement using ultrasound imaging. Animals will be sedated during the procedure. (Sedation procedure has been described in the anesthesia section V 4.1.2.1). After placement, the wound will be protected with aerosol bandage aid and the catheter will be covered with elasticon tape.

Temperature transponder At the time of catheter implantation, a temperature microtransponder (Implantable Electronic ID Transponder IPPT-300, Bio Medic Data Systems, Seaford, DE) will be implanted subcutaneously behind the neck, over the shoulder opposite to the site of VAP surgery, to facilitate body temperature measurements.

Blood draw from externalized catheter. Catheter will be flushed with 5 ml saline and the first 0.5 ml of blood will be discarded. Blood samples will be collected using a new syringe. After blood collection, catheter will be flushed again and locked with 3 ml of heparin lock (100 U).

Blood draw from peripheral veins. Alternatively, if placement of the catheter fails and/or catheter loses patency, we will collect blood from peripheral veins such as auricular, femoral, cephalic, saphenous etc. Animals may be sedated at the time of blood sampling and administration of supportive care (see section V.4.1 2.1) if necessary following the recommendations of an AFRRI veterinarian. All procedures will be

entered into the experimental record. Lidocain (5%) may be applied topically to the site of venipuncture to minimize discomfort to the animals about 15 minutes before starting the procedure; site will be cleaned with betadine and alcohol. Blood will be collected once before irradiation, and, with day 0 being the day of sham-irradiation, on days 0, 1, 3, and once a week after that, up to 60 days. Collection of samples will be performed with the minipig restrained in a sling; at the same time, we will take vitals. The entire procedure takes less than 30 min. After blood draw, animals will be returned to their cages and checked to ensure that the needle puncture wound is closed and the blood has clotted.

Health check status
Body weights and standard animal health check status (hydration status, hair coat, skin quality, vitals) will be determined at least once prior to treatment, on the first day of treatment, and on days of blood collection. Body temperature will be determined during week-days between 8 am and 4 pm, and on weekends if there are animal concerns. The time of each temperature collection will be recorded for each minipig.

V.4.4.8. Tissue Sharing Bio-samples (**V.4.4.2. Biosamples_Tissue and histological samples**) will be collected, to be used for histo-chemistry/protein/molecular assays among others, and to be shared with collaborators upon request and as experiments permit

V.4.4.9. Animal By-Products

V.4.5. Study Endpoint The data-point currently mandated by the FDA for approval of radiation countermeasures under the Animal Efficacy Rule is moribundity or mortality. Moribundity will be used as a surrogate for mortality, and euthanasia will be used in order to minimize pain and distress. Euthanasia will be carried out when any one of absolute endpoints or combination of the following non-absolute signs of moribundity are observed and in consultation with AFRRI veterinarians.

Absolute
1. Non responsive, assuming the animal has recovered from anesthesia.
2. Dyspnea
3. Loss of 20% of expected weight (based on Marshall Bio-resources growth chart –weight vs age- and day 0 baseline percentile).
4. Hypothermia (< 36 ºC)

Non-absolute
1. Hyperthermia (>41 ºC)
2. Anorexia (skip 3 consecutive meals)
3. Anemia/pallor, CRT >2 seconds. CRT will be performed behind the ears.
5. Petechiae/ecchymosis
6. Vomiting/diarrhea
7. Lethargy
8. Seizures or vestibular signs (falling, circling or head tilt)
9. Uncontrollable hemorrhage

At the time of euthanasia, the attached observation sheet (Attachment 1) will be filled out, and may be used retrospectively at the end of study to put together a score sheet for euthanasia criteria for minipigs, similarly to that for rodents.

V.4.6. Euthanasia
Animals will be euthanized according to current American Veterinary Medical Association (AVMA) guidelines. Animals will be sedated with Telazol® (6-8 mg/kg *IM*) or ketamine (20 mg/kg *IM*)/xylazine (2 mg/kg *IM*). Animals will then be euthanized with and injected IV Euthasol® (sodium pentobarbital, (1 ml/4.5 kg IV or IC) or another commercial euthanasia solution.
Alternative (only if the peripheral percutaneous venous access is not achieved or the external catheter is not functional in the pediatric model), peripheral or central venous cut down or cardiac stick may be performed, with the animals maintained under general anesthesia using isoflurane gas at a maintenance

rate of 1% to 3% and oxygen flow rate of 1 to 2 l/min. Death will be confirmed by VSD veterinarian or veterinary technician via auscultation of the heart, with cessation of sounds for at least 5 minutes. See item V.4.5 for euthanasia criteria before the end of the study

V.5. Veterinary Care

V.5.1. Husbandry Considerations

Animal observations - Throughout the course of the study, animals will be monitored twice a day by VSD caretakers and technicians. Frequency of observation will increase after animals have been irradiated and appear to get sick; in addition to the VSD check, research staff will monitor animals twice a day during week days, and if necessary, after hours and on weekends.

Housing - During quarantine/acclimation period, minipigs may be group-housed. After surgery and/or after irradiation, they will be singly housed to prevent damage to the catheter and to allow individual assessment of feed consumption and fecal/urine/blood production. Rooms will be maintained on a 12:12 h light (0600 to 1800) dark cycle. For piglets 1 – 2 months in age (weaned) room temperature should be maintained between 75 – 78 degrees F / 24 – 26 degrees C. **All young piglets will be provided with a sleeping mat to keep warm.**

Feed and water provisions – Animals will be fed twice a day according to their weight. Age appropriate food will be provided, after consultation with Harlan nutritionist, together with milk supplement, and additional nutritional support as described in Experiment 1. Each piglet will have 60 mL of milk/formula supplement, per piglet, 2 times daily, mixed with approximately ½ the scheduled pellet diet. Milk, alone and with pellet diet, will be provided either with a bottle or in a dish.The remaining ½ of diet will be offered in feeding trough, shallow dish or floor so the piglets are used to eating a dry diet. This procedure will be continued until animals are 8 weeks of age, when the piglets will be gradually transitioned to a grower maintenance diet (only dry pellets)**. We may continue to offer 60 mL of milk supplement twice a day, and Pedialyte until the animals recover, as a part of supportive care. After feeding, all troughs or dishes must be cleaned and disinfected properly to prevent bacterial infections which may result in piglet diarrhea.** During the weaning time, we will also provide pedialyte as nutritional supplements, to get the animals used to the taste, in view of the supportive care treatment they will receive after irradiation.

Supportive care will be provided after irradiation to all animals, accordingly to Table 1. Age-appropriate liquid food and/or moistened pellet will be offered if observed that the sick animal prefers it to dry food. Water is offered *ad libitum* to piglets from 5 days of birth and older via automatic watering. The proper height for automatic water nipples is about ½ - 1 inch above the top of the pig / piglets shoulder. It is very important to make routine adjustments (weekly) in the height of the water nipples as piglets grow. A bowl of water is also offered to all piglets accompanied with the automatic water for at least 3 days post weaning or until caretakers are sure that all piglets have found the automatic water source. It is a good practice to leave the bowl of water under the automatic water nipple until all piglets adjust to the location of their new water source. Dishes should be sanitized daily and filled with clean fresh water throughout the day as needed. The automatic water source should supply 0.5 – 1.0 quart or liter per minute.

V.5.1.1. Study Room

Minipigs will be located at AFRRI for the duration of the study. They will either be in a VSD surgical suite for catheter placement, in transit to and from the cobalt facility in a covered transport cage, in slings for irradiation in the cobalt facility, or in their housing cage or a VSD prep room for blood collections or euthanasia. They will be housed in stainless-steel cages in an environmentally controlled and continuously monitored animal room as described in Section V.5.1

V.5.1.2. Special Husbandry Provisions

Diet will be controlled in accordance with vendor's recommendations so as to prevent excessive weight gain. No sugar-rich treats, marshmallows, peanut butter, crackers and similar food will be offered to these animals, since they are on an age-appropriate caloric diet to prevent excessive weight. Instead, canned

fruits, vegetables and milk will be offered daily; age-appropriate nutritional supplement will be provided after irradiation. Tap water will be provided ad libitum. All dishes and containers need to be cleaned and sterilized daily.

V.5.1.3. Exceptions NA

V.5.2. Veterinary Medical Care

V.5.2.1. Routine Veterinary Medical Care
Animals will be acclimated for ≥1 week prior to beginning of procedures. Each animal will be observed at least twice daily for evidence of pain or distress. Body weights will be determined at least once a week and on days of blood collection. The time of each daily temperature collection will be recorded for each animal. Animals will be qualitatively assessed at least twice daily (a.m. and p.m.) for general behavioral status and food consumption by VSD techs and/or research techs. The heart rate will be measured at the time of each blood collection. Stool consistency, left-over food, demeanor and overall animal appearance will be recorded. Diarrhea has not been observed in minipigs irradiated at doses <8 Gy. Appropriate standard operating procedures will be followed by staff veterinarians in the event of pain or distress.

V.5.2.2. Emergency Veterinary Medical Care Emergency veterinary medical care is available 24/7 and will be provided based on the restrictions approved in earlier sections of this protocol

V.5.3. Environmental Enrichment

V.5.3.1. Enrichment Strategy
Enrichment will be done as per the VSD minipig enrichment SOP, except single housing after catheter implantation and irradiation.

V.5.3.2. Enrichment Restrictions
Minipigs will be single-housed after surgery and after irradiation until completion of the study, to avoid mechanical and infectious complications related to implanted catheters, but they will be in visual, olfactory and auditory contact with other minipigs in the same room.

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING

Trained personnel are certified by VSD.

NAME	DEGREE	TRAINING	DATE	PROCEDURES	YRS/MOS EXPERIENCE
(b)(6)				1, 3b, 4, 5, 7 (drug delivery) 1, 3b, 4, 5	(b)(6)

Procedure and manipulation codes:
Code 1= Animal handling and euthanasia
Code 2= Surgery (aseptic technique) pre- and post-operative care
Code 3= Injections (3a–ip, 3b-sc, 3c-gavage) - can say 3 if trained in all manipulations or add 3d-iv
Code 4= Blood collection under anesthesia (4a-cardiac, 4b-posterior vena cava)
Code 5= Tissue collection (after euthanasia) - doesn't need to be specific
Code 6 = Implantation (provide details)

Code 7 = Others - (provide protocol specific manipulations or procedures for e.g., retro-orbital bleeding, tail vein injection, or drug delivery)

X. ASSURANCES

Protocol Title: Effect of supportive care on irradiated Gottingen minipigs (*Sus scrofa domestica*)

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made every effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with a qualified individual who evaluated the experimental design with respect to the statistical analysis, and that the minimum number of animals needed for scientific validity will be used.

D. Biohazard / Safety: I have taken into consideration and made the proper coordinations regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R", namely, "Responsibility," which the DOD has embraced for implementing animal use alternatives where feasible and conducting humane and lawful research.

G. Scientific Review: This proposed animal use protocol has received appropriate peer scientific review and is consistent with good scientific research practice.

H. Painful Procedure(s): I **AM / AM NOT** conducting biomedical experiments, which may potentially cause more than momentary or slight pain or distress to animals. If applicable, potential pain and/or distress **WILL / WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

DOD ANIMAL CARE AND USE STANDARDIZED PROTOCOL FORMAT WITH EMBEDDED INSTRUCTIONS (March 2013)

Reference DOD Instruction 3216.01 & AFRRI Instruction 3216.2H

****

Information requested in the following animal use protocol template reflects the requirements of the Animal Welfare Act Regulations (AWAR), the Guide for the Care and Use of Laboratory Animals, and other applicable Federal regulations and DOD instructions.

****

This document is intended to be an aid in the preparation of DOD-sponsored animal use protocols. It is a companion document to an identical protocol template that does not have embedded instructions. Either template may be used to format DOD-sponsored animal research proposals; however, reference to the instructions during protocol preparation is highly recommended. If using the template with instructions, the instructions should be deleted prior to submitting the finished protocol for IACUC review. Please use Arial, regular, size 12, black font to prepare the protocol. With the exception of section headings, all paragraphs require a response. Paragraphs that do not apply should be marked N/A. There is no space limitation for responses to the information requested.

Approved standard operating procedures (SOPs) promulgated by the AFRRI Veterinary Sciences Department (VSD) or similar VSD-validated documents that describe specific procedures may be referenced by SOP number and title in lieu of repeating the details in the protocol. However, it is essential to include general descriptions of all animal manipulations to be carried out under the IACUC-approved protocol and to provide details where no approved references are cited. To do otherwise would constitute a breach of statutory regulations. Manipulations not covered in the originally approved protocol can be initiated only after IACUC approval of a formal amendment adding the new procedures. Additionally, Principal Investigators (PIs), or other delegated research personnel, should maintain accurate experimental records and be able to provide an audit trail of animal expenditures and use that correlates with their approved protocol. Protocol PIs will be required to provide this and other information during annual protocol reviews.

Any supporting information that may be of use to the IACUC during its review may be attached to the completed protocol. Adding subparagraphs within the body of the protocol template is permissible, *provided that the numbering sequence of paragraphs in the original standard format is maintained.* In other words, all of the labeled paragraphs and subparagraphs in this template must be retained, with additional information being presented as sub-numbered paragraphs containing information that supports or complements what is requested.

INTELLECTUAL PROPERTY STATEMENT

Research protocols drafted by Government scientists include intellectual property (e.g., concepts, ideas, experimental approaches, etc.), some of which is innovative or original and therefore considered proprietary to the investigators and/or the sponsoring agency. All Government and non-Government personnel handling this protocol shall exercise EXTREME CARE, to ensure that the information contained herein is NOT DUPLICATED OR DISCLOSED, in whole or part, for any purpose other than to evaluate the protocol, without the written permission of the principal investigator or the sponsoring agency.

PROTOCOL TITLE: *In vivo* combined therapy for ionizing radiation followed by wound trauma in the laboratory mouse (*Mus musculus*)

PRINCIPAL INVESTIGATOR: (b)(6)

CO-INVESTIGATOR(S):

AFRRI SCIENTIFIC RESEARCH PROTOCOL NUMBER: (b)(6)

I. NON-TECHNICAL SYNOPSIS Terrorist use of radiological weapons is considered an urgent threat to both military and civilian personnel. Radiation exposure combined with other injuries, such as thermal burns, wound, and increased susceptibility to infection characterize short-term casualties in many radiological incident scenarios. Our research has shown that the drugs, granulocyte-colony stimulating factor (G-CSF) and (b)(4) are very effective for increasing survival after irradiation followed by wound trauma (CI) in mice. Since CI results in depletion of neutrophils and platelets, G-CSF stimulates neutrophil generation, and (b)(4) increases platelet formation, we propose here to test combined treatment with G-CSF and (b)(4) for their ability to improve recovery of tissues from the combined effects of radiation and wound. Successful development of such a therapy would increase survival of personnel who are victims of such scenarios.

II. BACKGROUND

II.1. Background Radiation and wound injury would appear to have little in common. Radiation injury is triggered by production of free-radical species within the cell that damage or disable important biomolecules. Wound injury induces tissue trauma and systemic bacterial infection. Despite differences in the initiation events, evidence has accumulated in recent years that many of the subsequent cellular responses have mechanisms in common. Both injuries involve complex biochemical pathways of the stress response in tissues, which are now only beginning to be understood. It is clear that nitric oxide (NO) signaling plays a central role in the extent of damage that occurs after exposure to many stressors. This observation led us to consider the possibility that pharmacological approaches to alter NO metabolism, which we are currently investigating for treating wound trauma, might also be effective for treating radiation stress or a combination of the two injuries combined.

A. Effects of Combined Injury (CI)

Injury from ionizing radiation together with a non-lethal wound can have a wide range of harmful effects on humans, including leucopenia, purpura, hemorrhage, pneumonia, and hair loss between days 0 and 7 after radiation, followed by diarrhea, fever, electrolyte disturbance, convulsions, ataxia, tremor, and death 7-14 days after radiation. High doses of radiation suppress hematopoiesis and the immune responses and increase remarkably the risk of infection, which may become a lethal complication [Brook et al., 2004; Hoppe, 1989; Reigle and Dienger, 2003; (b)(4),(b)(6) Organs such as small intestine, lung, and bone are also relatively sensitive to ionizing

radiation, particularly the proliferative progenitor cells (b)(4) (b)(4) Multiple-organ dysfunction syndrome (MODS) and multiple-organ failure (MOF) can result [Baue, 1998].

The damage that ultimately leads to the generalized, systemic responses described above originates at the cellular and molecular level. Electromagnetic waves or particles constituting the various qualities of ionizing radiation induce damaging ionizations in biological molecules – either directly or indirectly through the production of reactive oxygen species (ROS) intermediates – resulting in altered biochemical activities that disrupt normal cell homeostasis. Studies in a variety of biological systems have shown that these alterations can involve a complex series of events that are often interrelated, affecting gene activities, protein expression, and basic metabolic pathways. For example, ionizing radiation can cause DNA double-strand breaks, which can lead to cell-cycle arrest via ATM-CHK2-NF-kB/p53/CDC25 pathways [review by Houtgraaf *et al.*, 2006]. Wound trauma enhances the DNA double-strand breaks, as indicated by increased γ-H2AX formation (b)(4),(b)(6)

The capacity of ionizing radiation and wound to induce apoptosis and thereby cause damage to organs and systems exemplifies the complexity of a response that might be better understood using the systematic analysis we are proposing. Excessive ROS levels can lead to impaired intracellular ionic homeostasis by damaging cellular macromolecules, including DNA, proteins, and lipids, resulting in caspase-independent apoptosis or cancer induction [Cadet et al., 2004; Ogawa et al., 2003; Olive, 1998]. High concentrations of ROS produced by radiation can attack mitochondria, resulting in the release of cytochrome C into the cytoplasm. Caspase-9 and Apaf-1 conjugate cytochrome C to form apoptosomes that in turn activate caspase-3 and -7. Active caspase-3 then activates caspase-2, -6, -8, and -10, resulting in apoptosis and elimination of the damaged cells [Hill et al., 2003; Kannan and Jain, 2000; Richter, 1993; Simon et al., 2000; Kiang, 2004; Jiang and Wang, 2004].

A possible role for NO metabolism in radiation injury and wound has been recognized only recently (b)(4),(b)(6) A high percentage of mammary tumors in animals receiving a whole-body radiation dose of 1.5 Gy gamma radiation was shown probably to be mediated by increased levels of the inducible form of nitric oxide synthase (iNOS) and NO level [Inano and Onoda, 2005]. Up-regulation of iNOS activity, which leads to increased levels of NO, was observed in cultured rat vascular smooth-muscle cells, which were given 14-25 Gy ^{60}Co gamma photons [Zhong et al., 2004]. Similar results have been reported in skin cells after UVB exposure [Chang et al., 2003]. Increased iNOS and radiation exposure have been shown to induce apoptosis in a caspase-dependent fashion [Chung et al., 2003], and radiation-induced apoptosis can be prevented by an iNOS inhibitor [Hirakawa et al., 2002]. Over-expression of iNOS [Ghosh et al., 2001] and NO induced after irradiation have been shown to be responsible for the subsequent cell death, and we have demonstrated that iNOS regulates caspase-dependent apoptosis (b)(4) atg-8-dependent autophagy (b)(4) and tight junctions between cells [Han et al., 2004].

Preliminary data from our experiments with human T cells indicate that gamma radiation-induced injury is mediated by the iNOS pathway. Inhibition of this pathway reduces radiation lethality and enhances cell survival. Additionally, preliminary data from

our laboratory (b)(4) and others [Antonsson et al., 1997; Hockenberry, 1995; Jacobson and Bergeron 2002; Yang and Korsmeyer, 1996; Di Masi et al., 2006; Li et al., 2007] suggest that interactions among Bcl-2, Bax, and p53 are implicated in radiation-induced cell death. Wound trauma further increases radiation-induced p21, Bax, DNA damage-binding protein 2 (DDB2) and telomerase reverse transcriptase (TERT) (b)(4)

In addition, wound trauma significantly furthers radiation-induced depletion of RBCs, platelets, splenocytes, neutrophils, eosinophils, basophils, and leukocytes (b)(4),(b)(6)

(b)(4),(b)(6) Serum concentrations of IL-1β, -6, -8, and G-CSF after irradiation are magnified by wound as well. Taken together with data on activation of the iNOS signaling, a wound significantly increases radiation-induced lethality (b)(4),(b)(6)

(b)(4),(b)(6)

A number of countermeasure candidates are emerging that display significant efficacy and low toxicity (b)(4) However, no pharmaceuticals are currently approved specifically for acute radiation syndrome (ARS). Preliminary data from our laboratory showed that either G-CSF or (b)(4) independently increased mouse survival significantly after CI (b)(4),(b)(6)

B. Effect of Granulocyte-colony stimulating factor (G-CSF)

Granulocyte-colony stimulating factor is a specific immunomodulator. rhG-CSF (Neupogen®), has a longer half-life in circulation than natural G-CSF and is an approved drug for human use. Consequently, rhG-CSF could be used off-label in radiation casualties to mitigate neutropenia [Waselenko et al., 2004]. Adapting from results of previous studies in irradiated canines and non-human primates (NHP), and following a human accident, Neupogen® will be tested for its ability to enhance survival and reduce neutropenia in irradiated mice. In canines, rhG-CSF was given as a 5-ml bolus, 10 µg/kg/day (100 µg/dog), s.c, once per day. Injections began in the morning one day after exposure, and were given for a total of 14-28 days [MacVittie et al., 2005]. rhG-CSF improved recovery of neutrophils and enhanced survival [MacVittie et al., 2005]. Similarly, in NHP, a dose of 10 µg rhG-CSF/kg/day (25-40 µg/NHP) was given s.c. starting the day after irradiation, continuing for a total of 14 days [Neelis et al., 1997]. In that report, rhG-CSF significantly shortened the period of neutropenia after whole-body irradiation [Neelis et al., 1997]. In 3-month-old unirradiated Göttingen minipigs, rhG-CSF elevated white blood cells [Takai et al., 2008]. In that study, a dose of 5-10 µg rhG-CSF/kg/day (no body mass provided) was injected s.c. once daily in the cervical region for 10 days. No abnormal clinical signs were observed. White blood cells (WBC) averaged about 15 x 10^3/µl in vehicle-injected animals, gradually increasing during rhG-CSF administration, and reaching a mean of 30 x 10^3/µl on day 3, 40-70 x 10^3/µl on day 7, and 40-90 x 10^3/µl on day 10, with no difference observed between rhG-CSF doses or gender. The increase was mostly attributed to segmented neutrophils. No effect of rhG-CSF on blood chemistry parameters was observed. Enlargement and increased weight of spleens, an increased number of granulocytic cells in bone marrow, and increased extramedullary hematopoiesis in liver and spleen were also observed in the rhG-CSF-treated minipigs, which are all expected effects of

G-CSF. However, no adverse changes were observed in any of the tests [Takai et al., 2008]. Pegylated G-CSF combined with stem cell factor and erythropoietin successfully saved a human victim exposed accidentally to 4.5 Gy ionizing radiation [Bertho et al., 2008]. In our B6D2F$_1$/J mouse model, administration of G-CSF s.c. once daily beginning 24 h (day 1) through day 14 after CI in combination with topical application of gentamicin cream once daily to the wound day 1 to day 10 and administration of levofloxacin *p.o.* once daily day 3 to day 21 increased mouse survival. In B6D2F1/J mice, which were given 9.5 Gy ^{60}Co gamma-photon radiation, G-CSF therapy increased survival to 100% compared to 67% in vehicle-treated control animals. In CI mice, G-CSF increased survival to 25% compared to 5% in vehicle-treated mice (b)(4),(b)(6)
(b)(4),(b)(6)

C. Effect of (b)(4)

Hematopoietic tissue is highly susceptible to cytotoxic effects of ionizing radiation, resulting in thrombocytopenia and/or neutropenia, followed by mortality.
(b)(4)
(b)(4) In CD2F$_1$ mice, 2 mg drug given s.c. was effective when given 12 h post-irradiation, increasing survival to 70% after 9-Gy ^{60}Co gamma irradiation at 0.6 Gy/min (b)(4)
(b)(4) In our B6D2F$_1$/J mouse model, s.c. administration of (b)(4) 24 h after CI in combination with topical application of gentamicin cream to the wound day 1 to day 10 and administration of levofloxacin *p.o.* day 3 to day 21 increased mouse survival. The treatment also improved body weight, numbers of platelets, neutrophils, and eosinophils, and spleen weights and the number of splenocytes after CI.

We propose here to evaluate G-CSF given at 4 h and (b)(4) given at 24 h after CI or *vice versa* or given together at the same time in combination with topical gentamicin for 10 days, days 1 through 10, and oral levofloxacin for 14 days, days 3 through 16. From these observations described above, it is **hypothesized** that this combined treatment regimen will demonstrate either additive or synergistic therapeutic effects on survival of CI mice.

II.2. Literature Search for Duplication

II.2.1. Literature Sources Searched
PubMed 1948-2013; Defense Technical Information Center (DTIC) no time period presented; DoD Biomedical Research Database (BRD) 1998-2009; and NIH Research Portfolio Online Reporting Tools (RePORTer) 1989-2013.

II.2.2. Date of Search December 5, 2013

II.2.3. Period of Search PubMed 1948-2013; Defense Technical Information Center (DTIC) no time period presented; DoD Biomedical Research Database (BRD) 1998-2009; and NIH Research Portfolio Online Reporting Tools (RePORTer) 1989-2013.

II.2.4. Key Words of Search Following key words and their combinations were used to perform the literature search for any duplication: mouse, pain, distress, analgesia, anesthesia, ionizing radiation, wound, combined injury, G-CSF, gentamicin, levofloxacin, and (b)(4)

II.2.5. Results of Search In summary, no duplication effort was found for the proposed study.
Search for key words mouse, pain, distress, analgesia, anesthesia, ionizing radiation, wound, combined injury, G-CSF, gentamicin, levofloxacin, and (b)(4) has reflected in "0" matches on NIH RePORTer, BRD, Pub Med, or DTIC. Therefore, no duplication effort was found.

Mouse/ionizing radiation/wound/pain/G-CSF+(b)(4) +gentamicin+LVX	0

III. OBJECTIVE / HYPOTHESIS Objectives:

1. Determine mortality after exposure to CI in the presence of G-CSF and (b)(4) It is evident that non-lethal γ-radiation combined with non-lethal wounding in mice significantly increases mortality; whereas mice treated with either drug displayed increased survival after CI. We expect that treatment with G-CSF and (b)(4) shall increase survival additively or synergistically.

2. Determine whether treatment with G-CSF and (b)(4) **ameliorates tissue injury from CI.** We have shown that lethal radiation alone or wound alone, or combination activates the iNOS pathways. We will examine whether treatment with G-CSF and (b)(4) ameliorates tissue injury including bone marrow and small intestine.

3. Elucidate the mechanism underlying the therapy provided by G-CSF and (b)(4) Because either radiation or wound activates the iNOS pathway and induces apoptosis and autophagy, the therapy from combined injury provided by G-CSF and (b)(4) should be mediated by its ability to inhibit the iNOS pathway, hematological depletion, cytokine imbalance and bacterial infection.

Hypothesis:
This combined treatment regimen will demonstrate either additive or synergistic therapeutic effects.

IV. MILITARY RELEVANCE Successful completion of the proposed study holds the prospect of identifying and characterizing highly radiotherapy compounds against acute and chronic forms of ionizing radiation combined injury, thereby helping sustain military operations in "RAD/NUC environments". Our previous and current work clearly demonstrates that either G-CSF or (b)(4) are therapeutically effective to improve survival after acute exposures to γ-rays. Most importantly, once being fully characterized, these compounds could be further developed into novel radiotherappy drugs used both by military and domestic authorities in the event of RAD/NUC incidents.

V. MATERIALS AND METHODS

V.1. Experimental Design and General Procedures

General. The overall experimental approach is in evaluating and developing G-CSF and (b)(4) as a safe and effective therapy for persons at risk of CI after RAD/NUC hazards. Our hypothesis is that this combined treatment regimen will demonstrate either additive or synergistic therapeutic effects.

Animals:

B6D2F$_1$/J female mice, approx. 12-22 weeks of age, will be housed in a facility accredited by the Association for Assessment and Accreditation of Laboratory Animal Care, International. Animal rooms will he maintained at 22° ± 4°C with 50% ± 20% relative humidity on a 12-hr light/dark cycle. Animals will be randomized prior to each experiment and housed in small shoebox cages (four animals per cage). Commercial rodent ration (Harlan Teklad Rodent Diet 8604) will be freely available as will acidified (pH=2.5 - 3.0) water to control opportunistic infections. All animal-handling procedures will be performed in compliance with *Guide for the Care and Use of Laboratory Animals*, eighth edition from the National Research Council (2011).

Female mice are used as they are less aggressive to cage mates than the males. Therefore, they will not cause further unnecessary wounding. The animals will be purchased from The Jackson Laboratory.

Irradiation procedures:

Exposure of animals to gamma radiation will be conducted using the AFRRI cobalt-60 source. Thirty to 40 min before irradiation, mice will be placed in perforated acrylic restrainers with partitions (four mice/box with separate compartments for each animal, loaded on a single side) designed for radiation exposure experiments. The calibration factor for the ionization chamber will be calculated by means of a standard obtained from an accredited dosimetry calibration laboratory (M. D. Anderson Cancer Center, Houston, TX) certified by the National Institute of Standards and Technology. Radiation exposures will be bilateral and whole-body as described previously (b)(4),(b)(6) Based on the extensive studies conducted previously at AFRRI, the standard radiation dose rate will be 0.4 Gy/min ^{60}Co at ambient temperature to deliver a dose. A single dose of $LD_{70/30}$ ^{60}Co γ-photon radiation delivered at 0.4 Gy/min will be used. The $LD_{50/30}$ in combined injured B6D2F$_1$/J female mice was determined to be 8.95 Gy in 2009 (b)(4),(b)(6) In the current investigations, a radiation dose of 9.5 Gy, which is approximately $LD_{70/30}$ (i.e., 70% lethal during 30 d following CI), will be used. Sham-treated

control mice will be handled in the same manner as those irradiated but will not be given a dose of gamma photons. The sham-treated mice will be returned to their cages in the vivarium.

Wound Trauma:

One to three days before irradiation and/or wounding, mice will be anesthetized by isoflurane inhalation and then their dorsal hair will be shaved. One h post-irradiation, mice will be anesthetized for approximately 3 to 4 minutes by inhalation of methoxyflurane until respiration rate is approximately once per second in a glass dressing jar on a warming pad at 21-27°C. (The water pump has a rheostat thermistor to control the water temperature.), or, as an alternative, by inhalation of isoflurane (2-chloro-2-(difluoromethoxy)-1,1,1-trifluoro-ethane). For induction of trauma, methoxyflurane is preferred because the animals remain predictably unconscious for a sufficient time to perform the procedure as well as to provide temporary pain relief. Isoflurane acts more quickly and animals recover more quickly, less than one minute, after removal from isoflurane-oxygen unit, which would be inappropriate during the wounding procedure, than with methoxyflurane anesthesia.

Similarly, during the cardiac puncture procedure, mice, which are anesthetized by inhalation of methoxyflurane, remain unconscious for a sufficient time to perform the procedure so that animals do not awaken and move; however, isoflurane can be used, if the dispensing machine with tubing and nose cone are readily available for this procedure.

We will collaborate with the veterinary services department to progressively transition to the use of isoflurane, if it can be demonstrated to maintain adequate anesthesia for the wound model (i.e., able to complete the wound procedure using isoflurane and not affect the timing of the wound injury post-irradiation as compared to methoxyflurane).

Non-lethal wounds to a double layer of dorsal surface skin caudal from the neck and between the shoulders in the center of the back will be created with a stainless steel punch (9/16-in) on a Teflon-covered board, both cleansed with 70% alcohol after each use. The panniculus carnosus muscle and overlying skin will be removed. The size of the wound approximates 15% of the total body skin surface (TBSS). Acetaminophen solution, 150 mg/kg, in 0.5 ml sterile saline given as a fluid therapy i.p., will be administered immediately following wounding to reduce pain and distress (b)(4),(b)(6) All wounded animals will be given a second dose of acetaminophen 4 hours after the first dose but not more than 8 hours after the first dose.

Previous studies in this mouse model show that, without treatment, full wound closure after irradiation requires more than 30 days. Closure to 50% of the initial wound size is accomplished in about 14 days. Without irradiation, the complete wound closure time is approximately 14 days (b)(4),(b)(6) . Sham-treated control mice will be handled in the same manner as those wounded but will not be given a wound. The sham-treated mice will be returned to their cages in the vivarium.

Other experimental considerations: The wounding process is labor intensive. It is only possible to wound 20 animals within a limited time frame after radiation exposure. Because the time of wounding has been shown to have an impact on the severity of the interaction, it is important to minimize the timeframe for this process. Consequently, it will be necessary to irradiate treatment groups of mice in pairs in six runs for each experiment.

Test drugs:

(1) Pegylated G-CSF (1000 µg/kg, s.c., 25 µg/mouse) or vehicle [sterile, clear, colorless, preservative-free solution containing acetate (0.35 mg), polysorbate 20 (0.02 mg), sodium (0.02 mg), and sorbitol (30 mg) in 0.6 ml Water for Injection, USP; 0.2 ml/mouse s.c.] and

(2) (b)(4) 1 mg/kg, s.c., 25 µg/mouse) or vehicle (sterile 0.9% sodium chloride solution for injection, USP; 0.2 ml/mouse s.c.) will be administered at specified times after irradiation.

Antimicrobial agents:

Antimicrobial agents, gentamicin sulfate (GEN, 0.1% cream) will be applied topically on the wound site for 10 days, on days 1 through 10; and levofloxacin (LVX, 90-100 mg/kg p.o.) will be given orally once daily for 14 days, on days 3 through 16.

Survival assessment:

After radiation exposure, mice will be returned to the animal facility and housed 4 mice per cage with free access to rations and water. The mice will be observed for 30 days and the percentage of mice surviving that period will be calculated for each treatment group.

Body-weight measurements:

The degree of body weight loss is a good predictor of radiation mortality. We will measure the body weight of mice treated with vehicle or drugs 1, 3, 7, 14, 21, and 28 d after irradiation.

Wound closure:

Wounded animals will be observed for 30 days to monitor wound closure by caliper measurements on days 1, 7, 14, 21, and 28 post skin wound trauma alone or with radiation.

Water consumption:

Daily water consumption for days 1, 2, 3, 4, 5, 6, and 7 after sham, wound, irradiation, and CI will be measured using graduated water bottles.

Blood collection:

At 4-5 hr, 1, 3, 7, 15, and 30 days after irradiation, animals will be anaesthetized appropriately by methoxyflurane inhalation. However, isoflurane can he used, if the dispensing machine with tubing and nose cone are readily available for this procedure. Blood will be collected using cardiac puncture with 23- to 26-G needles.

Tissue collection:

At each time point and after blood collection, the animal under isoflurane inhalation will be euthanized by cervical dislocation before terminal tissue collections are performed (section V.4.4.2-biosamples). Tissues will be frozen at −70°C until evaluated *in vitro*.

V.1.1. Experiment 1. Specific Aim #1: Determine survival, body weights, water consumption, and wound healing after CI and therapy with G-CSF and (b)(4)

Rationale: It is evident that non-lethal γ-radiation combined with wounding in mice significantly increases mortality; whereas mice treated with either drug 24 h after irradiation displayed

increased survival after combined injury. Since Department of Defense expects to treat irradiated personnel with drugs 4 h after irradiation, we will evaluate these drugs at this time point.

Experimental designs:

(i) Experiment 1.1. (240 mice) PEG-G-CSF and (b)(4) will be administered concurrently 4 h after sham, wound, RI, or CI. PEG-G-CSF will also be administered on days 8 and 15.

(ii) Experiment 1.2. (240 mice) PEG-G-CSF and (b)(4) will be administered sequentially 4 h and 24 h after sham, wound, RI, or CI. PEG-G-CSF will also be administered on days 8 and 15.

(iii) Experiment 1.3. (240 mice) (b)(4) and PEG-G-CSF will be administered sequentially 4 h and 24 h after sham, wound, RI, or CI. PEG-G-CSF will also be administered on days 8 and 15.

Beginning on Day 1, 0.1% gentamicin sulfate cream (GEN) will be applied topically daily through Day 10 (i.e., 10 consecutive days) via a sterile swab and gloved finger to specified mice (see table for treatment groups). In addition, levofloxacin (LVX; 90-100 mg/kg in 0.2 ml sterile water solution, p.o.) will be administered to mice once daily for 14 days on Days 3–16 post-irradiation using a 20-gauge oral feeding needle fitted to a 1-ml sterile syringe.

Water intake, bodyweights, wound healing, and survival in these mice will be monitored. On or after day 30, blood collection and terminal tissue collection (no more than 6 animals per group) may take place for analyzing blood cell composition and signal transduction pathways.

Mice will be randomly divided into 12 groups (n=20 per group) for evaluation of each of three drug regimens:

[3 drug regimens x 1 administration route x 1 administration time x 1 radiation dose x 12 experimental groups x 20 animals/group] = (Total: 720 mice)

Experiment 1. Design

Group	Treatment	No. mice
1	Sham	20
2	Sham+Veh	20
3	Sham+G-CSF+(b)(4)	20
4	Wound	20
5	Wound+Veh	20
6	Wound+G-CSF+(b)(4)	20
7	RI (9.5 Gy)	20
8	RI+Veh	20

11	CI+Veh	20
12	CI+G-CSF+(b)(4)	20
	Total mice =	240

Sham = no Radiation or Wound;
Wound = skin wound injury (15% TBSA on Day 0);
RI = Radiation Injury (9.5 Gy on Day 0);
CI = RI + Wound;
VEH = vehicles for G-CSF [sterile, clear, colorless, preservative-free solution containing acetate (0.35 mg), polysorbate 20 (0.02 mg), sodium (0.02 mg), and sorbitol (30 mg) in 0.6 ml Water for Injection, USP; 0.2ml/mouse s.c.] and (b)(4) sterile 0.9% sodium chloride solution for injection, USP; 0.2ml/mouse s.c);
LVX = levofloxacin (100 mg/kg, p.o.);
GEN = gentamicin (0.1% gentamicin sulfate cream applied topically to wound site).

Experiment 1. 4×4 statistical design (survival)

Groups	Sham	Wound	RI	CI	Total
Control	N=20	N=20	N=20	N=20	N=80
Veh	N=20	N=20	N=20	N=20	N=80
Drugs	N=20	N=20	N=20	N=20	N=80
Total	N=60	N=60	N=60	N=60	N=240

Expected Results: We expect that, at a minimum, combined treatment with (b)(4) and G-CSF will enhance survival from radiation combined with wound compared to vehicle-treated mice.

V.1.2. Experiment 2. Specific Aim #2. Determine whether treatment with G-CSF and (b)(4) ameliorates tissue injury from radiation combined with wound

Rationale: We have shown that RI alone or CI increase apoptosis and autophagy in ileum and skin 7 days after RI or CI. We will examine whether treatment with G-CSF and (b)(4) ameliorates tissue injury including bone marrow and small intestine.
Experimental designs: Effect of drugs on tissue morphology and hematology.
The optimal treatment regimen of combined PEG-G-CSF and (b)(4) will be determined by results of experiments 1.1, 1.2, and 1.3. A second dose of PEG-G-CSF alone will also be administered on Day 8.

Beginning on Day 1, 0.1% gentamicin sulfate cream (GEN) will be applied topically daily through Day 10 (i.e., 10 consecutive days) via a sterile swab and gloved finger to specified mice (see table for treatment groups). In addition, levofloxacin (LVX; 90-100 mg/kg in 0.2 ml sterile water solution, p.o.) will be administered to mice, which remain in the experiment after sampling intervals, once daily for 12 days on Days 3–14 post-irradiation using a 20-gauge feeding needle fitted to a 1-ml sterile syringe.

(i) Experiment 2.1: Histopathology of bone marrow, ileum, and skin. (360 mice)
At 4-5 h, 1, 3, 7, and 15 days after irradiation and wounding, mice will be removed from cages and euthanized (N=6 mice per group per time point) before administration of GEN and LVX to mice that will remain in the experiment. Their blood, bone marrow, ileum, and skin will be collected and prepared for histopathology with H&E staining and immunofluorescent staining. Apoptosis (TUNEL assay) and autophagy (LC-3 immunofluoresence) will be performed.
(ii) Experiment 2.2: Hematology analysis (0 mice)

Blood collected by cardiac puncture from mice in Experiment 2.1 will be used for blood cell analysis to determine changes in numbers of blood cells, including WBCs, RBCs, hemoglobin, hematocrit, platelets, lymphocyte, neutrophils, monocytes, eosinophils, and basophils.

Mice will be randomly divided into 12 groups (N=6 / group / time point):
[One administration route x 1 drug regimen x 1 administration time x 1 radiation dose x 12 experimental groups x 6 animals/group x 5 collection times = Total 360 mice]

Experiment 2. Design.

Group	Treatment	No. mice
1	Sham	30
2	Sham+Veh	30
3	Sham+G-CSF+(b)(4)	30
4	Wound	30
5	Wound+Veh	30
6	Wound+G-CSF+(b)(4)	30
7	RI (9.5 Gy)	30
8	RI+Veh	30
9	RI+G-CSF+(b)(4)	30
10	RI+Wound (CI)	30
11	CI+Veh	30
12	CI+G-CSF+(b)(4)	30
	Total mice =	360

Experiment 2. Sampling per time point:

Groups	Sham	Wound	RI	CI	Total
Control	N=6	N=6	N=6	N=6	N=24
Veh	N=6	N=6	N=6	N=6	N=24
Drugs	N=6	N=6	N=6	N=6	N=24
Total	N=18	N=18	N=18	N=18	N=72

Expected results: Because G-CSF and (b)(4) stimulate neutrophil generation and platelet production, respectively; we expect to see improvement of bone marrow morphology and hematological profiles. Whether structure of ileum and skin will be improved is not predictable. The results, however, will advance our understanding with two promising drugs as therapies for CI.

V.1.3. Experiment 3. Specific Aim #3. Elucidate the mechanism underlying the therapy provided by G-CSF and (b)(4)

Rationale: Because either radiation or wound activates the iNOS pathway to induce cell apoptosis and autophagy, and drastically increase cytokine concentrations in serum, the therapy for combined injury provided by G-CSF and (b)(4) should be mediated by its ability to inhibit the iNOS pathway and/or other possible signal transduction as well as inhibition of pro-inflammatory cytokines. CI-induced bacterial infection and barrier breakdown shall be blocked by these two drugs as well..

Experimental design: effects of drugs on signal transduction and systemic bacterial infection.
The optimal treatment regimen of combined PEG-G-CSF and (b)(4) will be determined by results of experiments 1.1, 1.2, and 1.3. A second dose of PEG-G-CSF alone will also be administered on Day 8.
Beginning on Day 1, 0.1% gentamicin sulfate cream (GEN) will be applied topically daily through Day 10 (i.e., 10 consecutive days) via a sterile swab and gloved finger to specified mice (see table for treatment groups). In addition, levofloxacin (LVX; 90-100 mg/kg in 0.2 ml sterile water solution, p.o.) will be administered to mice, which remain in the experiment after sampling intervals, once daily for 12 days on Days 3–14 post-irradiation using a 20-gauge feeding needle fitted to a 1-ml sterile syringe.

(i) Experiment 3.1: Measurements of cytokines in serum (Total 360 mice)
At 4-5 h, 1, 3, 7, and 15 days after irradiation and wounding, mice will be removed from cages and euthanized (N=6 mice per group per time point) before administration of GEN and LVX to mice that will remain in the experiment. Their blood will be collected by cardiac puncture and serum will be separated for cytokine measurement using multiplex Luminex assay.
(ii) Experiment 3.2: Detection and identification of systemic bacterial infection (0 mice)
Ventricular heart blood, liver, and spleen from mice in Experiment 3.1 will be collected aseptically and cultured for bacterial detection and identification.
(iii) Experiment 3.3: Determination of signaling transduction in bone marrow, ileum and skin (0 mice). The tissues will be removed from mice in Experiment 3.1 and processed for evaluation. Tissues collected from mice in Experiment 3.1 will be analyzed for iNOS, NO, lipid peroxidation (MDA), MPO, ATP, MMPs, and TLRs.

Mice will be randomly divided into 12 groups (N=6 / group / time point):
[1 administration route x 1 drug regimen x 1 administration time x 1 radiation dose x 12 experimental groups x 6 mice/group x 5 collection times = Total 360 mice]

Experiment 3. Design.

Group	Treatment	No. mice
1	Sham	30
2	Sham+Veh	30
3	Sham+G-CSF+(b)(4)	30
4	Wound	30
5	Wound+Veh	30
6	Wound+G-CSF+(b)(4)	30
7	RI (9.5 Gy)	30
8	RI+Veh	30
9	RI+G-CSF+(b)(4)	30
10	RI+Wound (CI)	30
11	CI+Veh	30
12	CI+G-CSF+(b)(4)	30
	Total mice =	360

Experiment 3. Sampling per time point:

Groups	Sham	Wound	RI	CI	Total

Control	N=6	N=6	N=6	N=6	N=24
Veh	N=6	N=6	N=6	N=6	N=24
Drugs	N=6	N=6	N=6	N=6	N=24
Total	N=18	N=18	N=18	N=18	N=72

Expected results: Because G-CSF and (b)(4) increase 30-day survival after CI, respectively, we expect to see inhibitions of activation of the iNOS pathway, increases in pro-inflammatory cytokine concentrations, and systemic bacterial infection.

V.2. Data Analysis Mean with standard error, or percentage will be reported if applicable. A significance level will be set at 5% for each test. All statistical tests will be two-sided. Kaplan-Meier curve and the log-rank test, ANOVA, one-way ANOVA, post-hoc test, chi-square test, and student's test will be used for statistical analyses.

The sample size N=20 per group for survival analysis and the sample size N=6 per group per time point for biomolecular assays will have 80% power to detect any significant difference between groups if any, given type I error of 5% and delta/sigma has at least 1.8, where the delta is the estimated mean differences between the two groups and sigma is the pooled standard deviation of the two groups.

For experiments addressing Specific Aim #1, data analysis will be performed among 12 groups. Kaplan-Meier plot and log-rank test will be used. For experiments addressing Specific Aims #2 and #3, analysis of variance (ANOVA) will be used to detect if there is a significant difference among the groups. If significant, Student-Newman-Keuls multiple range test will be used to do all the possible pair-wise comparisons to identify which group is significantly different from the other.

V.3. Laboratory Animals Required and Justification

V.3.1. Non-animal Alternatives Considered

Drug manufacturers use computer modeling – structure function relationship – and screening *in vitro* by cell cultures during the development of candidate drugs. Computer modeling and cell cultures are insufficient to determine whether or not a given regimen (prophylactic or therapeutic) is effective in promoting survival, resisting infection, or enhancing hemopoiesis and biochemical interruption. An integrated, functional, computer model of a mammal has not yet been achieved for the purpose of examining intricate physiological interactions among cells, tissues, and organs that occur after exposure to ionizing radiation. The resiliency of organs, such as the gastrointestinal system or hematopoietic system, to ionizing radiation depends on a complex network of interactive signaling systems to sense the magnitude of tissue damage, and to initiate repair, recovery, and other defense processes. The physiology of these interacting networks is altered by radiation in ways that cannot yet be modeled using non-animal alternatives. In fact, the proposed studies will provide data, which will contribute directly to future models to predict the progress of radiation injury and appropriate medical treatments.

V.3.2. Animal Model and Species Justification
The mouse was chosen as the best species of animal to use for radiation therapy protocol because:

(1) It is one of the least sentient mammalian species that will permit us to achieve our research objectives.
(2) The cellular proliferative characteristics of gastrointestinal tract and hematopoietic tissues in the mouse are qualitatively similar to those in the human.
(3) Studies in mice have had a direct impact on work with larger animals and humans, as well as clinical treatment.
(4) There are extensive published reports available for comparison, review, and analysis of major biological findings.

B6D2F$_1$/J mice have been used extensively by the PI and his co-investigators at AFRRI to study the effects of ionizing radiation on susceptibility to combined injury and bacterial infections. (b)(4),(b)(6)
(b)(4),(b)(6)

Female mice are utilized because they are less aggressive to each other when conspecifics are housed together. B6D2F$_1$/J mice are hybrid animals that offer an excellent comparison for the genomic distribution seen in humans and are not subject to the inbreeding pressures that affect responses to radiation exposure. The genes of the parental strains of this mouse differ markedly simulating the human situation. Unlike inbred mouse strains, F$_1$ hybrid mice are uniformly heterozygous for all loci at which the parental strains differ and are homozygous. They express hybrid vigor, as do all species, in terms of resistance to disease, better survival under stress, and demonstrate greater, longer, natural longevity. Furthermore, the B6D2F$_1$/J hybrid strain of mouse is naturally relatively resistant to radiation and induced infection (b)(4),(b)(6) It is not overly sensitive to microbial infections, the most common reason for early mortality in acutely irradiated mice. We have used this strain for many years and consequently are familiar with its immunological, hematological, microbiological, and pharmacological characteristics and responses. Lastly, both parental strains (C57BL6/J and DBA2/J) of the B6D2F$_1$ mouse have been genetically mapped which may allow focusing future studies on improved therapy strategies for molecular changes included by injuries.

V.3.3. Laboratory Animals

V.3.3.1. Genus / Species *Mus musculus*

V.3.3.2. Strain / Stock B6D2F$_1$/J

V.3.3.3. Source / Vendor Jackson Laboratories, Bar Harbor, Maine 04609-1500, 800-422-MICE or 207-288-5845, Fax: 207-288-6150, www.jax.org. USDA registration number 11-R-0001, Customer number 1960. This is the only vendor and the only breeding site that will supply the animals used for our work. JAX is the established premier breeder of healthy B6D2F$_1$/J mice that maintains a highly regarded quality

control breeding facility because only that facility can provide the numbers of mice needed in one shipment and because of the exemplary health record. This mouse strain will be designated for purchase only from the Bar Harbor facility. Our combined injury efforts in this animal use protocol are based upon the uniformity of breeding this mouse that allows comparisons with previously collected data. In our years of working with JAX providing this mouse, not once has an experiment been terminated due to undesirable microbial associations.

V.3.3.4. Age Approx. 10-14 weeks of age at purchase; approx. 12-22 weeks of age at use.

V.3.3.5. Weight Approx. 20-35 grams at the time of experimental manipulation.

V.3.3.6. Sex Female. The B6D2F$_1$/J female gender demonstrates less aggressive behavior than males to conspecifics and under stress conditions such as after wound trauma (b)(4),(b)(6) The estrous cycle of female mice did not interfere with the evaluation of 5-AED (b)(4),(b)(6) It is therefore unlikely that the estrous cycle will interfere with G-CSF and (b)(4) in the proposed study.

V.3.3.7. Special Considerations
Commercially procured animals must be adventitious disease free.
Pathogen-free, including *Pseudomonas aeruginosa* and *Pasteurella* sp. All mice need to be free of the following agents: Sendai, Pneumonia Virus of Mice (PVM), Reovirus-3 (Reo 3), Mouse Adenovirus (MAD-1, MAD-2), Mouse Cytomegalovirus Virus (MCMV), Ectromelia, K virus, Lymphocytic Choriomeningitis Virus (LCM), Epidemic Diarrhea of Infant Mice (EDIM), Hantaan virus, Rotavirus, Mouse Parvovirus (MPV), Polyoma Virus, Mouse Minute Virus (MMV), Mouse Thymic Virus (MTV), Theiler's Mouse Encephalomyelitis Virus (TMEV/GDVII), *Encephalitozoon cuniculi*, CAR bacillus, *Mycoplasma pulmonis*, and *Clostridium piliforme*. Endoparasite- and ectoparasite-free.

V.3.4. Number of Animals Required (by species) B6D2F$_1$/J mice: 1440

V.3.5. Refinement, Reduction, Replacement (3 R's)

V.3.5.1. Refinement This protocol will evaluate adjusted early experimental endpoints.
(1) Moribund animals will be considered to have arrived at the endpoint and will be euthanized.
(2) Endpoints that assess morbidity will include histology of ileum and lung, and concentration determinations of biomolecules including iNOS, NO, MDA, 3-N-Tyr protein nitration, ATP, LC3, and defensins at timed intervals for autophagy. The animals will have minimal pain or distress.
(3)
Acetaminophen will be administered after wound injury to help alleviate any discomfort.

(4) Animals will be housed in groups of 4 to encourage social behavior throughout the experiment and nestlets will be provided for comfort and to enhance the cage environment.

V.3.5.2. Reduction A statistician has reviewed this protocol to ensure that the minimum number of animals will be used to gain statistically significant results. We will collect multiple data from individual animals, providing information on histology, apoptosis, autophagy, and several biomolecule assessments.

V.3.5.3. Replacement We attempted to develop an *in vitro* CI model to reduce the number of mice used for CI studies. After a 6-month effort, the synergistic effect observed with our *in vivo* model was not obtained with the *in vitro* model. Therefore, we continue to use our *in vivo* model.

It is not feasible to use non-animal systems in place of animal models to address the research questions in this project. The mouse is considered to be a lower sentient mammalian species than is the rat, rabbit, cavy (guinea pig), canine, minipig, and nonhuman primate, which are other mammals that have been used for radiation research. The mouse is commonly used in laboratory studies to determine basic experimental principles before experimentation in larger mammals or in humans. The immune responses of the mouse are similar to those of the human. Blood cells and serum cytokine components of the mouse, while quantitatively different from other species, are qualitatively similar to other animal species. The intestinal tract of mice contains cellular components similar to those found in higher sentient animals, particularly a major component of the immune system that provides surveillance for and response to microorganisms.

V.4. Technical Methods

V.4.1. Pain / Distress Assessment

V.4.1.1. APHIS Form 7023 Information

V.4.1.1.1. Number of Animals 1440

V.4.1.1.1.1. Column C 180 (# of animals)

V.4.1.1.1.2. Column D 540 (# of animals)

V.4.1.1.1.3. Column E 720 (# of animals)

V.4.1.1.1.4. Pain Category Assignments Because blood will be collected by cardiac puncture from anesthetized mice, all sham-treated control mice will be included in category D, alleviated pain or distress for experiments 2 and 3.

Exp. #	Experimental/Control Group	C	D	E	Totals

Exp. #	Experimental/Control Group	C	D	E	Totals
1.1	PEG-G-CSF and (b)(4) will be administered concurrently 4 h after sham, wound, RI, or CI (survival).	60	60	120	240
1.2	PEG-G-CSF and (b)(4) will be administered sequentially 4 h and 24 h after sham, wound, RI, or CI (survival).	60	60	120	240
1.3	(b)(4) and PEG-G-CSF will be administered sequentially 4 h and 24 h after sham, wound, RI, or CI (survival).	60	60	120	240
2	Determine whether treatment with optimal combination of PEG-G-CSF and (b)(4) ameliorates tissue injury from radiation combined with wound (early endpoint).	0	180	180	360
3	Elucidate the mechanism underlying the therapy provided by optimal combination of PEG-G-CSF and (b)(4) (early endpoint).	0	180	180	360
Totals:		180	540	720	1440

V.4.1.2. Pain Relief / Prevention

V.4.1.2.1. Anesthesia / Analgesia / Tranquilization

Wound procedure: One to three days before irradiation and/or wounding, mice will be anesthetized by isoflurane inhalation and then their dorsal hair will be shaved. One h postirradiation, mice will be anesthetized for approximately 3 to 4 minutes by inhalation of **methoxyflurane** until respiration rate is approximately once per second in a glass dressing jar on a warming pad at 25°C., or, as an alternative, by inhalation of 1-4% **isoflurane** (2-chloro-2-(difluoromethoxy)-1,1,1-trifluoro-ethane). For induction of trauma and collection of blood by cardiac puncture, methoxyflurane is preferred because the animals remain predictably unconscious for a sufficient time to perform each of the two procedures. Isoflurane acts more quickly and animals recover more quickly than with methoxyflurane anesthesia. Similarly, during the cardiac puncture procedure, mice, which are anesthetized by inhalation of methoxyflurane, remain unconscious for a sufficient time to perform the procedure so that animals do not awaken and move; however, isoflurane can be used, if the dispensing machine with tubing and nose cone are readily available for this procedure.

Acetaminophen solution, 150 mg/kg , will be given in 0.5 ml sterile saline solution for injection, USP, as a fluid therapy i.p. (b)(4),(b)(6) immediately following wounding to reduce pain and discomfort.

Blood collection: At specified time points, animals will be anaesthetized under isoflurane inhalation. The isoflurane anesthetic system that is available in VSD might be able to overcome movement of mice in many cases by continuous delivery of vapor during this procedure. Blood will be collected using cardiac puncture with 23-26 G needles. Blood will be transferred into EDTA vials (lavender-topped) to for hematology studies and plasma or Capiject vials with gel separator (red-topped) for serum depending on the experimental purpose.

Tissue collection: At the end of blood collection, the animal under isoflurane inhalation will be euthanized with cervical dislocation before terminal tissue collections (section V.4.4.2-biosamples) are implemented. Tissues will be frozen at −80°C until use.

V.4.1.2.2. Pre- and Post-procedural Provisions Animals will be housed and cared for both before and after dosing and irradiation procedures, as described in Section V.5. Veterinary Care. Prior to irradiation, mice will be group-housed 4-8 per cage with conspecifics in Micro-isolator cages (IAW VSDH SOP), and observed at least twice daily by the veterinary staff conducting general health check rounds. Following irradiation and wounding, the investigative staff will monitor animals on experiment at least twice daily, in addition to the routine veterinary staff rounds. Supportive care will be observed more frequently by the investigative staff and moribund animals will be euthanized (See V.4.5. Study Endpoint).

V.4.1.2.3. Paralytics NA

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures

V.4.1.3.1. Sources Searched
Two sources were searched that contain major compilations of information on painful or distressful procedures. These included PUBMED and DoD Biomedical Research Database (BRD).

V.4.1.3.2. Date of Search December 5, 2013, PUBMED and DoD Biomedical Research Database (BRD)

V.4.1.3.3. Period of Search 1948 to 2013, PUBMED; 1998 to 2009, DoD Biomedical Research Database

V.4.1.3.4. Key Words of Search
Mouse, pain, distress, analgesia, anesthesia, ionizing radiation, wound, combined injury, G-CSF, gentamicin, levofloxacin, (b)(4) and alternative

V.4.1.3.5. Results of Search
There are no alternative procedures for irradiation because its effects cannot be otherwise duplicated. No alternatives for the research effort with mice were found. Radiation itself does not cause pain or distress, particularly at sublethal doses. A sizable number of animals in these experiments will receive either near-lethal or lethal doses. These dose levels will lead to the clinical syndromes following irradiation, which may lead to distress/pain and moribundity. There was no mention of employing tissue culture for combined injury work. Tissue culture testing for radiation combined injury would not be possible as whole animals are required for evaluation. End points such as survival, clinical chemistries, complete blood cell counts, and histopathologies, are, by their nature, not possible in a cell culture system. Whole living animal systems are required for determination of the endpoints identified in this proposal and mice are the species of choice to accomplish those goals and aims.

Terms	Results
Mouse/ionizing radiation/wound/alternative/G-CSF	0

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification Pain will be alleviated by drugs as described in V.4.1.2.1.

V.4.2. Prolonged Restraint Mice will be placed in perforated acrylic plastic boxes for up to two hours, but usually for less time, usually <1 h, during prompt irradiation procedures. Restraint of mice will be performed by the PI, Co-investigators, or qualified trained technical support staff.

V.4.3. Surgery

V.4.3.1. Pre-surgical Provisions One to three days before irradiation and/or wounding, mice will be anesthetized by isoflurane inhalation and then their dorsal hair will be shaved with electric clippers.

V.4.3.2. Procedure(s) No surgical procedures are planned. The infliction of wound trauma was described in section V.1., under general procedures.

V.4.3.3. Post-surgical Provisions No post-surgical provisions are planned other than that identified in section V.1., under specific methods following irradiation and wounding.

V.4.3.4. Location The wounding procedure will be performed in an assigned room in the Veterinary Sciences Department of the Armed Forces Radiobiology Research Institute.

V.4.3.5. Surgeon The wounding procedure will be performed by the principal investigator, the co-investigators, and trained technical staff of this research proposal. Technical assistance support such as anesthesia, preparing surgical facilities and obtaining animals for surgery will be provided by trained technical support staff that is identified in section VI Study Personnel and Qualifications.

V.4.3.6. Multiple Major Survival Operative Procedures NA

V.4.3.6.1. Procedures NA

V.4.3.6.2 Scientific Justification NA

V.4.4. Animal Manipulations

V.4.4.1. Injections

V.4.4.1.1. Pharmaceutical Grade Drugs

A. Sterile sodium chloride solution for injection USP
Sterile USP isotonic sodium chloride, 0.9%, will be given i.p., 0.5 ml, as fluid therapy with a 25- to 27-G sterile needle fitted to a sterile syringe after sham-operation, irradiation, wounding, and irradiation followed by wounding, i.e., combined injury. USP grade saline will be obtained from the USUHS pharmacy stock or from the WRNMMC hospital stock (or other suitable alternative sources for scientific supplies).

B. Acetaminophen solution
Acetaminophen for injection (NDC:43825-102-01; OFIRMEV. www.ofirmev.com, or equivalent) will be purchased from AmerisourceBergen (or other suitable alternative sources selected in consultation with a veterinarian) and given i.p., 150 mg/kg, i.e., 3.75 mg/25-g mouse, in 0.5 ml sterile saline for injection, USP (Davis J.A. Mouse and Rat Anesthesia and Analgesia *Curr. Protoc. Neurosci.* 42:A.4B.1-A.4B.21. 2008, John Wiley & Sons, Inc.; Coen M et al.. An Integrated Metabonomic Investigation of Acetaminophen Toxicity in the Mouse Using NMR Spectroscopy, *Chem. Res. Toxicol.* **2003,** *16*, 295-303).

C. Gentamicin
Gentamicin sulfate cream (GEN), 0.1%, pharmaceutical grade, will be purchased from Moore Medical LLC*, 1690 New Britain Ave, Box 4066, Farmington CT 06032-4066 (or other suitable alternative sources selected in consultation with a veterinarian) and will be applied topically daily from day 1 to day 10 for 10 consecutive days via a sterile swab No attempt will be made to quantify or measure the amount of gentamicin cream applied to the wound site. Rather, as in the case of human skin injuries, the site will receive an amount of antibiotic cream necessary to uniformly cover the area. This type of application is that expected to be provided to injuries of personnel involved in nuclear radiation disasters and has been used in burn management situations [Snelling et al., 1978]. In previous work from our laboratory, we never observed manifestations of toxicity to topical applications of gentamicin.

D. Levofloxacin
Levofloxacin (LVX), a sterilized pharmaceutical grade drug, will be purchased from AmerisourceBergen, Glen Allen, Va. (or other suitable alternative sources selected in consultation with a veterinarian). Levofloxacin is provided as Levaquin® oral solution 25mg/ml, Ortho-McNeil, Raritan, N.J., NDC 0045-1515-02, 480 ml, or in 20-ml vials.

LVX will be diluted in sterile water and provided *p.o.* 90-100 mg/kg in a 0.2 ml volume once per day for 14 consecutive days (starting day 3 through day 16 after CI) via a 20-G feeding needle with either silicone tip or stainless steel ball tip and a sterile 1-ml syringe. This therapy schedule is used because once-daily administration of a high dose reduces irritation of the soft tissues in the mouth and pharynx induced by the silicone-tipped feeding needles. The high dose attains a high concentration in blood and tissues, which attains over a 24-hr period similar pharmacokinetics as achieved by a lower dose given q12h.

E. Pegylated G-CSF
Pegylated G-CSF (Peg-G-CSF; Neulasta®), a polyethylene glycol pharmaceutical formulated grade drug, also known as pegfilgrastim, is prepared by Amgen Inc., Thousand oaks, CA and will be purchased from Bioscrip Pharmacy Services, Inc, 2787 Charter St. Columbus, OH 43228 800-378-4786 customercare@drugstore.com. Peg-G-CSF will be diluted to deliver 1000 µg/kg (25 µg for a 25-g average mouse) s.c. injection in a volume of 0.2 ml 4 h or 24 h via 25-28 G needle fitted to a sterile syringe. The PEG formulation has a much longer half-life thus reducing the necessity of daily injections of G-CSF [Scholz et al., 2009].

V.4.4.1.2. Non-Pharmaceutical Grade Drugs
(b)(4)
(b)(4) and will be tested at 1 mg/kg (25 µg for a 25-g average mouse), in 0.2 ml s.c. 4h or 24h as specified in experimental design before, after, or combined with Pegylated G-CSF. (b)(4) The selected vehicle will be the phosphate-buffered saline (Life Technologies, Inc). Needle size for s.c. injection is 25-26G. (b)(4) will be prepared with the phosphate-buffered saline and tested for the levels of endotoxins.

V.4.4.2. Biosamples Following anesthesia and/or euthanasia, tissues including blood, lung, liver, kidney, heart, brain, bone marrow and ileum will be collected. Whole anti-coagulated blood (EDTA) will be used for hematological analysis (complete blood count) or serum will be separated from the clotted blood cells. Ileum, lung, and serum will be evaluated *in vitro* by biochemical assays and immunoblotting analysis. Ileum and lung will also be examined for histopathological changes. Other tissues will be frozen at –80°C for future evaluation.

V.4.4.3. Adjuvants NA

V.4.4.4. Monoclonal Antibody (MAb) Production NA

V.4.4.5. Animal Identification Cage cards will be used in general. Marks on tails with marking pens will be used to identify individual animals in a cage if needed. The investigative staff will perform ear tagging with ear skin disinfected with 70% isopropyl rubbing alcohol, if individual identification is needed for periods greater than 3-4 days. No anesthesia will be used.

V.4.4.6. Behavioral Studies NA

V.4.4.7. Other Procedures Food and water consumption and body weights will be measured as a means of discerning the efficacy of therapy for RI and CI as compared to control-treated animals. Furthermore, we will measure wound closure and compare that endpoint to control-treated animals as another means to determine the efficacy of therapy based upon the fact that therapies may result in improved hematopoietic recovery that in turn enhance wound closure. These four variables will be determined on the same selected cage sets of mice at periodic intervals over the 30-day experiments. No aversive stimuli will be provided to the animals in order to elicit behavioral or physiologic changes other than RI and CI.

V.4.4.8. Tissue Sharing All tissues of the animals used in these investigations are appropriate for tissue sharing. Tissues for histopathologic analyses may also be provided to the AFRRI Veterinary Pathologist to obtain diagnoses to detect reasons for survival improvement (over controls) or lack of survival improvement (over controls).

V.4.4.9. Animal By-Products NA

V.4.5. Study Endpoint Animals in these studies may become morbid and moribund and hence it is critical to define criteria for euthanizing mice humanely without compromising the study objective. Mice will be considered **morbid** when they display mild dyspnea, kyphosis with ruffled hair, dried lacrimal fluid accumulated in the cul-de-sac of their eyes, are cool to the touch, show inappetance or diarrhea (i.e., score of 6-10 on Rodent Intervention Score Sheet, Table 1 in appendix, a modification of IACUC Policy #10). Experimental mice that are found morbid, but **not** moribund, will be allowed to continue in the experimental protocol in order to obtain an optimal number of specimens for evaluation of specimens at each time point, particularly to evaluate wound healing rate, namely to determine whether morbid mice are still likely to respond to the therapy. Once mice are considered morbid, the PI or other members of the investigative team will monitor these morbid mice at least twice daily, early morning and late afternoon. When morbid mice become moribund, the investigative team members will monitor those mice more frequently at two- to four-hour intervals.

Those animals found **moribund** with scores greater than 10 will be euthanized with CO_2. Animals will be considered **moribund** when, in addition to showing some or all of the signs of morbidity, they show severe dyspnea plus either an inability to remain upright or an inability to move when stimulated. VSD veterinarians will be consulted if questions should arise regarding difficult, labored breathing (dyspnea), lethargy, and anorexia or inanition. If any single category is above 12 (e.g., the mouse cannot stand or breathe normally, right itself within 5 seconds when placed gently on its side, or respond when the rear foot pads are pinched gently), the mouse will be euthanized.

For those experiments in which blood and tissues will be removed for assays *in vitro*, the anesthetized mice will be euthanized by cervical dislocation, immediately after drawing blood, without inhalation of CO_2 because use of this procedure is to avoid possible adverse effects of inhaled CO_2, i.e., particularly low pH of tissues following

asphyxiation, on the bacteria (low pH kills bacteria) or on metabolism and function of cells and peptides that are to be assayed. These animals will be scored as dead at the time of removal and will be recorded as euthanized in the medical record. PI, co-investigators, or other trained staff, and/or trained veterinary personnel will perform euthanasia.

V.4.6. Euthanasia For blood collection for analyses of blood cell composition, cytokine concentrations, and other biomolecular assays, mice will be anesthetized with isoflurane at specified time points, blood will be collected while under continuous anesthesia (i.e., isoflurane through a nose cone). Then, the mice under isoflurane inhalation will be euthanized by cervical dislocation and terminal tissue specimens will be collected. When mice are found moribund and euthanized as described above under Study Endpoint, blood and tissues will be collected from the individual mice.

Mice, which are found moribund and are not suitable for collection of specimens to be used for further analysis, will be euthanized by CO_2 inhalation and cervical dislocation, as described by VSD's SOP for euthanasia, by investigators or technicians. Animals, which have successfully survived the experimental procedures, including drug treatment and irradiation, will be euthanized by terminal inhalation of CO_2 and cervical dislocation. Briefly, the method of euthanasia for animals surviving the experimental procedures will be exposure to a regulated flow of CO_2 from a compressed gas cylinder in accordance with the current AVMA Guidelines on Euthanasia (only personnel trained and deemed proficient by the Attending Veterinarian are approved to perform this procedure) and a secondary confirmatory method (e.g., cervical dislocation or induced pneumothorax).

We follow the guide in the IACUC policy, a **Rodent Intervention Score Sheet** (Table 1, Appendix 1), to track morbidity and moribund state in injured groups of mice. Mice that have scores greater than 10 will be considered to be moribund. Mice will be euthanized promptly, If any single category is above 12 (i.e., the mouse cannot stand or breathe normally, right itself within 5 seconds when placed gently on its side, or respond when the rear foot pads are pinched gently). These morbid signs usually appear much earlier than body-weight loss of more than 20% original body weight. If there are no other signs apparent and the body-weight loss is the only indication, then mice with body-weight loss more than 20% will be euthanized immediately. These mice will be monitored very closely for their appearance, general behavior, respiratory rate, and provoked behavior prior to making a determination of euthanasia. Weights, which are measured prior to irradiation or within 6 h after irradiation, will be used as a baseline reference. Mice will be monitored at least twice a day (i.e., early in the morning and then again in the late afternoon) during the actual experiment. When mice appear to be morbid, they will be monitored at least three times a day (i.e., check the animals between 6:00-8:00 a.m., 11:00a.m. -1:00 p.m., and 4:00-6:00 p.m. If, during any of the checks, it is suspected that the animals may succumb before the next observation period, the animals should either be checked again before the next scheduled observation period or be euthanized immediately.

V.5. Veterinary Care

V.5.1. Husbandry Considerations Except as noted below, all mice will be group-housed in Micro-isolator cages in the vivarium in cages of 4 or 8 mice each in accordance with the *Guide for the Care and Use of Laboratory Animals* and the current Veterinary Sciences Department standard operating procedure. The animals will be maintained on a 12-h light-dark cycle and fed rodent chow *ad libitum*. Mice will have free access to acidified water via bottles and sipper tubes. Nestlet pads will be provided in each cage during bedding changes. Following irradiation and skin wounding, cages holding similarly treated mice will be placed on shelves in a vertical arrangement to allow similar exposures to environmental factors to all mice in each treatment within the experimental protocol. Mice will be housed for approximately 30 days during the course of survival experiments or for specified durations during the course of mechanistic experiments.

V.5.1.1. Study Room (b)(6) Room Number(s) as assigned by VSD

V.5.1.2. Special Husbandry Provisions Following irradiation and skin wounding, animals will be housed in cages fitted with Micro-isolator tops at Animal biosafety Level One (ASBL-1) within an assigned room of VSD. Gentle movement of injured animals via the tail (taking great care not to disturb the wound site) for purpose of changing the wood-chip bedding is required to insure that the injury site is not disturbed. Cages will be arranged in a specific vertical order to account for variation in environmental factors within experimental groups in the room as noted under "Husbandry Considerations" above.

V.5.1.3. Exceptions Mice are colonial creatures and thus will be group-housed with regard to housing requirements after experimental manipulation. However, during survival studies, as con-specifics within the cage die or are used for experimental purposes; there will be a period of time when an animal could be singly housed. When this occurs, singly housed animals will be able to view con-specifics in neighboring cages housed on the same rack in the same room.

V.5.2. Veterinary Medical Care

V.5.2.1. Routine Veterinary Medical Care Doses of ionizing radiation delivered in this study are expected to result in some illness or debilitation. Because of this, occasional animals may succumb after irradiation without revealing overt signs of stress. On the other hand, the radiation doses used in conjunction with skin wound trauma may result in significant illness, debilitation and death. To monitor these general events, VSD personnel will observe the animals twice daily during general rounds for general health, husbandry conditions, and humane treatment. In addition, the investigative staff will monitor animals at least two times a day, early morning and late afternoon. Supportive care, other than the use of a one-time i.p. injection of 0.5 ml sterile isotonic saline after irradiation and wounding and the use of topical application of gentamicin, oral administration of levofloxacin, and treatments with peg-G-CSF and (b)(4) will

not be provided. Animals found moribund will be euthanized (See Painful Procedure Justification).

V.5.2.2. Emergency Veterinary Medical Care Emergency veterinary medical care will be available from VSD veterinarians and technicians 24 hours daily to provide emergency veterinary medical care as necessary.

V.5.3. Environmental Enrichment

V.5.3.1. Enrichment Strategy Sterilized nestlet squares will be placed in the cages of experimental mice. The squares must be changed when cages and bedding are refreshed. Experimental mice will be housed in groups of 2-4 in polycarbonate cages. The cages allow viewing of con-specifics in neighboring cage environments. Husbandry provisions by all VSD staff monitoring activities throughout the day by veterinary personnel, and research staff provide an environment of enrichment.

V.5.3.2. Enrichment Restrictions Only sterilized nestlet squares are requested. The squares do not adhere to the wound site and provide a modicum of heat insulation when mice huddle together in their cage environment. The nestlets must be changed when cages and bedding are refreshed. Sterilized acrylic devices will not be used as enrichment devices because removing animals from under these microenvironments adds temporary stress and interferes with the applications of treatment agents to the mice. Further, previous research has not employed acrylic enrichment devices; use in this protocol could add another variable in the behavior of the animals and affect the outcome of the experiment.

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING

NAME	DEGREE	TRAINING	DATE	PROCEDURES	YRS/MOS EXPERIENCE
(b)(6)				1,2,3(all),4,5(aseptic), 7 irradiation, tail vein, anesthesia, oral feeding	(b)(6)
				1, 3a-c, 4, 5(aseptic), 7 oral feeding, irradiation	
				1,3a-c,5(aseptic), 7anesthesia, irradiation	
				1,3a-b,4a,5(aseptic)	
				1, 3a, 4a, 5, 7oral feeding, tail vein, irradiation	
				1,3b,3c,3d,4a,5,7oral feeding, irradiation	

Procedure and manipulation codes:

Code 1= Animal handling and euthanasia
Code 2= Surgery (aseptic technique) pre- and post-operative care
Code 3= Injections (3a–ip, 3b-sc, 3c-gavage) - can say 3 if trained in all manipulations or add 3d-iv
Code 4= Blood collection under anesthesia (4a-cardiac, 4b-posterior vena cava)
Code 5= Tissue collection (after euthanasia) - doesn't need to be specific
Code 6 = Implantation (provide details)
Code 7 = Others - (provide protocol specific manipulations or procedures for e.g., retro-orbital bleeding, tail vein injection, or drug delivery)

VII. BIOHAZARDS/SAFETY An AFRRI Safety and Health Department Protocol Hazard Analysis (AFRRI Form 210b) was submitted and approved by the University Safety Officer. We will meet or exceed ASBL-1 procedures to assure that we keep experimental animals separate from the general colony (Chosewood and Wilson 2009). Gaseous anesthetics, including methoxyflurane and isoflurane, will be used under appropriate recovery devices. All the personnel have been trained either as radiation users or as general radiation users annually. All investigators and technicians while in the vivarium will use appropriate procedures and personal protective equipment as described by Veterinary Sciences Department. This will include wearing of gown, mask, eye glasses, and gloves during manipulations and observations of mice. All investigators and technicians maintain current standards in safety training and medical surveillance.

Appendix 1.

Table 1. Rodent Intervention Score Sheet.

Rodent Intervention Score Sheet		
PARAMETER	**DESCRIPTION**	**SCORE**
Appearance	Normal (coats smooth, eyes/nose clear)	**0**
	Reduced grooming OR minor hunching	**1**
	Ocular/nasal discharge AND/OR rough coat and hunching OR facial edema	**3**
	Emaciated, dehydrated, OR soft stools (fecal matter around anus)	**5***
	Presence of bloody diarrhea	**9**
General behavior	Normal	**0**
	Minor changes – writhe or grimace, slightly less active than baseline	**1**
	Moderately less mobile and alert	**2**
	Ataxia, wobbly, appearing weak	**6***
	Unable to stand	**12**
Respiratory Rate	Normal breathing	**0**
	Increased (doubled) breathing rate, rapid or shallow	**6**
	Abdominal breathing (gasping +/- open mouth breathing)	**12**
Provoked behavior	Normal	**0**
	Subdued or weak, but moves away when stimulated	**1**
	Subdued even when stimulated (moves away slowly).	**3**
	Unresponsive when stimulated, weak, pre-comatose	**6***
	Does not right when placed gently on side within 5 seconds, or no response when pinch the paws	**12**
***Notify VSD immediately – may need to euthanize**		
<6 – Normal		
6-9 – Morbid, some pain/distress, monitor at least three times a day.		
>10 - Moribund. Either euthanize or notify VSD. If any single category is at 12, euthanize animal immediately.		

Notes: B6D2F$_1$ mice found to have lost greater than 20% of their body weight (relative to weight at start of experiment) will be brought to the attention of VSD staff. Those mice that lose more than 20% of initial body weight will be euthanized and scored as deceased.

X. ASSURANCES

Protocol Title: *In vivo* combined therapy for ionizing radiation followed by wound trauma in the laboratory mouse (*Mus musculus*)

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made every effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with a qualified individual who evaluated the experimental design with respect to the statistical analysis, and that the minimum number of animals needed for scientific validity will be used.

D. Biohazard / Safety: I have taken into consideration and made the proper coordinations regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R", namely, "Responsibility," which the DOD has embraced for implementing animal use alternatives where feasible and conducting humane and lawful research.

G. Scientific Review: This proposed animal use protocol has received appropriate peer scientific review and is consistent with good scientific research practice.

H. Painful Procedure(s): I **AM** / **AM NOT** conducting biomedical experiments, which may potentially cause more than momentary or slight pain or distress to animals. If applicable, potential pain and/or distress **WILL** / **WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

CO-INVESTIGATOR(S): N/A

AFRRI SCIENTIFIC RESEARCH PROTOCOL NUMBER: [(b)(6)]

I. NON-TECHNICAL SYNOPSIS: The threat of a limited radiological attack on American cities (i.e. a "dirty" bomb), or a nuclear accident, requires the development of a radiation countermeasure capable of protecting the gastrointestinal (GI) tract of military personnel, who might have to enter a contaminated area, or capable of mitigating GI lethality in the general population. At present there is no effective treatment for the acute radiation GI syndrome. [(b)(4)] promotes recovery of radiation damaged cells by stimulating DNA repair and cell survival pathways. Studies conducted at AFRRI [(b)(4)] both as a protector and a mitigator of ARS in mouse models. Clinical studies in humans support an excellent safety profile of [(b)(4)] In the current protocol the main focus is to optimize the dose of [(b)(4)] to mitigate the effects of radiation by monitoring the biomarkers, and to conduct efficacy studies in nonhuman primates. For efficacy study, drug will be tested by administering it through subcutaneous and oral routes.

II. BACKGROUND

II.1. Background:

Military and civil defense organizations have an urgent requirement for medically effective radiation countermeasures, including radiation protectors, mitigators and therapeutics. Radiation countermeasures that mitigate the harmful effects and promote recovery from radiation injury will have stringent requirements in terms of lack of toxicity, ease-of-use for administration, storage at environmental temperatures, suited for administration by non-medical personnel, and capability of enhancing survival in the absence of ancillary medical support. Although such efforts were initiated more than half a century ago, no safe and effective radiation countermeasure has been approved by the United States Food and Drug Administration (FDA) for ARS (1, 14, [(b)(4)]

Scientists at [(b)(4)] the Armed Forces Radiobiology Research Institute (AFRRI) [(b)(4)] and [(b)(4)] have conducted extensive studies to demonstrate radiation protecting and mitigating effects of injectable (subcutaneous, sc)

and oral (po) [(b)(4)] Safety and tolerability of [(b)(4)] have been established in GLP-compliant nonclinical studies and in 4 clinical safety trials in healthy adults. These results are published in peer-reviewed journals [(b)(4)] and included in 2 active U.S. FDA IND exemptions [(b)(6)] [(b)(4)] mitigates deleterious radiation effects by enhancing DNA damage repair pathways, rather than intervening in the free-radical cascade. Thus, its window of effectiveness is relatively long, extending from a day before to a day or more after exposure to radiation.

Preliminary studies on biomarker analysis in mouse tissue specimens using Nano-immunoassay: A novel analytical method termed, Nanoscale Immuno Assay

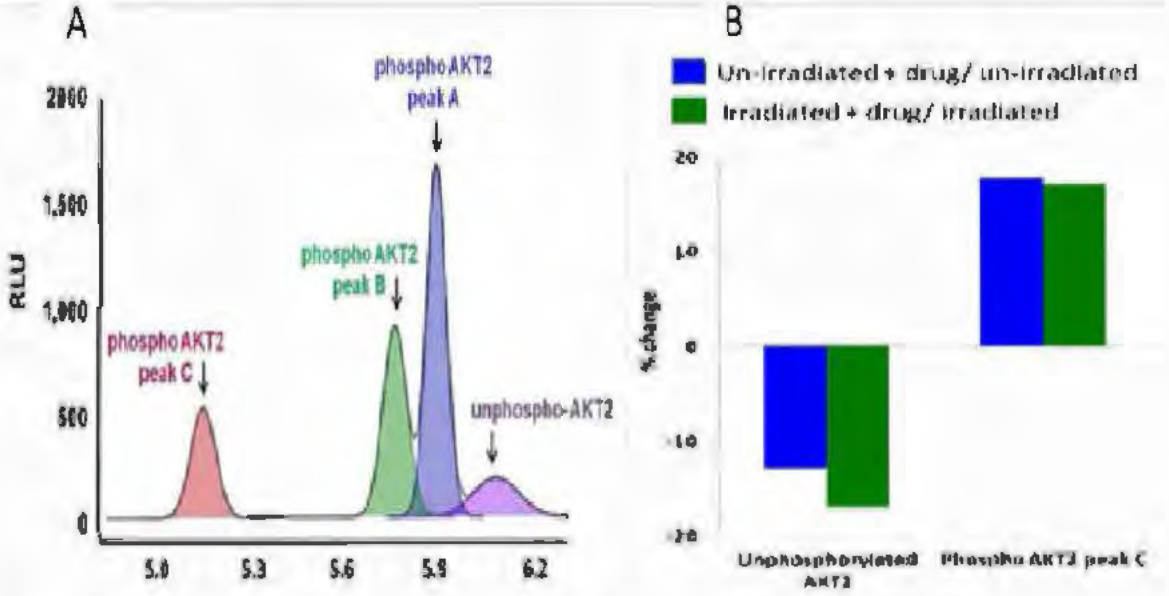

Figure 1. NIA analysis of AKT levels in mouse bone marrow +/- [(b)(4)] administration. A) NIA reveals three phosphorylated peaks of AKT2 in mouse bone marrow (control); B) [(b)(4)] treatment *in vivo* induces similar AKT profiles in bone marrow from un-irradiated and irradiated mice [AKT2 profiles, correlation = 0.94]

(NIA) is capable of rapidly and reproducibly quantifying proteins and their phosphorylation states in very small nonclinical and clinical specimens and has been developed by [(b)(4),(b)(6)] NIA assays have been validated to measure proteins that mediate cell survival, proliferation, cell cycle and apoptotic pathways. Preliminary studies were conducted in mice dosed orally with either vehicle or drug with or without radiation. After 24 h post-irradiation administration of drug, mice were sacrificed, bone marrow (BM) was removed and the cell lysates were analyzed by NIA. The data in **figure 1A** show that the unphosphorylated AKT and the various forms of phosphorylated AKT (A, B and C) were successfully resolved and quantified by NIA. The data in **figure 1B** confirms the up-regulation of Akt2 in BM samples from mice treated with [(b)(4)] with or without radiation. Simultaneously, there is a corresponding down regulation in unphosphorylated AKT. Importantly, correlation in fold change from baseline in AKT2 isoforms between "un-irradiated plus drug" and "irradiated plus drug" was 0.94. This innate effect of drug on the unphosphorylated

levels of AKT and p-AKT, in presence or absence of radiation, could be used to correlate the efficacy of drug in pivotal mouse and NHP studies in therapeutic settings. These preliminary studies demonstrate the potential value of p-AKT2 as a biomarker to follow the drug effect in the absence of radiation during pivotal safety studies in healthy human volunteers.

Understanding changes in signaling and correlating these changes with the mechanism of action provides a path to meeting the challenges of drug approval under the Animal Rule. Results herein provide a promising avenue towards this goal. Additional studies and confirmation under different scenarios, along with validation which is a part of this proposal, may permit correlation of an informative biomarker with expected efficacy parameters.

There are no references of using (b)(4) for its efficacy against radiation injury in NHPs. Initial studies investigating the efficacy and mechanism of (b)(4) have been conducted in mice and in-vitro models. Efficacy studies with radiation doses ranging from 5 - 15 Gy have been conducted. Results demonstrate that mice administered with drug (sc or po) and exposed to lethal radiation had significant survivors. These studies suggest that (b)(4) is a promising radiation countermeasure and warrants continued development (b)(4) Overall, the search did not reveal any duplication and the proposed study will provide valuable information about the development of (b)(4) as a radiation countermeasure.

III. OBJECTIVE/HYPOTHESIS:

The objective of this protocol is to advance the pre-clinical development of (b)(4) (b)(4) as radioprotector (and radiomitigator) of the acute radiation syndrome. Here, we propose to 1) Optimize the dose of (b)(4) to protect/mitigate the effects of radiation by monitoring the biomarkers in BM and peripheral blood mononuclear cells (PBMC) in NHPs. Preliminary studies in a mouse model have identified p-Akt2 as a potential biomarker for efficacy of (b)(4) as its level is upregulated both in the presence and absence of radiation in a mouse.. We are proposing to validate this marker by analyzing BM and blood samples from NHPs during efficacy studies; 2) Proof of concept study of subcutaneously (sc) administered (b)(4) as a protector/mitigator of hematopoietic ARS in NHPs using survival and hematopoietic rescue as end points; and 3) Confirm the efficacy of orally administered (b)(4) in NHPs using survival and hematopoietic recovery as end points. These studies will form the foundation for future pivotal studies to confirm the efficacy of (b)(4) in two animal models and safety in humans towards licensure from the FDA.

IV. MILITARY RELEVANCE

Currently, there are no FDA approved pharmaceutical agents that can prevent or treat injury from external ionizing radiation. The problem has become more acute in recent times due to the unpredictable nature of terrorist attacks. Recognizing this urgent need, the U.S. Department of Defense has assigned top priority to the "development of medical countermeasures to radiation exposure" against both early and late arising health effects. These concerns imply the urgent need to develop an appropriate countermeasure for radiation injuries potentially sustained by war fighters during combat operations and enable commanders to make judicious decisions in troop deployment. There are several drugs at different stages of the development. This study will perform essential research and development of a promising new agent (b)(4) as a therapy for potential injuries sustained by military personnel who have been accidentally exposed to ionizing radiation.

V. MATERIALS AND METHODS

V.1. Experimental Design and General Procedures

We propose to do the following experiments to utilize biomarkers for [redacted] to optimize dose of this drug and to evaluate its efficacy in subsequent experiments. [redacted] will be evaluated as radioprotector/mitigator when administered through sc and po routes. Details of subsequent experiments will be based on results obtained in previous experiment.

V.1.1. Experiment 1. Optimize the dose of [redacted] to mitigate the effects of radiation by monitoring the biomarkers in BM and PBMC in NHP model.

In the present protocol, we plan to optimize the dose of [redacted] administration by analyzing the biomarkers in BM and PBMC. The main objectives of this experiment is to demonstrate drug dose-response by evaluating biomarkers in BM and PBMC. BM and PBMC will be collected from NHPs to analyze the p-Akt2 levels using Western-blot (in-house) and Nanoscale Immuno Assay (NIA) method [redacted] The following specific study will be undertaken:

Two different doses of [redacted] (15 and 30 mg/kg body weight) will be administered to two NHPs in each group. A model based on allometric scaling was built, using the PK parameters in various animal species, to predict the expected concentration-time profile in humans. The results indicate that the predicted clearance of the drug matches very well with the clearance of drug observed in the clinical trial. Allometric data allows prediction of a starting dose in NHP efficacy studies and pivotal human safety trials.

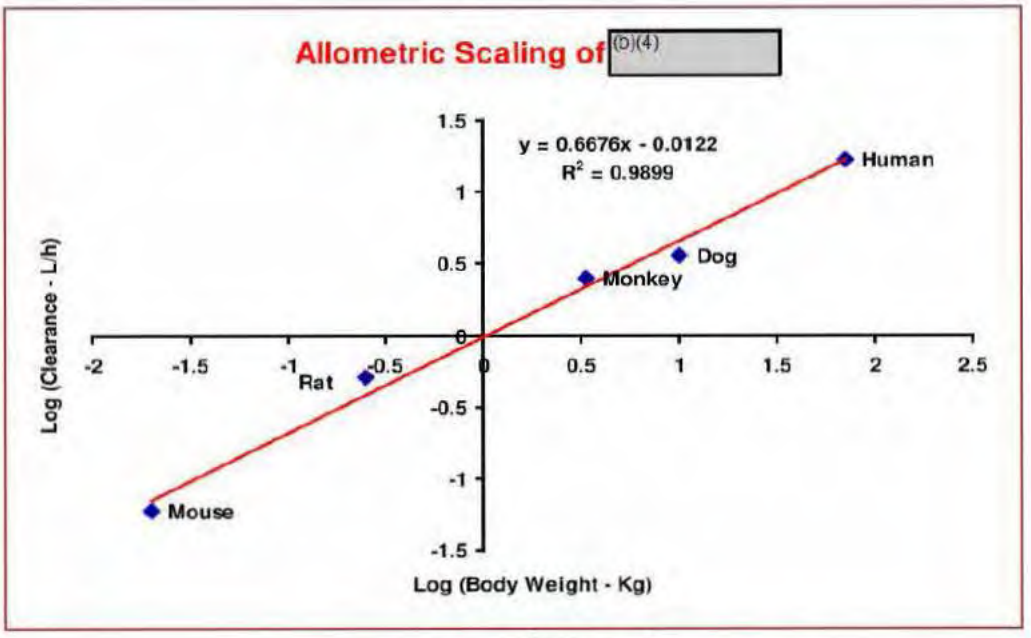

Figure 2. Allometric model and data for [redacted] clearance rates across animal species and humans. *Methodology used to relate pharmacodynamic dose requirement to pharmacokinetic parameter.*

Initially, (b)(4) will be administered (sc) to NHPs followed by collection of BM (2.0 ml) at 24 and 48 h after drug injection and blood (2 ml) (for PBMC) at 12, 24 and 36 h post drug administration. BM (2 ml) and blood (2 ml) collected prior to drug administration (-8 d) will serve as baseline control. If these two doses of drug do not provide dose response in biomarker analysis, same animals will be used after 30 d wash-out period with two additional doses of (b)(4) (above or below the drug dose used in the initial experiment depending on the results of biomarkers). Biomarker identification and validation are important objectives of this protocol. To accomplish this we need frequent BM and blood samplings close to drug administration and radiation exposure. Further, several putative biomarkers will be evaluated by two different techniques (gel electrophoresis/immunoblotting and NIA) for which we will require significant quantity of all samples collected.

Table 1. Sample collection for biomarker studies – sc drug administration

(b)(4) dose mg/kg	Time of blood/BM collection	BM	Blood	Total volume
	-8 d	2 ml	2 ml	4 ml
15 or 30 mg/kg	0 h			
	+12 h		2 ml	2 ml
	+24 h	2 ml	2 ml	4 ml
	+36 h		2 ml	2 ml
	+48 h	2 ml		2 ml

Summary of sample volume:-8 d = 4 ml, one week rest, 0 to 2 d = 10 ml. There will be 3 wk rest before further use of these animals. This will also allow one month wash-out period between drug administrations for two experiments to same animals.

If both sides are needed for a single BM collection attempt, an attempt on that side/site will not be attempted again for 1 week. There will be one week recovery period between pretreatment and post-treatment samplings. This will be applicable to all experiments involving BM collection mentioned below.

Table 2. Sample collection for biomarker studies - sc drug administration 2nd dose set

(b)(4) dose mg/kg	Time of blood/BM collection	BM	Blood	Total volume
	-8 d	2 ml	2 ml	4 ml
Based on results of above experiments	0 d			
	+12 h		2 ml	2 ml

	+24 h	2 ml	2 ml	4 ml
	+36 h		2 ml	2 ml
	+48 h	2 ml		2 ml

Summary of sample volume:-8 d = 4 ml, one week rest, 0 to 2 d = 10 ml. There will be 3 wk rest before further use of these animals. This will also allow one month wash-out period between drug administrations for two experiments to same animals.

Animals from above studies will be reused for biomarker studies with oral drug administration (15 and 30 mg/Kg body weight). Experimental details will be as above except drug administration will be po. BM samples will be collected at -8 d, and 24, and 48 h after drug administration. Blood samples for biomarker analysis will be collected at -8 d, 12, 24 and 36 h post last dose of drug administration.

Table 3. Sample collection for biomarker study - oral drug administration

(b)(4) dose mg/kg	**Time of blood/BM collection**	**BM**	**Blood**	**Total volume**
	-8 d	2 ml	2 ml	4 ml
Based on results of above experiments	0 d			
	+12 h		2 ml	2 ml
	+24 h	2 ml	2 ml	4 ml
	+36 h		2 ml	2 ml
	+48 h	2 ml		2 ml

Summary of sample volume:-8 d = 4 ml, one week rest, 0 to 2 d = 10 ml. There will be 3 wk rest before further use of these animals. This will also allow one month wash-out period between drug administrations for two experiments to same animals.

These animals will be used again after wash-out period of 30 d for study using drug and radiation exposure. Optimal dose of (b)(4) will be administered by sc route at -24 h, -12 h prior to and +4 h to two irradiated animals. Remaining two NHPs will serve as control (receive radiation exposure but no drug). Animals will be exposed to total body radiation (radiation dose $LD_{50/60}$ (6.5 Gy), dose rate 0.6 Gy/min). BM samples (2.0 ml) will be collected at 24 and 48 h after radiation exposure and PBMC will be collected at 12, 24 and 36 h post-irradiation. Again, BM and PBMC collected prior to start of the study (-8 d) before radiation exposure will be used as the baseline control. Drug dose for efficacy studies (expt 2 and 3) will be decided based on the results from above biomarker studies.

Table 4. Sample collection for biomarker study in irradiated animals treated with (b)(4) (b)(4) (sc)

[(b)(4)] dose mg/kg	Time of blood/BM collection	BM	Blood	Total volume
	-8 d	2 ml	2 ml	4 ml
	0 h – 6.5 Gy Radiation			
Based on results of above experiments	-24 h -12 h +4 h			
	+12 h		2 ml	2 ml
	+24 h	2 ml	2 ml	4 ml
	+36 h		2 ml	2 ml
	+48 h	2 ml		2 ml
				Total - 8 d = 4 ml 0 to 2 d = 10 ml

Summary of sample volume:-8 d = 4 ml, one week rest, 0 to 2 d = 10 ml.

The objective of this experiment is to demonstrate that biomarker levels are affected in the same manner by the drug administration both in the presence and absence of radiation. Animals will be euthanized at the end of the experiment (i.e. immediately after last sample collection – 48 h after irradiation). Tissue samples will be collected for histopathology.

V.1.2. Experiment 2. Evaluation of the efficacy of sc administered [(b)(4)] in nonhuman primates using biomarker–guided optimal dosing regimen

This will be a proof-of-concept study in NHPs evaluating the efficacy of optimal dose of [(b)(4)] administered by sc route following a known lethal irradiation dose (i.e. the $LD_{50/60}$ (6.5 Gy). To determine the efficacy of [(b)(4)] by sc route for survival in NHPs, two groups of 4 animals will be used. One will receive optimal dose of [(b)(4)] and other will serve as vehicle control. Optimal dose of [(b)(4)] will be administered by sc route at -24 h, -12 h and +4 h prior to and after radiation exposure. NHPs will be exposed to $LD_{50/60}$ TBI, following sc administration of [(b)(4)] at -24 h and -12 h prior to radiation exposure. One more optimal dose of [(b)(4)] will be administered 4 h after exposure to radiation.

Blood samples collected on -8 d, +12 h, +24 h and +48 h will be used for collecting PBMC for analysis of biomarkers by Western blot and NIA methods. Animals will be monitored for survival for 60 d. The drug efficacy will also be assessed by peripheral blood cell counts (see table 5 for time points). Blood biochemistry and serum citrulline will be also evaluated at various time points after irradiation (table 5). In addition, secondary end points, including 1) significant reduction in the incidence of infection, as manifested by febrile neutropenia, 2) the incidence, severity, and duration

of severe neutropenia (absolute neutrophil count [ANC] < 500/mm^3) following radiation, will be determined.

Blood pressure, pulse and temperature will be recorded before injection, 24 h after irradiation and every time sample is collected. Body weight will be measured before injection and weekly afterwards.

Table 5: Blood and BM collection schedule for experiment 2.

(b)(4) dose mg/kg	Time of blood draw	Blood					Total blood/BM, ml
		CBC 0.5 ml	Biomarker 2.0 ml	Biochemistry 0.5 ml	Bacteremia 0.5 ml	Citrulline 0.5 ml	
	-8 d	+	+	+	+	+	6.0
Optimum dose based on biomarker study	(b)(4) (b)(4) /vehicle oral admn. day –24 h, -12 h, and +4 h						
Radiation exposure 6.5 Gy	Day 0 +12 h		+				2.0
	Day 1 (24 h)	+	+				2.5
	+36 h		+				2.0
	Day 2	+	+				2.5
	Day 4	+				+	1.0
	Day 6	+					0.5
	Day 8	+					0.5
	Day 10	+			+	+	1.5
	Day 12	+					0.5
	Day 14	+					0.5
	Day 16	+					0.5
	Day 18	+					0.5
	Day 20	+				+	1.0
	Day 22	+					0.5
	Day 24	+			+		1.0
	Day 26	+					0.5
	Day 28	+		+		+	1.5
	Day 30	+					0.5
	Day 34	+			+		1.0
	Day 38	+		+		+	1.5
	Day 42	+					1.0
	Day 50	+		+	+	+	1.5
	Day 60	+		+		+	1.5

Summary of sample volume: -8 d = 6 ml. One week rest. 0 to 60 d = 34.5 ml

We will be well within the acceptable published blood collection volumes (4) that are followed at AFRRI. According to these guidelines 1% blood (2.8 ml per day for 4 kg NHP – minimum body weight of experimental NHP) can be withdrawn every 24 h. Up to 10% of circulating blood volume can be drawn in a single day repeated every 3-4 weeks. For the entire span of the study, the total blood drawn will be well below the recommended maximum limits.

V.1.3. Experiment 3. Confirmation of the efficacy of oral (b)(4) in non-human primates and validation of the biomarkers. Survival and hematopoietic recovery will be the primary end points

An oral (b)(4) would be attractive, convenient and able to deliver effective dose levels particularly to children, elderly and chronically-ill patients. Preliminary studies have shown that uptake of orally-administered (b)(4) was rapid, with higher plasma C_{max} and AUC values achieved than those observed with corresponding sc doses.

Similar to experiment proposed under experiment 2, two groups of 4 NHPs each will be used. During distribution of NHPs into two groups, various health parameters will be considered and distributed in a manner so that both groups should receive NHPs of similar health status. One will receive the optimal dose of (b)(4) and the other will get vehicle control. NHPs will be exposed to $LD_{50/60}$ or $LD_{70/60}$ TBI, following oral administration of (b)(4) at -24 h and -12 h prior to radiation exposure. One more optimal dose of (b)(4) will be administered 4 h after exposure to radiation. Animals will be sedated (ketamine 10-20 mg/kg, im) for oral gavage and gastric tube (3-7 fr or as VSD veterinarian recommendation) attached with syringe (needle 25 G) will be used for this purpose.

Blood samples collected on -8 d, +12 h, +24 h and +48 h will be used for collecting PBMC for analysis of biomarkers by Western blot and NIA methods as described above. Animals will be monitored for survival for 60 d. The drug efficacy will also be assessed by peripheral blood cell counts (see table 6 for time points). Blood biochemistry and serum citrulline will be also evaluated at various time points after irradiation (table 6). In addition, secondary end points, including 1) significant reduction in the incidence of infection, as manifested by febrile neutropenia, 2) the incidence, severity, and duration of severe neutropenia (absolute neutrophil count [ANC] < $500/mm^3$) following radiation, will be determined.

Blood pressure, pulse and temperature will be recorded before injection, 24 h after irradiation and every time sample is collected. Body weight will be measured before injection and weekly afterwards.

Table 6: Blood and BM collection schedule for experiment 3

(b)(4) dose mg/kg	Time of blood draw	Blood					Total blood/BM, ml
		CBC 0.5 ml	Biomarker 2.0 ml	Biochemistry 0.5 ml	Bacteremia 0.5 ml	Citrulline 0.5 ml	
	-8 d	+	+	+	+	+	6.0
Optimum dose based on biomarker study	(b)(4) (b)(4) vehicle oral admn. day –24 h, -12 h, and +4 h						
Radiation exposure 6.5 Gy	Day 0 +12 h		+				2.0
	Day 1 (24 h)	+	+				2.5
	+36 h		+				2.0
	Day 2	+	+				2.5
	Day 4	+				+	1.0
	Day 6	+					0.5
	Day 8	+					0.5
	Day 10	+			+	+	1.5
	Day 12	+					0.5
	Day 14	+					0.5
	Day 16	+					0.5
	Day 18	+					0.5
	Day 20	+				+	1.0
	Day 22	+					0.5
	Day 24	+			+		1.0
	Day 26	+					0.5
	Day 28	+		+		+	1.5
	Day 30	+					0.5
	Day 34	+			+		1.0
	Day 38	+		+		+	1.5
	Day 42	+					1.0
	Day 50	+		+	+	+	1.5
	Day 60	+		+		+	1.5

Summary of sample volume: -8 d = 6 ml, One week rest, 0 to 60 d = 34.5 ml

We will be well within the acceptable published blood collection volume (4) that is followed at AFRRI. For the entire span of the study, the total blood drawn will be well below the recommended maximum limits.

Total NHP needed for this Protocol:

Experiments	Total

Experiment 1	4
Experiment 2	8
Experiment 3	8
Total NHP required for this protocol	20

V.2. Data Analysis

Mean with standard errors, or percentages, will be reported if applicable. The significance level will be set at 5% for each test.

For experiment 1 to analyze the significant difference in the biomarker expression between the 2 groups of animals, the data will be tested by one-way ANOVA with Bonferonni's post-test correction to determine the statistically significant difference in biomarker profile. When needed we will also validate using a two-sided Student's *t* test, when comparing two groups to determine significant difference among sampling time. Values of $p < 0.05$ will be considered statistically significant. Values will be expressed as means ± standard error (SE).

Comparison of survival curves will be made using the log-rank test. Fisher's exact test will be used to detect if there is a significant difference across the groups in survival rates by performing pair-wise comparisons. Four NHPs (n = 4) per group would have 80% power to detect a significant difference between two groups if any, given type I error of 5% and delta/sigma of the differences between two group at least 2.4, where sigma is the common standard deviation, and delta is the mean difference (26).

V.3. Laboratory Animals Required and Justification

V.3.1. Non-animal Alternatives Considered

Both computer models and tissue culture have been considered as alternatives to animals. These alternatives lack the knowledge base and complexity needed to evaluate the effects of radiation and radiation countermeasures on the immune system. The phenomena under study involve complex information-processing networks comprising large number of cell types and biological signal transduction molecules. Responses to irradiation and radioprotective agents involve interactions between the central nervous system, the peripheral nervous system including the enteric nervous system, endocrine glands, the immune and inflammatory systems, hematopoietic system, gastrointestinal system etc. We do not know all of the cell types and tissues involved and many of the signal transduction molecules have not been discovered yet. Even if all of the tissues, cell types and signaling molecules were known, the present state of tissue culture would be incapable of reproducing their *in vivo* relationships. One would have to reproduce much of an entire mammalian organism in culture to study these phenomena *in vitro*. As for computer models, the most powerful supercomputers available in the near future would be incapable of analyzing interactions between so many elements in the network. Thus these drugs necessitate investigation in whole animal models to see overall outcome.

V.3.2. Animal Model and Species Justification:

As described above, preliminary studies have shown that (b)(4) is effective in mice when administered either sc or po as a protector or as a mitigator. Demonstrating

efficacy in a large animal species (LAS) is a critical requirement of the FDA Animal Rule. *Rhesus macaque* has 95+% DNA sequence identity with humans. NHPs are necessary for the pre-clinical development of a drug candidate intended for use in humans, because drug metabolism and physiology are so similar between NHPs and humans. Rhesus macaques are the model of choice for investigations of toxicity, pharmacokinetics, biomarkers, radiation injury, and countermeasures, because of the large database available from the existing literature. The FDA has accepted Rhesus macaques as the appropriate animal model for pivotal efficacy testing of radiation countermeasures under the Animal Efficacy Rule, where efficacy testing cannot be performed in humans. The biomarker and efficacy of the drug to be tested in this protocol have already been demonstrated in mice. Previous experience with other radiation countermeasures (e.g. Neummune or HE 2100 or 5-AED) has shown that testing in dogs is not always relevant to pharmacokinetics and efficacy in primates. Metabolism of 5-AED in dog hepatocytes was much different than in NHPs and human hepatocytes. Animal model of pig (specifically Gottingen minipig) is currently under initial stage of the development for studying radiation injury. This model is not well defined and mature enough to evaluate radiation countermeasures. Our ultimate goal is to generate data which will be submitted to US FDA and our data should be acceptable to them for approval of this radiation countermeasure (b)(4) Minipig model has not reached to that stage of acceptance yet. Therefore, this study in Rhesus macaque is being undertaken to guide future development of this class of radiation countermeasures. There are several reports for use of NHPs in radiation research and countermeasure development (6-8, 19).

V.3.3. Laboratory Animals

V.3.3.1. Genus/Species

*Macaca mulatta (*Rhesus macaques*)*

V.3.3.2. Strain/Stock

Chinese or Indian origin

V.3.3.3. Source/Vendor

AFRRI VSD will procure animals from vendors registered with the USDA or DoD.

V.3.3.4. Age

2.5 to 7 years

V.3.3.5. Weight

4 to 8 kg

V.3.3.6. Sex

Male and female

V.3.3.7. Special Considerations

Animals should test antibody negative for Herpes B virus (aka Macacine herpesvirus), Simian T-cell leukemia virus type 1 (STLV-1), Simian Immunodeficiency virus (SIV) and Simian Retrovirus (SRV) Types 1, 2, 3, and 5. Animals shall also test

negative by means of virus isolation or polymerase chain reaction (PCR) for SRV Type 2. NHPs will either be vaccinated for measles or, in the case of previously measles-vaccinated NHPs, tested for the presence of measles antibodies. NHPs shall come from the vendor colony negative for Salmonella, Shigella and Campylobacter. Additionally, the animals shall also test negative for Klebsiella pneumoniae. Animals will be pole and collar trained before use in experiment.

V.3.4. Number of Animals Required (by species)

Macaca mulatta: 20 (10 males and 10 females)

V.3.5. Refinement, Reduction, Replacement (3 R's)

V.3.5.1. Refinement

For biomarker study end point will be measurement of various parameters till predetermined days. For this purpose blood and BM samples will be collected at predetermined time points and analysis of relevant parameters will be carried out.

For efficacy study, the endpoint currently mandated by the FDA for approval of radiation countermeasures is mortality. Moribundity will be used as a surrogate for mortality, and euthanasia will be used in order to minimize pain and distress, using an extensive set of criteria (listed under section V.4.5). The actual irradiation procedure does not cause pain or distress. Animal care and use procedures will only be performed by trained and certified personnel.

V.3.5.2. Reduction

Two different doses of (b)(4) will be tested in two animals each for biomarkers. In case we don't get desired results, same animals will be used again after 30 d wash period with additional doses of the drug. We also plan to use same animals in biomarker study with radiation exposure. After 30 d wash period, these animals will be irradiated and dosed with (b)(4) In efficacy study, drug administration through two different routes (sc and po) will be tested. In each study, there will be only 4 NHPs in vehicle and another 4 in drug-treated group. Tissues will be shared with other investigators, wherever possible without compromising the objectives of the project.

As we move forward with experiments, plans will be reevaluated at every stage of the experiments, in light of incoming data in an attempt to reduce the numbers of experiments and groups, if possible. If deemed not necessary based on incoming data, some investigations may not be carried out to optimize the use of experimental animals.

V.3.5.3. Replacement

There are no *in vitro* techniques available to demonstrate that this drug will counter the effects of whole-body irradiation in humans. Efficacy and safety have already been demonstrated in rodents. The preferred large animal model for preclinical evaluation of radiation countermeasures intended for use in humans is non-human primates. This study represents the next step necessary to develop this drug for FDA approval. According to FDA scientists and the radiobiology community, the large database of radiation studies in *Macaca mulatta* makes this the most useful large animal model to evaluate interactions of radiation injury and drugs intended for use in humans.

V.4.1.1.1. Number of Animals

V.4.1.1.1.1. Column C.....0

V.4.1.1.1.2. Column D.....0

V.4.1.1.1.3. Column E.....20

V.4.1.1.1.4. Pain Category Assignments

Experiments	Total	C	D	E
Experiment 1	4	0	0	4
Experiment 2	8	0	0	8
Experiment 3	8	0	0	8
Total mice required for this protocol	20	0	0	20

V.4.1.2. Pain Relief/Prevention

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization

Microchips will be implanted to animals before initiating the other experimental procedures. BM will be collected under anesthesia. This procedure has been described in detail under section V.4.3.2 (not elaborated here to avoid duplication). Buprenorphine (0.005 – 0.03 mg/kg, im or sc or iv, every 12 h) will be administered for 3 days after each BM collection (will be given for longer if animals show limping or any other sign of pain is noticed) to NHPs of experiment 1. Since anesthesia, analgesia, and tranquilizers are known to affect functions of the immune system of animals, we plan to minimize their use during course of the experiment after irradiation (2, 9, 10).

Pain is not expected from actual irradiation process. The sequelae of high dose of radiation may result in pain but the animals treated with (b)(4) will experience reduced infections observed in immunosuppressed animals. As observed in mice, (b)(4) (b)(4) may enhance hematopoietic recovery after radiation and if it does, this should lead to improved health. Use of other bactericidal agents to combat unresolved infections during (b)(4) management is not warranted in this study as the scientific end points identified above will be abridged. It is important to note that the principle purpose of this study is to validate the biomarkers (Experiment 1) and evaluate efficacy of (b)(4) (Experiment 2 & 3). The use of antibacterial agents will interfere with principle purpose (efficacy study under experiment 2 & 3). However, if pain and/or distress are observed, the PI and attending veterinarian staff will be notified to evaluate and determine the appropriate treatment. If pain and/or distress cannot be alleviated, the animal will be evaluated for euthanasia.

Some animals may feel temporary discomfort such as nausea, emesis, and diarrhea that may occur after irradiation. In such situation, administration of fluid using bottle will be considered. No treatments for radiation-induced behavioral manifestations

will be provided as they may interfere with the evaluation of (b)(4) in post-irradiation recovery.

Use of ketamine for BM biopsy has been elaborated under section V.4.3.1. Pre-Surgical Provisions.

V.4.1.2.2. Pre- and Post-procedural Provisions

Animals will be observed for signs of pain and distress by either the veterinary or research staff at least twice daily. Before procedures that require general anesthesia, NHPs will be fasted for 12 h prior to administration of systemic anesthesia. After surgical procedure (such as BM aspiration in experiment 1), NHPs will be monitored at least twice daily for signs of surgical site complication such as infection or trauma. Buprenorphine (0.005 – 0.03 mg/kg, im or sc or iv) will be administered every 12 h for 3 days or longer after each BM collection (if animals show limping or any other sign of pain is noticed) to NHPs of experiment 1.

V.4.1.2.3. Paralytics

No paralytic agent will be used in this study.

No reports were found indicating administration of (b)(4) causes pain. Similarly, there were no reports indicating that irradiation itself causes pain. It has been reported that whole-body irradiation can cause sedative effect, as indicated in the tail-flick test in rats.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification

(a): BM aspiration: Animals will get proper analgesics for this procedure and they will not be in painful or distressful condition.

(b) Irradiation: As stated above, irradiated animals finally die due to a compromised immune response and microbial infections. In the event that there is pain and distress for animals, as we have already discussed under above headings, we cannot give anesthetic/analgesic agents to the animals (except at the time of BM aspiration which can't be performed without anesthesia) since these agents interact with the immune system, and in turn will affect experimental results. Buprenorphine (0.005 – 0.03 mg/kg, im or sc or iv) will be administered for 3 d or longer after BM collection if animals show limping or any other sign of pain is noticed.

There are conflicting reports regarding effects of buprenorphine on the immune system (3, 13, 15, 16, 18, 20, 21, 25). A majority of reports suggest that buprenorphine influences immune response. Since buprenorphine has been shown to influence various arms of cellular and humoral immune response (3, 16, 21, 25), we have decided not to use it in our efficacy study (experiment 2 and 3). This gent will be administered to NHPs

of experiment 1 for biomarker study as stated above. Non-steroidal anti-inflammatory drugs are not suitable for use in such experiments (17).

V.4.2. Prolonged Restraint:

Animals to be irradiated will be placed in restraint devices for irradiation in the cobalt facility. Animals will be sedated for this purpose (ketamine 10-20 mg/kg, im).

For blood collection, NHPs will be placed in a primate restraint chair. NHPs will not be left in the restraint chair for more than 30 minutes.

V.4.3. Surgery

V.4.3.1. Pre-surgical Provisions:

BM collection proposed in experiment 1 is considered a surgical procedure. Animals will be assessed for signs of pain and distress by either the veterinary or research staff at least twice per day or as often as needed. Antibacterial prophylaxis will be administered: Cefazolin iv or sc (20 - 25 mg/kg, one time before BM collection) or ampicillin (15 - 20 mg/kg, iv or im one time before BM collection). Food will be withheld from the animals 12 h prior to administration of the anesthetic. The NHPs will be chemically sedated with ketamine (5-15 mg/kg im) or Telazol (5-10 mg/kg im) with Atropiune (o.05 mg/kg im) or glycopyrrolate (0.005 – 0.1 mg/kg im) (needle 25 G). For induction, 3-5% isoflurane in 100% oxygen by mask will be used. For maintenance 1-3% isoflurane will be administered in 100% oxygen via endotracheal tube or mask. While the animal is under the anesthesia, vital signs will be monitored including SpO2, pulse, respiration rate and body temperature. Bair Hugger heated surgical table will be used for keeping animal warm. Animal body temperature will be recorded frequently using a rectal thermometer during the procedure.

V.4.3.2. Procedure(s):

The site of BM collection may be the iliac crest, scapula, ischial tuberosity, trochanteric fossa of the femur, tibial crest, or the proximal humerous. The site will be prepared as a surgical site: hair will be clipped using # 40 surgical blade and the site scrubbed at least 3 times using either betadine or chlorhexidine and 70% alcohol. Animal will be positioned appropriately (dorsal or ventral or lateral recumbency depending on the site being used for the BM collection. A sterile drape will be used to cover the site. A small stab incision (just enough for a 16 G needle to go through) will be made in the skin at the site of BM collection. Then, BM aspiration needle will be advanced through the incision into the cortex of the bone. The stylet is removed from the BM needle. A 2 - 5 ml syringe will be used to aspirate the BM. The needle will be removed and incision will be closed with tissue glue or a suture after BM collection. Either non absorbable nylon or absorbable monocryl suture will be used to close the skin. Only autoclaved or disposable sterile instruments will be used. Only one attempt will be made per site and only two sites will be attempted at any one sampling point. No more than 3 ml of BM will be collected per animal.

Food will be withheld for about 12 h prior to sedation.

V.4.3.3. Post-surgical Provisions:

Animals will be monitored at least twice per day for signs of surgical complications such as infection or trauma. If treatment for such conditions is needed, a VSD veterinarian will provide the appropriate medical intervention: Baytril 5-10 mg/kg im or po, sid for at least 5 days or longer (may be given to avoid infection). Buprenorphine (0.005 – 0.03 mg/kg, im or sc or iv) will be administered for 3 d or longer after BM collection if animals show limping or any other sign of pain is noticed. Cefazolin (20-22 mg/kg, iv) will be used as needed based on opinion of veterinarian.

V.4.3.4. Location:

The procedure will occur in the VSD surgical suite at the veterinarian's discretion.

V.4.3.5. Surgeon:

VSD personnel trained in the procedure and aspetic technique.

V.4.3.6. Multiple Major Survival Operative Procedures

V.4.3.6.1. Procedures: N/A

V.4.3.6.2 Scientific Justification:

Though BM collection is not major procedure per se, we are conducting repeated collections which may make it fall into this section. Biomarker identification and validation are important objectives of this protocol. To accomplish these objectives, we need frequent BM and blood samplings close to drug administration and radiation exposure (stated above in various tables). Further, several protein biomarkers will be evaluated by two different techniques (gel electrophoresis/immunoblotting and NIA) for which we will require significant quantity of all samples collected.

As stated above, one site will be used only once for the BM collection in an experiment over a period of one month. Same site will not be used for BM collection again in specific study. Same animal will be used to repeat study after one month rest period (applicable for experiment 1 only). We have identified several sites for BM collection in NHPs of experiment 1. There will be no bM collection in experiment 2 and 3.

V.4.4. Animal Manipulations

V.4.4.1. Injections

NHPs will be dosed with (b)(4) subcutaneously in the dorsal scapular region (midline). Drug will be injected with a sterile 21 – 23 gauge needle. Each injection volume will not exceed 1 ml. Injections will be performed by appropriately trained staff listed in this protocol under section VI.

V.4.4.1.1. Pharmaceutical Grade Drugs:

Currently (b)(4) is in Phase 1 clinical trials for safety and toxicity. (b)(4) (b)(4) for administration in healthy volunteers. We will be using the same formulation in this study.

(b)(4)

(b)(4) All aspects of the solution preparation involve GLP grade formulation.

V.4.4.1.2. Non-Pharmaceutical Grade Drugs: None

V.4.4.2. Biosamples

Blood withdrawals will be carried out according to the schedule presented above. Blood will be collected from a peripheral vessel rather than a femoral vein with a 21 - 23 gauge sterile needle attached to a needle holder, to reduce the chances of bleeding after blood collection in irradiated animals.

The area for the blood draw (samples for bacterial culture) will be swabbed with providone-iodine twice before inserting the needle. Providone-iodine will be swabbed off to reduce irritation to the tissue. For samples collected for other tests, only alcohol swab will be used. The blood sample will be drawn as described above. While withdrawing needle, pressure will be applied at the same time with a sterile bandage to reduce bleeding from the blood draw site. While making regular routine observation of animals, the blood-draw site will be checked for bleeding. In the event the site becomes infected, topical triple antibiotics (bacitracin, neomycin, and polymyxin) or similar agent will be applied.

BM samples will be collected as stated above under section V.4.3.2

V.4.4.3. Adjuvants:

No adjuvant will be used.

V.4.4.4. Monoclonal Antibody (MAb) Production: N/A

V.4.4.5. Animal Identification

Animals arrive tattooed and such tattoo will be used for identification. Additionally cage tags are used for identification.

V.4.4.6. Behavioral Studies:

No behavioral studies will be performed in this protocol.

V.4.4.7. Other Procedures:

Oral administration of (b)(4)

Animals will be sedated with 5 - 15 mg/kg ketamine im (needle 25 G). We will use either the stomach tube or nasogastric tube to administer (b)(4) Before drug administration, the length of the tube will be measured from mouth or tip of the nose up to the last rib. The tube will be lubricated before passing through the nose or the oral cavity. Appropriate size (diameter) tube will be used based on the animal's nostril diameter or trachea diameter. After drug administration, the tube will be flushed with normal saline to make sure the drug reaches to the stomach. Then the tube will be pulled out and animals will be held in vertical position until fully recovered from sedation. Then the animal will be transferred to home cage and any sign of vomiting will be monitored. If there is any discomfort to the animal, veterinarian will be called. This procedure will be conducted under close supervision/guidance of the veterinarian.

Drug volume will be well within the limit stated in Diehl's *et. al.* guidelines (max 15 ml/kg) (4). Currently drug is available at 50 mg/ml concentration (pharmaceutical grade). For 4 kg animal, at a dose of 30 mg/kg, volume will be 2.4 ml

Transport plan

The sedated animals in positioning aide devices will be transported inside a cart to the High Level Gamma Radiation (HLGR) facility. At no time will the animals be removed from the restraint boxes while outside of the VSD vivarium. Two personnel will accompany the animals with additional drugs as needed for chemical restraint (animals are not awake during irradiation), and provide animal handling support.

After irradiation, the NHPs in their restraint boxes will be removed from the platform, returned to the transport cart and returned to the vivarium.

(b)(4) will be administered orally to NHPs in experiment 3.

V.4.4.8. Tissue Sharing:

BM/PBMC samples will be sent to Dr (b)(6) (b)(6) for Nanoscale Immuno Assay (NIA) for validation of biomarkers. Tissue sharing form will be completed before sending sample to above collaborators.

Unused biological samples will be retained for additional studies. Studies planned will depend upon additional funding for supplies and staff in future.

V.4.4.9. Animal By-Products

No animal by-products will be used in the proposed study.

V.4.5. Study Endpoint

In biomarker study without radiation exposure (first phase of experiment 1), blood and BM samples will be collected at predetermined time points as stated above. No mortality or morbidity is expected in this study. BM collection should not be a painful procedure since we are using pain medication. There may be mortality or morbidity in biomarker study with radiation exposure (second phase of experiment 1) depending on dose of radiation used. These animals will be taken care as described below for efficacy study (experiment 1 and 2).

The endpoint used in the efficacy studies (experiment 2 and 3) is mortality. Moribundity will be used as a surrogate for mortality, and euthanasia will be used in order to minimize pain and distress. Euthanasia will be carried out when one or more of the following signs and symptoms of moribundity are observed as determined by or in consultation with AFRRI veterinarians. Once platelet count is <30x10^3/µl, PM checks ((~5-6 PM) will begin and continue until solid evidence of recovery in consultation with AFRRI VSD veterinarian.Necropsy and histopathological analysis will be performed on all euthanized animals by the board certified veterinary pathologist. Following parameters will provide the guidelines for moribundity (all signs will be taken together along with the recommendation of a VSD veterinarian for euthanasia decision):

1. Weight loss: loss of more than 20% body weight over a 3-day period.

2. Inappetance: complete anorexia for 2 days with deteriorating conditions based on clinical examination

3. Weakness/inability to obtain feed or water: Inability or extreme reluctance to stand which persists for 1 h.

4. Minimal or absence of response to stimuli (animal does not move when prodded).

5. Core body temperature: Below 96.6ºF following a period of febrile neutropenia (such as >103 ^{0}F and <500 neutrophils/μl).

6. Severe acute anemia: <13% hematocrit or <40 g/L hemoglobin (decision in consultation with AFRRI veterinarians).

7. Severe thrombocytopenia (<10,000 platelets/μl) (decision in consultation with AFRRI veterinarians)

8. Other signs of severe organ system dysfunction with a poor prognosis as determined by a veterinarian:

8.1 Respiratory: any dyspnea or severe cyanosis.
8.2 Gastrointestinal: sustained vomiting or diarrhea, obstruction, intussusceptions; peritonitis. NOTE: Transient vomiting and diarrhea are expected results of whole-body gamma irradiation. Therefore, as criteria for euthanasia, these symptoms should be severe and life-threatening per se, i.e., hemorrhagic diarrhea to the point of causing anemia as listed above or severe uncompensated dehydration.
8.4. Urogenital: renal failure
8.3 Nervous: sustained CNS depression, seizures, paralysis of one or more extremities.
8.4 Integumentary: Non-healing wounds, repeated self-trauma, severe skin infections, indicating severe organ system dysfunction with a poor prognosis.

The actual irradiation procedure does not cause pain or distress. Animal care and use procedures will only be performed by trained and certified personnel. Secondary endpoints will be incidence of bacteremia, standard hematology measurements in peripheral blood (numbers of neutrophils, platelets, erythrocytes, lymphocytes, mean corpuscular hemoglobin, etc.), body temperature, body weight, and occurrence of bloody stools. Body weights will be determined at least once prior to treatment, on the first day of treatment, and at the time of blood collection. Body temperature (implanted chip) will be determined daily between 10 am and 12 noon beginning approximately one week prior to the first treatment. The time of each temperature collection will be recorded for each NHP.

Surviving animals at the end of the study (60 d post-irradiation) will be euthanized for gross necropsy and tissue collection as described under section V.4.6. Histopathology of various organs will be conducted to study the effects of radiation and drug.

V.4.6. Euthanasia

Animals will be humanely euthanized using American Veterinary Medical Association (AVMA) guidelines. These animals will be given sodium pentobarbital

intravenously (100 mg/kg). Prior to pentobarbital administration, animal will be sedated using Ketamine (5-15 mg/kg intramuscularly).The animals will be euthanized only under the guidance and supervision of a staff veterinarian. After sodium pentobarbital administration, the animals will be examined (heart auscultation and pulse) to confirm death. A full body necropsy and histopathology analysis will be performed by a Board Certified Veterinary pathologist, after confirmation of the death.

V.5. Veterinary Care

V.5.1. Husbandry Considerations

Special care will be given to irradiated animals as their natural immunity will be suppressed (more prone to infections). Irradiation boxes will be sanitized after every use or more often as needed.

V.5.1.1. Study Room:

As assigned by VSD.

V.5.1.2. Special Husbandry Provisions: None

V.5.1.3. Exceptions: None

V.5.2. Veterinary Medical Care

V.5.2.1. Routine Veterinary Medical Care

All animals will be quarantined for 45 days prior to any experiment. As per Standard Operating Procedures, VSD staff will monitor all animals at least twice daily during morning and afternoon rounds. Any abnormalities will be reported immediately to the on-call veterinarian and PI. In addition, animals will be observed daily by this protocol's research staff. Any sick animal will be observed twice a day (early morning and late afternoon/night) by the research staff. When animals become ill or debilitated, a veterinarian will be contacted immediately to assess the animal and provide adequate/emergency care. If the animal becomes moribund, it will be euthanized via intravenous administration of pentobarbital sodium at a dose of 100 mg/kg body weight under the guidance of the veterinarian. Prior to pentobarbital administration, animal will be sedated using Ketamine (5-15 mg/kg intramuscularly) (needle 25 G).

V.5.2.2. Emergency Veterinary Medical Care

The on-call veterinary office will be available via 24 h a day.

Euthanasia will be carried out according to pre-defined criteria as determined by AFRRI veterinarians (see criteria in section V.4.5, and also section V.4.6 for details).

V.5.3. Environmental Enrichment

V.5.3.1. Enrichment Strategy

Food will be withheld for about 12 h prior to sedation. Citrus fruits will be restricted to animals under experiment # 2 and 3 as citrulline will be measured in experiment 2 and 3.

V.5.3.2. Enrichment Restrictions:

None

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING

Following employees are trained for NHP work. They have handled NHP work of earlier protocols at AFRRI.

NAME	DEGREE	TRAINING	DATE	PROCEDURES	YRS/MOS EXPERIENCE
(b)(6)				1,3,4,5,7 for mice 7, NHP (off-h observation)	(b)(6)
				1,3,4,5 mice 1,3,4,5, mice 1,3,4,5, mice 1,3,4,5, mice 1,7, NHP (off-h observation)	
				1,3,4,5,7, mice 1,3b,3d, 4,5,7, NHP (off-h observation)	
				1,3,4,5,7, mice 1,3b,3d, 4,5,7, NHP (off-h observation)	

Procedure and manipulation codes:
Code 1= Animal handling and euthanasia
Code 2= Surgery (aseptic technique) pre- and post-operative care
Code 3= Injections (3a–ip, 3b-sc, 3c-gavage) - can say 3 if trained in all manipulations or add 3d-iv
Code 4= Blood collection under anesthesia (4a-cardiac, 4b-posterior vena cava)
Code 5= Tissue collection (after euthanasia) - doesn't need to be specific
Code 6 = Implantation (provide details)
Code 7 = Others - (provide protocol specific manipulations or procedures for e.g., retro-orbital bleeding, tail vein injection, or drug delivery)

VII. BIOHAZARDS/SAFETY

There is no plan to use any potential biohazard. Standard laboratory safety precautions will be observed throughout this study

VIII. ENCLOSURES

Form 310

X. ASSURANCES

Protocol Title: Biomarker and efficacy studies of (b)(4) in Rhesus macaques (*Macaca mulatta)*

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made every effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with a qualified individual who evaluated the experimental design with respect to the statistical analysis, and that the minimum number of animals needed for scientific validity will be used.

D. Biohazard/Safety: I have taken into consideration and made the proper coordinations regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures/manipulations/observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures/manipulations.

F. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R", namely, "Responsibility," which the DOD has embraced for implementing animal use alternatives where feasible and conducting humane and lawful research.

G. Scientific Review: This proposed animal use protocol has received appropriate peer scientific review and is consistent with good scientific research practice.

H. Painful Procedure(s): I **AM** / **AM NOT** conducting biomedical experiments, which may potentially cause more than momentary or slight pain or distress to animals. If applicable, potential pain and/or distress **WILL** / **WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

DOD ANIMAL CARE AND USE STANDARDIZED PROTOCOL FORMAT WITH EMBEDDED INSTRUCTIONS (March 2013)

Reference DOD Instruction 3216.01 & AFRRI Instruction 3216.2H

****

* ***Information requested in the following animal use protocol template reflects the requirements of the Animal Welfare Act Regulations (AWAR), the Guide for the Care and Use of Laboratory Animals, and other applicable Federal regulations and DOD instructions.***

****

*

This document is intended to be an aid in the preparation of DOD-sponsored animal use protocols. It is a companion document to an identical protocol template that does not have embedded instructions. Either template may be used to format DOD-sponsored animal research proposals; however, reference to the instructions during protocol preparation is highly recommended. If using the template with instructions, the instructions should be deleted prior to submitting the finished protocol for IACUC review. Please use Arial, regular, size 12, black font to prepare the protocol. With the exception of section headings, all paragraphs require a response. Paragraphs that do not apply should be marked N/A. There is no space limitation for responses to the information requested.

Approved standard operating procedures (SOPs) promulgated by the AFRRI Veterinary Sciences Department (VSD) or similar VSD-validated documents that describe specific procedures may be referenced by SOP number and title in lieu of repeating the details in the protocol. However, it is essential to include general descriptions of all animal manipulations to be carried out under the IACUC-approved protocol and to provide details where no approved references are cited. To do otherwise would constitute a breach of statutory regulations. Manipulations not covered in the originally approved protocol can be initiated only after IACUC approval of a formal amendment adding the new procedures. Additionally, Principal Investigators (PIs), or other delegated research personnel, should maintain accurate experimental records and be able to provide an audit trail of animal expenditures and use that correlates with their approved protocol. Protocol PIs will be required to provide this and other information during annual protocol reviews.

Any supporting information that may be of use to the IACUC during its review may be attached to the completed protocol. Adding subparagraphs within the body of the protocol template is permissible, *provided that the numbering sequence of paragraphs in the original standard format is maintained.* In other words, all of the labeled paragraphs and subparagraphs in this template must be retained, with additional information being presented as sub-numbered paragraphs containing information that supports or complements what is requested.

INTELLECTUAL PROPERTY STATEMENT

Research protocols drafted by Government scientists include intellectual property (e.g., concepts, ideas, experimental approaches, etc.), some of which is innovative or original and therefore considered proprietary to the investigators and/or the sponsoring agency. All Government and non-Government personnel handling this protocol shall exercise EXTREME CARE, to ensure that the information contained herein is NOT DUPLICATED OR DISCLOSED, in whole or part, for any purpose other than to evaluate the protocol, without the written permission of the principal investigator or the sponsoring agency.

(b)(6)

I. NON-TECHNICAL SYNOPSIS

The first objective of the protocol is to provide, in the event of radiological/nuclear accident, an extra level of biological protection to first responders including military personnel, fire fighters, and security personnel. The second objective is to identify therapeutic agents to treat civilian population who may be accidently exposed to ionizing radiation. Acute total body irradiation (TBI) at a moderate dose induces extensive apoptotic/mitotic death of actively dividing progenitors wherein the hematopoietic system is identified as among the most highly susceptible tissues to radiation injury. Profound and persistent hematological syndromes develop as a result of death and ablation of the blood forming elements in bone marrow resulting in severe neutropenia (loss of circulating neutrophils) and thrombocytopenia (loss of platelets), thereby increasing the risk of death due to opportunistic infections and/or hemorrhage.

The (b)(4) AFRRI interagency agreement (IAA) has been established to evaluate several agents @ AFRRI as radiation countermeasure in a mouse model for potential post exposure countermeasure treatment against nuclear threats to the civilian population. The Department of Defense (DoD) is interested in providing additional protection to the military and first responders in harm's way to a nuclear incident and pre-exposure countermeasure (the prophylaxis) study arm addresses this issue and is supported by the AFRRI Intramural funds.

A standard protocol developed at AFRRI will be used to evaluate 10 potential countermeasures per year for efficacy in reducing radiation mortality. Depending upon these screening tests, some drugs will be short listed for further detailed investigations to include a. optimization studies (drug route, concentration, multiple administrations and time of drug administration), b. Dose reduction factors (DRF) studies (testing efficacy of promising candidates using various radiation doses), and c. hematological and mechanistic studies (to elucidate drug response).

Due to the inherent variations in radiation sensitivities arising from genetic differences, we will test promising radiation medical countermeasures (MCM) in rodent strains

representative of most sensitive (C3H/HeN) to radioresistant (B6C3F1) strains. The C57BL/6 strain represents the wild type, moderately radioresistant model most commonly used for screening radiation MCMs. The current protocol will continue our efforts to study efficacy of promising MCM in different mouse strains.

II. BACKGROUND

II.1. Background Acute Radiation Syndrome (ARS) represents the clinical response of key radiation-sensitive tissues following whole body or extended partial body exposure to high doses of ionizing radiation. New drugs and new therapeutic strategies are still required to cope with the high morbidity/mortality of ARS. The Acute Radiation Syndrome represents a dose-dependent graduate response of key tissues of decreasing radiosensitivity and the clinical continuum of hematopoietic (>2 Gy TBI), gastrointestinal (>10Gy) then neurovascular (>30 Gy) syndromes (Stone *et al* 2004). The (b)(4) is charged with implementing research to identify, characterize and develop medical countermeasures (MCM) against injuries caused by radiological/nuclear attack. A robust research and development program, initiated in 2005, supports the development of many MCM to treat radiation injury as well as development of diagnostic/radiation dose triage tools. (b)(4) partnered with AFRRI via an interagency agreement (IAA) to screen agents in a mouse model with potential for radiation MCM efficacy dating back to 2006. This protocol represents the continuation of the (b)(4) AFRRI radiation countermeasure screening program under protocol (b)(6) due to expire in February, 2014.

We have established a standard system for evaluating MCM for radiation countermeasure efficacy at AFRRI using the CD2F1 mouse model. This screening program was instrumental in identifying several promising MCM, some which have advanced to studies in higher mammals (b)(4) The screening program is a conduit for low through-put screening of drugs. Other AFRRI investigators select promising drugs from this pool for product development in specific areas such as mixed field irradiation, mechanistic studies, and in combined injury models.

Funding sources: PI requests the inclusion of 3 site numbers (b)(6) (b)(6) in the protocol since they are all related to successful evaluation of potential radiation countermeasures.

The major thrust of the protocol will be supported by the (b)(4) AFRRI interagency agreement (IAA). The emphasis will be the therapeutic/mitigation (drug administered after irradiation) modality. Each of the agents being screened were selected based on technical input from biotechnology companies, and scientific interactions between (b)(4) and AFRRI scientists. Several criteria, such as cytoprotective effects, radical scavenging activity, hematopoietic growth factor activity, and colony stimulating activity that rescue or replenish hematopoietic cells and other radiation sensitive organs including GI, are considered in selection. (Herodin *et al* 2007). The funding for this will be under site number (b)(6)

In addition, promising candidates from the previous years that need additional studies (for e.g. optimization) are funded by both (b)(6) (b)(4) and AFRRI (b)(6) Further, prophylaxis arm of the drugs being screened as well as some of the mechanistic studies will be supported by (b)(6) and PI requests that these funding lines be conveyed in a single protocol to maximize animal use. Strain comparison studies to be conducted in the present proposal will either be supported by (b)(6) depending on the experimental conditions (prophylaxis vs. mitigation).

Table 7 in section V.3.4. "Number of animals required (by Species)" provides a breakdown of animal numbers per site number.

Classification of drugs (for the study):
The new drugs included in the current protocol are subject to legal requirements of confidentiality and material transfer agreement (moderated (b)(4) (b)(4). As of this submission, several compounds are undergoing legal due process. Once approved, they will be added to the current protocol by an amendment. Further, since the (b)(4) AFRRI contract is valid up to 2018, the process of testing new drugs will continue in the next Fiscal year (2015) under this protocol.

New drugs: (b)(4) (b)(4) (b)(4) (Table 3 in section V.1.2 details route and schedule of administration and Table 9 in section V.4.4.1.summarizes physical characteristics and proposed drug doses).

Optimization studies: (b)(4) a drug that showed mitigation efficacy in earlier screening requires additional optimization. Other candidates from the current list may also require optimization depending on the preliminary screening study.

Strain comparison studies: (b)(4) and **Filgrastim** are two drugs to be evaluated in different mouse strains (Table 4 in section V.1.2)

II.2. Literature Search for Duplication

II.2.1. Literature Sources Searched BRD, NIHRePORTER, PUBMED , Embase

II.2.2. Date of Search 11/25/2013 to 12/10/2013

II.2.3. Period of Search The search period extended from 1998 to 2005 for BRD, 2009-present for NIHReporter, 1970 to present for PubMed, 2006 to present for Embase.

II.2.4. Key Words of Search Each individual term (b)(4) (b)(4)

(b)(4)

II.2.5. Results of Search

Literature search in PubMed and Embase resulted in >**5000** hits; the relevant references have been used for background information and cited under bibliography. There were **no hits** under **BRD**. These were the results using NIHRePORTER:

(b)(4),(b)(6)

The studies proposed in the current amendment are not a duplication of any of the above-mentioned studies.

Radiation: 64730 hits
Radiation+countermeasures: 290 hits
Radiation+mitigation: 267 hits

Table 1 provides a summary of these searches.

Filgrastim: G-CSF is a hematopoietic cytokine that increases granulocyte regeneration in radiation-induced myelosuppressed animals (McVittie *et al* 1990, Patchen *et al* 1990). The most relevant study in literature is by Patchen *et al* (1991), where 2.5 µg/mouse G-CSF in saline administered from 1-16 d following TBI increased the survival benefit (DRF=1.06) (Figure 6; from Patchen *et al* 1991).

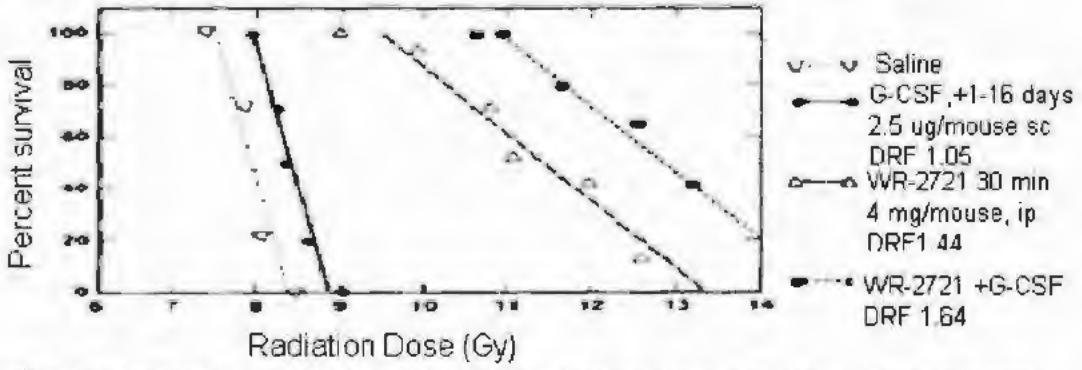

Figure 6 Effect of saline, G-CSF, WR-2721, and WR-2721+G-CSF treatments on survival of mice. C3H/HeN mice were administered WR-2721 4 mg/mouse, ip) 30 min before Cobalt 60 gamma irradiation and G-CSF (2.5 ug/mouse sc) on days 1-16 after irradiation. each data point represents results obtained from 30 mice. Patchen et al 1991, IJROBP, 22: 773-779

The proposed study differs from the reported one in that we will use the pharmaceutical grade Filgrastim in the recommended vehicle, i.e. dextrose. We will use the optimal drug dose schedule of 0.17 mg/kg Filgrastim administered 4 h, 1 and 2 d or 1-3 d post-TBI in the strains.

III. OBJECTIVE / HYPOTHESIS We hypothesize that drugs screened in the current protocol will lead to identifying promising radiation countermeasures in mice that can be advanced to efficacy studies in large animal model, and ultimately for human use in the event of a large scale nuclear casualty.

Due to genetic variations in individuals, the radiation response to the drugs will also differ. We will test any promising radiation MCM in three other strains (C3H/HeN, C57BL/6 and B6C3F1) for differences in survival.

IV. MILITARY RELEVANCE The current lack of radiation protectants (pre-TBI) and mitigators (post-TBI) that are safe, effective and approved for use in victims of an accidental or deliberate radiation exposure constitutes a major problem for emergency preparedness. In the event of a nuclear related accident or terrorist activity, first responders will be comprised of the HAZMAT team, military, fire and police departments and experts from the Radiological Assistance Program; potentially they will all be at risk for exposure. Death is certain at doses of 10 Gy and above while exposure to 2-8 Gy results in severe hemaptopoietic ablation, GI injury and ensuing infectious diseases. All triage procedure instructs first responders and other health care providers to provide treatment, including antibiotic administration and blood product support and supportive care. In a mass casualty scenario, there will be significant delays in transport, disruption of communication and overfilling of limited hospital resources. At these times, the availability of safe and effective countermeasures is a valid alternative for medical management of patients. The agents proposed for testing in the current protocol are derived from various backgrounds, with abilities such as scavenging of deleterious radicals, increase in survival, proliferation and differentiation of hematopoietic progenitors, antiapoptotic, enhancement of microbicidal activity, management of radiation-induced bone marrow aplasia and immunmodulators. The current AFRRI protocol meets the goals of the Department of Defense (DoD) mission in protecting the armed personnel and the Human Health Services (HHS) interest of treating civilian population.

V. MATERIALS AND METHODS

V.1. Experimental Design and General Procedures

Section V.1.1.

The ODDS method for determining safe dose (modified up and down procedure [UDP]): Previously, we have used the modified up and down procedure at AFRRI for selection of a safe dose for radiation studies. This was derived from the original UDP for establishing LD50 toxicity by oral route. The UDP is an in vivo acute systemic toxicity test adopted by the US regulatory agencies to **reduce and refine** animal use (OEDC Test Guidelines 425) which have replaced the conventional acute toxicity test method. According to these guidelines, testing can be carried out using **6 animals**, the animals can be of the **same sex** (usually females, but males can be used when justified) and dosing is escalated in **fixed-time interval** (48 h) survival outcomes of all the animals up to that time. This is especially applicable when there is very little information available to make a preliminary estimate of the LD50 dose of the agent and the slope of the dose-response curve. In such a case, starting doses near 175 mg/kg and using half-log units (dose progression of factor 3.2) will increase efficiency of animal use and increases accuracy in prediction of the LD50 dose.

The AFRRI approach is similar to the UDP test, with a few variations. We use 6 animals/group/dose and stagger the doses over 48 h intervals. Only males are used, since all our radiation studies are carried out in male mice. After dosing, the animals

are observed continuously for 1 h, and 4 h and then daily for 14 days using the observation codes listed (Table 2). After the initial 48 h observations, if no changes in body weight, behavior, activity, temperature and irritation at injection site, or mortality is observed, the drug dose is escalated 3 times (a half log unit, note: a change of 3.2 times theoretically equals half log unit). If any adverse effect is noted (weight loss, decreased or increased activity, death), the dose is reduced to 3 times the tested dose. Drug dose for radiation countermeasure studies is 1/4th the non-toxic dose. However, when there is sufficient background information about the drug or indication of effective dose, a single dose four times higher than the dose to be used in the radiation screening study will be tested as a reduction and refinement strategy. Given that 1 or 2 drugs out of 10 may pass the initial screening for radiation, this is a vastly preferable procedure to the conventional toxicity study using 2 genders of mice and a much larger number.

Procedure: There will be six animals per group housed three per box. Each mouse will be individually monitored for weight changes by standard ear punch/notch system. The punches or holes correspond to a predetermined numbering code for individual animals. Here, in a group of three, we will have the right ear punch, left ear punch and no punch to distinguish between each animal. In case of 5 animals, we will have right and left punch, right and left notch, and a no punch/notch to identify individual animals. The procedure is described under section G (surgical methods or procedures).

(b)(4)

different routes (b)(4) *was previously tested in CD2F1 mice* (b)(4),(b)(6) (b)(4) *and no mice are requested in this protocol to evaluate the* (b)(4) Similarly, (b)(4) and filgrastim will not be tested in this section.

(b)(4)

6 groups (1 naïve, 1 vehicle, 4 doses) x 1 route (*sc*) x 6 mice per group x 6 drugs
Subtotal = **216 CD2F1 mice**

(b)(4) will be tested via the oral route, using oral gavage.

6 groups (1 naïve, 1 vehicle, 4 doses) x 1 route (*po*) x 6 mice per group x 4 drug
Subtotal = **144 CD2F1 mice**

Intravenous route: (b)(4) will be tested via this route.

6 groups (1 naïve, 1 vehicle, 4 doses) x 1 route (*iv*) x 6 mice per group x 1 drug
Subtotal = **36 CD2F1 mice**

Intraperitoneal route: (b)(4) will be tested via this route.

6 groups (1 naïve, 1 vehicle, 4 doses) x 1 route (*ip*) x 6 mice per group x 1 drug
Subtotal = **36 CD2F1 mice**

Section V.1.2.
Radiation survival study:

1) We will use the LD-70 radiation dose, a dose that results in 70% (±20%) mortality within 30 days following exposure.

2) There are three major arms to the survival study: one prophylaxis (24 h pre-TBI), and two mitigation (post-irradiation) arms, viz. 4 h and 24 h post-TBI.

3) Survival of ≥30% over vehicle is considered the 'pass criteria'.

4) Only those countermeasures that meet the AFRRI pass criteria in CD2F1 mice will be evaluated in C3H/HeN, C57BL/6 and B6C3F1 strains.

The efficacy of each drug in enhancing survival of lethally irradiated CD2F1 mice will be tested in both the prophylactic and therapeutic regimen (-24 h, +4 h or +24 h after exposure [0 h]) to LD-70 radiation) as described below. Numbers of mice include two iterations.

For each drug, the animal requirement was calculated as follows:

Drug + vehicle (2 groups) x 3 regimen (one pre- and two post-TBI) x 1 rad dose (LD-70/30) x 1 route (*sc*, *po*, or *iv*) x 24 CD2F1 mice per group = **144 mice/drug**. (Table 3)

Positive controls

Vehicle + 5-AED control (2 groups) x 1 regimen (-24 h) x 1 radiation dose x 1 route (*sc*) x 10 mice per group x 7 iterations Subtotal = **140 CD2F1 mice**

Iterations

Assuming five of the listed agents achieve ~30% increase in survival over vehicle, the study will be repeated for concordance.

Drug+vehicle (2 groups) x 3 regimen (-24 h, +4 or +24 h) x 1 radiation dose x 1 route (*sc*, *po*, *iv*, or *ip*) x 24 mice per group x 5 drugs Subtotal = **720 CD2F1 mice**

MCM efficacy of lead countermeasures in different strains

There are inherent differences in response to total/partial body ionizing radiation arising from genetic differences in the same species. Certain drugs that improve survival following TBI in one mouse strain will not necessarily show similar efficacy in another strain. An ideal countermeasure should be able effective across strain variations. To this end, (b)(4) directive is to test the gold standard, Filgrastim, in several strains. Similarly, AFRRI intramural funding supports development of (b)(4)

Table 4: Countermeasure efficacy in mouse strains: C3H/HeN, C57BL/6 and B6C3F1

Drug	Vehicle	Route	Pre-TBI	Post-TBI	Post-TBI	#animals
(b)(4)	PBS	*sc*	-1 d	+4 h	+1 d	144
Filgrastim*	5% dextrose	*sc*	-1 d	+4 h, 1, 2 d	+1, 2, 3 d	144
*These two agents showed significant mitigation in CD2F1 mice previously- hence no CD2F1 mice will be required.						

Number of mice required for V.1.2. (Table 5)

Strain	C3H/HeN	C57BL/6	B6C3F1	CD2F1
# of mice needed	288	288	288	0

Section V.1.3. Optimization studies: Optimization studies will be initiated in CD2F1 mice only if any of the drugs tested meets the AFRRI criteria of >30% survival than vehicle in the preliminary radiation survival screen. Assuming that three of the eleven drugs meet the AFRRI criteria, we request animals to carry out optimization studies and DRF for three drugs.

Drug dose optimization study: 6 groups (Five drug doses + 1 vehicle) x 1 radiation dose (LD-70) x 2 regimen (pre- and post-exposure) x 1 route (*sc*, *iv*, or *po*) x 3 drugs x 24 animals per group Subtotal = **864 CD2F1 mice**

Time optimization study: 4 different time points x 1 optimum dose + 1 vehicle (2 groups) x 1 radiation dose (LD-70) x 1 route (*sc*, *iv*, or *po*) x 3 drugs x 24 animals per group Subtotal = **576 CD2F1 mice**

Section V.1.4. Dose reduction factor study (DRF):

The dose reduction factor (DRF) studies will use the optimum drug dose and times to evaluate the effectiveness of the drug against a range of radiation dose in CD2F1 mice.

6 irradiated vehicle groups (8.5, 9, 9.5, 9.75, 10 and 10.5 Gy, 0.6 Gy/min)* + 6 irradiated drug groups (8.5, 9, 9.5, 10, 10.5, and 11 Gy)* x 24 mice per group x 3 drugs. Subtotal = **864 CD2F1 mice**

*These radiation doses are projected based on an earlier probit study and are considered a guidance. The appropriate radiation doses will be determined using the new dosimetry map (02/28/2013)

Section V.1.5. Hematology, clinical chemistry, and bone marrow studies .These studies are anticipated only for those candidates that demonstrate 30% increase in survival. Data from these studies will form the basis of understanding the mode of action of the drug,
Naïve + vehicle + drug alone (3 groups) x 7 time-points x 10 mice per group x 1 route of administration x 2 drugs **Subtotal = 420 CD2F1 mice**

2 experimental groups (vehicle-irradiated, Drug-irradiated) X 7 time-points X 10 mice per group x 1 route of administration X 2 radiation doses x 2 drugs **= 560 CD2F1 mice**

V.2. Data Analysis All data will be reported as means with standards errors or percentages where applicable. Experiment V.1.1 (ODDS) –probit analysis will be used to generate LD_{50} of the drugs under study using PASW Statistics (version 18). V.1.2 (preliminary survival study) and V.1.3 (Optimization study)- Using calculations based on log rank test with 80% power and 5% two-sided significance level, we have determined that this protocol design has adequate power for screening purposes. The standard for declaring a test promising is a 30 percent increase in survival over vehicle from a radiation dose producing approximately 70 percent mortality (±10%) in the vehicle group. With N of 24 for the vehicle and treated groups this has a one-tailed p value of approximately 0.001 and with N of 20 this has a one-tailed p value of 0.005. This low p value is required, rather than the usual 0.05 for significance, which would use fewer mice, due to sources of intrinsic variability in the biological system that cause departure from the underlying assumption of independence, e.g. occasional cage effects where most or all the mice co-housed in one cage (4 mice per cage) die due to infection. Therefore, further reduction of N below 24 is not feasible. Experiment V.1.4. (Dose Reduction Factor study)- In past experience, 20 animals per dose with six radiation doses has been sufficient to determine a probit line fit to mortality data for DRF calculations. At least three out of the six doses should sustain survival other than 100 or 0 percent. Finney's methods will be adhered to in making probit fits and estimating DRF.
Experiment V.1.5: For testing the overall difference between groups (averaging over time points), a repeated measures ANOVA with 6 animals per group measured at 7 time points will have 80% power to detect a difference of 0.91 standard deviations if the within-subject correlation is 0.2. For comparisons between groups at a single time point, the proposed sample size will have 80% power to detect a difference of 1.8 standard deviations between groups, based on a t test for independent samples with a 5%, two-sided significance level. Previous studies have yielded differences of this magnitude.

V.3. Laboratory Animals Required and Justification

V.3.1. Non-animal Alternatives Considered Although high throughput screening and computer modeling have advanced significantly in recent years in identification of promising drugs, it would be simplistic to assume that cell systems or artificial intelligence modeling can replace the data that can be generated by using an animal model. Irradiation of animals will result in a cascade of changes including death of stem and progenitor cells in bone marrow, alterations in signal transduction pathways, multiple organ dysfunctions etc. due to differing radiosensitivities of organs. Currently, there are no alternatives in existence that can predict or compute the complexity of the response to total body irradiation. The US FDA recognizes the ethical considerations involved in testing the efficacy of radioprotective drugs in humans. Therefore FDA requires preclinical drug assessments (safety and efficacy) to be performed using both small and large animal models (FDA 2002) prior to granting approval for safety testing in humans.

V.3.2. Animal Model and Species Justification Recent advances in molecular techniques have allowed significant improvements in understanding the cellular and biochemical processes. These advances are possible only due to whole animal modeling of human ailments. The mouse, in particular, has high sequence homology to humans at a genomic level as well as similar hematological and immunological response to radiation. Mouse models not only confirm primary pathological processes but have also provided a venue for studying basic molecular, cellular, biochemical, and cytological processes. Further, there are extensive data on the mouse for comparison, review and analysis. The practicalities of breeding and housing these small mammals have made the mouse model invaluable. The Principal Investigator's group at AFRRI has significant training and experience in handling mice in radiation countermeasure studies.

V.3.3. Laboratory Animals

V.3.3.1. Genus / Species: Mouse, *Mus musculus*

V.3.3.2. Strain / Stock: CD2F1, C3H/HeN, B6C3F1 and C57BL/6

V.3.3.3. Source / Vendor: CD2F1, C3H/HeN, B6C3F1from Harlan Inc., VA, and C57BL/6 from Charles River Laboratories or Jackson labs.

V.3.3.4. Age: (procurement) 7-8 weeks

V.3.3.5. Weight (delivery) 25-30 grams

V.3.3.6. Sex Males have been used historically and will continue to be used in this study.

V.3.3.7. Special Considerations Commercially procured animals must be adventitious disease free. Specific pathogen-free, including *Pseudomonas*

aeruginosa, and *Pasteurella*: All mice need to be free of the following agents: Sendai, Pneumonia Virus of Mice (PVM), Reovirus-3 (Reo 3), Mouse Adenovirus (MAD-1, MAD-2), Mouse Cytomegalovirus Virus (MCMV), Ectromelia, K virus, Lymphocytic Choriomeningitis Virus (LCM), Epidemic Diarrhea of Infant Mice (EDIM), Hantaan virus, Rotavirus, Mouse Parvovirus (MPV), Polyoma Virus, Mouse Minute Virus (MMV), Mouse Thymic Virus (MTV), Theiler's Mouse Encephalomyelitis Virus (TMEV/GDVII), *Encephalitozoon cuniculi*, CAR bacillus, *Mycoplasma pulmonis*, and *Clostridium piliforme*. Endoparasite- and ectoparasite-free.

V.3.4. Number of Animals Required (by species) (Table 6)

Animal (genus, species and common names)	**Original**
CD2F1	5872
C57BL/6	288
C3H/HeN	288
B6C3F1	288

Total number of animals in different fund sites (Table 7)

Site number	**C57BL/6**	**C3H/HeN**	**B6C3F1**	**CD2F1**
G1B2DB14	144	144	144	2780
G1B2HF13	0	0	0	1440
RAB2GY14	144	144	144	1652

V.3.5. Refinement, Reduction, Replacement (3 R's)

V.3.5.1. Refinement: PI will take necessary steps to all personnel in the project to be rigorously trained in handling techniques (ear-punch, injections, oral gavage, intraperitoneal injections, and routine cage-side observations) to minimize distress and pain to the animals. Specifically, during capture and restraint of the rodents, care will be taken to ensure that handling does not contribute to distress. Topical ointment/lubrication gel will be used, if necessary, to prevent drying of the cornea as well as at the site of drug injection in consultation with attending veterinarian and veterinary staff.

V.3.5.2. Reduction The protocol will use a tiered approach to reduce the number of animals for testing 10 drugs/year. Although basic toxicity and survival will be carried out on all 10 drugs, additional studies will depend on the initial results. Positive controls and negative controls are used to confirm robustness of experimental conditions and drugs that don't meet our minimal criteria of 30% increased survival over the vehicle control will be eliminated. Based on previous experience, we have proposed that only 3 drugs out 10 may be advanced for optimization and dose reduction factor studies (see section V.1.3 and V.1.4). Further, control groups (such as vehicle) will be shared whenever possible between drugs that are dissolved in similar vehicles (for example Phosphate buffered saline-PBS). In classical toxicology testing, groups of 10-20 mice and both sexes were routinely used; in using the ODDS method (current protocol), we reduce the number of animals to 6 per group, and use only males, thereby reducing animal numbers significantly. Five drug doses have been

proposed for toxicity screening; however, in some cases a smaller number (i.e. 3) might be selected based on literature search and recommendation by the manufacturers. Similarly, several routes of drug administration have been contemplated in the experimental design; but depending on the existing data and company suggestions, a single and optimal route may be chosen. Wherever possible we have reduced the number of repeats planned for the experiments shown above.

V.3.5.3. Replacement It is not feasible to use non-animal systems in place of actual animal models to address the questions in this project. Rodents are considered sentient and hence rodents will be used for screening large number of potential radiation countermeasures. Only those drugs that pass the AFRRI criteria for significant survival benefit will advance to studies in higher mammals.

V.4. Technical Methods
V.4.1. Pain / Distress Assessment
V.4.1.1. APHIS Form 7023 Information

V.4.1.1.1. Number of Animals 6736

V.4.1.1.1.1. Column C 0 (# of animals)

V.4.1.1.1.2. Column D 852 (# of animals) These mice have the potential to be sickand die due to drug administration (toxicity study, #432) or will have blood collected via cardiac stick or the inferior vena cava.

V.4.1.1.1.3. Column E 5884 (# of animals). These mice will be irradiated and will not receive any intervention for pain relief. However, they will be euthanized if found moribund.

V.4.1.1.1.4. Pain Category Assignments: (Table 8)

Exp. #	Experimental/Control Group	C	D	E	Totals
V.1.1.	ODDS safety/toxicity study		432		432
V.1.2.	Radiation survival studies			3020	3020
V.1.3.	Optimization studies			1440	1440
V.1.4.	Dose reduction factor studies			864	864
V.1.5.	Hematology, clinical chemistry and bone marrow studies		420	560	980
Totals:			852	5884	6736

V.4.1.2. Pain Relief / Prevention Minimizing and alleviating pain in laboratory animals without compromising the methodological integrity of a research project is important both ethically and legally. Pain in animals is difficult to access, mostly due to lack of methods that can validate and objectively measure it.

V.4.1.2.1. Anesthesia / Analgesia / Tranquilization The protocol will not use anesthetics or analgesics during radiation since they will adversely affect the outcome of the experiments. The proposed study is to determine the effects of radiation and

countermeasures on the function of the immune and blood forming systems; use of any analgesics and anesthetics would interfere with the function of the immune system and therefore compromise the interpretation of the results. It is anticipated that at high radiation doses, animals will demonstrate varying degrees of morbidity and moribund, which makes it critical to define the criteria for euthanizing the animals without undermining the study objective. Euthanasia will be performed by trained personnel in accordance to the current AVMA guidelines (AMVA Guidelines on Euthanasia, 2013). In toxicity studies, if animals show discomfort (hunching, decreased activity, inappetence, separation from cage-mates), that animal will be under careful observation on consultation with the attending VSD veterinarian. If the animal becomes moribund (defined in V.4.5.), it will be euthanized. Antibiotics will be applied if wounding occurs via in-cage fighting, under the guidance of the clinical veterinarian in accordance with standard treatment measures.
Anesthesia using standard Isoflurane apparatus under the guidance of the VSD will be carried out in mice receiving intravenous injections and for blood collection. All personnel will be extensively trained for efficient administration of the agents as well as to minimize handling stress.
Animals will be placed in the Isoflurane chamber and delivered a metered amount of 5% Isoflurane mixed with 100% oxygen until all voluntary motor movement ceases and the animal is recumbent for 10 seconds. Animal's respiration rate will be closely monitored through the Plexiglas chamber during induction of anesthesia. When animals are recumbent, they will be removed from the chamber and their nose/mouth placed in the anesthesia apparatus breathing/gas administration cone for maintenance of anesthesia at 3% Isoflurane and 100% O_2.

V.4.1.2.2. Pre- and Post-procedural Provisions Mice will be housed under standard conditions both before and after radiation procedures in accordance with current VSD rodent husbandry Standard Operating Procedures (see section V.5).

V.4.1.2.3. Paralytics: N/A

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures

V.4.1.3.1. Sources Searched AGRICOLA, PubMed, EMBASE

V.4.1.3.2. Date of Search 12/10/2013

V.4.1.3.3. Period of Search AGRICOLA: 1975-2004, EMBASE 1974-present PubMed~1950 to present.

V.4.1.3.4. Key Words of Search Radiation and pain, [Filgrastim, (b)(4) (b)(4) and pain, and [drug name]+toxicity, anesthesia, analgesia, distress, humane.
In order to increase specificity of literature review, several combinations such as radiation plus specific drug, mice plus specific drug, radiation plus specific drug plus mice were evaluated.

V.4.1.3.5. Results of Search There are no alternatives to irradiation. While radiation itself does not cause pain or distress, it induces a number of changes in the body that alters immune response and destroys hematological tissues, resulting in opportunistic infections, and multiorgan dysfunction leading to death. It is anticipated that animals exposed to high lethal radiation doses will become moribund. Unfortunately, literature clearly demonstrates that use of analgesics alters radiation response and therefore leads to increase in animal number for better statistical results or for iteration of entire experiments. The nonsteriodal analgesic (b)(4) is reported to decrease the effect of radiation therapy in head and neck cancer cells (Czemirek *et al* 2009). Ginseng, with known analgesic properties, is a potent radioprotector (Lee *et al* 2005).
No references were found suggesting distress due to the drugs, though some drugs are well documented as having side effects associated with the pathophysiology of biological response to the drug. For instance, (b)(4) increases white blood cells and platelets, as does (b)(4) Filgrastim is documented as causing bone pain, but is well tolerated in human volunteers. (b)(4) is reported to cause feelings of discomfort, lower back pain, decreased appetite and diarrhea.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification: Because exposure to irradiation is potentially lethal or cause debilitating effects in humans, it is ethically impermissible to test the effectiveness of radiation countermeasures on human volunteers. Irradiation compromises the immune and blood forming systems leading to mortality. The radiation-induced mortality and potential percentage increase of survivors over 30 days using potential radiation countermeasures are study endpoints for this protocol. Administration of drugs and analgesics is not an option since it is well documented that they interact with the immune system which will confuse the interpretation (Galley *et al*, 1997, 1998). Pain relieving measures are not used because such measures may compromise the experimental integrity of the study.

V.4.2. Prolonged Restraint : The experimental animals will receive radiation at a dose rate 0.6 Gy per/min in the AFRRI Cobalt 60 gamma radiation facility. Animals will be irradiated in Lucite boxes (8 animals/box) and arranged in an array (dosimetry 02/28/2013;or the latest dosimetry map) using plastic racks. Mice will be inserted into the standard radiation boxes just prior to irradiation (~15 min of exposure time) and taken to the cobalt facility for irradiation. Animals will be restrained for no more than 60 min and returned to cages at the end of the irradiation period. They will be monitored daily (twice a day when necessary) for 30 days and euthanized at the completion of the observational period.

V.4.3. Surgery: N/A

V.4.3.1. Pre-surgical Provisions: N/A

V.4.3.2. Procedure(s) : N/A

V.4.3.3. Post-surgical Provisions : N/A

V.4.3.4. Location : N/A

V.4.3.5. Surgeon : N/A

V.4.3.6. Multiple Major Survival Operative Procedures : N/A

V.4.4. **Animal Manipulations:**
V.4.4.1 Ear punch: Three animals/group will be housed per shoe box during toxicity study (section V.1.1.). They will be identified by ear punch (one animal will have a right punch, the second will have a left punch and the third will have no punch).

Procedure for ear-punch

a. Soak the ear punch (Fine Science Tools, Cat# 24212) in a disinfectant (100% ethanol) before use and between animals.
b. Place the device on the pinna of the ear (external ear) where the skin is thin avoiding the cartilage.

Press firmly to punch a circular hole through the ear

For the oral route, drug(s) will be administered using a 20 G gavage needle (Fisherbrand-Animal feeding needles, disposable-sterile, non-toxic and nonpyrogenic-20 G, 1 ½" length). Non-disposable, metal ball ended, oral gavage needles are included as an alternative to the disposable needles. Drug volume will be 0.2 ml (with a maximum of 0.5 ml). The animal will be restrained in a vertical position to align the spine straight. The bulb will be introduced into the mouth horizontally. Using the needle as lever, the syringe will be moved into a vertical position and the needle dropped down the esophagus into the stomach. The needle contents will be administered when the needle hub touches the animal's mouth. All precautions will be taken to ensure that the placement of the needle is properly positioned and that the animal is not struggling severely. No forceful feeding will be done to prevent perforation of the esophagus.

Intravenous injections: Mice will be anesthetized as described earlier, in the Isoflurane units. Once deeply unconscious (tail or toe pinch), the animals will be moved to a station with nose cone for continued anesthesia. The tail will be cleaned with alcohol and the test agent injected to the tail vein using a 25 or 27 G needle. Mice will be returned to their cages and monitored until they recover before being placed in their assigned rooms. Heat packs, warm platform, or heat lamps may be employed during anesthesia to prevent hypothermia.

Irradiation: These will follow the standard AFRRI protocol with mice placed in restrainers shortly prior to exposure, irradiation at the cobalt facility and return to VSD for further monitoring. Briefly, the experimental animals will receive radiation at a dose rate 0.6 Gy per/min in the AFRRI Cobalt 60 gamma radiation facility. Animals will be irradiated in Lucite boxes (8 animals/box) and arranged in an array (dosimetry 02/28/2013) using plastic racks. Animals will be restrained for no more than 60 min and returned to cages at the end of the irradiation period. They will be monitored daily

(twice a day when necessary) for 30 days and euthanized at the completion of the observational period. In case of non-lethal exposures, mice will be harvested at specific time-points after irradiation, and tissues collected after terminal blood draw.

Blood collection: Mice will be anesthetized as described under section V.4.1.2.1 (anesthesia). Blood draw for hematology is collected either by cardiac stick or from the inferior vena cava (IVC). The animals will be deeply anesthetized in the rodent anesthesia machine; the tail will be pinched for reflexive movement, indicative of insufficient anesthesia. If there is no response, the animal will be moved to the station with individual nose cone for continued anesthesia. An incision will be made on the right side below the abdomen of the animal, closest to the IVC, the vein exposed and blood drawn with a 23 G needle. Similarly, cardiac stick will be performed on the animal positioned at the platform under anesthesia. In both cases, the animals will be immediately euthanized on completion of blood draw by cervical dislocation.

V.4.4.2. Injections: The vehicles for the different compounds depends upon solubility and include sterile water for injection, phosphate buffered saline, polyethylene glycol-400 (PEG-400). Based on literature data, PEG-400 is associated with limited radioprotective property and hence will be administered as a control in a given study. Because there is a drift in $LD_{70/30}$ over time each experiment requires an internal vehicle group from the same batch of mice. Subcutaneous injections will be given with either 23 or 25 G needle to the nape of the neck of 0.1 ml (maximum volume 1 ml for 25 to 38 g animals). Intravenous injections to tail vein will use a 25 or 27 G needle in a volume of 0.1 ml per mouse (maximum volume-0.2 ml for 25 to 38 g animals).Intraperitoneal injections will be given with either a 23 or 25 G needle in a volume of 0.25 ml (maximum volume 1 ml for 25 to 38 g animals). Disposable sterile needle will be used for all *sc* and *iv* injections. One needle will be used per cage containing generally 4 animals. The purpose of the table shown below is to provide available information for the drugs to be tested. The information in the table should be considered only as guidance. It should be noted that the information on several drugs is incomplete since material transfer agreements (MTA) are not in place and the companies have not shared information with us. Once MTAs are in place, the PI will request additional information on the drug including details of preferred vehicle, pH, osmolarity, endotoxin level, schedules, and the route of injection, from the collaborator/manufacturer (if purchased in the open market or through a pharmaceutical company [pharmaceutical grade]). It is expected that the osmolarity will not be more than AFRRI IACUC's recommended levels (Policy#9). Further, ODDS method clearly states that the PI will decide on the drug dose based on limited toxicity studies unless otherwise provided by the collaborator/drug manufacturer. The PI will initiate ODDS method using a safe dose (using the data provided in the Table shown below) or a dose recommended by the collaborator in order to obtain the best drug dose for survival studies.

Table 9: Physical characteristics and vehicles for the countermeasure agents

Drug	Vehicle	Projected Dosage*	pH range	Endotoxin levels	Grade
(b)(4)	PEG-400	30 mg/kg	6-8	Not done**	N-PG
	PBS	2000 µg/kg	7	0.014 EU/ml	N-PG

(b)(4)	PBS	50 mg/kg	¥	<0.0025 EU/mg	N-PG
	Saline	150 mg/kg	¥	Not done**	N-PG
	PBS	100-250 µg/kg	7-7.4	Not done**	N-PG
	PBS	350-750 µg/Kg	¥	Not done**	N-PG
	PBS	100 µg/kg	¥	Not done**	N-PG
	PBS	180 mg/kg	6	<0.05 EN/ml	N-PG
	PBS	TBD	¥	Not done**	PG
	Saline	250 mg/kg	¥	Not done**	N-PG
	PBS	2.5 mg/kg	¥	Not done**	N-PG
	PBS	1-8 mg/kg	7.4	<0.001 EU/mg	N-PG
Filgrastim	5% dextrose	0.17 mg/kg	5.3	N/A	PG

*These doses should be considered only as guidance. Actual drug doses will be determined by PI based on additional information made available from collaborators/manufacturers and/or by ODDS test. PG=pharmaceutical grade; N-PG=non pharmaceutical grade drug

¥ To be evaluated.

**Endotoxin testing for all drugs will be completed prior to any animal testing at AFRRI and a report submitted for IACUC/VSD review and approval. The endotoxin tests are conducted by Charles River Laboratories. At the same time, pH will be tested to ensure that it falls in the range (6-8 for *sc* administration) stipulated by IACUC.

However, if there are significant changes in the protocol including drug dose or route of administration, the PI will initiate an IACUC amendment prior to evaluating that specific drug.

V.4.4.1.1. Pharmaceutical Grade Drugs We will use pharmaceutical grade Filgrastim, 5% Dextrose, and (b)(4) All attempts will be made to obtain pharmaceutical or veterinarian grade drug(s) for the protocol. However, most drugs listed here are of research grade.

V.4.4.1.2. Non-Pharmaceutical Grade Drugs Some of the drugs (eg. (b)(4) (b)(4) under study will require a carrier such as poly ethylene glycol (PEG 400). All drugs will be tested for endotoxin levels if this information is not supplied by the manufacturers. Physical characterization, including osmolality and pH of final solutions will be in the range stipulated by IACUC by its policy letter on testing non-pharmaceutical grade drugs (policy #9). We do not anticipate filtering the test agents due to the limited availability of drugs, and uncertainty as to how much of the drug will be filtered out. However, we will ensure that drug preparation is carried out under hygienic conditions (use of PPE, clean surface area for drug preparation, use of clinical grade solvents) to preclude contamination of test samples.

(b)(4) an inhibitor of microtubule polymerization will be injected intraperitoneally (*ip*) into mice (0.5% in saline) 2 h before euthanasia and collection of bone marrow cells for processing chromosomal aberrations in metaphase spreads (b)(4), (b)(6)

V.4.4.2. Biosamples: N/A

V.4.4.3. Adjuvants: N/A

V.4.4.4. Monoclonal Antibody (MAb) Production : N/A

V.4.4.5. Animal Identification Generally, cage cards will be used to distinguish drug-treated and control groups. Some experiments might necessitate ear punch or notch by personnel to identify individual animals in a cage. Ear punch is performed as described in V.4.4.1).

V.4.4.6. Behavioral Studies: N/A

V.4.4.7. Other Procedures : N/A

V.4.4.8. Tissue Sharing All tissues from the animals used in toxicity study will be preserved for histopathological analysis by the VSD pathologist. The pluck method will be used to harvest all the organs from tongue to rectum, brain, sternum, femur and blood may be collected at euthanasia. Tissue from irradiated mice (brain, GI, spleen, lung, liver, kidney) will be collected for histopathology at intervals.

V.4.4.9. Animal By-Products: N/A

V.4.5. Study Endpoint The time frame for experiment V.1.1 (basic toxicity) will be 14 days after final drug dose administration (for instance, oral gavages are administered once a day for four days and the day of the last dose is considered day 0).
The radiation survival studies will span 30 days after radiation exposure (experiments V.1.2, V.1.3. and V.1.4.). Serial sampling by terminal procedures is projected on 7 different time points after drug or irradiation for experiment V.1.5.

It is anticipated that the animals involved in these studies may succumb to death either due to a drug administration or radiation or a combination of the two. To maintain a suitable baseline for humane treatment of the animals while adhering to the study objective, the IACUC recommendations stipulated in Policy Letter #10 will be implemented for judging morbidity and moribundity. Signs of morbidity in the mouse include difficulty in breathing, ruffling of hair, drying of lachrymal fluid, fall in body temperature, loss of appetite with/ without diarrhea. Morbid animals will proceed in the experimental observation to sustain survival accuracy and to monitor the efficacy of drug intervention. No supportive care is proposed, but the morbid mice will be examined at least twice daily, early morning and late afternoon by the research staff (including weekends and holidays) in addition to the regular VSD health checks.

The moribund condition is defined as a clinically irreversible condition leading inevitably to death. Animals involved in experiments that may lead to moribundity or death will be monitored daily by personnel experienced in recognizing signs of moribundity (illness, injury, or abnormal behavior) for at least the following: abnormal posture, rough hair coat, head tucked into abdomen, exudates around eyes and/ or nose, skin lesions, or abnormal breathing, difficulty with ambulation, cyanosis, decreased food or water intake, or self-mutilation (Toth 1997, AFRRI policy #10).

Animals will be will be immediately euthanized when they display abnormal breathing, are recumbent, or unable to respond to mild external stimulus by the

research staff and scored as dead on removal, while recorded as euthanized in the medical records. VSD veterinarians will be consulted for all matters regarding the animal welfare.

V.4.6. Euthanasia Mice found moribund will be euthanized by CO_2 inhalation plus confirmatory cervical dislocation by investigator/ technician according to the directives of the VSD-SOP and in accordance with current AVMA Guidelines on Euthanasia (AMVA 2013). At the conclusion of the experimental time frame, all animals that survived the procedures of irradiation, drug intervention and controls, will be sacrificed by CO_2 inhalation plus confirmatory cervical dislocation and their carcasses disposed of according to VSD regulations.

V.5. Veterinary Care

V.5.1. Husbandry Considerations The AFRRI vivarium follows stringent protocols for the housing and care of all animals. The PI and designated team members will adhere to all the policy and guidelines set forth by standard operating protocols of the VSD. The specific requirements for mice housing should meet the following criteria of opportunity for social interaction, opportunity to carry out normal behavior and the opportunity to rest and withdraw from each other (AWIC website). Mice are social animals and hence will be caged together in groups of 4 or 8. For ODDS testing, mice will be housed in groups of 3 or 5 mice per cage and identified individually as described. Nestling pads will be provided in each cage during bedding changes. In cage shelters will also be provided as an enrichment strategy at the discretion of the PI depending on experimental conditions. Animals will receive Harlan Teklad Rodent Diet (w) 8604 and water *ad libitum.* Acidified water (pH 2.5 – 3.0) is routinely provided to AFRRI mice used in radiological experiments. Cages will be regularly changed and cleaned by VSD staff in accordance with Standard Operating Procedure. Animals will have 12 h light/dark cycle. Animals will be habituated to their surroundings and routine procedures prior to experimentation. In the event of procedures that last into the night cycle, care will be taken to minimize exposure to light and the quality of light used will be of the diffused, dim type.

V.5.1.1. Study Room As assigned by VSD

V.5.1.2. Special Husbandry Provisions N/A

V.5.1.3. Exceptions Mice will be socially (group) housed as described above, except when there is a possibility that during survival studies cage mates may be lost through attrition and for a period of time the sole surviving mouse may remain singly housed until the end of the 30-day study.

V.5.2. Veterinary Medical Care We do not project routine veterinary medical care. However, in some cases of drug testing, if the mice are anesthetized, we will use a topical lube to prevent the eyes from drying out, on consultation with the VSD. Further, in case of minor injuries arising from fighting, topical application of antibiotics is acceptable with consensus from the PI and VSD.

V.5.2.1. Routine Veterinary Medical Care Experimental animals will be observed daily by either the investigator or technician or both. VSD personnel will monitor all animals during their routine rounds as per VSD SOPs. In the course of the study, as animals approach morbidity, the research staff observations will be increased to a minimum of twice a day, early morning and late afternoon (includes weekends and holidays). There is no supportive therapy contemplated since this would compromise the experimental results (described earlier in the end point and pain category sections).

V.5.2.2. Emergency Veterinary Medical Care Moribund animals (gasping, recumbent, non-responsive to mild stimulus) will be euthanized by trained personnel.

V.5.3. Environmental Enrichment: As provided by the husbandry staff to animals not on active experiments.

V.5.3.1. Enrichment Strategy Nestling pads will be provided in each cage during bedding changes as per AFRRI-VSD SOPs.

V.5.3.2. Enrichment Restrictions

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING (Table 10)

NAME	DEGREE	TRAINING	DATE	PROCEDURES	YRS/MOS EXPERIENCE
(b)(6)				1, 3, 4b, 5	(b)(6)
				1, 3, 3d, 4a, 4b, 5, 7*	
				1, 3, 4a, 5	

Procedure and manipulation codes:
Code 1= Animal handling and euthanasia
Code 2= Surgery (aseptic technique) pre- and post-operative care
Code 3= Injections (3a-*ip*, 3b-*sc*, 3c-gavage) - can say 3 if trained in all manipulations or add 3d-*iv*
Code 4= Blood collection under anesthesia (4a-cardiac, 4b-posterior vena cava)
Code 5= Tissue collection (after euthanasia) - doesn't need to be specific
Code 6 = Implantation (provide details)
Code 7 = Others - (provide protocol specific manipulations or procedures for e.g., retro-orbital bleeding, tail vein injection, or drug delivery)
*Trained in retro-orbital injection, tail vein injection and tumor implantation.

VII. BIOHAZARDS/SAFETY All personnel working in the protocol have undergone necessary training in handling experimental animals. The amount of drug used will be small and standard safety precautions will be taken while handling them in the laboratory and in the vivarium. All personnel listed in the present protocol have been trained as general radiation users on a regular basis. All investigators and personnel will use appropriate protective gear while in the vivarium as described by the VSD. All listed personnel are current in safety training and medical surveillance.

X. ASSURANCES

Protocol Title: Radiation Countermeasure Screening for Protection and Mitigation in the lab Mouse, *Mus musculus*.

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made every effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with a qualified individual who evaluated the experimental design with respect to the statistical analysis, and that the minimum number of animals needed for scientific validity will be used.

D. Biohazard / Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R", namely, "Responsibility," which the DOD has embraced for implementing animal use alternatives where feasible and conducting humane and lawful research.

G. Scientific Review: This proposed animal use protocol has received appropriate peer scientific review and is consistent with good scientific research practice.

H. Painful Procedure(s): **I AM** / **AM NOT** conducting biomedical experiments, which may potentially cause more than momentary or slight pain or distress to animals. If applicable, potential pain and/or distress **WILL** / **WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

MEMORANDUM FOR: IACUC Administration

SUBJECT: Unexpected outcome of the study (b)(6) amendment# (b)(6)

As part of the (b)(4) countermeasure screening program under IACUC protocol (b)(6) was begun on Tuesday, July 14, 2015 to test synthetic pre-implantation factor (b)(4) as a potential radiation countermeasure. Drug (b)(4) or vehicle was injected twice a day for 14 days as described below (Table 1). 160 animals were included in this study as follows:

Table 1. (b)(6) Design for radiation countermeasure screening with sPIF, sc

Group #	Cage #	Drug	Dose	Volume	Route	Admin (time)
1 a-b	1-2	PEG	-	0.1 ml	sc	-1 d
2 a-b	3-4	5-AED	30 mg/kg	0.1 ml	sc	-1 d
3 a-f	5-10	PBS	-	0.1 ml	sc	-24 h, -12 h, (+0 – 13 d bid)
4 a-f	11-16	(b)(4)	0.75 mg/kg	0.1 ml	sc	-24 h, -12 h, (+0 – 13 d bid)
5 a-f	17-22	PBS	-	0.1 ml	sc	+4 h, (+1-14 d bid)
6 a-f	23-28	(b)(4)	0.75 mg/kg	0.1 ml	sc	+4 h, (+1-14 d bid)
7 a-f	29-34	PBS	-	0.1 ml	sc	+24 h, (+1-14 d bid)
8 a-f	35-40	(b)(4)	0.75 mg/kg	0.1 ml	sc	+24 h, (+1-14 d bid)

Research staff began the dosing schedule on Tuesday, July 14, 2015, according to the above table. Mice were injected with 0.75 mg/kg (b)(4) *sc* at a volume of 0.1 mL per dose every 10-12 hours. Staff performed injections using a one-handed restraint technique, and one needle per cage of four animals was used, as is stated in the (b)(6) protocol. All mice were irradiated on Wednesday, July 15, at AFRRI's cobalt-60 facility at an $LD_{70/30}$ dose of 9.25 Gy at 0.6 Gy/min.

Critical period began on Wednesday, July 22. The first death was observed on Thursday, July 23. On Saturday, July 25, research staff noticed a large, clotted wound on the right side of an animal's abdomen. On the following day, research staff euthanized five mice with clotted wounds on the right side of the body, either on the abdomen or nape of the neck. Three of these mice did not meet criteria for euthanasia as stated in IACUC Policy 10, but research staff decided to euthanize to prevent possible infection in the rodent colony. Research staff also changed any cages where dried blood was observed. A total of six mice with wounds were euthanized at this time; three mice from the PBS vehicle groups and three mice from the (b)(4) groups were euthanized. Please note that the unexpected clinical signs were observed only in groups with multiple injections (in random animals either PBS or (b)(4) treated), but not in the 5-AED or PEG-400 treated groups (injected only once).

An emergency meeting was called with veterinary staff on Monday, July 27. Dr (b)(6) instructed research staff to continue with dosing with increased monitoring of injection technique by a vet tech for

Monday evening's dosing. Prior to this meeting, research staff placed green concern cards on three cages where animals exhibited open wounds. Directly after this meeting, research staff showed these animals to Drs. (b)(6) and photographs were taken for documentation. Two animals that were found dead at this time, one from the PEG-400 vehicle group and one from a (b)(4) group, were taken for histopathology analysis.

Research staff is continuing to monitor surviving animals closely in coordination with veterinary staff. The study will end on Aug 14, 2015.

Sincerely,

(b)(6) PhD
Principal Investigator, SRD

DOD ANIMAL CARE AND USE STANDARDIZED PROTOCOL FORMAT WITH EMBEDDED INSTRUCTIONS (October 2012)

Reference DOD Instruction 3216.01 & AFRRI Instruction 3216.2H

****

Information requested in the following animal use protocol template reflects the requirements of the Animal Welfare Act Regulations (AWAR), the Guide for the Care and Use of Laboratory Animals, and other applicable Federal regulations and DOD instructions.

****

This document is intended to be an aid in the preparation of DOD-sponsored animal use protocols. It is a companion document to an identical protocol template that does not have embedded instructions. Either template may be used to format DOD-sponsored animal research proposals; however, reference to the instructions during protocol preparation is highly recommended. If using the template with instructions, the instructions should be deleted prior to submitting the finished protocol for IACUC review. Please use Arial, regular, size 12, black font to prepare the protocol. With the exception of section headings, all paragraphs require a response. Paragraphs that do not apply should be marked N/A. There is no space limitation for responses to the information requested.

Approved standard operating procedures (SOPs) promulgated by the AFRRI Veterinary Sciences Department (VSD) or similar VSD-validated documents that describe specific procedures may be referenced by SOP number and title in lieu of repeating the details in the protocol. However, it is essential to include general descriptions of all animal manipulations to be carried out under the IACUC-approved protocol and to provide details where no approved references are cited. To do otherwise would constitute a breach of statutory regulations. Manipulations not covered in the originally approved protocol can be initiated only after IACUC approval of a formal amendment adding the new procedures. Additionally, Principal Investigators (PIs), or other delegated research personnel, should maintain accurate experimental records and be able to provide an audit trail of animal expenditures and use that correlates with their approved protocol. Protocol PIs will be required to provide this and other information during annual protocol reviews.

Any supporting information that may be of use to the IACUC during its review may be attached to the completed protocol. Adding subparagraphs within the body of the protocol template is permissible, *provided that the numbering sequence of paragraphs in the original standard format is maintained.* In other words, all of the labeled paragraphs and subparagraphs in this template must be retained, with additional information being presented as sub-numbered paragraphs containing information that supports or complements what is requested.

INTELLECTUAL PROPERTY STATEMENT

Research protocols drafted by Government scientists include intellectual property (e.g., concepts, ideas, experimental approaches, etc.), some of which is innovative or original and therefore considered proprietary to the investigators and/or the sponsoring agency. All Government and non-Government personnel handling this protocol shall exercise EXTREME CARE, to ensure that the information contained herein is NOT DUPLICATED OR DISCLOSED, in whole or part, for any purpose other than to evaluate the protocol, without the written permission of the principal investigator or the sponsoring agency.

AFRRI SCIENTIFIC RESEARCH PROTOCOL NUMBER:

I. NON-TECHNICAL SYNOPSIS

Development of large animal models for drug testing under the U.S. Food and Drug Administration (FDA) Two Animal Rule is still representing the main bottleneck for drug licensure and commercialization. In spite of the many promising drug candidates developed for the Acute Radiation Syndrome (ARS) and proven successful in rodents, only one drug (G-CSF, Neupogen®) has been approved by the FDA for use in nuclear/radiological emergency under an Emergency Use Authorization (EUA). Only three large animal models have been characterized for the ARS: the Non-Human Primate (NHP), the dog, and the minipig (M-P). However, both NHP and the dog have several practical and ethical limitations. High regulatory oversight, low availability, and public opinion sensitivity issues are among the major factors limiting the applicability of these animal models for drug testing. The minipig provides an ideal system for drug testing, of scientific rigor and efficacy equal to other non-rodent models.

We propose to continue to characterize the minipig (M-P) as a less controversial alternative non-rodent model of hematopoietic ARS (H-ARS) for the evaluation, development and licensure of radiation mitigators and therapeutics for use in a mass casualty scenario. To address FDA requirements that test drugs need to be assessed under the same conditions they will most likely be used (i.e. in combination with antibiotics, cytokines, etc), we will establish a probit curve at doses bracketing the hematopoietic syndrome in the presence of minimal supportive care, and we will follow survival for 60 days. In light of the relationship between poor nutritional status, weight loss and poor outcome after radiation treatments, and to align our model with other large animal models, we will provide nutritional supplementation together with minimal supportive care. Our hypothesis is that minimal supportive care and nutritional support will increase the hematopoietic LD50 and reduce the steepness of the slope.

Our approach significantly differs from what had been done by us in the past and from what currently is being done by other centers working with the M-P model. Our (b)(4) project focuses on nutritional support in pediatric animals, and our (b)(4) project evaluates the effect on 30-day survival of gentamicin+amoxicillin, rimadyl, oral hydration (through a watered down preparation of pumpkin or applesauce) and blood products in adult animals. The current protocol uses adult animals and addresses not only minimal medical management but also nutritional supplementation and extended survival time (60-day period), to be in alignment with other large animal models.

II. BACKGROUND

II.1. In case of the Acute Radiation Syndrome (ARS), damage to a specific organ appears to affect proper function of many other organs, and multiple organ failure (MOF) is being recognized as one of the main causes of radiation-induced lethality. Swine display close similarity to humans in terms of overall organ anatomy and physiology and have been extensively used in biomedical research in a variety of areas (cardiovascular, gastrointestinal, metabolic, liver, reproductive and infectious disease). We therefore selected the minipig because of its physiological properties similar to humans across several organs (14), with the expectation that it will more faithfully reproduce the physiopathology of MOF observed in ARS, and will provide an ideal tool for drug efficacy testing for total body irradiation (TBI).

(b)(4) We have taken a step-by-step approach to the development of the minipig as an animal model for drug testing [redacted] and we established a basic model for the hematopoietic Acute Radiation Syndrome (H-ARS) [redacted] in the absence of supportive care and under TBI conditions, and characterized dose-response relationship for the Gottingen minipig at doses spanning from H-ARS to GI-ARS. During our past studies, we have optimized procedure for housing, handling and sampling in the M-P. Animals were kept on a calorie-restricted diet, as per provider recommendation, to maintain the small size characteristic of this animal. Use of a vascular access port [redacted] allowed us to obtain serial samples and to analyze hematological changes over time, hematopoietic progenitor stem cells, kinetics of DNA damage/repair and residual foci (gamma-H2AX), circulating citrulline levels and microbiological status. From those studies, we demonstrated that the bone marrow syndrome (H-ARS) in the minipig closely resembles that in humans and other large animal models. The sequence of sign development, dynamics of hematological cell loss, susceptibility to infection and occurrence of multi-organ dysfunction leading to death, all confirmed the potential validity of this model to study ARS [redacted] Kinetics of DNA double strand break formation and repair were nearly identical between M-P, humans and NHP [redacted] Administration of G-CSF to irradiated minipigs stimulated recovery of bone marrow, induced mobilization of progenitor stem cells, hastened neutrophil recovery and increased survival, similarly to what was described for NHP, canine and mouse models of ARS (6), confirming the high potential of the model for radiation countermeasure screening. The only major difference between M-P and other animal models or human was represented by extensive hemorrhages and a significant lower LD50 (no supportive care): M-P 1.73 Gy (3) and 1.96 Gy [redacted] -personal communication); dog 2.6 Gy (6); human 3.2-4.5 Gy (7-9); NHP 4.9 – 6.71 Gy) [redacted]

(b)(4) (b)(4) (b)(4) (b)(6) (b)(4)

During our previous proof-of-concept study, survival was followed for 30 days, and the animals were kept on a calorie-restricted diet as per provider recommendation. Here we propose to address the sensitivity of the minipig to radiation using minimal supportive care and nutritional supplementation. Our ultimate goal is to characterize the model for testing of medical drugs to be used in a mass casualty scenario, under the FDA Animal Rule. In a mass casualty scenario, the standard of care used for small-scale accidents (administration of antibiotics, iv fluids, parenteral nutrition, and blood products) may be problematic. We will use minimal supportive care (defined here as antibiotics and dietary supplementation –no iv fluids, blood products or parenteral nutrition), as a potential tool for testing drugs relevant to Warfighter population as well as civilians. Nutritional intake will be increased with a diet containing 20% protein instead of 16% (historical diet, Tekland 8753), to be comparable to that in dogs and NHP. The amount of food provided will be equivalent to 3-4% of body weight, instead of 2.3-3.3% as recommended by Marshall Bioresources (Gottingen minipig provider) (see Appendix 1: Housing and Feeding of Gottingen Minipigs). Because of the possibility of potential delayed mortality, dissociated hematologic recovery, and secondary relapse, we will extend the observation period to 60 days, as routinely done for NHPs.

II.2. Literature Search for Duplication
II.2.1. Literature Sources Searched BRD, RePORTER, PubMed
II.2.2. Date of Search January 6, 2014
II.2.3. Period of Search
BRD: 1998 – 2009
RePORTER: 1998-2013
Pubmed: 1998-2013

II.2.4. Key Words of Search
Minipigs OR pigs OR swine AND Radiation AND supportive care OR antibiotic

II.2.5. Results of Search
Search of the combination minipig OR pig OR swine AND radiation AND supportive care did not result in any document.

Search of the combination minipig OR pig OR swine AND radiation AND antibiotic resulted in articles about dermal phototoxicity, vascular access port implantation (our publication), dentine formation, bone marrow transplantation, restenosis, ex vivo ocular toxicity, and effect of antibiotic on small intestine mucosa. These studies are irrelevant to our project. Other articles met the key words search criteria but were not relevant to this study as they pertained to Guinea pigs or ex vivo/in vitro observations.

III. OBJECTIVE / HYPOTHESIS

Rationale: in order to develop a new countermeasure under the FDA Animal Rule, it is required that the mechanism of action are understood and the interaction between test drug and supportive care (additive, synergistic, antagonistic or none) is investigated. Recommendations for medical management of radiation victims under mass casualty scenario requiring immediate and delayed treatment include administration of antibiotics and routine care. It is therefore imperative to develop an animal model that will mimic conditions under which mitigators will be administered. It is reasonable to assume that antibiotics, oral fluids and nutritional support will be available in a mass casualty scenario.

Hypothesis: it is possible to estimate the dose response relationship (DRR) for total-body gamma-irradiation and moribundity in a M-P model of H-ARS, in the presence of minimal supportive care (antibiotics, and nutritional support). The resulting probit curve will provide estimates of lethal doses ranging from the LD10/60 to LD90/60, to be used for testing radiation countermeasures.

IV. MILITARY RELEVANCE

According to the DoD Chemical and Biological Defense Program 2009 Annual Report to Congress: "Although the overall number of nuclear weapons continues to decline because of Russian and U.S. treaty commitments, the United States anticipates an increase in weapon numbers in China, India, and Pakistan. Motivated by economic and strategic interests, Russia and China (or political entities in each) and North Korea continue to supply technologies and components that are dual use and could support weapons of mass destruction and missile programs, especially in the Middle East and South Asia. Iran continues to develop its enrichment program in defiance of United Nations (U.N.) Security Council resolutions and also continues to build a heavy water reactor in Arak, which will be capable of producing plutonium that could be weaponized. While North Korea has halted portions of its nuclear program, it is possible that it has stockpiled several nuclear weapons from plutonium produced at Yongbyon. Non-nuclear radiological dispersal devices (RDD) and radiological exposure devices (RED) pose a significant potential threat especially in the hands of non-state groups. Contamination and recovery issues associated with operating in a radiological environment remain significant concerns for military operations and underscore the need for robust detection, protection, and decontamination systems."

An important barrier to advanced development of radiation countermeasures is the paucity of large, long-lived, non-rodent animal models of radiation injury. The only choices at present are NHPs and canines. The advanced evolutionary stage of NHPs, and the danger of working with NHPs, are also disadvantages. Canines are notoriously sensitive to NSAID and vomiting. The addition of miniature swine to available large animal radiation injury models will facilitate development of promising countermeasures.

V. MATERIALS AND METHODS

V.1. Experimental Design and General Procedures

The purpose of this study is (i) to establish the effect on the survival of irradiated minipigs of a prophylactic empirical antibiotic regimen, similar to that likely to be administered to patients in case of a radiological accident, in combination with dietary supplementation; and (ii) to build a novel probit curve under these conditions. The expected results from empirical antibiotic treatment and dietary supplementation are a higher LD50 and a less steep dose-survival curve.

Primary endopoints will be 60 day survival. Secondary endpoints will be CBC-counts, clinical signs, gross- and histo-pathology, and C-reactive protein. Measurements of blood elements and circulating analytes will be useful to establish the utility of the minipig as a biodosimetry model and will provide a useful term of comparison for intra- and inter-laboratory validation efforts.

Prophylactic empirical antibiotic regimen.
Guidelines for treatment of neutropenic patients from chemotherapy and from ablative radiation treatment

for hematopoietic stem cell transplantation (13; 14; 15), as well as prototype medical orders during a radiation incident (17) suggest administration of prophylactic empirical antibiotic treatment to reduce the risk of infections. Antibiotic prophylaxis with fluoroquinolones is recommended for afebrile neutropenic patients (15), as it significantly reduces all-cause mortality for cancer patients following chemotherapy (16). Broad spectrum oral fluoroquinolone plus amoxicillin/clavulanate are among the recommended antibiotics for initial empiric therapy in neutropenic patients; length of treatment is based on bone marrow recovery and attainment of stable neutrophil levels above neutropenia. In case of resistance to fluoroquinolone (fever for >3-5 days during fluoroquinolone treatment), it is recommended to switch to gentamicin+amoxicillin/clavulanate (NCCN), and to start on oral triazole (antifungal) if fever still persists for >3-5 days.

A number of micro-organisms have been identified in the blood and tissues of the irradiated minipigs (b)(4),(b)(6) Gram-positive (*Staphylococcus aureus, S. chromogenes, S. saprophyticus, S. warneri, Streptococcus agalactiae, S. alactolyticus, S. dysgalactiae* ssp. *equisimilis, S. infantarius* ssp. *coli, S. mitis/S. oralis, Streptococcus anginosus, Streptococcus bovis, Streptococcus hyointestinalis, Enterococcus cecorum, E. columbae, E. faecalis, Enterococcus faecium, Enterococcus hirae,* Enterococcus sp., *Gemella morbillorum,* Leuconostoc mesenteroides ssp. cremoris, *Actinomyces naeslundii,* Bifidobacterium sp., *Lactobacillus gasseri, Actinomyces naeslundii,* Corynebacterium sp.), Gram-negative (*Acinetobacter baumannii, Aeromonas hydrophila, Escherichia coli, Klebsiella pneumonia,* ssp. *pneumoniae, Pasteurella penumotropica, Pseudomonas aeruginosa*), Yeast (*Candida tropicalis*). The variety of opportunistic pathogens that is capable of producing infections in the minipig justifies the use of broad spectrum antibiotics and anti-fungal that we propose to use for prophylactic empirical antibiotic regimen.

We will follow the regimen for neutropenic, afebrile patients suggested by the American Society of Cancer Oncology, ASCO (15), and the guidelines from the Department of Health and Human Services, Radiation emergency medical management and the Radiation Injury Treatment Network, RITN (17). Furthermore, we will define neutropenia as neutrophil counts <500/μL (18) to be in alignment with the NHP model, and we will use this parameter as trigger point to start/end treatment.

We will start treatment at ANC<500/μL or expected to decrease to <500/μL within the next 48 hours, with or without concurrence of fever (Table 2). We will administer levofloxacin plus amoxicillin/clavulanate (po) for 3 days or until bone marrow recovers and ANC remain stable above >500/μL. In case of resistance to levofloxacin (temperature higher than 39° Celsius for >3-5 days during fluoroquinolone treatment), we will switch to a different class of antibiotic and we will use gentamicin in combination with amoxicillin/clavulanate (13). If fever still persists for >3-5 days, we will switch to fluconazole. Oral administration of drugs is preferred over iv administration because of negative impact of venipuncture on animal survival. Oral administration is also likely to be preferred in case of mass casualties due to limited availability of infrastructure for iv administration of drugs. The table below summarizes drug regimen. If the animals show an adverse reaction to levofloxacin, we will switch to ciprofloxacin.

Table 1: Prophylactic empirical antibiotic regimen: trigger points to start/end treatment	
ANC<500/μL or expected to decrease to <500/μL within the next 48 hours	**Start** levofloxacin plus amoxicillin/clavulanate
ANC stable above >500/μL (2 consecutive CBC reading at 3-4 days distance) and T<39° C	**Stop** treatment
If T > 39° C for >3-5 days while taking levofloxacin	**Stop** levofloxacin plus amoxicillin/clavulanate. **Start** gentamicin plus amoxicillin/clavulanate. Administer until ANC stable above >500/μL (2 consecutive CBC reading at 3-4 days distance) and T<39° C
T > 39° C for >3-5 days while taking gentamicin	**Stop** gentamicin plus amoxicillin/clavulanate. **Start** fluconazole plus amoxicillin/clavulanate. Administer until ANC stable above >500/μL (2 consecutive CBC reading at 3-4 days distance) and T<39° C

Levofloxacin (LEVAQUIN®)
Levofloxacin is a fluoroquinolone agent for oral and intravenous administration with antibiotic activity against a broad spectrum of Gram-negative and Gram-positive bacteria responsible for infections to the respiratory, urinary and gastrointestinal tract. Spectrum of activity includes the Gram- negative *Escherichia coli, Haemophilus influenzae, Klebsiella pneumoniae, Legionella pneumophila, Moraxella catarrhalis, Proteus mirabilis,* and *Pseudomonas aeruginosa,* and the Gram positive *Staphylococcus Aureus, Streptococcus pneumoniae, Staphylococcus epidermidis, Enterococcus faecalis, and Streptococcus pyrogenes*), as well as atypical bacterial pathogens (*Chlamydophila pneumoniae* and *Mycoplasma pneumoniae*). Fluoroquinolones (ciprofloxacin and levofloxacin) are widely used in the treatment of human disease and are likely to be used in the event of radiation exposure to prevent infections. Because levofloxacin exhibits enhanced activity against *Streptococcus pneumoniae* with respect to ciprofloxacin, we selected to characterize the model in the presence of levofloxacin although we maintain ciprofloxacin as a possible alternative in case oral administration of levofloxacin proves difficult in the minipigs. Table 2 below summarizes drug administration routes and doses.

Amoxicillin/clavulanate (Augmentin)
Amoxicillin/clavulanate is an oral antibacterial combination consisting of amoxicillin and the beta-lactamase inhibitor, clavulanate potassium. Amoxicillin is a semisynthetic, third generation penicillin (beta-lactam antibiotic); clavulanate is a beta-lactam that inhibits beta lactamase, the major bacterial enzyme responsible for penicillin resistance. Amoxicillin/clavulanate is used to treat mild-to-moderate bacterial infections including sinusitis, bronchitis, and otitis media. Amoxicillin/clavulanate is the recommended antibiotic to be used in combination with fluoroquinoloes for empiric therapy regimen (Flower, 2013). Table 2 below summarizes drug administration routes and doses.

Fluconazole (DIFLUCAN®)
Fluconazole, an oral triazole, is a drug used in the treatment and prophylaxis of superficial and systemic fungal infections. Fluconazole is effective against a number of fungi including Candida. Table 2 below summarizes drug administration routes and doses.

Table 2: Prophylactic empirical antibiotic regimen: drug dosage and modality of administration	
Drug	**Regimen/route**
Levofloxacin (Levaquin)	500 mg SID, po *
Ciprofloxacin	2.5 - 7.5 mg/kg, BID, po. *
Gentamicin	2-6 mg/kg SID, po. *
Amoxicillin/clavulanate	11-13 mg/kg every 12-24 h, po. *
Fluconazole (Diflucan)	10-12 mg/kg, SID, po. *

*or iv or im if PO not possible, at dosage prescribed by and in consultation with VSO veterinarian or assigned stufy veterinarian

Dietary supplementation

In our initial, historical studies we have been using a 16% protein diet for minipigs and we have kept the animals on a calorie-restricted diet in order to avoid excessive weight gain, as per provider recommendation (Marshall Bioresources, see Appendix 1). No supportive care was given to the animals after irradiation. Indeed, it is well known that nutritional support for cancer patients undergoing radiation therapy is vital, and other large animal models (dogs and NHPs) receive supportive care after irradiation, to include nutritional support rich in proteins, anti-oxidants and fats.

For the current study, we will increase the food amount to 3-4% (grams/animal kg) instead of 2-3% as recommended by the vendor. We will use a "starter" diet for minipigs which has a higher content of proteins (20% instead of the 16% protein content, as done in our previous studies); the diet will be supplemented with fatty acids and probiotics to counteract the effects of antibiotics on the intestinal flora (Table 1). The proposed nutritional support is what is currently been used for piglets (ongoing study, approved protocol (b)(6) has shown no adverse effects and has provided some advantage in terms of survival at 2 Gy (preliminary data, n=3 per radiation dose). Traditional enrichment will be maintained as part of the diet.

Nutritional support	
Starter diet (i.e. 5080 from Quality Lab Products)	20% protein, 4% grams/kg animal (average for group of animals and updated on a weekly basis)
Probiotics	approximately 2 grams, daily
omega-3 fatty acids	DHA, 1 capsule every 3 kg body weight
electrolytes, hydrating gels	as needed
milk formula	up to 20ml/kg, twice a day as necessary
yogurt	daily
nutritional support if not eating solid food	as needed, includes additional milk formula
only canned/dried fruits and vegetables	as needed
metamucil	as needed

Probit curve

Briefly, a vascular access port (VAP) will be implanted approximately one-to-two weeks after the arrival of animals at AFRRI, to facilitate collection of blood samples. Three weeks after VAP implantation, we will expose minipigs to a range of doses of whole-body gamma irradiation to bracket the hematopoietic

syndrome. Animals will be administered the minimal supportive care listed in Table 1, and survival will be observed for 60 days.

V.1.1. Experiment 1: LD50/60 range finding pilot study

To limit the number of animals used, we will adopt the "range finding approach" for the initial assessment of a rough estimate of the LD50/60.

In toxicology, the purpose of conducting a dose range finding study is to establish a dose response and to provide preliminary data to enable appropriate dose selection for full-scale studies (15). A range-finding test ordinarily consists of a down-scaled test in which small groups of animals are exposed to several widely-spaced doses, to estimate the LD50/60. The study design usually includes an assessment of basic toxicological parameters including clinical observations, hematology, chemistry and pathology. This study design is in alignment with 'three R' concepts for animal welfare (refinement, reduction, and replacement) and is intended to obtain optimal, standardized study conditions for protocol transferability and data reproducibility.

In Experiment 1, we will use 2 animals per dose and we will test 4 separate doses for each of three reiterations (24 animals, total). Since administration of supportive care in other species (i.e. dogs, NHP) and in humans increased survival so that the LD50 was shifted of up to 0.5-2 Gy, we will test doses ranging between 2.0 and 3.5 Gy, given that the LD100 in the M-P in the absence of supportive care is 2.0 Gy. Initially we will test doses equivalent to 2.0, 2.5, 3.0 and 3.5 Gy (2 animals per dose; group A). Based on the results of the group A, we will then refine the dose interval in consultation with the statistician, and perform 2 additional experiments, each consisting of 4 doses and 8 animals (2 animals per dose; group B and C). This pilot study will provide a rough estimate of the LD50, as well as the doses bracketing the hematopoietic syndrome (LD10 and LD90).

Animal requested for experiment 1: 2 animals/dose, 12 doses = 24 animals

V.1.2. Experiment 2: **Construct a full lethality probit curve to be used for establishing radiation doses during countermeasures drug testing**

For the generation of the dose-response curve, the LD30, 50 and 70 will be estimated using the probit method, and including results from experiment 1 (pilot study). This method allows for construction of confidence intervals to describe the precision of the estimated lethal doses. The width of the confidence interval depends on the number of doses, number of animals per dose, and the slope of the dose-response curve, and a narrow interval indicates a more reliable estimate. We propose to use five doses and six animals per dose (0.6 Gy/min, TBI, Cobalt-60). Doses will be evenly spaced. Minipigs already irradiated at those doses in the pilot study will be incorporated into the data from this experiment, to increase statistical power.

Animal requested for experiment 2: 4 animals X 5 doses = 20

V.2. Data Analysis

The dose response relationship (DRR) will be plotted as probit percent mortality versus linear dose. Probit regression analysis will be used to generate the probit curves, using the PASW Statistic 18 software (SPSS Inc, IL, USA), and preliminary values for LD30, LD50, and LD70 will be obtained. For a sample size of 6 per dose (including 2 per dose from experiment 1), a dose-response curve ranging from 1.5 to 3.5 Gy with mortality rates of .1, .3, .5, .7 and .9 percent for the five doses, the expected width of the 95% confidence interval for the LD50 will be 1.5 Gy, and the expected width of the 95% confidence interval for the LD30 and LD70 will be 2.5 Gy. Expected confidence interval widths are based on the average of 1,000 simulated data sets using the study design and mortality parameters indicated. Actual confidence interval widths will vary depending on the specific doses selected and the slope of the dose-response curve.

V.3. Laboratory Animals Required and Justification

V.3.1. Non-animal Alternatives Considered.

The purpose of this project is to determine the effect of minimal supportive care on survival. There is no computer model or tissue culture that can mimic the effect of radiation on the whole organism and predict lethality. Survival depends on an intricate network of organ cross-talks and cellular microenvironment that cannot be recreated *in vitro*. Consequently, administration of supportive care to cellular components grown *in vitro* will not allow any assessment on survival. Effect of supportive care also cannot be reproduced *in vitro*.

We do not know all of the cell types and tissues involved in radiation injury or how radiation injury causes lethality. The concept of multi-organ failure has been suggested, but how the injured organs affect each other's vital functions is unknown. The present state of the art of tissue culture is still incapable of reproducing the *in vivo* relationships. Computer modeling is similarly limited by lack of full characterization of the biological elements and interactions under study.

These considerations are consistent with the FDA requirement for preclinical research in both small and large mammals before granting approval for drug testing in humans.

V.3.2. Animal Model and Species Justification
We have been developing the adult Gottingen minipig as an additional large animal model for the study of the ARS and advanced development of radiation countermeasures. Large, long-lived, and development-matched models are required for drug studies submitted to the FDA for licensure applications. The close similarity to humans in anatomy and physiology of organs such as the liver, pancreas, kidney and heart has made the pig the primary species of interest as organ donors for xenographic procedures. Minipigs are routinely used for toxicity testing. As such, further and rapid characterization at physiological, molecular and genetic level of the minipig is likely to occur, thus increasing acceptance of this model and facilitating advanced drug development. Our previous studies have employed male Gottingen minipigs to develop a probit curve. Since we are testing the effect of minimal supportive care on survival and we are using our own historical data as one of the terms of comparison, we will continue to use male minipigs for this study.

V.3.3. Laboratory Animals

V.3.3.1. Genus / Species *Sus scrofa domestica*

V.3.3.2. Strain / Stock Gottingen

V.3.3.3. Source / Vendor Marshall BioResources/Marshall Farms Group Ltd

V.3.3.4. Age Approximately 4 months at arrival

V.3.3.5. Weight Age appropriate (9-11 kg)

V.3.3.6. Sex Male

V.3.3.7. Special Considerations NA

V.3.4. Number of Animals Required (by species): 46

V.3.5. Refinement, Reduction, Replacement (3 R's)

V.3.5.1. Refinement
The study data-points currently mandated by the FDA for approval of radiation countermeasures under the Animal Efficacy Rule is mortality. Hence the primary study data-point in our development of Gottingen minipigs as a model for ARS is survival. Moribundity will be used as a surrogate for mortality, and

euthanasia will be used in order to minimize pain and distress, using an extensive set of criteria (see animal endpoints, paragraph V.4.5 – Lethargy, weight loss, temperature, respiratory distress, food intake, bleeding etc). Animal care and use procedures will only be performed by trained personnel. We have considerable experience in the care and handling of minipigs. Extensive human interaction every weekday will reduce stress in the animals. Use of slings, topical anesthetics, and the catheters will minimize distress during blood collections and the animals will be gradually acclimated to the slings for these procedures.

V.3.5.2. Reduction
Control animals used to optimize protocols for animal handling, housing and blood draw will be used also to obtain data on growth of normal animals, and to set up dosimetry for future studies and to obtain baseline CBC data in pediatric animals. For irradiated animals, blood samples obtained from minipigs before irradiation will serve as controls, thus reducing the number of animals required for this study. Use of historical controls will also reduce the number of animals needed for this study.

V.3.5.3. Replacement NA

Totals:				**46**	**46**

V.4.1.2. Pain Relief / Prevention

V.4.1.2.1. Anesthesia / Analgesia / Tranquilization
Irradiation
Prior to irradiation, animals will be sedated with Telazol® (Telazol, 6-8 mg/kg *IM*, Fort Dodge Laboratories, IA). Alternatively, Telazol® (4.4 mg/kg *IM*), in combination with dexmedtomidine (0.05-0.1 mg/kg *IM*) or ketamine (20 mg/kg *IM*)/xylazine (2 mg/kg *IM*) can also be used for sedation. Atropine (0.5 ml *IM* or *IV*; atropine sulfate, Butler, Columbus, OH) or glycopyrrolate (0.01 mg.kg) may be given to reduce mucosal secretions. At the end of the irradiation procedure, once the animals are back in their quarters, dexmedetomidine can be reversed by atipamezole *IM* (same volume as dexmedotmidine) to facilitate recovery.

Blood sampling
Animal may be sedated at the time of blood sampling and administration of minimal supportive care with Midazolam (0.1-0.5 mg/kg s.c.or *IM*), or acepromazine (1.1 mg/kg *IM*), 10 minutes prior to venous access. Telazol or Telazol +dexmedetomidine or Ketamine + Xylazine or isoflurane could be used as an option as well.

V.4.1.2.2. Pre- and Post-procedural Provisions
Irradiation
Pre-Irradiation: Animals will be fasted overnight (approximately 16–18 h) and sedated as described above. Once sedated in the VSD animal facility, minipigs will be transported to the AFRRI cobalt facility in an approved, covered transport cage. Heart rate and temperature will be measured prior to irradiation. At least one vet tech or one veterinarian will be present at the time of irradiation. Immediately before irradiation, the vet or vet tech will determine whether or not to administer additional sedative to keep the animal asleep during irradiation.

Irradiation procedure: To enable proper positioning, anesthetized animals will be strapped in place into slings in polyvinylchloride PVC frames for irradiation. Effect of anesthesia will be monitored in real time through video cameras positioned in the Cobalt waiting area; if, during irradiation, signs are observed that the animal is attempting to get loose, we will immediately stop the irradiation and we will promptly recover the minipig. Minipigs will be removed from the slings once irradiation is completed. Once in the procedure room adjacent to Cobalt and before returning the minipigs to their home cages, temperature will be taken with the transponder or rectally; heart rate will be measured using a stethoscope. .

Post-Irradiation: After irradiation, animals will be transported back to their cages, where they will be allowed to recover from sedation under the careful surveillance of VSD and/or research staff who will monitor vital signs and provide thermal support (e.g. Bair Hugger blanket) if necessary. Atipamezole *IM* (same volume as dexmedetomidine) may be used to reverse the anesthetic effect of dexmedetomidine.

V.4.1.2.3. Paralytics N/A

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures

V.4.1.3.1. Sources Searched Altweb, Pubmed

V.4.1.3.2. Date of Search

V.4.1.3.3. Period of Search All available

V.4.1.3.4. Key Words of Search The aspects of the study relevant to alternatives to painful or distressful procedures are the sequelae to exposure to TBI at doses causing ARS. We used the following key words in the search for alternatives: swine, radiation, ARS, sequelae, pain, distress, alternatives

V.4.1.3.5. Results of Search
Cell culture based alternative were found to study the intestinal barrier function of piglets and for organ specific drug toxicity testing. However techniques are not fully developed yet and are not representative the entire organism.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification
Depending upon the irradiation dose irradiated animals die due to compromised immune responses and opportunistic infections. The percentage of surviving animals is the indicator of the efficacy of a countermeasure. We are not planning to administer analgesics post-irradiation, as NSAID may aggravate bleeding disorders in combination with the radiation-induced thrombocytopenia, and opiates can induce sedation and drowsiness and may confound proposed euthanasia criteria. However, we are providing

minimal supportive care in terms of antibiotics, and fluids/ nutritional support to increase survival. Use of supportive care is expected to mitigate the pain associated to the sequelae of irradiation.

V.4.2. Prolonged Restraint
Only short periods of restraint in the sling (<30 minutes) will be necessary for blood collections and the irradiation procedure. To minimize discomfort, we have designed a new type of sling that uses softer, elastic material to support the animal, and utilizes a more efficient restraint design that maintains the animal in place while reducing manipulation by technicians and consequently stress to the animals. After the quarantine period, animals are acclimated to the sling for 5-10 minutes, 2-3 times before initiating blood draws. Acclimation to the sling is very rapid and non-stressful; animals are petted and gently spoken to while restrained. It has been our experience that resting on the sling does not agitate the animal at all. Animals are anesthetized and transported to the Cobalt Facility holding area before being put into slings for irradiation (<20 minutes). Animals will be kept under continuous observation while in the sling. Slings will be spot-cleaned between animals and sent to wash at the end of each collection day; slings will be sanitized at the conclusion of each irradiation day.

V.4.3. Surgery: implantation of vascular access port (VAP).

V.4.3.1. Pre-surgical Provisions Animals will be cared for according to section V.5.1. They will be fasted overnight (approximately 16 – 18 h) prior to VAP implantation surgery.
For antibiotic, Cefazolin sodium 20 mg/kg *IV* or ampicillin sodium 10-20 mg/kg *IV* will be given just prior to the surgery, or intra-operatively, for prophylaxis. At the time of surgery, a temperature microtransponder (Implantable Electronic ID Transponder IPPT-300, Bio Medic Data Systems, Seaford, DE) will be implanted subcutaneously behind the neck, over the shoulder opposite to the site of VAP surgery, to facilitate body temperature measurements.

V.4.3.2. Procedure(s) VAP catheters (SoloPort subcutaneous access port, either PMID or MID model; Instech Solomon, PA) will be surgically implanted in the right external jugular veins under general anesthesia according to the principles of aseptic surgery. Animals will be lying on their back; vital signs will be taken at regular intervals by vet techs. The catheter tip will be introduced through a 2-3 mm incision in the right jugular vein and advanced to the junction of the external jugular vein and vena cava. Prior to securing the VAP catheter within the vein, sutures will be used to ligate the vessel just cranial to the insertion point of the catheter tip. Additional ligature will be placed around the caudal portion of the vessel containing the VAP catheter and retention bead, with 1 ligature on either side of the bead. The port will be secured within the incision site on the neck to the underlying musculature by use of sutures, at a minimum of 2 of the 5 anchor holes on the port. Sutures will be 3-0 PDS or others (with the exception of silk) as deemed appropriate by surgeon. Catheter function will be confirmed intra-operatively through aspiration of locking solution and withdrawal of a blood sample via the septum. The port reservoir and catheter will be flushed again with 6 ml saline and locked with 3 ml of a heparin lock flush solution (100 IU/ml) all subsequent lock solutions will be heparin (100 IU/ml).

During closure of the surgical sites, special attention will be given to eliminating dead space around the port and around the catheter loop on the neck. The muscle and subcutaneous layers will be closed with sutures. Skin incisions will be closed in a continuous intradermal pattern. Tissue glue (VetBond, 3M, St Paul, MN) may be used to help seal surgical sites as necessary to help prevent contamination.

V.4.3.3. Post-surgical Provisions Pre-, intra- or postoperative intramuscular buprenorphine (0.01 to 0.02 mg/kg; Buprenex, Reckitt Benckiser, Richmond, VA) or Carprofen (2.2 mg/kg) will be provided for analgesia before full recovery from anesthesia. Additional post-operative analgesia will be given as Carprofen (2.2 mg/kg *po* BID) for three days starting the day after surgery, or as recommended by an AFRRI veterinarian in consultation with the PI. Alternatively, fentanyl transdermal patch at 5mcg/kg/hr or buprenorphine sustained release 0.12 – 0.27 mg/kg sc for analgesia can be used as determined by the veterinarian. The fentanyl patch, if used, will be applied to a shaved portion of skin and secured. It takes approximately 12 hrs for the fentanyl patch to take effect. Animals will continue to be monitored until fully

recovered from anesthesia; they will be returned to their home cage when ambulatory. Supplemental heat may be provided in the home cage post-operatively (e.g. Bair Hugger warm air blanket)

After surgery, 25-50 mg/kg trimethoprim-sulfa *po* (500 mg *po* for 10 kg pig or 5mg/kg im), *SID*, will be given for 5 days or more as determined by veterinarian to lessen the risk of post-op infection. Alternatively, enrofloxacin 5-10 mg/kg iv/po can be given every 24 hrs for 3-5 days or more if needed as determined by the veterinarian. Convenia 5-10 mg/kg sc may be used as an antibiotic as determined by the veterinarian. The advantage of this antibiotic is that the single injection provides protection against the bacterial infection for several days.

Postsurgical recovery and pain will be monitored twice daily by visual examination of the incisions and overall conditions of the animals. Parameters monitored will be food and water intake, activity, alertness, vocalization, guarding, and response to human contact.

V.4.3.4. Location VSD surgical suite

V.4.3.5. Surgeon Surgeons will be AFRRI veterinarians

V.4.3.6. Multiple Major Survival Operative Procedures NA

V.4.3.6.1. Procedures

V.4.3.6.2 Scientific Justification

V.4.4. Animal Manipulations

V.4.4.1. Injections

All injections listed in section **V**.4.1.2.1 will be administered *im, sc*, using sterile needles (23 – 21 gauge) and syringes, or iv through the catheter or *po*.

V.4.4.1.1. Pharmaceutical Grade Drugs

Bactrim (sulfamethoxazole and trimethoprim)
Lidocain (5%), topical
Telazol®
Ketamine/xylazine
Atropine atropine sulfate
Heparin lock, IV
Saline
Metamucil
Levofloxacin
Ciprofloxacin
Gentamicin
Amoxicilline/clavulanate
Fluconazole
Midazolam
Acepromazine
All the drugs listed above are ordered from veterinary product distributors by VSD and they all are pharmaceutical grade drugs.
Atipamezole (Antisedan, Pfizer)
Dexmedtomidine (Dexdomitor, Pfizer)

V.4.4.1.2. Non-Pharmaceutical Grade Drugs NA

V.4.4.2. Biosamples

Collection of blood samples. We will obtain blood samples from the VAP or from peripheral veins. If the VAP fails, the sample will be collected from accessible peripheral vessels (see section **V.4.4.7. Other Procedures**). Mean blood volume for pigs is 55-65 ml/kg. at arrival, animals weigh approximately 9 kg and gain 0.5 kg per week. Up to 1% of total blood will be drawn per time point (corresponding to 4.9 ml - 5.8 ml for a 9 kg animal), and no more than 7.5 % per week.

Depending on the volume of blood taken, appropriate recovery time will be allowed between sampling intervals (21, 22):
0.75% circulatory blood removed = 1 day recovery period
7.5% circulatory blood removed = 1-2 weeks recovery period

Collection of samples will be performed with the minipig restrained in a sling; at the same time, we will take vitals. The entire procedure takes less than 30 min. After blood draw, animals will be returned to their cages and checked to ensure that the needle puncture wound is closed and the blood has clotted. Blood samples will be obtained at these time points: with day 0 being the day of irradiation, we will collect blood at -2 weeks, -1 week, -1 day, day 0 and on days +1, +2, +3, +7, +10, +14, +17, +20, +23, +27, +35, +42, +49, +56 and at euthanasia.

Time point (day)	volume	% total blood volume*	Total % blood volume (Cumulative volumes from the beginning of the study)
-14	1 ml	0.17	0.17
-7	3 ml	0.5	0.67
-1	3 ml	0.5	1.17
0	1 ml	0.17	1.34
1	1 ml	0.17	1.51
2	1 ml	0.17	1.68
3	1 ml	0.17	1.85
7	1 ml	0.17	2.02
10	1 ml	0.17	2.19
14	1 ml	0.17	2.36
17	1 ml	0.17	2.53
20	1 ml	0.17	2.7
23	1 ml	0.17	2.87
27	1 ml	0.17	3.04
35	1 ml	0.17	3.21
42	1 ml	0.17	3.38
49	1 ml	0.17	3.55
56	1 ml	0.17	3.72

*Assuming a body weight of 9kg and total blood volume of 585 ml

Dates of collection may be changed by +/- 48 hours or collection may be cancelled if contingencies arise. VAPs will still be flushed at least once a week.

Tissue and histological samples. Tissue samples, to include organs, blood and hair may be taken at the time of euthanasia for tissue blocks and for frozen tissue repository.

V.4.4.3. Adjuvants NA

V.4.4.4. Monoclonal Antibody (MAb) Production NA

V.4.4.5. Animal Identification Tattoos or ear tags and cage cards/tags

V.4.4.6. Behavioral Studies NA

V.4.4.7. Other Procedures
Catheter implantation

Temperature transponder At the time of catheter implantation, a temperature microtransponder (Implantable Electronic ID Transponder IPPT-300, Bio Medic Data Systems, Seaford, DE) will be implanted subcutaneously behind the neck, over the shoulder opposite to the site of VAP surgery, to facilitate body temperature measurements.

Blood draw from peripheral veins. Alternatively, if VAP fails we will collect blood from peripheral veins such as auricular, femoral, cephalic, saphenous, cranial vena cava.. Animals may be sedated at the time of blood sampling and administration of minimal supportive care (see section V.4.1.2.1) if necessary, following the recommendations of an AFRRI veterinarian. All procedures will be entered into the experimental record. Lidocaine (5% ointment) may be applied topically to the site of venipuncture to minimize discomfort to the animals about 15 minutes before starting the procedure; site will be cleaned with alcohol.

Health check status
Body weights and standard animal health check status (hydration status, hair coat, skin quality, vitals) will be determined at least once prior to treatment, on the first day of treatment, and on days of blood collection. Body temperature will be determined during week-days between 7 am and 4 pm, and on weekends if there are animal concerns. The time of each temperature collection will be recorded for each minipig. Monitoring will be increased during critical period.

V.4.4.8. Tissue Sharing Bio-samples (**V.4.4.2. Biosamples_Tissue and histological samples**) will be collected, to be used for histo-chemistry/protein/molecular assays among others, and to be shared with collaborators upon request and as experiments permit

V.4.4.9. Animal By-Products

V.4.5. Study Endpoint The data-point currently mandated by the FDA for approval of radiation countermeasures under the Animal Efficacy Rule is moribundity or mortality. Moribundity will be used as a surrogate for mortality, and euthanasia will be used in order to minimize pain and distress. Euthanasia will be carried out when any one of absolute endpoints or combination of the following non-absolute signs of moribundity are observed and in consultation with AFRRI veterinarians.

Absolute
1. Non responsive, assuming the animal has recovered from anesthesia.
2. Dyspnea
3. Loss of 20% of expected weight (based on Marshall Bio-resources growth chart –weight vs age- and day 0 baseline percentile).
4. Hypothermia (< 36ºC)

Non-absolute
1. Hyperthermia (>41ºC)
2. Anorexia (skip 2-3 consecutive meals)
3. Anemia/pallor, CRT >2 seconds (CRT will be performed behind the ears), sudden severe drop in HCT (>10% over 3 consecutive days).
5. Petechiae/ecchymosis
6. Vomiting/diarrhea

7. Lethargy
8. Seizures or vestibular signs (falling, circling or head tilt)
9. Uncontrollable hemorrhage

When non-absolute endpoints are being evaluated, the frequency of monitoring of the animals will be increased to four times per day. At the time of euthanasia, the attached observation sheet (Attachment 1) will be filled out, and may be used retrospectively at the end of study to put together a score sheet for euthanasia criteria for minipigs, similarly to that for rodents.

V.4.6. Euthanasia
Animals will be euthanized according to current American Veterinary Medical Association (AVMA 2013) guidelines. Animals will be sedated with Telazol® (6-8 mg/kg im) or ketamine (20 mg/kg im)/xylazine (2 mg/kg im). Animals will then be euthanized through the VAP with and injected iv Euthasol® (sodium pentobarbital, (1 ml/4.5 kg iv or intracardiac) or another commercial euthanasia solution.
Alternative, in case of VAP malfunction or loss, peripheral or central venous cut down or cardiac stick or catheter without cutdown may be performed, with the animals maintained under general anesthesia using isoflurane gas at a maintenance rate of 1% to 3% and oxygen flow rate of 1 to 2 l/min, to prevent the possibility that the telazol might wear off during this time. Death will be confirmed by VSD veterinarian, assigned study veterinarian, or veterinary technician via auscultation of the heart, with cessation of sounds for at least 5 minutes. See item V.4.5 for euthanasia criteria before the end of the study

V.5. Veterinary Care

V.5.1. Husbandry Considerations

Minipigs will be housed in stainless steel cages/runs, in tactile, visual and olfactory contact with adjacent animals. During quarantine/acclimation period, up to day of surgery, minipigs may be group-housed. After surgery, they will be singly housed to prevent damage to the VAPs and to allow individual assessment of feed consumption and fecal/urine/blood production. Rooms will be maintained on a 12:12 h light (0600 to 1800) dark cycle with the temperature set to 27 to 29°C and 30% to 70% relative humidity. Commercial diet with 20% protein content will be provided (i.e. Labdiet Minipig starter diet 5080). Water will be provided ad libitum. Minimal supportive care will be provided after irradiation to all animals, accordingly to Tables 1-3.

V.5.1.1. Study Room
Minipigs will be located at AFRRI for the duration of the study. They will either be in a VSD surgical suite for catheter placement, in transit to and from the cobalt facility in a covered transport cage, in slings for irradiation in the cobalt facility, or in their housing cage or a VSD prep room for blood collections or euthanasia. They will be housed in stainless-steel cages in an environmentally controlled and continuously monitored animal room as described in Section V.5.1

V.5.1.2. Special Husbandry Provisions
No sugar-rich treats, marshmallows, peanut butter, cereal, crackers and similar food will be offered to these animals. Instead, any one of canned fruits, vegetables, yogurt and milk will be offered daily; age-appropriate nutritional supplement will be provided after irradiation. Tap water will be provided ad libitum. Pedialyte or other oral rehydration fluid will be offered when the animals show signs of dehydration.

V.5.1.3. Exceptions NA

V.5.2. Veterinary Medical Care

V.5.2.1. Routine Veterinary Medical Care
Animals will be acclimated for ≥1 week prior to beginning of procedures. Each animal will be observed at least twice daily for evidence of pain or distress. Body weights will be determined at least once a week and on days of blood collection. The time of each daily temperature collection will be recorded for each animal. Animals will be qualitatively assessed at least twice daily (a.m. and p.m.) for general behavioral

status and food consumption by VSD techs and/or research techs. The heart rate will be measured at the time of each blood collection. Stool consistency, left-over food, demeanor and overall animal appearance will be recorded. Diarrhea has not been observed in minipigs irradiated at doses <8 Gy. Appropriate standard operating procedures will be followed by staff veterinarians in the event of pain or distress.

V.5.2.2. Emergency Veterinary Medical Care Emergency veterinary medical care is available 24/7 and will be provided based on the restrictions approved in earlier sections of this protocol

V.5.3. Environmental Enrichment

V.5.3.1. Enrichment Strategy
Enrichment will be done as per the VSD minipig enrichment SOP, except single housing after catheter implantation and irradiation.

V.5.3.2. Enrichment Restrictions
Minipigs will be single-housed after surgery and after irradiation until completion of the study, to avoid mechanical and infectious complications related to implanted catheters, but they will be in visual, olfactory and auditory contact with other minipigs in the same room.

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING

NAME	DEGREE	TRAINING	DATE	PROCEDURES	YRS/MOS EXPERIENCE
(b)(6)				**1, 3b, 4, 5, 7 (drug delivery)**	(b)(6)
				1,2,3,4,7	
				1, 3	
				1,2,3b, 4, 5	
				1,2,3b, 5	

NAME	DEGREE	TRAINING	DATE	PROCEDURES	YRS/MOS EXPERIENCE
(b)(6)					(b)(6)
				1, 2, 3, 4, 5	
				3, 4	

Trained personnel are certified by VSD.
Procedure and manipulation codes:
Code 1= Animal handling and euthanasia
Code 2= Surgery (aseptic technique) pre- and post-operative care
Code 3= Injections (3a–ip, 3b-sc, 3c-gavage) - can say 3 if trained in all manipulations or add 3d-iv
Code 4= Blood collection under anesthesia (4a-cardiac, 4b-posterior vena cava)
Code 5= Tissue collection (after euthanasia) - doesn't need to be specific
Code 6 = Implantation (provide details)
Code 7 = Others - (provide protocol specific manipulations or procedures for e.g., retro-orbital bleeding, tail vein injection, or drug delivery)

X. ASSURANCES

Protocol Title: Minipig model of H-ARS for drug screening protocols relevant to mass casualty-scale treatment

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made every effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with a qualified individual who evaluated the experimental design with respect to the statistical analysis, and that the minimum number of animals needed for scientific validity will be used.

D. Biohazard / Safety: I have taken into consideration and made the proper coordinations regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R", namely, "Responsibility," which the DOD has embraced for implementing animal use alternatives where feasible and conducting humane and lawful research.

G. Scientific Review: This proposed animal use protocol has received appropriate peer scientific review and is consistent with good scientific research practice.

H. Painful Procedure(s): I **AM / AM NOT** conducting biomedical experiments, which may potentially cause more than momentary or slight pain or distress to animals. If applicable, potential pain and/or distress **WILL / WILL NOT** be relieved with the use of enesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment

(b)(6)

Principal Investigator (Printed Name) Principal Investigator (Signature) (Date)

DOD ANIMAL CARE AND USE STANDARDIZED PROTOCOL FORMAT WITH EMBEDDED INSTRUCTIONS (March 2013)

Reference DOD Instruction 3216.01 & AFRRI Instruction 3216.2H

****

Information requested in the following animal use protocol template reflects the requirements of the Animal Welfare Act Regulations (AWAR), the Guide for the Care and Use of Laboratory Animals, and other applicable Federal regulations and DOD instructions.

****

This document is intended to be an aid in the preparation of DOD-sponsored animal use protocols. It is a companion document to an identical protocol template that does not have embedded instructions. Either template may be used to format DOD-sponsored animal research proposals; however, reference to the instructions during protocol preparation is highly recommended. If using the template with instructions, the instructions should be deleted prior to submitting the finished protocol for IACUC review. Please use Arial, regular, size 12, black font to prepare the protocol. With the exception of section headings, all paragraphs require a response. Paragraphs that do not apply should be marked N/A. There is no space limitation for responses to the information requested.

Approved standard operating procedures (SOPs) promulgated by the AFRRI Veterinary Sciences Department (VSD) or similar VSD-validated documents that describe specific procedures may be referenced by SOP number and title in lieu of repeating the details in the protocol. However, it is essential to include general descriptions of all animal manipulations to be carried out under the IACUC-approved protocol and to provide details where no approved references are cited. To do otherwise would constitute a breach of statutory regulations. Manipulations not covered in the originally approved protocol can be initiated only after IACUC approval of a formal amendment adding the new procedures. Additionally, Principal Investigators (PIs), or other delegated research personnel, should maintain accurate experimental records and be able to provide an audit trail of animal expenditures and use that correlates with their approved protocol. Protocol PIs will be required to provide this and other information during annual protocol reviews.

Any supporting information that may be of use to the IACUC during its review may be attached to the completed protocol. Adding subparagraphs within the body of the protocol template is permissible, *provided that the numbering sequence of paragraphs in the original standard format is maintained.* In other words, all of the labeled paragraphs and subparagraphs in this template must be retained, with additional information being presented as sub-numbered paragraphs containing information that supports or complements what is requested.

INTELLECTUAL PROPERTY STATEMENT

Research protocols drafted by Government scientists include intellectual property (e.g., concepts, ideas, experimental approaches, etc.), some of which is innovative or original and therefore considered proprietary to the investigators and/or the sponsoring agency. All Government and non-Government personnel handling this protocol shall exercise EXTREME CARE, to ensure that the information contained herein is NOT DUPLICATED OR DISCLOSED, in whole or part, for any purpose other than to evaluate the protocol, without the written permission of the principal investigator or the sponsoring agency.

CO-INVESTIGATOR(S): N/A**AFRRI SCIENTIFIC RESEARCH PROTOCOL NUMBER:** (b)(6)

I. NON-TECHNICAL SYNOPSIS: The threat of a limited radiological attack on American cities (i.e. a "dirty" bomb), or a nuclear accident, requires the development of a radiation countermeasure capable of protecting the hematopoietic system and gastrointestinal (GI) tract of military personnel, who might have to enter a contaminated area, or capable of mitigating radiation lethality in the general population. At present there is no effective treatment for the acute radiation syndrome. (b)(4) (b)(4) promotes recovery of radiation damaged cells by stimulating DNA repair and cell survival pathways. Studies conducted at AFRRI (b)(4) have shown promising efficacy of (b)(4) both as a protector and a mitigator of acute radiation syndrome (ARS) in mouse models. Clinical studies in humans support an excellent safety profile of (b)(4) In the current protocol the main focus is to optimize the dose of (b)(4) to mitigate the effects of radiation by monitoring the biomarkers, and to conduct efficacy study in mice. For efficacy study, drug will be tested by administering it through subcutaneous and oral routes. Drug will be evaluated in two different strains of mice.

II. BACKGROUND

II.1. Background:

Military and civil defense organizations have an urgent requirement for medically effective radiation countermeasures, including radiation protectors, mitigators and therapeutics. Radiation countermeasures that mitigate the harmful effects and promote recovery from radiation injury will have stringent requirements in terms of lack of toxicity, ease-of-use for administration, storage at environmental temperatures, suited for administration by non-medical personnel, and capability of enhancing survival in the absence of ancillary medical support. Although such efforts were initiated more than half a century ago, no safe and effective radiation countermeasure has been approved by the United States Food and Drug Administration (FDA) for ARS (1, 10, 19).

Scientists at (b)(4) the Armed Forces Radiobiology Research Institute (AFRRI) (b)(4) (b)(4) have conducted extensive studies to demonstrate radiation protecting and mitigating effects of injectable (subcutaneous, sc)

and oral (po) [(b)(4)] Safety and tolerability of [(b)(4)] have been established in GLP-compliant nonclinical studies and in 4 clinical safety trials in healthy adults. These results are published in peer-reviewed journals [(b)(4)] and included in 2 active U.S. FDA IND exemptions [(b)(6)] [(b)(4)] mitigates deleterious radiation effects by enhancing DNA damage repair pathways, rather than intervening in the free-radical cascade. Thus, its window of effectiveness is relatively long, extending from a day before to a day or more after exposure to radiation.

Preliminary studies on biomarker analysis in mouse tissue specimens using Nano-immunoassay: A novel analytical method termed, Nanoscale Immuno Assay (NIA) is capable of rapidly and reproducibly quantifying proteins and their phosphorylation states in very small nonclinical and clinical specimens and has been developed by [(b)(4),(b)(6)] NIA assays have been validated to measure proteins that mediate cell survival, proliferation, cell cycle and apoptotic pathways. Preliminary studies were conducted in mice dosed orally with either

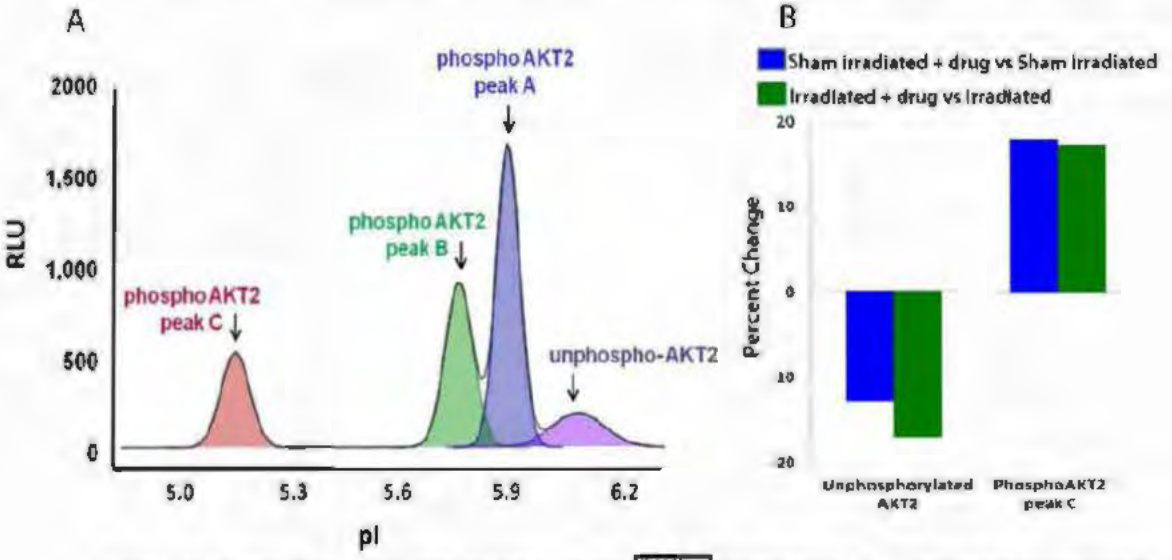

Figure 1. NIA analysis of AKT levels in mouse bone marrow +/- [(b)(4)] administration. A) NIA reveals three phosphorylated peaks of AKT2 in mouse bone marrow (control); **B)** [(b)(4)] treatment *in vivo* induces similar AKT profiles in bone marrow from sham-irradiated and irradiated mice (AKT2 profiles, correlation = 0.94)

vehicle or drug with or without radiation. After 24 h post-irradiation administration of drug, mice were sacrificed, bone marrow was removed and the cell lysates were analyzed by NIA. The data in **figure 1A** show that the unphosphorylated AKT and the various forms of phosphorylated AKT (A, B and C) were successfully resolved and quantified by NIA. The data in **figure 1B** confirms the up-regulation of Akt2 in bone marrow samples from mice treated with [(b)(4)] with or without radiation. Simultaneously, there is a corresponding down regulation in unphosphorylated AKT. Importantly, correlation in percent change from baseline in AKT2 isoforms between "sham irradiated plus drug" and "irradiated plus drug" was 0.94. This innate effect of drug on the unphosphorylated levels of AKT and p-AKT, in presence or absence of radiation, could be used to correlate the efficacy of drug in pivotal mouse and NHP studies in therapeutic settings. These preliminary studies demonstrate the potential

value of p-AKT2 as a biomarker to follow the drug effect in the absence of radiation during pivotal safety studies in healthy human volunteers.

Understanding changes in signaling and correlating these changes with the mechanism of action provides a path to meeting the challenges of drug approval under the Animal Rule. Results herein provide a promising avenue towards this goal. Additional studies and confirmation under different scenarios, along with validation which is a part of this proposal, may permit correlation of an informative biomarker with expected efficacy parameters.

Initial studies investigating the efficacy and mechanism of (b)(4) have been conducted in mice and in-vitro models. Efficacy studies with radiation doses ranging from 5 - 15 Gy have been conducted. Previous results demonstrated that mice injected with the drug subcutaneously at one dose at -24h and -15 min prior to TBI resulted in significant protection of mice. These preliminary studies suggested that (b)(4) is a promising radiation countermeasure and warrants continued development. Previous studies have not systematically determined the optimal dose and schedule of

administration using biomarkers and oral route of administration. In this study we will be using biomarkers, identified from the *in vitro* cell-based studies, to optimize the dose and schedule of administration of (b)(4) and to correlate the biomarker levels with its efficacy. In addition we are evaluating the oral route of administration to determine the efficacy of (b)(4) We believe that this is a systematic approach to optimize the dosing regimen, evaluate the efficacy of (b)(4) and validate the biomarkers at the same time. Overall, the search did not reveal any duplication and the proposed study would provide valuable information about the development of (b)(4) as a radiation countermeasure.

III. OBJECTIVE/HYPOTHESIS:

In the current protocol we are proposing to utilize the biomarkers to optimize dose and schedule of administration and validate these markers in mouse models of radiation protection. Validation of biomarkers is a critical step in the development of radiation countermeasures since human efficacy studies are neither ethical nor feasible. FDA guidance on "Animal Rule" (21 CFR 314.600 for drugs) states, "The data or information on the pharmacokinetics and pharmacodynamics of the product or other relevant data or information, in animals and humans, allows selection of an effective dose in humans." (21 CFR 314.610(a) (1)-(4); 21 CFR 601.91(a)(1)-(4)). Hence, a validated biomarker will be a critical milestone for optimizing the effective dose in humans (1, 23).

We plan to optimize the dose and schedule of oral administration of (b)(4) in mouse models using biomarker expression in bone marrow (BM) and peripheral blood mononuclear cells (PBMCs). Using these optimal conditions, we will evaluate the efficacy of (b)(4) in mouse models of radiation protection and also validate the biomarkers. The main objectives are (a) optimize the dose and schedule of administration based on biomarker response; (b) demonstrate drug dose-response in enhancing survival and hematopoietic recovery; (c) validate the biomarkers identified from cell line studies; d) determine dose reduction factor (DRF) at optimum (b)(4) dose and schedule; and e) evaluate the effectiveness of (b)(4) in two additional mouse strains (C57BL/6 and CD2F1), to address the genetic heterogeneity such as encountered in human populations.

IV. MILITARY RELEVANCE

Currently, there are no FDA approved pharmaceutical agents that can prevent or treat injury from external ionizing radiation. The problem has become more acute in recent times due to the unpredictable nature of terrorist attacks. Recognizing this urgent need, the U.S. Department of Defense has assigned top priority to the "development of medical countermeasures to radiation exposure" against both early and late arising health effects. These concerns imply the urgent need to develop an appropriate countermeasure for radiation injuries potentially sustained by war fighters during combat operations and enable commanders to make judicious decisions in troop deployment. There are several drugs at different stages of the development. This study will perform essential research and development of a promising new agent (b)(4) as a therapy for potential injuries sustained by military personnel who have been accidentally exposed to ionizing radiation.

V. MATERIALS AND METHODS

V.1. Experimental Design and General Procedures

We propose to do the following experiments to utilize biomarkers of (b)(4) treatment to optimize dose and schedule of administration. Optimal dose and schedule of (b)(4) administration will be used to evaluate its in protecting mice from total body irradiation and thus validate the biomarkers. Details of subsequent experiments will be based on results obtained in previous experiment.

V.1.1. Experiment 1. Dose optimization of (b)(4) using biomarker levels in C3H/HeN mice: In this experiment our main objective is to analyze biomarker (p53, mdm2, p21, p73, c-abl, chk1, pAKT, pGsk-3, pS6, pMAPK, pRAF, PTEN etc) levels, identified from the cell-based assays, in bone marrow (BM) and peripheral blood mononuclear cells (PBMCs) of mice as a function of (b)(4) dose response. C3H/HeN mice will be dosed orally with (b)(4) (Low = 250 mg/kg, medium = 500 mg/kg; high = 750 mg/kg body weight) along with appropriate vehicle controls at -24 h and -15 minutes prior to TBI (LD50/30). Following groups will be included in the study: 1) Radiation alone, 2) Vehicle control (oral) + Radiation, 3) Radiation +250 mg/kg of drug (oral), 4) Radiation+ 500 mg/kg of drug (oral), 5) Radiation + 750 mg/kg of drug (oral), 6) Drug alone at 250 mg/kg (oral), 7) Drug alone at 500 mg/kg (oral), 8) Drug alone at 750 mg/kg (oral), 9) Vehicle alone. Mice will be sacrificed 24 and 48 h after final drug administration to collect BM and PBMCs. Biomarker levels will be analyzed by Western-blot. Radiation dose for this study will be 7.5 Gy (TBI). We expect the biomarker level to be responsive to (b)(4) administration in a dose dependent manner both in the presence and absence of radiation. Earlier studies indicate optimal dose is 500 mg/kg. (b)(4)

C3H/HeN mice needed: 9 treatment groups x 6 mice per group x two time points (24 and 48 h) = 108

V.1.2. Experiment 2. Biomarker-guided optimization of schedule of (b)(4) administration in C3H/HeN mice: The objective here is to optimize the schedule of administration of (b)(4) using biomarker levels in BM and PBMCs and the optimal dose determined from the previous experiment. Previous studies have used -24 h and -15 min prior to TBI to administer (b)(4) by sc route. We will explore administering multiple doses of (b)(4) prior to TBI to determine the effect on biomarker levels in C3H/HeN mice and determine the optimal schedule of administration. Optimal dose of (b)(4) as determined from the above experiment will be administered orally to C3H/HeN mice (6 mice per group + appropriate vehicle controls for each time point) at 1) -24 h and -15 min; 2) -24 h, -12 h and -15 min; 3) -24 h, -18 h, -12 h and -15 min; 4) -24 h, -18 h, -12 h, -6 h and -15 min and 5) vehicle control for each schedule administered before TBI (7.5 Gy). Mice will be sacrificed to collect BM and PBMCs at 24 and 48 h after final drug administration. BM and PBMC cell pellets will be lysed for biomarker analysis by Western-blot.

C3H/HeN mice needed: 2 treatments groups (drug and vehicle) x 5 treatment regimens x 6 mice per group x 2 time points = 120 mice

V.1.3. Experiment 3. Experiment 3. Dose response survival study and validation of biomarkers in C3H/HeN mice: To determine survival efficacy as a function of oral drug dose post-TBI and to correlate with biomarker levels from previous experiments, C3H/HeN mice will be dosed orally with optimal dose of (b)(4) and one dose below and one dose above the optimal dose, along with appropriate vehicle controls, at the optimal schedule as determined from above experiment. Following groups will be included in the study: 1) Radiation alone, 2) Vehicle control for lower dose of (b)(4) (oral) + Radiation, 3) Radiation + (b)(4) dose lower than optimal dose (oral), 4) vehicle control for optimal drug dose + radiation, 5) Radiation+ optimal dose of (b)(4) (oral), 6) vehicle control for higher drug dose + radiation, 7) Radiation + (b)(4) dose higher than optimal dose (oral), and 8) subcutaneous (sc) administration of drug at 500 mg/kg body weight and radiation as positive control. Mice will be monitored for survival for 30 d post-irradiation. Radiation dose for this study will be 7.5 Gy (TBI).

C3H/HeN mice needed: 8 treatment groups x 16 mice per group x 2 experiments = 256

V.1.4. Experiment 4. Dose reduction factor (DRF) survival study at optimum dose and schedule in C3H/HeN mice: The objective of this experiment is to determine the dose reduction factor (DRF) at the optimal oral dose and schedule determined from above studies along with appropriate vehicle controls. C3H/HeN mice (16 mice per group) will be administered drug prior to TBI at 6 doses (6 different doses of radiation between 6 and 11 Gy, sub-lethal to 100% lethal for both sets of mice) will be selected for vehicle and drug treated animals. We have published such studies earlier with several agents (b)(4) Mice will be monitored for survival for 30 d.

C3H/HeN mice needed: 2 treatments groups (drug and vehicle) x 6 radiation doses x 16 mice per group = 192)

V.1.5. Experiment 5. Hematopoietic rescue study in C3H/HeN mice

To evaluate hematopoietic rescue by oral (b)(4) administration in C3H/HeN mice, mice (6 mice per group per time point) will be exposed to sublethal TBI dose (4 Gy), followed by optimal oral dose regimen of (b)(4) (+ appropriate vehicle controls). Hematopoietic response will be assessed by peripheral blood cell counts and by the number of surviving BM progenitors committed to the myeloid lineage of differentiation. Peripheral blood will be collected from posterior vena cava using 1 ml syringe and 23 G needle (please also see section V.4.4.2. Biosamples) and counted at 3, 5, 7, 14, 21 and 28 d after TBI. We have published such results with other radiation countermeasures (17). Values for vehicle and drug alone (no radiation) at 3 d will serve as baseline controls.

C3H/HeN mice needed: (2 treatments groups (drug and vehicle) x 6 time points x 6 mice per group + 12 animals for baseline control without radiation – with and without drug – 6 each) x 2 experiments = 168

V.1.6. Experiment 6. Radiation dose survival study in C57BL/6 and CD2F1 mice strains: To determine radiation dose-response on oral (b)(4) efficacy in two other mouse strains to address genetic heterogeneity, C57BL/6 mice (16 mice per group) and CD2F1 mice (16 mice per group) will be exposed to varying doses of radiation including $LD_{30/30}$, $LD_{50/30}$, and $LD_{70/30}$ (will be determined based on results above experiment # 4

for DRF) after oral administration of (b)(4) or vehicle at optimal dose and schedule. Mice will be scored for survival for 30 d.

C57BL/6 and CD2F1 mice needed: 2 treatments groups (drug and vehicle) x 3 radiation doses x 16 mice per group x 2 experiments = 192 of each strain

V.1.7. Experiment 7. Hematopoietic rescue study in C57BL/6 mice and CD2F1 mice strains: To confirm the hematopoietic rescue by oral (b)(4) in two other mouse strains to address genetic heterogeneity, C57BL/6 mice (6 mice per time point) and CD2F1 strain (6 mice per time point) will be exposed to sub-lethal dose of radiation after oral administration of (b)(4) or vehicle at optimal dose and schedule. Peripheral blood cell counts and the number of surviving BM progenitors committed to the myeloid lineage of differentiation will be determined at 3, 5, 7, 14, 21 and 30 d after TBI as described above under experiment 5. Values for vehicle and drug alone (no radiation) at 3 d will serve as baseline controls.

C57BL/6 and CD2F1 mice needed: (2 treatments groups (drug and vehicle) x 6 time points x 6 mice per group + 12 animals for baseline control without radiation – with and without drug – 6 each) x 2 experiments = 168 of each strain

Total C3H/HeN mice needed for this Protocol:

Total CD2F1 mice required for this protocol	378	0	42	336

Unirradiated animals used for blood collection under anesthesia have been placed under category D.

V.2. Data Analysis

Mean with standard errors, or percentages, will be reported if applicable. The significance level will be set at 5% for each test. Under the similar situations for a given experiment, two independent replicates of data will be pooled. Poolability will be assessed. Statistical software, PC SAS will be used for statistical analyses.

Experiment 1: Analysis of variance (ANOVA) will be used to detect if there is a significant difference among the groups for a biomarker. If significant, Student-Newman-Keuls multiple range test will be used to do all the possible pair-wise comparisons to identify which group is significantly different from the other. A two-way ANOVA will be used to detect if there is any significant difference between the two replicated experiments across the groups. If not significant, then we will pool the two replicated experiments for each group for our statistical analysis. If we can pool them (as expected), then the sample size per group (N=16) would have 80% power to detect a significant difference between two groups if any, given type I error of 5% and delta/sigma has at least 1.03, where the delta is the estimated mean differences between the two groups and sigma is the standard deviation of the ANOVA model (14).

Experiment 2, 3 and 6: Comparison of survival curves will be made using the log-rank test. Fisher's exact test will be used to detect if there is a significant difference across the groups in survival rates. N = 16 mice per group would have 80% power to detect a significant difference between two groups, given type I error of 5%, a treatment group survival rate of at least 79%, and vehicle group survival of 25%. A similar statement would apply, provided the treatment group survival was at least 84%, 88%, or 91%, if the vehicle group survival was 30%, 35% or 40%, respectively (*52*).

Experiment 4: Probit analysis will be used to estimate the DRF. The DRF will be estimated as the ratio of the radiation LD-50/30 for mMPc versus vehicle, and 95% confidence interval will be derived.

Experiment 5 and 7: Analysis of variance (ANOVA) will be used to find overall significant differences among treatment groups. If a difference is significant, pair-wise Tukey-Kramer comparisons will be used to identify specific differences between groups. Similarly additional data will be analyzed.
The eight mice per group for each experiment, N=8 per group will have 80% power to detect any significant difference between groups if any, given type I error of 5% and delta/sigma has at least 1.6, where the delta is the estimated mean differences between the two groups and sigma is the pooled standard deviation of the two groups [26].

V.3. Laboratory Animals Required and Justification

V.3.1. Non-animal Alternatives Considered

Both computer models and tissue culture have been considered as alternatives to animals. These alternatives lack the knowledge base and complexity needed to evaluate the effects of radiation and radiation countermeasures on the immune system. The phenomena under study involve complex information-processing networks comprising large number of cell types and biological signal transduction molecules. Responses to irradiation and radioprotective agents involve interactions between the central nervous system, the peripheral nervous system including the enteric nervous system, endocrine glands, the immune and inflammatory systems, hematopoietic system, gastrointestinal system etc. We do not know all of the cell types and tissues involved and many of the signal transduction molecules have not been discovered yet. Even if all of the tissues, cell types and signaling molecules were known, the present state of tissue culture would be incapable of reproducing their *in vivo* relationships. One would have to reproduce much of an entire mammalian organism in culture to study these phenomena *in vitro*. As for computer models, the most powerful supercomputers available in the near future would be incapable of analyzing interactions between so many elements in the network. Thus, these drugs necessitate investigation in whole animal models to see overall outcome.

V.3.2. Animal Model and Species Justification: Evaluation of radiation countermeasures in *in vivo* model is the only option available for identifying clinically safe and non-toxic radiation countermeasures. The murine model is immunologically the most well defined animal model for research. The murine model is also the most studied animal model, and has significant immunological similarity to higher animals and humans. This model is also preferred over any other *in vivo* model due to readily available immunological and molecular biology research reagents. AFRRI staff has extensive experience with several strains of mice in radiation injury and radioprotection research. PI has extensive experience with C57BL/6, CD2F1, and C3H/HeN mice. We will be using C3H/HeN, C57BL/6, and CD2F1 mice for selected experiments in this protocol. (b)(4) is effective against moderately low dose of radiation and has been evaluated earlier only in C3H/HeN strain of mice (mostly sc route, few expt with oral route) as stated above. C3H/HeN is comparatively radiosensitive strain. Its LD_{50} value is lower than C57BL/6 and CD2F1. We are interested to conduct limited evaluation in two other strains (C57BL/6 and CD2F1 – comparatively radioresistant) of mice. Such study will demonstrate that this drug efficacy is not strain specific or efficacy is limited to radiosensitive sensitive strains.**V.3.3. Laboratory Animals**

V.3.3.1. Genus/Species

Mus musculus, Laboratory mouse

V.3.3.2. Strain/Stock

C3H/HeN, C57BL/6, and CD2F1

V.3.3.3. Source/Vendor

C3H/HeN, C57BL/6, and CD2F1 mice will be purchased from a VSD approved vendor (the preferred vendor for C57BL/6 is Jackson Laboratory, 600 Main St., Bar

Harbor, Maine 04609-1500; Tel: 207-288-5845; State of Maine animal welfare license is R012, the preferred vendor for C3H/HeN and CD2F1 mice is Harlan Labs Indianapolis, Indiana 46229 – 0176; USDA License Number 32-A-0083).

V.3.3.4. Age

6-12 weeks old

V.3.3.5. Weight

20 – 25 g

V.3.3.6. Sex

Male

Justification for using only male mice: Previous studies have been performed using male mice, so males are needed for data comparison. Also there is possibility that female hormone variation may interfere with our results. To see the effect of this drug in both sexes, we need to repeat such experiments in females. To minimize the number of animals, and to keep variables minimized, it was decided that the study will be performed only in one sex (male).

V.3.3.7. Special Considerations

Commercially procured animals must be adventitious disease free, including: *Pseudomonas aeruginosa,* and *Pasteurella.* All mice need to be free of the following agents: Sendai, Pneumonia Virus of Mice (PVM), Reovirus-3 (Reo 3), Mouse Adenovirus (MAD-1, MAD-2), Mouse Cytomegalovirus Virus (MCMV), Ectromelia, K virus, Lymphocytic Choriomeningitis Virus (LCM), Epidemic Diarrhea of Infant Mice (EDIM), Hantaan virus, Rotavirus, Mouse Parvovirus (MPV), Polyoma Virus, Mouse Minute Virus (MMV), Mouse Thymic Virus (MTV), Theiler's Mouse Encephalomyelitis Virus (TMEV/GDVII), *Encephalitozoon cuniculi*, CAR bacillus, *Mycoplasma pulmonis*, *Clostridium piliforme, and C. difficile.* Mice should also be endoparasite- and ectoparasite-free.

V.3.4. Number of Animals Required (by species)

V.3.5. Refinement, Reduction, Replacement (3 R's)

V.3.5.1. Refinement

Moribund animals will be euthanized immediately to minimize the magnitude and duration of suffering those animals might experience when they are subjected to toxic effects of ionizing radiation. Under such situation moribundity will be used as a surrogate for death in animals and will be considered to have arrived at the endpoint. Pain experienced by injection will be minimized by the use of higher gauge needles.

V.3.5.2. Reduction

As we move forward with experiments, plans will be reevaluated at every stage of the experiments, in light of incoming data in an attempt to reduce the numbers of experiments and groups, if possible. If deemed not necessary based on incoming data, some investigations may not be carried out to optimize the use of experimental animals.

V.3.5.3. Replacement

It is not feasible to use non-animal systems in place of *in vivo* animal models to address the research questions proposed in this IACUC protocol.

Unirradiated animals used for blood collection under anesthesia have been placed under category D

V.4.1.2. Pain Relief/Prevention

V.4.1.2.1. Anesthesia/Analgesia/Tranquilization

Since anesthesia, analgesia, and tranquilizers are known to affect functions of the immune system of animals, we do not plan to use analgesic/anesthetic agents during course of the experiment after irradiation (2, 5, 6).

Animals in experiments involving blood/tissue collection (different organs) will be deeply anesthetized using isofluorane before blood collection. Next, animals will be euthanized by exsanguination with confirmation by cervical dislocation before tissue collection.

V.4.1.2.2. Pre- and Post-procedural Provisions

Mice will be housed under standard conditions both before and after radiation procedures in accordance with VSD mouse Standard Operating Procedure (see section V.5).

V.4.1.2.3. Paralytics

No paralytic agent will be used in this study.

No reports were found indicating administration of (b)(4) causes pain. Similarly, there were no reports indicating that irradiation itself causes pain. It has been reported that whole-body irradiation can cause sedative effect, as indicated in the tail-flick test in rats.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification

As stated above, irradiated mice succumb to a compromised immune response. In the event that there is pain and distress for animals, as we have already discussed under above headings, we cannot give anesthetic/analgesic agents to the animals since these agents interact with the immune system, and in turn will affect experimental results.

There are conflicting reports regarding effects of buprenorphine on the immune system (3, 9, 11, 12, 14-16, 24). A majority of reports suggest that buprenorphine influences immune response. Since buprenorphine has been shown to influence various arms of cellular and humoral immune response (3, 12, 16, 24), we have decided not to use it in our study. Non-steroidal anti-inflammatory drugs are not suitable for use in such experiments (13).

V.4.3.4. Location: N/A

V.4.3.5. Surgeon: N/A

V.4.3.6. Multiple Major Survival Operative Procedures

V.4.3.6.1. Procedures:

Irradiation: Mice will be placed in a perforated and well ventilated acrylic plastic restrainer (maximum 8 mice in one restrainer). These mice will be exposed to desired dose of gamma radiation from bilaterally positioned cobalt-60 sources.

V.4.3.6.2 Scientific Justification: N/A

V.4.4. Animal Manipulations

V.4.4.1. Injections

(b)(4) will be administered sc with 23 G needle in the nape of the neck. The maximum volume for sc administrations will be 0.20 ml per 20 - 25 g animal.

(b)(4) given *p.o.* will be administered in a 0.2-ml volume with a 1-ml syringe and a 20-gauge feeding canula, which has a ball tip, or a disposable feeding needle, which has a silicone rubber tip. One sterile syringe and needle will be used for mice in each cage. The feeding needle will be wiped and disinfected between inoculations on a gauze sponge that is moistened with 70% ethanol (absolute alcohol diluted to 70%) to reduce the microorganisms and saliva on the needle as an extra precaution even though the mice share the sipper tube in the water bottle and oral microorganisms as well. First p.p. experiment will be conducted in the presence of a veterinarian/vet tech.

V.4.4.1.1. Pharmaceutical Grade Drugs:

Currently (b)(4) is in Phase 1 clinical trials for safety and toxicity. (b)(4) (b)(4) for administration in healthy volunteers. We will be using the same formulation in this study.

(b)(4) (b)(4) All aspects of the solution preparation involve GLP grade formulation.

V.4.4.1.2. Non-Pharmaceutical Grade Drugs: N/A

V.4.4.2. Biosamples

Animals in experiments involving blood/tissue collection (different organs) will be deeply anesthetized using isofluorane before blood collection (posterior vena cava). Next, animals will be euthanized by exsanguination with confirmation by cervical dislocation before tissue collection tissue (jejunum, sternum and femur bones). GI tract, sternum and femur bones will be collected post-mortem for histopathology and bone marrow analysis for biomarkers. Blood will be used for CBC, blood chemistry, citrulline, and biomarker analysis.

V.4.4.3. Adjuvants: N/A

V.4.4.4. Monoclonal Antibody (MAb) Production: N/A

V.4.4.5. Animal Identification

Each cage will have a cage card. In addition to cage card, another experimental card will be displayed before starting the experiment. One cage will have mice of only one treatment/control group. Each card will state the investigator's name, protocol number, experiment number, cage number, start date, end date, species, item number (animal lot), birthdate, gender, strain, number of animals in the cage, vendor, arrival date, treatments, and dates of death, including the initials of the staff person who found and removed the dead animals.

V.4.4.6. Behavioral Studies: N/A**V.4.4.7. Other Procedures: None**

V.4.4.8. Tissue Sharing:

Bone marrow/PBMC samples will be sent to Dr. (b)(6) (b)(6) for Nanoscale Immuno Assay (NIA) for validation of biomarkers. Once protocol is approved, tissue sharing document will be initiated.

Unused biological samples will be retained for additional studies. Studies planned will depend upon additional funding for supplies and staff in future.

V.4.4.9. Animal By-Products: N/A

V.4.5. Study Endpoint

In all experiments involving blood/tissue collection, mice will be deeply anesthetized using isofluorane before blood collection (posterior vena cava). Next, animals will be euthanized by exsanguination with confirmation by cervical dislocation before tissue (jejunum, sternum and femur bones) collection at a preset time as described under experimental design section. All mice that have survived beyond experimental duration (30 day post-irradiation) or for moribund mice, if any, will be euthanized by CO_2 followed by cervical dislocation. Naïve mice, if not used in the experiments, will be transferred to another approved protocol, if possible, or euthanized. Animals in these studies may become morbid and hence it is critical to define criteria for euthanizing mice humanely without compromising the study objective and complying with the IACUC recommendations stipulated in Policy Letter #10. Mice will be considered morbid based on criteria described in policy # 10. Experimental mice that are found morbid, but not moribund, will be allowed to continue in the experimental protocol. Once mice are considered morbid, we will monitor them more than twice daily, early morning and late afternoon, and evening.

Mice found moribund will be euthanized by trained and experienced personnel listed on this protocol or by trained/experienced VSD staff. Compressed CO_2 gas in a cylinder with a regulator will be used for euthanasia in accordance with the current American Veterinary Medical Association (AVMA) Guidelines on Euthanasia - 2013. Cervical dislocation will be done following CO_2 overdose as a secondary method of euthanasia. Mice will be considered moribund based on criteria described in policy # 10.

V.4.6. Euthanasia

As already mentioned above under various headings, in all experiments involving blood/tissue collection, mice will be deeply anesthetized using isofluorane before blood collection (posterior vena cava). Next, animals will be euthanized by exsanguination with confirmation by cervical dislocation before tissue collection. Terminal CO_2 euthanasia will be used for mice that have survived beyond experimental duration (30 day post-irradiation) or for moribund mice, if any. Compressed CO_2 gas in a cylinder with a regulator will be used for euthanasia in accordance with the current American Veterinary Medical Association (AVMA) Guidelines on Euthanasia - 2013.

VIII. Appendix A: Clinical Observations with Criteria for Euthanasia (Rodent)

DATE:	Time:	Animal ID#	Score
Appearance:			
	Normal (smooth coat, clear eyes/nose)		0
	Hunched and/or fluffed		1
	Ocular discharge, and/or edema		3
	Emaciated, dehydrated (skin tent) **		5
	Soft stools (fecal matter around anus)		5
	Bloody diarrhea		9
Respiratory rate:			
	Normal breathing		0
	Increased breathing (double normal rate, rapid, shallow)		6
	Abdominal breathing (gasping +/- open mouth breathing)*		12
General Behavior:			
	Normal (based on baseline observations)		0
	Stretching of hind limbs with abdominal motion (writhe) or grimace (App. B and C)		1
	Decreased mobility		2
	Ataxia, wobbly, weak**		6
	Inability to stand*		12
Provoked Behavior:			
	Normal (moves when cage is disturbed, runs from hand (mice) or investigates (rat))		0
	Subdued; responds to stimulation (moves away briskly)		1
	Subdued even to stimulation (moves away slowly)		3
	Unresponsive to gentle prodding **		6
	Does not right when placed gently on side within 5 seconds*		12
TOTAL			_____

Definitive criteria for morbidity:
Weight Loss up to 10% baseline (if available)**
Pale, white mucous membranes/ skin * *
Fever >104F/40C (if available)**

Definitive criteria for moribundity:
Weight Loss > 20% OR <15g (adult mouse)*
Blue mucous membranes/ skin (cyanosis)*
Cool to the touch or <86F/30C (if available)*

**** Regardless of score, notify appropriate person immediately.**

*** Regardless of score, immediately euthanize (death is imminent)**

Score:
< 6 Normal
6 - 9 Morbid: Monitor at least 3 times per day; notify appropriate personnel immediately
> 10 Moribund: Notify responsible personnel immediately for euthanasia (if no single criteria is 12*)
Any single criteria of 12* euthanize immediately; consider as 'found dead'

(Note: This form does not have to filled out for every individual at every observation, so long as the criteria are used in informing decisions on increased monitoring and/or euthanasia. This form may be used to make a spreadsheet for greater ease of multiple animal observations, as long as the criteria and numbering system are exactly copied.)

V.5. Veterinary Care

V.5.1. Husbandry Considerations

No special husbandry consideration needed.

V.5.1.1. Study Room:

As assigned by VSD.

V.5.1.2. Special Husbandry Provisions: None

V.5.1.3. Exceptions:

Mice will be socially (group) housed, except where there is a possibility that during survival studies cage mates may be lost through attrition and for a period of time the sole surviving mouse may remain singly housed until the end of the 30-day study.

V.5.2. Veterinary Medical Care

V.5.2.1. Routine Veterinary Medical Care

As per Standard Operating Procedures, VSD staff will monitor all animals at least twice daily during morning and afternoon rounds. Any abnormalities will be reported immediately to the on-call veterinarian and PI. In addition, animals will be observed daily by this protocol's research staff. Any morbid mice will be observed twice a day (early morning and late afternoon) by the research staff. PI staff will be responsible for before and after working h observations of morbid mice. Any moribund mice will be euthanized as soon as possible. If needed, VSD veterinarian will be contacted for decision.

V.5.2.2. Emergency Veterinary Medical Care

Emergency veterinary medical care will include immediate euthanasia of any moribund mice.

V.5.3. Environmental Enrichment

V.5.3.1. Enrichment Strategy

Mice will be group housed and enrichment will be provided as per the VSD rodent enrichment SOP.

V.5.3.2. Enrichment Restrictions: None

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING

Following employees are trained for mice work. They have handled mice work of earlier protocols at AFRRI.

NAME	DEGREE	TRAINING	DATE	PROCEDURES	YRS/MOS EXPERIENCE

X. ASSURANCES

Protocol Title: Characterization and validation of biomarkers of (b)(4) a promising radiation countermeasure, in mice (*Mus musculus)*

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made every effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with a qualified individual who evaluated the experimental design with respect to the statistical analysis, and that the minimum number of animals needed for scientific validity will be used.

D. Biohazard/Safety: I have taken into consideration and made the proper coordinations regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures/manipulations/observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures/manipulations.

F. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R", namely, "Responsibility," which the DOD has embraced for implementing animal use alternatives where feasible and conducting humane and lawful research.

G. Scientific Review: This proposed animal use protocol has received appropriate peer scientific review and is consistent with good scientific research practice.

H. Painful Procedure(s): I (**AM**) / **AM NOT** conducting biomedical experiments, which may potentially cause more than momentary or slight pain or distress to animals. If applicable, potential pain and/or distress **WILL** / (**WILL NOT**) be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

rDOD ANIMAL CARE AND USE STANDARDIZED PROTOCOL FORMAT WITH EMBEDDED INSTRUCTIONS (December 2013)

Reference DOD Instruction 3216.01 & AFRRI Instruction 3216.2H

****

Information requested in the following animal use protocol template reflects the requirements of the Animal Welfare Act Regulations (AWAR), the Guide for the Care and Use of Laboratory Animals, and other applicable Federal regulations and DOD instructions.

****

This document is intended to be an aid in the preparation of DOD-sponsored animal use protocols. It is a companion document to an identical protocol template that does not have embedded instructions. Either template may be used to format DOD-sponsored animal research proposals; however, reference to the instructions during protocol preparation is highly recommended. If using the template with instructions, the instructions should be deleted prior to submitting the finished protocol for IACUC review. Please use Arial, regular, size 12, black font to prepare the protocol. With the exception of section headings, all paragraphs require a response. Paragraphs that do not apply should be marked N/A. There is no space limitation for responses to the information requested.

Approved standard operating procedures (SOPs) promulgated by the AFRRI Veterinary Sciences Department (VSD) or similar VSD-validated documents that describe specific procedures may be referenced by SOP number and title in lieu of repeating the details in the protocol. However, it is essential to include general descriptions of all animal manipulations to be carried out under the IACUC-approved protocol and to provide details where no approved references are cited. To do otherwise would constitute a breach of statutory regulations. Manipulations not covered in the originally approved protocol can be initiated only after IACUC approval of a formal amendment adding the new procedures. Additionally, Principal Investigators (PIs), or other delegated research personnel, should maintain accurate experimental records and be able to provide an audit trail of animal expenditures and use that correlates with their approved protocol. Protocol PIs will be required to provide this and other information during annual protocol reviews.

Any supporting information that may be of use to the IACUC during its review may be attached to the completed protocol. Adding subparagraphs within the body of the protocol template is permissible, *provided that the numbering sequence of paragraphs in the original standard format is maintained.* In other words, all of the labeled paragraphs and subparagraphs in this template must be retained, with additional information being presented as sub-numbered paragraphs containing information that supports or complements what is requested.

INTELLECTUAL PROPERTY STATEMENT

Research protocols drafted by Government scientists include intellectual property (e.g., concepts, ideas, experimental approaches, etc.), some of which is innovative or original and therefore considered proprietary to the investigators and/or the sponsoring agency. All Government and non-Government personnel handling this protocol shall exercise EXTREME CARE, to ensure that the information contained herein is NOT DUPLICATED OR DISCLOSED, in whole or part, for any purpose other than to evaluate the protocol, without the written permission of the principal investigator or the sponsoring agency.

I. NON-TECHNICAL SYNOPSIS

Despite advances in precision of targeting tumors with radiation therapy (RT), regrowth of tumors does occur. Higher doses of radiation that would be needed to completely destroy a tumor cannot be used because of damage to the underlying normal tissues of the body. Tumors in which regional control is difficult include locally advanced breast, lung, head and neck, brain, cervical cancer, and others. Two other situations where radiation protection may be useful are: 1) in children, where RT can impair normal growth and development; and 2) in patients receiving combined RT and chemotherapy, where the acute effects of treatment may be severe, particularly when RT and chemotherapy are given concurrently. One method to improve the therapeutic index is by use of agents that differentially protect normal tissues relative to tumors.

The only FDA-approved radioprotector is amifostine. Amifostine is approved to reduce side effects in patients receiving head and neck irradiation, but its use is limited because it must be given intravenously shortly before RT and it has systemic toxicity (b)(4)

(b)(4)

(b)(4) Our proposed studies here will examine the effects of (b)(4) radiation injuries in murine models for these injuries. We will utilize C57L mice exposed to (b)(4) X-ray irradiation at (b)(4) to determine the efficacy and mechanisms of (b)(4) for the protection of the (b)(4) against radiation injury. Our aim is to develop an effective, non-toxic radioprotectant/ radiotherapeutic treatment strategy that can be used for protection against radiation injury to normal tissues during clinical radiation for cancer treatment.

II. BACKGROUND

II.1. Background The acute toxic effects of exposure to high doses of ionizing radiation in humans have been shown to occur due to two sequential effects: first the ablation of immune cells, resulting in loss of immune function and increasing likelihood of pathogenic infection (b)(4) (b)(4) and subsequently the loss of epithelial progenitor cells of the gastrointestinal (GI) crypt (b)(4) Both of these events have been shown to be due to the loss of fast-growing pluripotent and/or progenitor cell types. The time course of the acute injuries correlates with the life span of the mature cell types of the tissue, which are not replaced because of radiation damage to the adult pluripotent cells and adult stem cells. There is currently no FDA approved prophylactic or treatment for prevention of acute radiation injuries following high-dose (b)(4) radiation exposure.

(b)(4)

(b)(4)

In humans, severe radiation (b)(4) can result in death (b)(4) (b)(4) Cumulative evidence from a number of laboratories, including our own, shows that there is a threshold dose of radiation of (b)(4) to induce sufficient (b)(4) for the (b)(4) to occur in mice; below these doses, no permanent injury manifests, although some short-term effects are observed (b)(4) (b)(4) However, in humans, there is currently no accepted protocol for preventative treatment of radiation-induced (b)(4) and morbidity as high as 50% is associated with each phase (b)(4) (b)(4) injuries from radiation is considered to be a serious problem in the field for the development of agents to prevent these radiation injuries.

III. OBJECTIVE / HYPOTHESIS

(b)(4)

IV. MILITARY RELEVANCE

Military personnel and their families receive medical treatment for cancer, including clinical radiation. The development of agents for the protection of normal tissues during cancer radiotherapy would allow the use of higher doses of radiation which has been shown to improve the level of tumor control and cancer irradiation. The goals of this research are consistent with improved cancer treatment in military personnel and their families.

Additionally, the Department of Defense is prepared to execute military missions within radiation environments, to manage radiation crises associated with terrorist activities, and to manage consequences in the event of nuclear weapons detonation. Recent studies indicate that there is an increasing risk of exposure to ionizing radiation to military personnel due to increasing terrorist activities, including potential use of stolen nuclear weapons or dispersal of radioactive material in a "dirty bomb" (b)(4) Because of potential exposure of military personnel to radiation, the DoD is committed to protect members of the Armed Services from the adverse health effects of ionizing radiation. High dose ionizing radiation causes short term, acute injuries including hematopoietic and GI syndromes. However, both high and low dose ionizing radiation (as may result from a radiation dispersal device) can cause (b)(4) as demonstrated by Japanese atomic bomb survivor data as well as accidental exposures to Russian populations (b)(4) . While early effects of radiation injury now have treatment/ prophylactic strategies, the delayed effects currently have no treatment. Lack of treatment for late effects of radiation, including (b)(4) will likely lead to delayed morbidity and mortality for personnel exposed to ionizing radiation.

The Department of Defense (DoD) Chemical and Biological Defense Program 2007 Annual Report to Congress, Chapter 2.7.6 Medical Radiological Defense, addresses the requirements for the development of radioprotectants. This priority is outlined for the development of

protectants for both acute and delayed radiation injuries, with an emphasis on (b)(4) (b)(4) According to this report, the mitigation of (b)(4) is a major research thrust area. This project is also designed to investigate mechanism(s) of protection to aid in the development of such agents.

V. MATERIALS AND METHODS

V.1. Experimental Design and General Procedures

The goal of this project is to investigate the protective effects and mechanisms of (b)(4) for radiation-induced (b)(4) injuries.

(b) Rationale for Doses and Times of Administration:

(b)(4),(b)(6)

(b)(4) For animals receiving i.p. injections on consecutive days, inspections will be performed by the AFRRI veterinary staff to ensure that peritonitis does not occur. If any indications occur of abdominal swelling, sensitivity or other potential indicators of peritonitis, animals will be switched to s.c. injection.

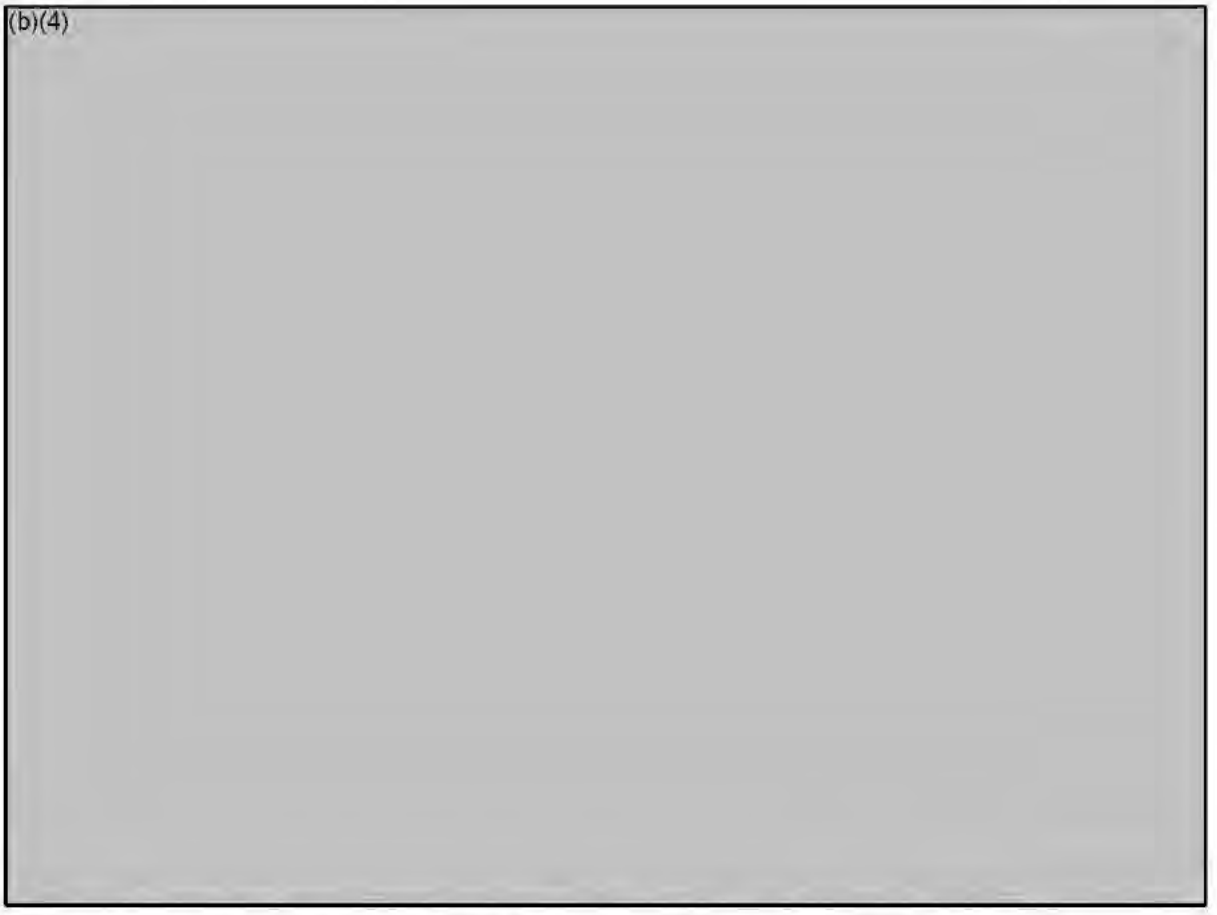
(b)(4) will also be administered by gavage, for the same time course as for injected routes of administration. The survival outcomes will be observed for injectable or gavage administration in Experiment 1 (see below), and the optimal route of administration will be selected for subsequent experiments. The optimal route of administration will be utilized throughout an entire study. If injection is selected as the optimal route of administration, the site of injection will be altered in consecutive injections to avoid injuries from multiple injections in the same site.

Radiation Rationale for Doses and Times of Administration

(b)(4)

5 Criteria for Determining Radiation-induced (b)(4)

(b)(4)



V.1.1. Experiment 1. Pilot study for protection C57L mice: category E)

This pilot experiment will be performed to assess survival from

Four groups will be studied:

Survival will be determined at days postirradiation. For these studies mice are required per radiation dose

Animals will be examined by AFRRI veterinarians following initiation of injections to ensure that peritonitis is not an issue for these injections. If it is determined that animals exhibit any potential indications of peritonitis (for example, abdominal swelling or sensitivity), then the route of administration will be switched to injection.

Because the time course for radiation-induced is shorter than for radiation-induced animals will be euthanized from this study prior to the completion of experiments in this AFRRI protocol.

This information can also be used to determine the effects of administration of

Future experiments will be performed following the completion of experiment 1 and are dependent upon the results of experiment 1. If improved survival is not observed with any of the routes of

administration for the proposed times of administration, further discussions will be held with the AFRRI IACUC prior to the initiation of further experiments.

(b)(4) [redacted] mice per group) x (4 treatment groups) x (1 time point) = [redacted] mice (total) (b)(4)

Endpoint: The final endpoint for the experiment is [redacted] days. Mice displaying obvious dyspnea, lethargy, or other markers of moribundity and which appear to be in distress will be euthanized. (b)(4) [redacted] Mice scoring a total of >10 under any measurement on the revised pain score sheet (based on Appendix A: Clinical Observations with Criteria for Euthanasia [rodent]) will be euthanized.

V.1.2. Experiment 2 Dose-modifying effect of (b)(4) protection ([redacted] mice: [redacted] in category C, [redacted] in category E) (b)(4)

(b)(4) Once we have established the efficacy (b)(4) for protecting mice from (b)(4) irradiation at the (b)(4) level, we will determine the dose modifying effect using three doses of (b)(4) irradiation (b)(4) (b)(4) (b)(4) Two groups of mice will be studied: 1) ionizing radiation +vehicle (control) and 2) ionizing radiation (b)(4) (experimental). For these studies, we will require (b)(mice per group in the radiation groups. We will include controls with (b) animals per group: 1) Sham irradiation + vehicle and 2) Sham irradiation (no treatment). The experiment will be repeated because it is a generally accepted principle of the scientific method that experiments must be repeated to evaluate a hypothesis.

Radiation groups

(b) (4) mice per group) x (2 treatment groups) x (1 time point) x (3 (b)(4) radiation levels) = (b)(4) mice/experiment) x (2 experiments) = (b)(4 mice

Control groups

(b)(4) [redacted] mice per group) x (2 treatment groups) x (1 time point) = [redacted] mice (b)(4)

(b)(4) Total mice required for this experiment = [redacted] mice (total)

Endpoint: The final endpoint for the experiment is (b) days. Mice displaying obvious dyspnea, lethargy, or other markers of moribundity and which appear to be in distress will be euthanized. (b)(4) [redacted] Mice scoring a total of >10 under any measurement on the revised pain score sheet (based on Appendix A: Clinical Observations with Criteria for Euthanasia [rodent]) will be euthanized.

V.1.3. Experiment 3 Survival from fractionated-dose irradiation [redacted] mice: [redacted] in category E) (b)(4)

Humans receive radiation for cancer treatment in fractionated doses. Our preliminary studies will utilize single doses of radiation for the induction of (b)(4) injuries. Once we have established the efficacy (b)(4) for the protection of (b) tissue against radiation injury from single high doses of radiation, we will investigate the use of (b)(4 for protection against fractionated radiation. A schedule of fractionated radiation (b)(4) given equally spaced (b)(4)

(b)(4) over [redacted] days, has been demonstrated in a murine model to be effective for the induction of radiation (b)(4 injuries (b)(4) We will utilize two treatment groups: 1) ionizing radiation + vehicle; 2) ionizing radiation + (b)(4) The experiment will be repeated because it is a generally accepted principle of the scientific method that experiments must be repeated to evaluate a hypothesis.

(b)(4) [redacted] mice per group) x (2 treatment groups) x (1 time point) = (b)(4)

(b)(4) mice/experiment) x (2 experiments) = mice (total)

Endpoint: The final endpoint for the experiment is days. Mice displaying obvious dyspnea, (b)(4) lethargy, or other markers of moribundity and which appear to be in distress will be euthanized. (b)(4) Mice scoring a total of >10 under any measurement on the revised pain score sheet (based on Appendix A: Clinical Observations with Criteria for Euthanasia [rodent]) will be euthanized.

V.1.4. Experiment 4 (b)(4) protection against (b)(4) mice: in category C; in category E) (b)(4)

(b)(4) We will investigate the degree of protection against radiation-induced (b)(4) We will determine levels of (b)(4) C57L mice will develop significant (b)(4) and we want to have as much survival as possible for the endpoint of this experiment. The selection of (b)(4) will allow increased survival while still provide a significant (b)(4) For this experiment we will require only (b)(4) mice/group, and we will examine 4 groups: 1) sham irradiation + vehicle; 2) sham irradiation + (b)(4) 3) ionizing radiation + vehicle; 4) ionizing radiation + (b)(4) The experiment will be repeated because it is a generally accepted principle of the scientific method that experiments must be repeated to evaluate a hypothesis.

(b)(4) mice per group) x (4 treatment groups) x (1 time point) = (b)(4)

(b)(4) mice/experiment) x (2 experiments) = mice (total)

Endpoint: The final endpoint for the experiment is days. Mice displaying obvious dyspnea, (b)(4) lethargy, or other markers of moribundity and which appear to be in distress will be euthanized. (b)(4) Mice scoring a total of >10 under any measurement on the revised pain score sheet (based on Appendix A: Clinical Observations with Criteria for Euthanasia [rodent]) will be euthanized.

(b)(4) **V.1.5. Experiment 5 protection against (b)(4) (b)(4) mice: in category C; in (b)(4) category E)**

(b)(4)

(b)(4) For this

(b)(4) experiment we will require only mice/group, and we will examine 4 groups: 1) sham irradiation + vehicle; 2) sham irradiation+(b)(4) 3) ionizing radiation + vehicle; 4) ionizing radiation +(b)(4) The experiment will be repeated because it is a generally accepted principle of the scientific method that experiments must be repeated to evaluate a hypothesis.

(b)(4) mice per group) x (4 treatment groups) x (4 time points) = (b)(4)

(b)(4) mice/experiment) x (2 experiments) = mice (total)

Endpoints: Endpoints for the experiments will be (b)(4) days. Early time points will be taken if any animal exhibits signs or symptoms of morbidity or moribundity. Such animals will be euthanized at the time of observation. Mice scoring a total of >10 under any measurement on the revised pain score sheet (based on Appendix A: Clinical Observations with Criteria for Euthanasia [rodent]) will be euthanized.

V.2. Data Analysis

Mean with standard error, or percentage will be reported if applicable. A significance level is set at 5% for each test. All statistical tests are two-sided. A statistical software, SAS will be used for statistical analyses.

Experiments 1-3: Analysis of variance (ANOVA) will be used to detect significant difference among the groups. If significant, then the pair-wise comparison by Tukey-Kramer will be used to identify which group is different from the other. For experiment 2, N = [redacted] mice per group could have 80% power to detect any significant difference between groups if any, given type I error of 5% and delta/sigma has at least 1.4, where the delta is the estimated mean differences between the two groups and sigma is the pooled standard deviation of the two groups (b)(4) (b)(4) [redacted]

Experiments 4 and 5: Previous data from this laboratory indicate that the coefficient of variation (CV) of the data is about 0.5, and that differences of between 2- and 30- fold are likely to be observed. A sample size of [redacted] per group will have 80% power to detect 3-fold increases in biomarkers based on a lognormal t test with a 5% two-sided significance level and a CV of 0.5. (b)(4)

V.3. Laboratory Animals Required and Justification

V.3.1. Non-animal Alternatives Considered

For the past 9 years, we have utilized primary cell culture systems to examine anti-apoptotic mechanisms; however, we must determine whether our culture findings are relevant in whole animals. We will continue to use primary cell culture whenever possible to avoid unnecessary use of animals. We have also considered computer models as alternatives to animals. However, this alternative also lacks the knowledge base and complexity needed to evaluate radioprotective and radiotherapeutic agents.

V.3.2. Animal Model and Species Justification

Tissue culture conditions cannot fully substitute for the complexities of whole organisms in response to radiation injury. Such injury involves the interactions between the (b)(4) [redacted] system and other organ systems. In order to develop viable treatments for humans, we find that our research must be conducted in whole animals.

Work by (b)(6) [redacted] also advocates the mouse as the best species to use for radiation protection and radiotherapy protocols: 1) mice provide the least sentient species available whose response to radiation has been clearly identified, with physiological responses to radiation and radioprotectants that are similar to human physiology, 2) extensive literature is available on responses of mice to radiation and countermeasures, 3) more reagents are available to study the relevant cell types and molecules in mice than in any other species except humans, and the availability of transgenic and knockout mice make this model extremely attractive for further research into molecular mechanisms, and 4) (b)(6) [redacted] (b)(6) have extensive experience with the mouse model in radiation (b)(4) injury and radioprotection research.

V.3.3. Laboratory Animals

V.3.3.1. Genus / Species *Mus musculus*

V.3.3.2. Strain / Stock C57L (NOT C57BL/6)

V.3.3.3. Source / Vendor (b)(4) [redacted]

V.3.3.4. Age animals will be purchased at 6 weeks of age and held (b)(6) until they are irradiated at 10-14 weeks

V.3.3.5. Weight Normal adult weight range for this strain: 17-21 g.

V.3.3.6. Sex
Female. Only females will be used in this study for the following reasons: 1) we have so far utilized female mice to lay the foundation of our studies for radiation-induced (b)(4) (b)(4) injuries; 2) because of long housing periods, it is advantageous to use female mice that are less aggressive toward each other.

V.3.3.7. Special Considerations Commercially procured animals must be adventitious disease free. Mice- Pathogen-free, including *Pseudomonas aeruginosa*, and Pasteurella: All mice need to be free of the following agents: Sendai, Pneumonia Virus of Mice (PVM), Reovirus-3 (Reo 3), Mouse Adenovirus (MAD-1, MAD-2), Mouse Cytomegalovirus Virus (MCMV), Ectromelia, K virus, Lymphocytic Choriomeningitis Virus (LCM), Epidemic Diarrhea of Infant Mice (EDIM), Hantaan virus, Rotavirus, Mouse Parvovirus (MPV), Polyoma Virus, Mouse Minute Virus (MMV), Mouse Thymic Virus (MTV), Theiler's Mouse Encephalomyelitis Virus (TMEV/GDVII), *Encephalitozoon cuniculi*, CAR bacillus; *Helicobacter* spp. *Mycoplasma pulmonis*, and *Clostridium piliforme*. Endoparasite- and ectoparasite-free.

V.3.4. Number of Animals Required (by species) C57L (b)(4)

V.3.5. Refinement, Reduction, Replacement (3 R's)

V.3.5.1. Refinement
Animals demonstrating moribundity due to radiation exposure (b)(4) will be considered to have arrived at the study endpoint and will be immediately euthanized (See sections V.4.5 Study Endpoint and V.4.6 Euthanasia).

Ketamine/xylazine and/or inhaled isoflurane anesthesia will be used during X-ray irradiation to prevent stress from the time the mice are placed in restraint. Isoflurane will be the preferred method. Mice will be restrained using either an approved jig or using surgical tape to secure the animal to the SARRP platform. Under the training protocol at AFRRI inconjunction with the AFRRI veterinary staff, we found that in female CBA or C57BL/6J mice, ~12 weeks old, i.p. injection of 150 mg/kg ketamine plus 18 mg/kg xylazine results in ~30-60 min anesthesia with no morbidity or mortality (b)(4) (b)(4) We have also observed that the animals require at least 10-20 additional minutes on heating pads to become fully ambulatory. The injectable anesthesia may also be used in combination with isoflurane if deemed necessary by the AFRRI veterinary staff.

As stated above, we use a heating pad to keep mice warm during the period of recovery from anesthesia. The temperature in room where the mice will be irradiated will be measured, and if necessary an alternate heating divice approved by VSD (such as Beir hugger to blow warm air into the room) will be used to increase the temperature. Standard intraperitoneal injection methods are used for injection of the anesthesia, as recommended and approved by the AFRRI veterinary staff and for which all laboratory personnel have received training at AFRRI.

V.3.5.2. Reduction
Whenever possible, control groups will be shared between experimental groups for our experiments. Tissues will be collected for multiple assays from the same animals further

reducing the total number of animals needed. At every stage of the research, planned experiments will be reevaluated, in an attempt to reduce the numbers of experiments and eliminate repeats of experiments where statistical significance has already been obtained.

V.3.5.3. Replacement

At this time, it is not feasible to use non-animal systems in place of animal models to address the research questions in this protocol.

V.4. Technical Methods

V.4.1. Pain / Distress Assessment

V.4.1.1. APHIS Form 7023 Information

V.4.1.1.1. Number of Animals C57L

V.4.1.1.1.1. Column C (b)(4) (# of animals)

V.4.1.1.1.2. Column D (# of animals)

V.4.1.1.1.3. Column E (# of animals)

V.4.1.1.1.4. Pain Category Assignments

(b)(4)

V.4.1.2. Pain Relief / Prevention

V.4.1.2.1. Anesthesia / Analgesia / Tranquilization

A portion of our study is aimed at determining the effect of the radiation countermeasure on all effects of radiation, including those effects on the (b)(4) especially radiation-induced (b)(4) Some analgesics may suppress (b)(4) function that may interfere with the interpretation of our results (b)(4) Additionally, some nonsteroidal anti-inflammatory drugs (NSAIDs) have been demonstrated to exacerbate (b)(4) inflammation in some disease states (b)(4) The response to murine (b)(4) to analgesics following radiation has not been thoroughly investigated, but the induction of additional levels of inflammation would severely compromise our experimental results.

Several studies indicate that exposure to γ-radiation induces altered reactions of opioid receptors to nociception and causes the direct release of endogenous beta-endophins, thus altering the effectiveness of opioid administration (b)(4) (b)(4) Some sedatives have been reported to contribute to postoperative (b)(4) which likely reduce some functions of radiation.

Published IACUC Guidelines define prolonged restraint as the physical restraint of an animal for more than 30 min. Restraint of mice for more than 30 min will be required for the time of irradiation plus time required for positioning the animal in the SARRP. For prolonged restraint required for (b)(4) irradiation, mice will be anesthetized with inhaled and/or injectable anesthesia.

For inhaled isoflorane anesthesia, a protocol will be developed in conjunction with the AFRRI veterinary staff. We will use 3-5% for the induction of anesthesia and 1-2% for maintenance during irradiation. Isoflorane will be delivered using 100% oxygen.

An injectable anesthesia protocol was developed for use during the X-ray irradiation under the training protocol at AFRRI in conjunction with the AFRRI veterinary staff. In female C57BL/6 and CBA mice, ~12 weeks old, i.p. injection of 100-150 mg/kg ketamine plus 10-18 mg/kg xylazine (25 G needle) results in ~30-60 min anesthesia with no morbidity or mortality (b)(4) (b)(4) We have also observed that the animals require at least 10-20 additional minutes on heating pads to become fully ambulatory. Injectable anesthesia may include ketamine 50-100 mg/kg + xylazine 5-10 mg/kg + acepromazine 1-2 mg/kg. Total volumes of injection will not exceed 0.5 ml/mouse. Standard i.p. injection methods are used for injection of the anesthesia, as recommended and approved by the AFRRI veterinary staff and for which laboratory personnel have received training at AFRRI.

V.4.1.2.2. Pre- and Post-procedural Provisions
Animals will be housed and cared for as described in Section V.5. Veterinary Care both before and after dose administrations and irradiation procedures.

V.4.1.2.3. Paralytics none

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures

V.4.1.3.1. Sources Searched DoD Biomedical Research Data Base (BRD), CRISP, PubMED

V.4.1.3.2. Date of Search 1/30/14

V.4.1.3.3. Period of Search Search covered published manuscripts from ~1965-present. (BRD search included all available years 1998 -2014).

V.4.1.3.4. Key Words of Search Pain, analgesia, anesthesia, mice, radiation, ionizing radiation, humane, (b)(4)

V.4.1.3.5. Results of Search
The literature search revealed that, at present, there are no alternative procedures for irradiation because its effects cannot be otherwise duplicated. In some cases radiation has been demonstrated to reduce pain in laboratory mice (b)(4) and has been in humans reported to alleviate cancer related bone pain (b)(4) (b)(4) A recent report showed that administration of botulinum toxin A was effective for reduction of pain and muscle spasms after clinical radiation for treatment of tumors (b)(4) (b)(4) Application of natural honey 20 min prior to radiation exposure was also shown to reduce mucositis with associated pain in humans following head/neck radiotherapy (b)(4) it has not been determined whether honey acts as a local radioprotectant. Spinal cord stimulation has also been reported in humans to alleviate pain

resulting from radiotherapy (b)(4) however, this method would not be practical for use in mice because of the extensive spinal cord manipulation required. Human administration of morphine also relieves pain (b)(4) but again this would not be practical for mice in our experiments because of side effects of the drug. In humans, exposure to total body irradiation may induce vomiting and diarrhea, causing pain and distress. However, mice are not susceptible to vomiting.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification

Anesthesia will be used before (b)(4) irradiation to avoid stress from restraint. (b)(4) (b)(4) (b)(4) we will be unable to use analgesics after irradiation since they have effects on (b)(4) function that would interfere with the interpretation of our results (b)(4) (b)(4) (b)(4). Pain will be evaluated using several standard indications including: grimacing, abnormal breathing, hunched or fluffed fur and inactivity, or ataxia. In experiments where tissue collection is needed, animals will be euthanized with pentobarbitol prior to sample collection as described elsewhere. We will utilize the attached score sheets to provide a scale for measurement of criteria for euthanasia. Any animal scoring Mice scoring a total of >10 under any measurement on the revised pain score sheet (based on Appendix A: Clinical Observations with Criteria for Euthanasia [rodent]) will be euthanized.

V.4.2. Prolonged Restraint

(b)(4) irradiation will require restraint in designed jigs or using surgical tape for ~20-40 min for SARRP positioning to receive X-ray exposure (b)(4) animals will be anesthetized during this period and tails and limbs will be taped with surgical tape. The maximal time for actual irradiation is 30 minutes; the maximal estimated time for the SARRP setup for the irradiation is 20 minutes. The estimated maximal total time for restraint is therefore 50 minutes.

The jigs for use during (b)(4) irradiation were examined and approved by the AFRRI Veterinary staff. An image of the jigs is attached, and jigs are available for inspection. The restraint is needed to ensure that animals do not move during irradiation. Positioning of the mice must be done carefully to ensure that all animals receive the same exposures. AFFRI Veterinary staff provided training and supervision for the placement of anesthetized animals in the approved jigs for irradiation.

V.4.3. Surgery Not applicable

V.4.3.1. Pre-surgical Provisions Not applicable

V.4.3.2. Procedure(s)

V.4.3.3. Post-surgical Provisions Not applicable

V.4.3.4. Location Not applicable

V.4.3.5. Surgeon Not applicable

V.4.3.6. Multiple Major Survival Operative Procedures Not applicable

V.4.3.6.1. Procedures Not applicable

V.4.3.6.2 Scientific Justification Not applicable

V.4.4. Animal Manipulations

V.4.4.1. Injections

The methodology of intraperitoneal (i.p.) injections by our laboratory technical staff will be monitored and approved by the AFFRI veterinary staff prior to the initiation of i.p. injections of (b)(4) for this study.

Intraperitoneal injections of pentobarbital for euthanasia 0.01-0.02 ml/mouse Fatal Plus (39-78 mg pentobarbital/mouse) will be performed with a 23-25 G needle. Injectable anesthesia administered i.p. may include ketamine 50-100 mg/kg + xylazine 5-10 mg/kg + acepromazine 1-2 mg/kg. Total volumes of injection will not exceed 0.5 ml/mouse, and will be done using a 23-25 G needle. This level of anesthesia was first developed for our use in collaboration with the AFRRI Veterinary staff. This drug combination provides ~30-60 min anesthesia with no morbidity or mortality (b)(4) (b)(4) We have also observed that the animals require at least 10-20 additional minutes on heating pads to become fully ambulatory.

(b)(4)

(b)(4)
(b)(4) Because the time course for radiation-induced (b)(4) is shorter than for radiation-induced (b)(4) animals will be euthanized from this study prior to the completion of experiments in this AFRRI protocol. (b)(4)
(b)(4)
(b)(4) If this information is available prior to the initiation of Experiment 1 of this protocol, this information will be used to determine whether the route of (b)(4) administration in the AFFRI studies.

When possible, same route of administration will be utilized throughout an entire study, but the site of injection will be changed to avoid injuries from multiple injections in the same site. (b)(4) Animals receiving injections will be examined by the AFRRI veterinary staff daily to ensure that there are no signs of (b)(4) If it is determined that peritonitis is a risk from injection (b)(4) (b)(4) or if it is determined that any individual animal is exhibiting signs of (b)(4) the route of administration will be switched to (b)(4)

V.4.4.1.1. Pharmaceutical Grade Drugs

(b)(4)

V.4.4.1.2. Non-Pharmaceutical Grade Drugs None

V.4.4.2. Biosamples

All biosamples will be taken after euthanasia. (b)(4) will be removed *en bloc*. (b)(4) will be removed from (b)(4) as control tissue. All other tissues will be available to other researchers for tissue sharing.

V.4.4.3. Adjuvants None

V.4.4.4. Monoclonal Antibody (MAb) Production Not applicable

V.4.4.5. Animal Identification
All cages will have cage cards identifying the treatment groups for each experiment.

V.4.4.6. Behavioral Studies Not applicable

V.4.4.7. Other Procedures

(b)(4) **irradiation**
(b)(4) irradiation will be performed using (b)(4),(b)(6) The methodology for (b)(4) irradiation of mice (b)(4) will be developed with the AFRRI IACUC and (b)(4) Once the procedure is approved by VSD, an amendment to this protocol with a standard operating procedure (SOP) will be submitted prior to the initiating the studies.

Mice will be anesthetized by injection and/or using inhaled anesthesia. Anesthetized mice will be placed in ventilated Lucite jigs, or animals will be restrained using surgical tape to prevent lateral or vertical movement. Tails and forelimbs will be taped to the jig to prevent any forward motion of animals and to keep the limbs out of the radiation field. Mice will be irradiated at (b)(4) (b)(4) irradiation. The temperature in room where the mice will be irradiated will be measured, and if necessary a space heater or other method approved by VSD will be used to increase the temperature. Following radiation exposure, mice will be recovered in a VSD and IACUC approved location or immediately returned to the AFRRI vivarium and allowed to recover from anesthesia under supervision with heating pads. Immediately upon recovery, animals will be returned to standard cages that house 4 animals per cage. Lucite jigs will be sanitized after each use by washing with soap and water.

V.4.4.8. Tissue Sharing
For the proposed studies, (b)(4) will be obtained. All other tissues will be available for tissue sharing with other investigators.

V.4.4.9. Animal By-Products None

V.4.5. Study Endpoint
(b)(4) The endpoint for Experiment 1-3 is days. The endpoint for Experiment 4 is days, and (b)(4) the endpoints for Experiment 5 are (b)(4) days postirradiation. Morbid animals will be monitored at least three times daily. Monitoring will be performed twice by the PI or laboratory technical staff. The experimental design does not contemplate supportive therapy. Criteria to be used for health evaluation while the animals are on study include: severe weight loss, ruffled fur, dehydration, decreased activity, and hunched body position, dyspnea, or panting. Animals exhibiting these signs may be euthanized, and considered to be at the study endpoint. From our previous experience, (b)(4) (b)(4)

V.4.6. Euthanasia

Animals will be euthanized at the stated early endpoints of the experiments by i.p. injection of 0.01-0.02 ml/mouse Fatal Plus. PHS policy is intraperitoneal injection of at least 200 mg/kg sodium pentobarbital euthanasia solution; Fatal Plus: 390 mg pentobarbitol/1 ml

1 ml/390 ml x 0.02 kg/mouse x 200 mg/1 kg = 0.01-0.02 ml

Injection i.p. will be performed using a 25 G needle. (Please note that Euthasol cannot be used as additives in this preparation have effects on (b)(4) IP using a 25 G needle. Pentobarbital has been utilized as a euthanasia methodology by our laboratory to induce as little injury as possible to (b)(4) CO_2 would be unacceptable because of potential damage (b)(4) and cervical dislocation could potentially tear the trachea (b)(4) (b)(4)

Animals which appear to be experiencing pain or distress as a result of radiation exposure or are found to be moribund will also be euthanized by pentobarbitol and necropsied. If a moribund animal is found that must be euthanized by VSD techs working on the weekend or holidays, 100% CO_2 euthanasia may be used instead of pentobarbitol. At the end of experiments, unused animals will be transferred to other protocols or euthanized by exposure to 100% CO_2 from a compressed gas cylinder in accordance with the current American Veterinary Medical Association (AVMA) Guidelines for Euthanasia. Cervical dislocation will be used to ensure euthanasia.

V.5. Veterinary Care

V.5.1. Husbandry Considerations

Routine animal husbandry will be provided in accordance with AFRRI VSD Husbandry SOPs for each species in this protocol. Food and acidified water and Rodent Diet will be available ad libitum. The 12:12 hr (lights off at 6 pm) room light cycle is fine for all the studies.

V.5.1.1. Study Room

(b)(6)

V.5.1.2. Special Husbandry Provisions None

V.5.1.3. Exceptions None

V.5.2. Veterinary Medical Care

V.5.2.1. Routine Veterinary Medical Care

Experimental animals will be observed at least twice a day, including weekends and holidays, by one of the study investigators or technicians during the period (b)(4) days postirradiation (b)(4) when effects of radiation are expected to be incurred. VSD personnel will also monitor the animals twice a day during their rounds. As described in the study endpoint section animals will be monitored at least three times daily, morning, early afternoon and late afternoon during the critical period of the experiment following (b)(4) irradiation, from (b) days postirradiation through the study endpoint. The experimental design does not contemplate supportive therapy. The justification for not providing supportive care has been described in the study end point section as well as in the pain category section. Criteria to be used for health evaluation while the animals are on study include: severe weight loss, ruffled fur, dehydration, decreased activity, and hunched body position, dyspnea, or panting. Animals exhibiting these signs may be euthanized, and considered to be at the study endpoint. Mice scoring a total of >10 under any

measurement on the revised pain score sheet (based on Appendix A: Clinical Observations with Criteria for Euthanasia [rodent]) will be euthanized.

V.5.2.2. Emergency Veterinary Medical Care Emergency veterinary care is provided 24 hrs/7 days a week by on call VSD veterinary technician and veterinarian as per the AFRRI-VSD SOPs. Essential husbandry procedures and health rounds are conducted by VSD personnel once daily during weekend and holidays.

V.5.3. Environmental Enrichment

V.5.3.1. Enrichment Strategy

All animals on this protocol will be provided with routine environmental enrichment in accordance with AFRRI VSD SOPs and IACUC Policies. Examples include nestlets and tunnels for rodents.

V.5.3.2. Enrichment Restrictions None.

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING

The methodology of intraperitoneal (i.p.) injections by our laboratory technical staff will be monitored and approved by the AFFRI veterinary staff prior to the initiation of i.p. injections of DIM for this study.

NAME	DEGREE	TRAINING	DATE	PROCEDURES	YRS/MOS EXPERIENCE
(b)(4)	Ph.D.	AFRRI	(b)(4)	1,3,5	10
	M.S.	AFRRI/AALAS	Multiple dates	1,3,5	9+

Procedure and manipulation codes:
Code 1= Animal handling and euthanasia
Code 2= Surgery (aseptic technique) pre- and post-operative care
Code 3= Injections (3a-ip, 3b-sc, 3c-gavage) - can say 3 if trained in all manipulations or add 3d-iv
Code 4= Blood collection under anesthesia (4a-cardiac, 4b-posterior vena cava)
Code 5= Tissue collection (after euthanasia) - doesn't need to be specific
Code 6 = Implantation (provide details)
Code 7 = Ear tagging

VII. BIOHAZARDS/SAFETY None

VIII. ENCLOSURES

X. ASSURANCES

Protocol Title: (b)(4) Protection from Radiation-Induced (b)(4) Injuries in a Murine Model (*Mus musculus*)

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made every effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with a qualified individual who evaluated the experimental design with respect to the statistical analysis, and that the minimum number of animals needed for scientific validity will be used.

D. Biohazard / Safety: I have taken into consideration and made the proper coordinations regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R", namely, "Responsibility," which the DOD has embraced for implementing animal use alternatives where feasible and conducting humane and lawful research.

G. Scientific Review: This proposed animal use protocol has received appropriate peer scientific review and is consistent with good scientific research practice.

H. Painful Procedure(s): I **AM / AM NOT** conducting biomedical experiments, which may potentially cause more than momentary or slight pain or distress to animals. If applicable, potential pain and/or distress **WILL / WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

AFRRI SCIENTIFIC RESEARCH PROTOCOL NUMBER: (b)(6)

I. NON-TECHNICAL SYNOPSIS Exposure to ionizing radiation can lead to death due to infection and failure to recovery from infection by loss of white blood cell precursors in the body, especially within bone marrow. This loss of blood cell precursors results in a low number of circulating white blood cells and platelets which protect the body from opportunistic infections and uncontrolled bleeding, respectively. We have shown that (b)(4) specifically increases platelets by 5-fold compared to normal untreated mice. Other studies at AFRRI have established that (b)(4) a good radiation countermeasure in mice. Advancement of this drug (alternatively, the class of compounds that enhance platelets in circulation) alone or combined with other countermeasures such as Granulocyte Colony Stimulating Factor (G-CSF) to human use requires studies in a large animal model such as nonhuman primates (NHPs). We evaluated (b)(4) in NHPs for safety and efficacy. Our preliminary studies show that the drug administered as a single subcutaneous injection or multiple injections does not cause any adverse effects. It also significantly enhanced platelets in both non-irradiated and irradiated NHPs. G-CSF on the other hand has been widely studied as a radiation countermeasure in several animal models. In the present protocol, we will evaluate various combinations of these two potential radiation countermeasures in NHPs subjected to cobalt 60 gamma radiation.

General note to IACUC members: Technically this new protocol represents continuation of an ongoing NHP project. The current active protocol will be expiring on July 31, 2014. The experiments described in this (new) protocol were previously approved as an amendment to the existing protocol. Further, PI has not proposed any new experiments. However, a new arm (G-CSF alone) has been added based on full committee review and recommendation of IACUC members. The reasons for the new protocol and continuation of the project are as follows:

a. Animal procurement: AFRRI has an established vendor selected through proper USUHS contracting procedures. This vendor has not met the required orders and animals for this project have not arrived. (b)(4)
(b)(4)
b. Program manager notification: The funding agency has been informed of the delay.
c. Completion: PI hopes to complete the project within one year of the approval.
d. This protocol should be considered as a pilot study with the intent of demonstrating potential efficacy of radiation mitigators.

II. BACKGROUND

II.1. Background

Because of increasing terrorist activity and dissemination of nuclear materials, the chances of military or civilian personnel being exposed to dirty bombs or improvised nuclear devices have risen dramatically in recent years. The prevailing sentiment of the US government is that it is a matter of when, not if, an attack with radiological or nuclear weapons will take place. The nation needs to be prepared for this eventuality. Acute radiation syndrome (ARS) results when ionizing irradiation causes defective hematopoiesis as a function of the radiation dose, dose-rate, and radiation quality. Defective hematopoiesis results in a decline in all blood cell counts for several weeks after initial exposure. The primary cause of death during the early phase of the radiation-induced hematopoietic syndrome is sepsis resulting from opportunistic infection due to a decline in the numbers of neutrophils (neutropenia) and increased translocation of bacteria across the gastrointestinal mucosa. Sepsis and shock result in eventual multiple organ failure and death. Acute radiation syndrome is often complicated by hemorrhage as a consequence of thrombocytopenia (reduced platelet counts Stickney *et al,* 2007).

The current treatment practice for radiation victims is the off-label administration of bone marrow growth factors, which are not yet approved for this purpose by the Food and Drug Administration (FDA), and must be used under the constant supervision of physicians because of possible adverse effects. Other agents that may be used for radiation victims, like potassium iodide (KI), Prussian blue, Calcium diethylene-triamine-penta-acetate (Ca-DTPA), and Zinc diethylene-triamine-penta-acetate (Zn-DTPA), address the internalization of specific radioactive isotopes, not the general injury caused by external exposure to ionizing radiation. For example, KI is used to prevent thyroid cancers by competing with internalized radioactive iodine for binding sites. Other potential radiation countermeasures are still in the pre-clinical research stage. There is a pressing need to develop countermeasures to ionizing radiation that will have a general beneficial effect on blood-forming tissues and immune competence. In order to expedite such studies which cannot be undertaken in humans due to ethical reasons, the FDA established "the animal efficacy rule" (FDA 2002). Under this rule, pivotal efficacy studies in Rhesus macaques exposed to lethal doses of ionizing radiation are appropriate to support approval of novel radiation countermeasure agents for human use.

The effectiveness of drugs to reduce or eliminate deleterious biological effects of ionizing radiation depends mostly on their effectiveness in controlling neutropenia, thrombocytopenia, and possibly anemia. Off-label drugs such as growth factors (GFs), G-CSF, and GM-CSF are available to treat neutropenia, but no such treatment exists for thrombocytopenia (although thrombopoietic GFs interleukin 11 [IL-11] and thrombopoietin [TPO] have been studied). However, first generation TPOs caused adverse effects in clinical trials (Kuter 2002, 2007, 2008) (b)(4)

(b)(4)

Brief background information on (b)(4) as a radiation countermeasure agent:

The drug for the present study will be synthesized by incorporation of a 14 amino acid peptide into a fully human antibody (PA83) scaffold at both the end region of the light chain

and the hinge region of the heavy chain (shown below). Control antibody without the 14 amino acid drug ligand will be used as control.

(b)(4)

We evaluated this (b)(4) (b)(4) as a radiation countermeasure in mice. We showed that the drug administered subcutaneously pre- or post-irradiation enhanced 30-day survival (b)(4),(b)(6) Briefly, thrombopoietin (TPO) receptor agonists lacking sequence homology to TPO were designed by grafting a known peptide sequence into the hinge and/or kappa constant regions of a human anti-anthrax antibody. Some of these proteins were equipotent to TPO in stimulating cMpl-r (the product of the c-mpl proto-oncogene, mpl= Myeloproliferative leukemia virus oncogene) activity *in vitro*, and in increasing platelet levels *in vivo*. (b)(4) the best agonist in this series with a Kd of 30 nM for cMpl-r, exhibited potent activity as a radiation countermeasure in CD2F1 mice exposed to lethal total body irradiation (TBI of 9.25 Gy) from a cobalt-60 gamma source. (b)(4) once either 24 h pre- or 6 h post-TBI showed superior protection to five daily doses given pre- or post-TBI. Prophylactic administration (aver. 82% 30-day survival) was superior to therapeutic schedules (60% 30-day survival). (b)(4) conferred significant survival benefit ($p<0.01$) when administered 4 days before or even 12 h after exposure, and across a dose range of 0.1 to 8 mg/Kg. The dose reduction factors (DRFs) with a single dose of (b)(4) 24 h pre- or 12 h post-TBI were 1.32 and 1.11, respectively ($p<0.0001$). Furthermore, (b)(4) increased bone marrow cellularity, megakaryocytic development, and accelerated multi-lineage hematopoietic recovery in irradiated mice demonstrating the potential of (b)(4) as both protectant and mitigator in the event of a radiological incident.

Nonhuman primate studies using (b)(4) (b)(4) rhesus macaque. Our results show that the drug (b)(4) is effective in enhancing platelets although to a lesser degree than seen in mice (Figure 1A). The research strategy for the present study is to evaluate a combination study involving (b)(4) and G-CSF or multiple (b)(4) administration on post-irradiation survival in NHPs. We showed recently (b)(4) (b)(4) (b)(4) that the proposed drug (b)(4) is safe for use with NHPs. Figure 1 shows preliminary data on enhancement of platelets (1A) in unirradiated animals administered a single *sc* injection of (b)(4) as well as changes in neutrophil counts (1B).

Figure 2 shows that a single *sc* injection of 2 mg/kg of (b)(4) administered either pre-irradiation (-24 h) or post-irradiation (+24 h) to NHPs subjected to 6.5 Gy resulted in survival and recovery of circulating platelets (platelet levels > 20,000/µl) by day 18. Although the non-drug treated control animal survived, it had a prolonged platelet recovery (day 29). The data represents animals that survived the 60 study.

Figures 3A (platelet levels) and 3B (absolute neutrophil counts) summarizes the hematological data for NHPs that were administered a single higher dose of the drug (b)(4) (b)(4) either pre-irradiation (-24 h) or post-irradiation (+24 h) and subjected to 7 Gy radiation. The results of drug treatment were not as effective as shown with the lower dose of radiation (Figure 2). We therefore proposed a combination of pre irradiation and multiple post irradiation drug administrations (the current protocol).

(b)(4)

II.2. Literature Search for Duplication

II.2.1. Literature Sources Searched PubMed, BRD, NIH Reporter, Embase

II.2.2. Date of Search: 5-20-2014

II.2.3. Period of Search: Pubmed 1946-present, NIH Reporter Fy1989 to present, BRD 1987 to active, and Embase 1966-present.

II.2.4. Key Words of Search

II.2.5. Results of Search There is no duplication based on the literature search.

III. OBJECTIVE / HYPOTHESIS Exposure to ionizing radiation can result in significant biological effects leading to mortality. The mission requirements of our military and homeland security personnel operating in a radiological environment are to provide rescue operations, security, radiological surveying, intelligence gathering, and decontamination. In a mass exposure scenario, where personnel are cut off from clinical support and treatment time is of the essence and administration of countermeasure agents could ameliorate the deleterious effects of ionizing radiation. The (b)(4) (b)(4) is a promising candidate based on mouse data. It is being evaluated in NHPs under the existing active but expiring protocol. The present protocol (new) will continue the NHP studies and extend ongoing observations with (b)(4) We intend to study (b)(4) either alone (pre and post irradiation) as a multiple regimen or combined with G-CSF.

Note: Please refer to the note to IACUC members on page 4 (below non-technical summary). This proposal represents continuation of an approved project- no new experiments are proposed although an extra arm (G-CSF alone) has been added to experiment 1 and 2 based on recommendation of IACUC members during full committee review.

Scientific relevance and hypothesis: Exposure to ionizing radiation increases susceptibility to infection and mortality due to significant loss of hematological regeneration capabilities. This is relevant to the context of military personnel, first responders, and other personnel who may be involved in rescue, security, and decontamination associated with accidental nuclear exposures. Over the years, several promising candidates have evolved that enhanced hematological recovery. Although none of these have been approved for treating radiation injuries, the FDA has recommended the use of cytokines, such as G-CSF (already in the U.S. stockpile) to control neutropenia in combating opportunistic infections. The relevance of this proposal is one that addresses an area (platelet recovery) that has not been extensively studied. Radiation-induced thrombocytopenia associated with loss of platelets has been implicated in the deleterious effects of ionizing radiation, especially mortality in NHP under acute exposure (Stickney *et al* 2007). Since other investigators have shown that enhancement of platelet response is associated with improved quality of life in patients with thrombocytopenia, it is imperative to develop drugs that can work by reducing radiation-induced thrombocytopenia. The present proposal will evaluate (b)(4) in nonhuman primates (NHPs) exposed to cobalt-60 gamma radiation. We hypothesize, based on our radiation countermeasure studies in CD2F1 male mice that the drug will be as effective in NHP as it has been in mice. Further, we expect (b)(4) will produce robust hematological recovery that will not be restricted to a single lineage. For instance, administration of this drug will not only increase circulating platelets but will also increase neutrophils and monocytes.

IV. MILITARY RELEVANCE Nuclear proliferation, terrorist activity, and the distribution of nuclear and radioactive materials through underground networks make incidents involving radiation injuries increasingly likely. As explained in a Department of Defense (DoD) Report to Congress (http://www.acq.osd.mil/cp), Al-Qaeda is known to have ambitious plans to acquire or develop nuclear weapons and is receptive to outside nuclear assistance. That group has also attempted to purchase enriched uranium. In view of the increasing likelihood of accidental radiation exposure and bioterrorism, the need for field able radiation countermeasures has been recognized as a high priority by the DoD.

Advances in radiation countermeasure strategies may enable military forces to operate, when required, in nuclear or radioactive combat environments while minimizing both short- and long-term consequences of exposure to ionizing radiation. Accurate casualty prediction models promote effective command decisions and force structure planning. Advanced biological dosimetry methodology is used in triage, treatment decisions, and risk assessment. Together, the results of the three research thrusts improve therapeutic strategies for the treatment and prevention of early and long-term health effects and mitigate the risks to our personnel and their offspring (AFRRI mission statement).

Most deaths due to radiation occur as a result of bone marrow damage and secondary infection. Any treatment that stimulates hematopoietic recovery could be advantageous.

We have recently shown that (b)(4) enhanced platelet levels in circulation 3-5 fold in normal and sublethally irradiated mice. This protocol involving evaluation of the drug in NHPs will allow advancement of the drug to stockpiling for emergency use against ionizing radiation.

The scientific basis for the combination of pre- and post- administration of a drug or a combination of drugs is to enhance the beneficiary effects of radiation countermeasures. Using two drugs with different modes of action (b)(4) promoting platelet regeneration; G-CSF stimulating neutrophils) is hypothesized to be beneficial in irradiated subjects. We have previously shown that (b)(4) is a good radioprotectant (administered -24h) and a mitigator (effective +12 h and in some instances up to +24 h) in mice. Farese *et al.*, (2012) recently demonstrated that G-CSF (10 µg/kg) administered daily (until absolute neutrophil counts (ANC) ≥ 1000 cells/µl) and in conjunction with full supportive care increased survival of lethally irradiated Nonhuman primates (NHPs). Growing evidence in large animal models such as NHPs, have demonstrated that G-CSF plays a significant role in the treatment of the acute radiation syndrome (Bertho *et al.*, 2005; Drouet *et al.*, 2008). More recently (May, 2013) FDA has recommended that G-CSF could be used in radiation patients without the President's directive; however, the FDA panel also indicated the need for additional studies to optimize the drug response in NHPs or other large animal models.

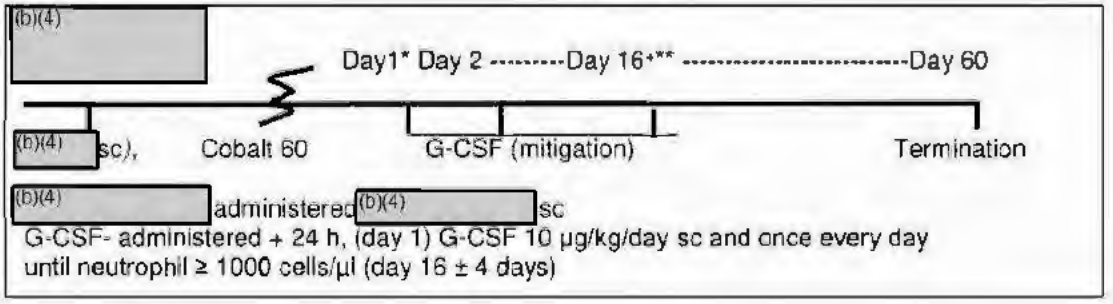
We will be conducting studies in animals with minimal supportive care (no antibiotic or blood transfusions). As described below in Experiment 1, we intend to pretreat animals with a single dose of (b)(4) and subject them to whole body Cobalt 60 gamma radiation. These animals will receive G-CSF following radiation exposure. The end point will be survival and hematological changes over 60-days post-irradiation. We hypothesize that pretreatment with (b)(4) and followed by G-CSF treatment post irradiation will synergistically increase radiation survival of NHPs.

V. MATERIALS AND METHODS

V.1. Experimental Design and General Procedures

V.1.1. Experiment 1: Effect of 1 pre-irradiation administration of (b)(4) + multiple postirradiation administrations of G-CSF (once daily) until neutrophil recovery: The first experiment will evaluate hematological indices at periodic intervals and monitor animals for survival until 60 days postirradiation. In this experiment based on experimental design (b)(4) will be administered (b)(4) prior to irradiation (Schematic 1). Filgrastim (G-CSF) administration will be initiated +24 h postirradiation and will be continued on a daily basis until neutrophils return back to ≥ 1000 cells/µl. This is anticipated to be around 16 days (± 4 days).

Schematic 1



Experimental design

The following groups will be included in the study:

Group 1-Control – will receive PBS sc pre- and postirradiation, n = 3

Group 2- G-CSF alone- will receive G-CSF daily (starting +24 h, and until neutrophil recovery (≥ 1000 cells/µl) n = 3

Group 3-(b)(4) -G-CSF- Will receive (b)(4) and G-CSF (+24 h, and until neutrophil recovery (≥ 1000 cells/µl) n = 3

Radiation dose: The dose in the present study will be 7.2 Gy @ 0.6 Gy/min representing approximately the LD70/60 dose with minimal supportive care (unpublished preliminary data).

(b)(4) regimen: (b)(4) will be administered sc 24 h before irradiation

G-CSF regimen: The first G-CSF administration (10 µg/kg) will be administered sc 24 h postirradiation. Additional G-CSF will be administered sc daily (10 µg/kg) until absolute neutrophil count (ANC) increases to ≥ 1000 cells/µL.

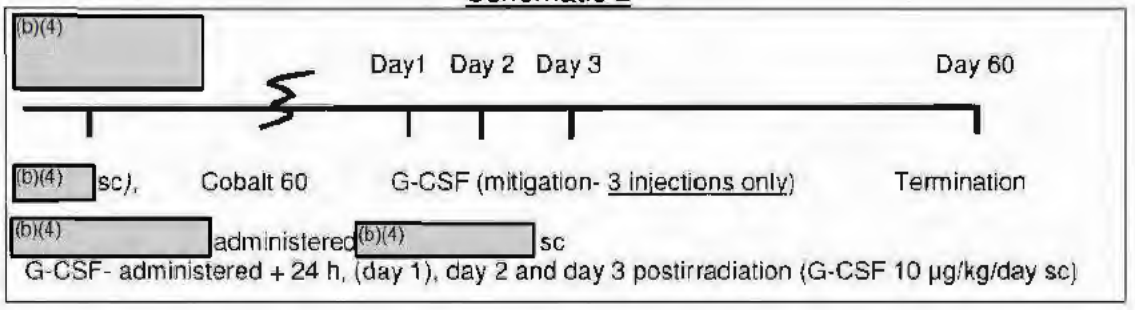
Postirradiation monitoring: Animals will be monitored for 60 days postirradiation.

Euthanasia: Experimental animals will be euthanized at the end of 60 day observation period and all relevant tissues including bone marrow will be collected for histopathological and biochemical analysis.

V.1.2. Experiment 2: Effect of 1 pre-irradiation administration of (b)(4) + three postirradiation administrations of G-CSF (on day+1, +2, and +3 postirradiation).

This experiment will evaluate hematological indices at periodic intervals and monitor animals for survival until 60 days postirradiation. In this experiment based on experimental design, (b)(4) will be administered (b)(4) prior to irradiation (Schematic 2). Filgrastim (G-CSF) administration will be initiated +24 h postirradiation and will also be administered on day +2 and day +3 postirradiation (Schematic 2). This experiment is based on mouse studies where in PI has demonstrated that 3 daily postirradiation injection of G-CSF alone are effective in increasing 30-day postirradiation survival (unpublished data).

Schematic 2



Experimental design
The following groups will be included in the study:

Group 1-Control – will receive PBS sc pre- and postirradiation, n = 3

Group 2- G-CSF alone- will receive G-CSF (+24 h, + day 2, and + day 3 postirradiation) n = 3

Group 3-(b)(4) -G-CSF- Will receive (b)(4) and
G-CSF (+24 h, + day 2, and + day 3 postirradiation) n = 3

Note: All other experimental conditions such as radiation dose, euthanasia etc will be similar to experiment 1 and hence are not described.

V.1.3. Experiment 3: Effect of 1 pre-irradiation administration of (b)(4) + three postirradiation administrations of (b)(4) (on day +1, +7, and +10): This experiment will evaluate pre and postirradiation (b)(4) administration on hematopoietic recovery and 60-day postirradiation survival. This concept is based on clinical use of (b)(4) (b)(4) in activity. (b)(4) (b)(4) is given once a week for treating idiopathic thrombocytopenia purpura (ITP). However, (b)(4) has not been evaluated as a radiation countermeasure.

Experimental design
The following groups will be included in the study:

Group 1-Control – will receive PBS sc pre- and postirradiation, n = 3

Group 2- (b)(4)
(-24 h, +1 day, +7 day, and +10 day) n = 3

Radiation dose: The dose in the present study will be 7.2 Gy @0.6 Gy/min representing approximately LD70/60 dose with minimal support care (unpublished preliminary data).

(b)(4) regimen: (b)(4) will be administered sc 24 h before irradiation and on day 1, day 7 and day 10 postirradiation.

Postirradiation monitoring: Animals will be monitored for 60 days postirradiation.

Euthanasia: Experimental animals will be euthanized at the end of 60 day observation period and all relevant tissues including bone marrow will be collected for histopathological and biochemical analysis.

V.2. Data Analysis

Comment: As mentioned in the non-technical synopsis, the experiments described in the protocol should be considered as pilot studies and hence statistical evaluation will be limited.

Statistician's remarks and approval:

Working Hypothesis for declaring a test agent effective; An observed 30% increase in survival over the vehicle-treated group exposed to a radiation dose producing ~ 70% (±10%) mortality, monitored over 60 days post irradiation. *(This criterion is based on data from previous extensive mouse studies/literature /scientific discussions & agency requirements to evaluate radiation countermeasures agents).*Means and SE with a significance level at 5% set for each test has to be performed. In order to evaluate the hypothesis set forth and establish a comparison of significance of deviation from the hypothesis, Fisher Exact Test to be used. The test can provide the significance and deviation of efficacy of the measure used. Type-1 error is controlled at 5%, type-2 error is 20% and sample sizes are equal between the different groups. The Exact Log Rank test (one-tailed) and the generalized Savage (Mantel-Cox) procedure (BMDP Statistical Software Inc., CA) will be used to compare survival of drug-treated and control groups in the radiation-survival experiments. The log-rank test or the Mantel-Cox test evaluates the test hypothesis of survival distribution statistics and potential effectiveness of drug response among the groups of samples at the established time points to ascertain the drug efficacy and effectiveness. It provides the statistics to differentiate dose-response efficacy based time distributions among groups of samples for potential new treatment evaluation comparison to controlled treatment with or without combination. This test is widely used in clinical trials to establish the efficacy of the drug or drug combinations and to establish the drug effectiveness. When inferential statistics is used such as t-test, Fisher's tests, ANOVA etc, to evaluate the outcome and comparisons, sample size (n) need to be determined to provide sufficient statistical capability for performance. Based on the power analyses the sample size proposed by the investigator is appropriately sufficient to deliver more than 80%. Although experiments with 8 NHPs (4 NHPs per group) have ~80% of power to detect significant differences between the drug-treated and vehicle controls, for the present protocol 3-6 animals per group (24 NHPs in total) are used since these studies are exploratory in nature (b)(4) has not been systematically analyzed in large animal model).

Demographic, hematology, vital signs, blood counts, chemistry, antibody levels, and cytokine estimations in both blood and urine will be compiled as summarized using mean, standard deviation, minimum, median and maximum values.

Vital signs will be summarized using descriptive statistics at each assessment time for each treatment group.

V.3. Laboratory Animals Required and Justification

V.3.1. Non-animal Alternatives Considered The effectiveness of drugs such as (b)(4) against radiation cannot be adequately assessed using current *in vitro* technologies. The U.S. FDA recognizes the ethical considerations involved in testing the efficacy of radioprotective drugs in humans. Therefore, the FDA requires preclinical drug assessments (safety and efficacy) to be performed using both small and large animal models (FDA 2002) prior to granting approval for safety testing in humans. The proposed experiments will provide efficacy data with NHPs, one of the preferred large-animal models. If these studies are successful, full-fledged GLP studies will be conducted for safety and efficacy. GLP studies are very expensive and cannot be done with the grant for this study.

V.3.2. Animal Model and Species Justification NHPs are necessary for the pre-clinical development of a drug candidate intended for use in humans because drug

metabolism and physiology are very similar between humans and NHPs. Testing a drug with potential for human application in NHPs ensures safety and specificity prior to the drug entering into the clinic. This is true especially because of safety risks and the chance of unexpected autoimmune or hyper-immune reactions. Due to the species-specific nature of immune reactions, the drugs can only be studied *in vivo* in hosts whose immune systems are very closely related to that of humans. Rhesus macaques are the model of choice for investigations of radiation injury and countermeasures because of the large database available from the existing literature that allows for robust comparison. The FDA has accepted rhesus macaques as the appropriate animal model for pilot and pivotal efficacy testing of radiation countermeasures under the Animal Efficacy Rule, where efficacy testing cannot be performed *in* humans. The safety and efficacy of (b)(4) was demonstrated in mice. (b)(4) (b)(4) it is appropriate to conduct the present set of experiments to advance the drug for human use.

V.3.3. Laboratory Animals: *Macaca mulatta* (rhesus macaque) will be obtained from vendors registered with the USDA.

V.3.3.1. Genus/Species: *Macaca mulatta*

V.3.3.2. Strain/Stock: Preference will be given to animals of Chinese origin so that comparisons can be made with existing data on NHPs from AFRRI. Male and female *M. mulatta* are required that have been pole and collar trained, have normal cardiovascular parameters, no infections or wounds, and which have normal liver and kidney enzyme functions.

V.3.3.3. Source/Vendor: In general, the sources for these animals are commercial vendors registered with USDA. (b)(4) (b)(4)

V.3.3.4. Age: Animals of 3 to 8 years of age are requested for the present study.

V.3.3.5. Weight: Animals must weigh in the range of 3–8 kg.

V.3.3.6. Gender: Male and female

V.3.3.7. Special Considerations: NHPs shall test negative for Herpes B Virus (aka, *Macacine herpesvirus*), simian T-cell leukemia virus type 1 (STLV-1), simian immunodeficiency virus (SIV), and simian retrovirus (SRV) Types 1, 2, 3, and 5. Animals shall also test negative by means of virus isolation or polymerase chain reaction (PCR) for SRV Type 2. NHPs will either be vaccinated for measles or, in the case of previously measles-vaccinated NHPs, tested for the presence of measles antibodies.

NHPs coming from the vendor colony must test negative for Salmonella sp. and Shigella sp. On the advice of the attending veterinarian, in consultation with the PI, the exclusion criteria for certain viral and bacterial pathogens may be waived.

CBC and blood chemistry will be obtained from vendors for each primate and screened for abnormalities by an AFRRI veterinarian. Any abnormal findings will be discussed with the PI and a determination of the fitness of the animal for use on the protocol will be made. Individual medical records will be maintained during the entire length of the study. Tuberculosis testing will be performed in accordance with VSD SOPs.

Use of collared animals allows them to sit in special chairs for blood draw as well as for other examinations/treatments.

V.3.4. Number of Animals Required (by species): Total (24): 12 males and/or 12 females

V.3.5. Refinement, Reduction, Replacement (3 R's)

V.3.5.1. Refinement: Pain is not expected from the irradiation *per se* but the sequelae of radiation exposure at the levels indicated in this protocol will cause pain and distress. Unexpected circumstances that elicit pain and/or distress will immediately be brought to the attention of the principal or co-investigator and attending staff veterinarian for appropriate action as detailed in AFRRI Protocols.

The use of pole and collar trained animals (preferably from vendor) will reduce the stress on the animals during blood draw and injections. Acclimatization to bottle for oral supplementation such as drinking water, juices, Gatorade and electrolytes will facilitate working with the animals and relieve the discomfort from radiation-induced vomiting or diarrhea. Prior to placement of the animals within comfortable radiation restraining chairs they will receive light immobilizing doses of ketamine (as determined by veterinarian) to reduce the anxiety of moving. The time in the chair will be kept to a maximum of 1 h. In addition, the animals will be transported to the radiation facility in a closed HEPA-filtered cart to reduce the excitement of moving from their home cages to the radiation area. Medications will be provided in case of fever, diarrhea, vomiting, and bloating.

Lastly, relative to a humane endpoint, moribund animals will undergo euthanasia. Euthanasia will only be provided by qualified veterinary staff. The endpoint of the studies will be either death from the squeal of radiation injury or euthanasia for moribund animals. To minimize animal suffering, pain, or distress, moribund animals will be considered to have arrived at the study endpoint. Such animals will be euthanized and recorded as "mortality".

Animals will be considered morbid when they display symptoms listed in V.4.5 Experimental animals that are morbid, but not moribund, will be allowed to continue in the experimental protocol with minimal supportive care in order to evaluate survival accurately.

Animals will be considered moribund when showing some or all of the signs of morbidity, the animals also display severely debilitated state and are in terminal distress. Animals will be monitored more frequently during this critical phase of the study.

V.3.5.2. Reduction: Further, we propose to use multiple sampling points for blood collection. Baseline data obtained from individual animals pre-irradiation (3 time points) will be used for assessing post-irradiation alterations in hematological parameters.

V.3.5.3. Replacement: None

V.4. Technical Methods

Animal procedures: NHPs will be pair-housed as much as possible after observing compatibility. Animals will be quarantined for 4-6 weeks prior to the inception of the experiment. Environmental enrichment will be in the form of fruit, vegetable, or additional dietary supplements, and various cage-enrichment devices. Fruits will be washed in fresh water, treated with dilute chlorine solution (200 ppm chlorine/5 gallons water) and rinsed before providing it to animals.

Chair training: Animal order request will include installation of collars and training in the technique of pole and collar with chair restraint. This training will be further reinforced at AFRRI by VSD staff and project personnel.

Irradiation: On the morning of irradiation, the NHPs will not be fed. Animals will be sedated, loaded into specialized restraint boxes, transported to the AFRRI cobalt facility using a self-contained breathing unit (HEPA-filter equipped) transport container and irradiated. Following radiations, animals will be returned to their original room and kept in clean cages. Since the NHPs will be sedated prior to restraining in the specialized boxes for radiation, "restraint" training in this instance is not mandatory.

Animals will be assigned to treatment groups using either a computerized randomization procedure or a physical randomization procedure depending upon the sample size. Randomization is designed to achieve balance in terms of neutrophil counts and body weights. Body dimensions (waist) will be measured prior to radiation. Animals may be removed from the study based on abnormal neutrophil counts or clinical signs (physical exam, clinical chemistry) during the weeks before irradiation, in which case backup animals will be randomized. The list of animals, with assigned groups and irradiation pairings, will be discussed with AFRRI dosimetrists in advance before the irradiation day to facilitate dosimetry.

Radiation dosimetry will be performed by the AFRRI dosimetrists using different sized cylindrical monkey phantoms inside monkey restraint boxes (b)(4) (b)(4)

General procedures:

Drug formulation:

(b)(4) will provide the drug. The drug will be endotoxin tested by Charles River laboratories and the drug will be diluted appropriately in sterile PBS prior to injection (within 1-2 h after preparation). The drug will be maintained undiluted at 4 ºC until injection. The drug dose will be (b)(4) administered sc.

Filgastrim (Neupogen®) recombinant human methionyl granulocyte colony stimulating factor (r-metHuG-CSF) will be purchased from Amgen, Inc. (Thousand Oaks, CA). The drug will be diluted appropriately in sterile 5% Dextrose prior to injection (within 1-2 h after preparation). The drug will be maintained undiluted at 4 ºC until injection. The drug dose will be 10 µg/kg administered *sc.*

Blood collection: Blood samples will be collected under appropriate SOPs. Blood (0.5 ml to 1.5 ml/day depending on the time point) will be collected from a peripheral vessel or femoral vein with a 22-25 G needle attached to a syringe to reduce the chances of bleeding after blood collection in irradiated animals. An aliquot (0. 5 ml) from each sample will be taken immediately for CBC/differential. Further, 0.5 ml will be used to prepare serum that

will be frozen at -70 °C for clinical chemistry and antibody measurements. If additional blood collection (extra 1 ml/collection) is required for bacteremia (in case of severe neutropenia) or for evaluation of other parameters such as antibody assays then amendments will be submitted to request such collections.

The area for the blood draw will be swabbed with disinfectant to include 70 % alcohol (isopropyl or ethanol) solution for routine collections and additionally with providone-iodine for microbial sample collections (left in place for 3 minutes) before inserting the needle. Providone-iodine, if used, will be swabbed off to reduce irritation to the tissue .The blood sample will be drawn as described above. While withdrawing needle, pressure will be applied at the same time with a clean gauze to reduce bleeding from the blood draw site. While making routine observation of animals, the blood-draw site will be checked for bleeding. If the site becomes infected, topical antibiotics will be applied, under supervision by VSD.

Urine collection:
Free Catch Method: Urine collection procedure will involve the use of standard trays with fiberglass mesh filters (Johnson *et al*., 2012).Trays will be placed under NHP cages after morning cleaning has been performed by VSD animal husbandry personnel (placed at approximately 10:00 am) and will remain under cages for approximately 4-6 h. Normal feeding and watering will be performed while trays are under cages. Urine will then be carefully removed from the tray with a disposable 2 ml pipette, aliquoted and stored at -80^0 C. Baseline urine collections will be performed at least 1 week before radiation. Urine collection will continue at every other from day 0-8 and then approximately once to twice per week through day 35. Samples will remain frozen at -80^0 C indefinitely until cytokine, trace element and metabolic analysis can be performed.
Alternative Methods: Other methods including the use of metabolic cages and diapers have also been described for urine collection in Non-human primates as reviewed by Kurien *et al* in 2004. The PI will reserve the initiative to explore other options if the free catch method is insufficient to obtain pure animals urine for qualitative and quantitative purposes.

Identification of pain: NHPs demonstrate remarkably little reaction to surgical procedures and injury in the presence of humans. An NHP in pain has a general appearance of misery and dejection. We will observe all irradiated animals for grimace and glassy eyes, loud and persistent vocalization, avoidance of social interaction, and grooming. Gastrointestinal injury may be associated with abdominal pain displayed as facial contortions, teeth clenching, and restlessness. Headaches manifest by pressing the head against the enclosure surface. Self-directed injurious behavior may be a sign of more intense pain. Since most primates in pain will refuse food and water, daily food and water intake will be closely monitored. Further, response to a familiar personnel and changes in willingness to cooperate may also indicate pain, which will be closely monitored and recorded.

Euthanasia: Animals will be sedated according to current American Veterinary Medical Association (AVMA, 2013) guidelines. All animals will first be sedated with ketamine (IM, 10 mg/Kg). Animals will then be euthanized with sodium pentobarbital (IV, 100 mg/kg). See item V.4.6 for euthanasia criteria before the end of the study.

Veterinary Care: All animal procedures performed will be in compliance with the Animal Welfare Act, the Guide for the Care and Use of Laboratory Animals, and applicable VSD

SOPs. Our facilities are accredited by the Association for Assessment and Accreditation of Laboratory Animal Care International. Animal usage will be approved by the Institutional Animal Care and Use Committee in accordance with approved protocols. Species specific environmental enrichment and dietary supplements are provided according to standard operating procedures.

Routine and emergency veterinary medical care: Animals will be quarantined for 4-6 weeks on arrival and could be assessed for pole and collar training during the quarantine period. Each animal will be observed twice daily for evidence of pain or distress. Body weights will be determined at least once prior to the start of the study, and on a regular basis when the animals are chaired for blood collections. Body temperature will also be determined at least once prior to the start of the study, and on a regular basis when the animals are chaired for blood collections using chips implanted by VSD trained staff. The time of each blood collection will be recorded for each NHP. Animals will be qualitatively assessed twice daily (a.m. and p.m.) for general behavioral status and food consumption. Appropriate standard operating procedures will be followed by staff veterinarians in the event of pain or distress.

Minimal supportive care: We define minimal supportive care as clinical care that does not involve platelet or blood transfusion. Clinical care will be minimal; platelet counts may drop below 20,000 cells/µl for several days, but whole blood will not be transfused, as this would negate the purpose of the study. Skin characteristics will be monitored daily for signs of dehydration, which may be possible if animals avoid drinking after exposure. In this case, supplemental fluids will be administered (Table 1).

Table 1. Summary of Minimal Supportive Care

Drug class	Allowed medication or supportive care agents	Indication and/or criterion for administration
Anesthetics	Ketamine 10 ± 5 mg/kg, IM	**Sedation during procedures:** • Administered before animal manipulations to minimize stress and anxiety.
Analgesics	Acetaminophen (Tylenol) 5–10 mg/kg PO BID-QID	**Pain Management:** • Acetaminophen can be administered when evidence of pain is present.
Antipyretic	Acetaminophen (Tylenol) 5–10 mg/kg PO BID-QID	**Fever [temperature ≥ 104 °F (40°C)]**
Supplemental Fluids	Hydrating fruits and pop sickles. PRANG 15 ± 5 ml/kg PO in consultation with VSD staff.	**Dehydration: (At the request of the investigator or veterinarian)** • Symptoms include diminished skin turgor, dry mucous membranes, dry nose, increased hematocrit, and sunken eyes **Fever [temperature ≥ 104 °F (40°C)]:**
Nutritional Support	BIO-SERV certified Rhesus Liquid Primate Diet	**Weight Loss (Anorexia):** Nutritional support can be administered when body weight is <85% of baseline and be continued as long as the body weigh remains <85% of baseline, and the animal is not eating.

Antibiotics (Topical)	As per veterinarian consultation	**Evidence of subcutaneous infections, open wounds:** Antibiotic cream can be administered (under supervision of VSD staff) to ameliorate discomfort due to skin lesions.
Anti-diarrheal	Loperamide hydrochloride (Imodium), Initial dose 0.04 mg/kg QID.	**Diarrhea:** At the first sign of soft to loose stools: Imodium will be administered up to twice daily and should continue for 3 days. It may be stopped earlier than 3 days if the diarrhea resolves.
Barbiturates	Pentobarbital sodium, 100 mg/kg IV.	**Euthanasia.**

If pain and/or distress are seen, the PI and VSD veterinarian will be notified immediately to evaluate and determine the appropriate treatment, even on the weekends and after normal business hours. Body temperature may be monitored daily. Hematology will be monitored one week before irradiation, and at appropriate times after irradiation. Symptomatic therapy will be provided with development of abnormal clinical signs. For example, fruit or treats may be given in case of anorexia. In cases of open wounds with significant defects following skin necrosis due to subcutaneous infections, the area will be thoroughly cleaned and appropriate care will be provided by technical staff and VSD veterinarian. If pain and/or distress are observed, affected NHPs will be evaluated by a staff veterinarian and will be treated as determined by the staff veterinarian.

Inappetence or dehydration with or without signs of gastrointestinal distress will be treated with either fluid supplementation (*per os* tubing) or Liquid Primate Diet at the request of the investigator or staff veterinarian. Antibiotic cream may be administered topically (under supervision by VSD staff) in order to ameliorate discomfort due to skin lesions.

Estimation of hematological indices: Blood (0.5-1.5 ml/day depending on time point (see Table 2)) will be obtained from the saphenous vein (or femoral vein) using a 22–25 G needle attached to a 3 ml (generally) heparinized syringe from non-anesthetized NHP, transferred immediately into pre-coated ethylenediaminetetra-acetic acid (EDTA, Sigma-Aldrich, St. Louis, MO, USA) tubes and mixed gently on a rotary shaker until analysis. The coded tubes will be analyzed for white blood cell (WBC), absolute neutrophil counts (ANC), monocytes, lymphocytes, reticulocytes, hemoglobin and platelet counts using the ADVIA 2120 (Siemens Medical Solutions Diagnostics, Dublin, Ireland) and data will be generated using the MS software, version 5.9.

Estimation of peripheral blood progenitor cells: The primary effect of (b)(4) is on the hematopoietic stem and progenitor cell (HSPC) proliferation. Since we have not included bone marrow collection during the 60 day observation period in these NHPs, assay of the peripheral blood for HSPCs will serve as a substitute for determining the effect of (b)(4) on the hematopoietic cells in normal and irradiated NHPs. Heparinized blood will collected as described above and total CFCs [i.e., granulocyte-macrophage colony-forming units (CFU-GM), erythroid burst-forming units (BFU-E), and multilineage (granulocyte, erythrocyte, macrophage, megakaryocyte) CFU (CFU-GEMM)] and high-proliferative potential CFC (HPP-CFCs) will be assayed.

Totals:				24	24

V.4.1.2. Pain Relief / Prevention

V.4.1.2.1. Anesthesia / Analgesia / Tranquilization

Microchips will be implanted under ketamine (10 mg/Kg, IM) sedation or local (lidocaine) anesthesia and are placed before the initial start of the study. If necessary a drop of surgical glue will be placed at the chip insertion site to ensure that the chip stays in place.

Bone marrow collection will be made pre-euthanasia. It will be carried out under "Clean" and not "sterile" conditions. Animals will be euthanized after bone marrow collection before the animal is allowed to recover from anesthesia.

Bone marrow is expected to be a painful procedure. As such, the primates will be under general anesthesia at the time of marrow cell harvesting. NHPs will be sedated with 10mg/Kg ketamine IM in order to facilitate placement of an IV catheter, the animal is intubated and maintained on isoflurane at a surgical plane of anesthesia. Additional local anesthesia with Lidocaine (approximately 1 ml) will be provided at the marrow harvesting site at the recommendation of the staff veterinarian. Bone marrow sampling will be performed in the VSD under clean conditions and not aseptic conditions.

V.4.1.2.2. Pre- and Post-procedural Provisions Animals will be assessed for signs of pain and distress by either the veterinary or research staff at least twice per day or more often as needed according to VSDM SOP. Before procedures that require general anesthesia, NHPs will be fasted for 12 h prior to administration of anesthetic. However, terminal bone marrow collection to be carried out in the protocol would not require 12 h fasting. Clinical signs of acute radiation sickness can be treated with medications on the advice of a VSD veterinarian (e.g., acetaminophen, Imodium, lomotil, but not ibuprofen or drugs that may affect the immune system, or induce platelet aggregation). For any NHPs that are not taking in sufficient food and/or water, additional foods can be offered to entice them to eat. In addition, NHP will be prior-acclimated to feeding syringes and sipper bottles to allow for the use of supplemental oral fluids if dehydration is noted. Criteria for

euthanasia are listed in Section V.4.5. NHP will be assessed at least 2X daily and additional observational time point(s) will be added during critical phases of the animals undergoing procedures that are appropriate for the study.

V.4.1.2.3. Paralytics No paralytics will be used in this study.

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures Because the principle purpose of this study is to determine the PK/PD and benefits on survival by treatment with (b)(4) against radiation-induced mortality, there are no alternatives to irradiation. Supporting information such as the clinical chemistry analyses, hematological analysis of the blood and bone marrow, bacterial studies, and histopathology analyses of selected tissues will help identify the usefulness or problems associated with the use of (b)(4) as prophylactic/therapeutic agent in irradiated animals.

V.4.1.3.1. Sources Searched Agricola, Pubmed, altweb

V.4.1.3.2. Date of Search 05-20-2014

V.4.1.3.3. Period of Search Agricola (1974-preent), Pubmed (1946-present), Altweb

V.4.1.3.4. Key Words of Search

Keywords	AGRICOLA 1974-present	PubMed 1946-present	Altweb
Alternatives to painful procedures (radiation)	6	14493/389*	3
primates+bone marrow harvesting	4	608 / 82**	1

*From radiation exposure [all methods], **Other animals, ***Other animals only			

V.4.1.3.5. Results of Search: The search clearly demonstrated that there are no alternatives or pain relief in literature that could be used in the present study.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification: There are no alternative procedures for irradiation because it is a unique stimulus/stress that cannot be otherwise duplicated. Radiation itself does not cause pain or distress. Nevertheless, the sequelae of nausea, vomiting, and diarrhea causes pain and distress in humans in the early post-irradiation period, when high doses (8 Gy and above) are used. Although radiation does not induce pain, animals in these experiments might experience pain and distress prior to death because of hematological and gastrointestinal damage.

Bacteria translocation from the alimentary canal may cause infections that result in discomfort either locally or systemically. Many opportunistic pathogenic bacteria have unusual or even unique virulent characteristics, but they have common attributes, including binary multiplication and penetration of tissues, and cause common responses and disease process in animals, which cannot be mimicked readily by substitutes. The investigators and animal care staff will provide as much comfort and well-being to the animals as is

consistent with the scientific integrity of the work plan. The principle purpose of these studies is to evaluate the efficacy of (b)(4) in enhancing survival of irradiated NHPs. As stated, bone marrow, peripheral blood, liver and kidney (liver and kidney analysis done by blood chemistry with the hematological studies) analyses will also be performed after (b)(4) and G-CSF administration. Moribund animals will be euthanized in consultation with VSD veterinarian.

We expect that (b)(4) as well as G-CSF will provide some relief from pain and or discomfort due to the sequelae of irradiation by its protective effect and by the possibility that it will advance hematopoietic recovery in some or all of the (b)(4) treated and irradiated primates. Microchip implantation is not considered a surgical procedure. Bone marrow extraction is considered a surgical procedure. Prior to general anesthesia for all surgical procedures, all NHP will be fasted for 12-18 h, however, terminal bone marrow collection described in the protocol does not require 12-18 h fasting.

V.4.2. Prolonged Restraint None

V.4.3. Surgery

V.4.3.1. Pre-surgical Provisions:

Microchip implantation is not considered a surgical procedure. Bone marrow extraction is considered a surgical procedure. Since the bone marrow collection in this protocol will occur prior to euthanasia, fasting of animals 12-18 h prior to anesthesia will not be required.

V.4.3.2. Procedure(s) NHPs may be sedated or given local anesthesia for microchip implantation. The chips are manufactured by Bio Medic Data Systems, Inc (BMDS) and used to monitor body temperature. They come pre-loaded in a specially designed needle/syringe device.

General Anesthesia:

Animals are sedated using ketamine (10mg/Kg IM) and chips are inserted subcutaneously between the shoulder blades. Once the chip is deposited, the needle is withdrawn and the skin is pinched between 2 fingers for about 10-20 seconds to ensure that the chip itself (about the size of a grain of rice) does not dislodge through the puncture site. If a chip fails, a second chip will be inserted. If necessary a drop of surgical glue will be placed at the puncture site to ensure that the chip stays in place.

Local Anesthesia:

Animals will be restrained in a chair. A small patch of fur on the left or right side of upper back may be shaved for microchip placement. Lidocaine ointment may be applied to the area, a 5 min time lapse will be allowed for the lidocaine to be effective and then a microchip will be inserted by a trocar. If necessary a drop of surgical glue will be placed at the chip insertion site to ensure the chip stays in place.

Bone marrow collection.

The method proposed for the marrow collection is adapted from those used by Fortman *et al.*, (2001) and Kushida *et al.*, (2002).

- General anesthesia
- Premedication-ketamine-5-15 mg/kg IM
- Induction – 3-5% Isoflurane in 100% Oxygen by Mask

- Maintenance-1-3 % Isoflurane in 100% Oxygen by endotracheal tube or mask
- Site of bone marrow sample: Iliac crest, trochanteric fossa of the femur, or proximal humerus.
- Procedure: Animal will be positioned appropriately (dorsal or ventral, or lateral recumbency, depending on site). A sterile drape will be used to cover the site.
- A Biospy or Aspirate sample will be collected as determined by the PI.
- Biopsy: A small 1-2 cm incision will be made in the skin at the site of bone marrow collection. A bone marrow biopsy needle will be advanced through the incision into the cortex of the bone. The stylet will be removed and the needle advanced 1-2 cm with gentle rotation and rocking of the needle. The needle is then retracted and advanced slightly before being gently removed from the bone. The included expeller is used to remove the sample from the needle and in to a cassette with a foam insert, if necessary, which is then put in 10% formalin for fixation and processing.
- Aspirate: A small 1-2 cm incision will be made in the skin at the site of bone marrow collection. A bone marrow aspiration needle will be advanced through the incision into the cortex of the bone. The stylet is removed from the bone marrow needle. A 2-5 ml syringe will be used to aspirate 2-3 ml of bone marrow.

V.4.3.3. Post-surgical Provisions N/A since animals after bone marrow collection will be euthanized.

V.4.3.4. Location All surgical procedures will take place in the VSD surgical suite.

V.4.3.5. Surgeon AFRRI VSD trained staff or veterinarian will perform implantation of microchip and the bone marrow collection.

V.4.3.6. Multiple Major Survival Operative Procedures None

V.4.3.6.1. Procedures

V.4.3.6.2 Scientific Justification

V.4.4. Animal Manipulations

V.4.4.1. Injections Trained personnel will carry out Injections within the scope of VSD SOPs.

Drug injection: The drug in sterile PBS will be freshly prepared from a liquid formulation of the drug on the day of injection. Depending on the drug concentration and dilution, drug injection volume may vary between 0.2 to 1.0 ml/animal/injection.

Needle: Drug will be administered in unanesthetized but restrained animals using 22-25G needle.

V.4.4.1.1. Pharmaceutical Grade Drugs: G-CSF is a pharmaceutical grade product and will be used in the study. It will be procured through USUHS pharmacy- (Neupogen® Filgrastim 300 mcg/1 ml), Amgen Inc., CA. The drug will be diluted in 5% dextrose and if required further diluted in PBS for *sc* injection.

V.4.4.1.2. Non-Pharmaceutical Grade Drugs (b)(4) (b)(4)

Sterile phosphate-buffered saline will be used as the vehicle. An aliquot of the solution will be sent to Charles River Laboratories for endotoxin testing; a copy of the results will be sent to IACUC. At the same time, pH will be tested to ensure that it falls in the range stipulated by IACUC (pH 6-8). A 23-25G needle will be used to administer subcutaneous injections.

V.4.4.2. Biosamples Chair restraint of NHPs for the purposes of phlebotomies was previously discussed as a technique to obtain blood samples over a short period of time that would reduce stress to the animals. In place of this procedure, or in addition to it, training may be provided to the NHPs such that they offer their limbs for the blood sampling procedure.

Table 2: Blood collection; time-points and volumes

Time of blood draw	PK (0.5 ml)	CBC (0.5 ml)	Colony forming Unit assay (CFU) (0.5 ml)	Total blood, ml
-7d	+	+	+	1.5
-3d		+		0.5
-2d	+	+	+	1.5
day -1 (Pre-TBI injection)				
Irradiation (DAY 0)				
Day 1 (post-TBI injection)				
Day 2	+	+	+	1.5
Day 4	+	+	+	1.5
Day 8	+	+	+	1.5
Day 10	+	+	+	1.5
Day 12	+	+		1.0
Day 14		+		0.5
Day 16		+		0.5
Day 18		+		0.5
Day 20	+	+	+	1.5
Day 22		+		0.5
Day 24		+		0.5
Day 26		+		0.5
Day 28	+	+	+	1.5
Day 35	+	+	+	1.5
Day 49	+	+		1.0
Day 60	+	+		1.0
Day 60	Bone	marrow	(terminal)	3.0 ml

V.4.4.3. Adjuvants N/A

V.4.4.4. Monoclonal Antibody (MAb) Production N/A

V.4.4.5. Animal Identification The animals are identified by indelible markings on their chest and/or leg. If the primate is not tattooed upon arrival, a VSD colony number will be assigned and tattooed onto the chest.

V.4.4.6. Behavioral Studies: None

V.4.4.7. Other Procedures None

V.4.4.8. **Tissue Sharing Tissue sharing will be allowed with appropriate paperwork filed with the IACUC.**

V.4.4.9. Animal By-Products N/A

V.4.5. Study Endpoint

Many of the primates that are administered (b)(4) G-CSF are expected to survive. However, vehicle-treated animals, may show 70% ±10% mortality. Moribund animals will be closely monitored and euthanized at the advice of attending veterinarian to minimize excessive pain. Moribundity will be used in place of mortality to relieve the animal from pain and distress. Euthanasia will be carried out when any one or more of the following signs of severe morbidity or moribundity are observed by AFRRI veterinarians and in consultation with the principal investigator (see below). Necropsies and histopathological analyses will be performed on all euthanized animals by the veterinary pathologist or pathology staff. The parameters to provide guidelines for moribundity have been described under 'study end-points' of 'General procedure' in the experimental design.

Treatment with (b)(4) and G-CSF may result in the survival of all irradiated animals, based on high level protection of mice from exposure to supra-lethal radiation dose and its potential to stimulate hematopoietic recovery. Therefore, an endpoint for individual animals will be related to success or failure of treatment with (b)(4) At the end of 60 days, bone marrow collection will be made and animals euthanized.

Study endpoints: Experimental animals will be euthanized based on an assessment and in consultation with attending veterinarian. Moribund animals will be euthanized. Animals will be declared moribund in consultation with a veterinarian when generally in poor condition and exhibiting one or more of the following signs:

1. Weight loss: loss of more than 20% body weight over a 3-day period when compared to baseline weight. Normally animals will be weighed twice a week, however, if inappetence sets in then we will monitor weight on a daily basis.
2. Inappetence: complete anorexia for 24 hours. This is defined as refusing regular food and all food enrichment items).
3. Weakness/inability to obtain food or water: Inability to stand would be a criterion for euthanasia and would not allow the animal to persist in this state for 24 hours.
4. Minimal or absence of response to stimuli (animal does not move when prodded), assuming the animal has recovered from anesthesia.

5. Core body temperature: below 35.9ºC following a period of febrile neutropenia (≤500x10^3 cells/µl) by way of microchip will be done on a daily basis.
6. Severe acute anemia: (<40 g/L hemoglobin, <13% hematocrit)
7. Infection documented by blood culture (septicemia) and accompanied by severe systemic signs of illness.
8. Other signs of severe organ system dysfunction with a poor prognosis as determined by a veterinarian that may need additional diagnostic tests:

8.1 Respiratory: severe dyspnea, severe cyanosis.

8.2 Gastrointestinal: severe vomiting or diarrhea, evisceration (immediate euthanasia required). NOTE: Transient vomiting and diarrhea are expected results of whole-body gamma irradiation. Therefore, as criteria for euthanasia, these symptoms should be severe and life-threatening per se, i.e., hemorrhagic diarrhea to the point of causing anemia as listed above or severe uncompensated dehydration.

8.3 Urogenital: renal failure characterized by elevated BUN and creatinine.

8.4 Neural: CNS depression, seizures, paralysis of one or more extremities.

8.5 Integumentary: Non-healing wounds, repeated self-trauma, severe skin infections, indicating severe organ system dysfunction with a poor prognosis.

V.4.6. Euthanasia Animals will be euthanized according to current American Veterinary Medical Association (AVMA, 2013) guidelines. All animals will first be anesthetized with ketamine (IM, 10 mg/Kg). Animals will be euthanized with sodium pentobarbital (IV 100 mg/kg). The animals will be euthanized only under the guidance and supervision of a staff veterinarian. After euthanasia solution has been administered, the animals will be examined by VSD veterinarian or technician to confirm death. A full body necropsy and histopathology analysis will be performed by a veterinary staff in consultation with a pathologist, after death has been confirmed.

V.5. Veterinary Care Animal procedures performed at AFRRI will be in compliance with the Animal Welfare Act, the Guide for the Care and Use of Laboratory Animals. AFRRI facility is accredited by Association for Assessment and Accreditation of Laboratory of Animal Care (AAALAC) International.

V.5.1. Husbandry Considerations NHPs will be housed according to IAW VSD SOPs.

V.5.1.1. Study Room All animals will be assigned room(s) designated by VSD staff.

V.5.1.2. Special Husbandry Routine and emergency veterinary medical care: Animals will be quarantined for 4–6 weeks on arrival and chair-trained during the quarantine period. Each animal will be observed twice daily for evidence of pain or distress. Body weights will be determined at least once prior to the start of the study and at periodical intervals or when chaired for blood collection. Body temperature will be determined using a microchip installed in animals. Temperature will be measured during blood collection schedule when the animals are chaired. Animals will be qualitatively assessed twice daily (a.m. and p.m.) for general behavioral status and food consumption. Additional observation points will be added based on recommendation from attending veterinarian and will depend on the health of experimental animals. Appropriate standard operating procedures will be followed by staff veterinarians in the event of pain or distress.

V.5.1.3. Exceptions N/A

V.5.2. Veterinary Medical Care

V.5.2.1. Routine Veterinary Medical Care All primates will be quarantined for 4–6 weeks prior to any experiment. Animals will be tested for TB. Also, note the requirements given under V.3.3.2 and V.3.3.3 above.

All NHPs will be observed at least twice per day by veterinary staff (IAW VSDM SOP 2002, Animal Health Rounds). A veterinarian and a veterinary technician will provide 24 h emergency care to the animals if needed (IAW VSD SOPs). When animals become ill or debilitated, a veterinarian will be contacted immediately to assess the animal and provide adequate/emergency care. If the animal becomes moribund, it will be euthanized according to current American Veterinary Medical Association (AVMA, 2013) guidelines.

V.5.2.2. Emergency Veterinary Medical Care The on-call veterinary officer will be available via telephone 24 h daily.

V.5.3. Environmental Enrichment

V.5.3.1. Enrichment Strategy In these studies, all primates will receive regular enrichment (IAW VSDM SOPs).

V.5.3.2. Enrichment Restrictions N/A

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING

NAME	DEGREE	TRAINING	DATE	PROCEDURES	YRS/MOS EXPERIENCE
(b)(6)				1 with NHP handling only	(b)(6)
				Basic training	
				1, 3, 5	
				1 (handling only), 3b	
				1 (handling only)	
				1, 2, 3, 4	
				1,2,3,4,5,7(gavage,& Mandibular bleeds)	
				1-5	
				Basic training	

Procedure and manipulation codes:
Code 1= Animal handling and euthanasia
Code 2= Surgery (aseptic technique) pre- and post-operative care
Code 3= Injections (3a–ip, 3b-sc, 3c-gavage) - can say 3 if trained in all manipulations or add 3d-iv
Code 4= Blood collection under anesthesia (4a-cardiac, 4b-posterior vena cava)
Code 5= Tissue collection (after euthanasia) - doesn't need to be specific
Code 6 = Implantation (provide details)
Code 7 = Others - (provide protocol specific manipulations or procedures for e.g., retro-orbital bleeding, tail vein injection, or drug delivery)

In-protocol training of personnel: The presence of two trained vet techs in the protocol allows for an opportunity to train other staff including PI with procedures such as pole and collar, injections, blood draw on sedated animals and blood draw on physically restrained animals. For this purpose either naïve or experimentally used animals may be used. The

training will be certified by VSD staff (responsible for training) as well as approved by attending veterinarian.

VIII. ENCLOSURES : None

X. ASSURANCES

Protocol Title: Radiation countermeasure studies using (b)(4) and G-CSF in Nonhuman Primates (*Macaca mulatta*)

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made every effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with a qualified individual who evaluated the experimental design with respect to the statistical analysis, and that the minimum number of animals needed for scientific validity will be used.

D. Biohazard / Safety: I have taken into consideration and made the proper coordinations regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R", namely, "Responsibility," which the DOD has embraced for implementing animal use alternatives where feasible and conducting humane and lawful research.

G. Scientific Review: This proposed animal use protocol has received appropriate peer scientific review and is consistent with good scientific research practice.

H. Painful Procedure(s): I **AM** / **AM NOT** conducting biomedical experiments, which may potentially cause more than momentary or slight pain or distress to animals. If applicable, potential pain and/or distress **WILL** / **WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

I. NON-TECHNICAL SYNOPSIS There is a pressing need for drugs to prevent ionizing radiation injury, for use in the field by military personnel, emergency responders and by the civilian population in harm's way. Radiation damages blood-forming tissues, resulting in mortality due to infection and hemorrhage (hematopoietic syndrome). The vast majority of studies on the acute radiation syndrome (ARS) and countermeasure efficacy have been performed using photon irradiation (gamma and x-rays). However, historical data from Hiroshima and Nagasaki, as well as the potential use of radiation dispersal devices underscore the need to understand the impact of radiation containing mixed neutrons and gamma photons, hereby called mixed fields (MF). Neutrons have different mechanisms of injury to cells and tissues compared to photons, with a higher relative biological effectiveness (RBE). Therefore, countermeasure efficacy may be different between gamma and mixed field exposures, depending on the mechanisms of action of the countermeasure. The present work will confirm and extend preliminary studies with CDX-301, a promising radiation countermeasure. Preliminary studies performed at AFRRI in CD2F1 mice demonstrated the efficacy of CDX-301 as a significant radiation prophylactic agent with 91-100% of mice administered a single dose of CDX-301 24 h prior to total body irradiation Further, CDX-301 demonstrated efficacy as a radiation mitigant; when administered at a single dose to CD2F1 mice 4 after TBI, CDX-301 improved 30-day survival by 25-33% compared to vehicle-treated group. The proposed studies will:

1). a. generate dose response curves for radiation dose versus mortality for two qualities of total body irradiation in mice: 2:1 neutron/gamma and pure gamma, b. optimize dosing schedule for CDX-301under both mixed 2:1 neutron/gamma field and pure gamma, and c. determine dose reduction factor (DRF) for CDX-301 with mixed neutron/gamma field. A DRF is the estimate of the relative degree of efficacy of a radiation countermeasure, based on a shift of the radiation-mortality dose-response curve to the right and is expressed as a ratio between vehicle and drug response at a dose of radiation that causes 50% mortality in both groups. DRF helps to compare various drug responses under standard conditions.

2) evaluate the effects of pure gamma and mixed neutron/gamma fields, with and without treatment with CDX-301, on core hematological parameters known to affect

recovery during the hematopoietic syndrome, such as numbers of circulating blood elements, numbers of blood progenitors in bone marrow, numbers of immune cells in spleen, liver and lungs, and concentrations of cytokines (hematological and immune system hormones) in blood.
3) Irradiate mice at a low dose rate with gamma photons to simulate radiation fall out conditions and measure the effect of CDX-301 on the above mentioned hematological parameters, as well as DNA damage and reactive oxygen species effects in tissues. The survival is expected to be 100% in low dose rate studies.

II. BACKGROUND

II.1. Background The risk of exposure to ionizing radiation from war, terrorism or nuclear accidents is thought to be increasing (1-3). A nuclear detonation in an urban environment could result in hundreds of thousands of casualties. These casualties would include a large proportion of people who would experience Acute Radiation Syndrome (ARS) from being exposed either to a mixture of neutrons and gamma rays initially, or to gamma rays from cutaneous fallout. In light of these facts, it would be extremely helpful to have safe and effective radiation countermeasures for treatment of casualties after exposure (4-7). Although radiation countermeasures generally have been studied in subjects exposed to pure photons (gamma- or X-rays), the mechanisms of injury of these low linear energy transfer (LET) radiations differ from those of high LET radiation such as neutrons, and these differences may affect countermeasure efficacy. (b)(4)

(b)(4)

(b)(4) In contrast, preliminary studies at AFRRI suggest that CDX-301 is effective against exposure to both MF and pure gamma-irradiation.

CDX-301 is the soluble recombinant human protein form of the Fms-related tyrosine kinase 3 ligand (Flt3L), a hematopoietic cytokine (10). It is expressed on multiple cell types in both soluble and membrane forms, and interacts with a receptor found on hematopoietic stem cells (HSC), early progenitor cells, and immature thymocytes, resulting in the proliferation, differentiation, development and mobilization of these cells in the bone marrow, peripheral blood, and lymphoid organs. CDX-301 represents the 153 N-terminal amino acids of the human Flt3L extracellular domain after the cleavage of the N-terminal signal peptide (Figure 1).
It is a clear, colorless liquid soluble in saline with a pH of 7.0. It has been produced by Celldex Therapeutics, Inc. (Needham, MA; (b)(6) under GMP conditions and with GLP toxicology studies. There is no detectible endotoxin or mycoplasma contamination. CDX-301 mobilized hematopoietic stem and progenitor cells (HSPC) in a Phase 1 Clinical Program leading towards the treatment of cancer patients requiring hematopoietic stem cell transplantation (HSCT) (11).

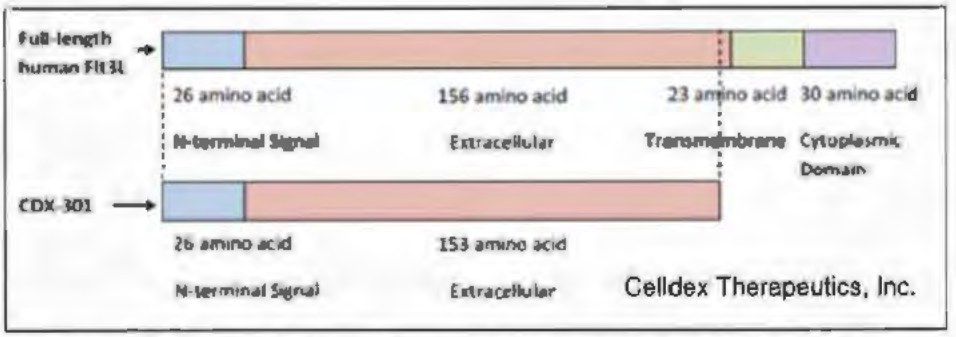

Figure 1

Early studies in the C57Bl/6J model demonstrated significant improvement in survival (40% with vehicle vs 100% with CDX-301) when mice irradiated at 7.76 Gy were treated with CDX-301 (25 μg) for 10 days (days -1, 0, 1, 2, 3, 4, 5, 6, 7, 8) (personal communication, Celldex Therapeutics Inc.) (b)(4)

(b)(4)

(b)(4) The proposed study builds on the reported and ongoing studies using CDX-301. Three main goals (specific aims) are:
a. optimize drug response in MF,
b. conduct parallel studies in Cobalt 60,
c. characterize drug response in animals exposed to prolonged low dose rate gamma radiation.
Mechanistic studies (tissue response) will be another focus in all these experiments.

II.2. Literature Search for Duplication

II.2.1. Literature Sources Searched BRD, NIH Reporter, PubMed

II.2.2. Date of Search May 8, 2014

II.2.3. Period of Search All available years:
BRD: FY2005-FY2009
NIH Reporter: 1988-2013 (Projects and Publications)
PubMed: includes MEDLINE (1966-present) and OLDMEDLINE (1950-1965).

II.2.4. Key Words of Search neutron, gamma, ionizing radiation, Flt3 ligand, CDX-301, cytokine, protracted radiation, chronic radiation, low dose rate

II.2.5. Results of Search BRD: There were no results from: CDX-301, Flt3 ligand, Flt3 ligand + ionizing radiation, Flt3 ligand + gamma, Flt3 ligand + neutron, Flt3 ligand + protracted radiation, Flt3 ligand + chronic radiation, Flt3 ligand + low dose rate. When the search was generalized to cytokines, the following results were obtained:

1. Cytokine + ionizing radiation = 4 hits; consisted of AFRRI work on 5-Androstenediol (5AED) and work on herpes virus therapy
2. Cytokine + radiation = 11 hits; consisted of AFRRI work on 5AED and work on herpes virus therapy.
3. Cytokine + gamma = 3 hits; consisted of AFRRI work on 5AED and work on herpes virus therapy
4. Cytokine + neutron = 0 hits

5. Cytokine + protracted radiation = 0 hits
6. Cytokine + chronic radiation = 0 hits
7. cytokine + low dose rate = 0 hits

NIH Reporter: 1990-present

1. CDX-301 = 2 hits; CDX-301 and Plerixafor Combination in Stem Cell Mobilization for Transplantation
2. Flt3 ligand + ionizing radiation = 2 hits; consisted of work on pleitrophin and epidermal growth factor
3. Flt3 ligand + radiation = 33 hits; consisted of work on pleitrophin and epidermal growth factor; Flt3 ligand as a therapeutic against glioblastoma and acute myeloid leukemia. The closest body of work consisted of the use of Flt3 ligand as an immunoprotectant against ARS in a dog model.
4. Flt3 ligand + gamma = 34 hits. Of these only one referred to the use of Flt3 ligand as a radioprotectant against gamma photons, and this was in a dog model. Other references included immune cell studies, structure/function studies, Flt3 ligand as a therapeutic against chlamydia trachomatis, and Flt3 ligand in various cancer models.
5. Flt3 ligand + gamma radiation = 10 hits. These consisted of the use of Flt3 ligand and other cytokines as a radioprotectant in a dog model.
6. Flt3 ligand + neutron = 5 hits. These were structural studies were neutrons were discussed in the context of X-ray crystallography.
7. Flt3 ligand + neutron radiation = 5 hits. These were identical to those found in the Flt3 ligand + neutron search.
8. Flt3 ligand + protracted radiation = 0 hits
9. Flt3 ligand + chronic radiation = 4 hits. These consisted of treatments of the elderly with Flt3 ligand for acute myeloid leukemia (AML).
10. Flt3 ligand + low dose rate = 0 hits

Note: We did not use the generalized term cytokine in this search because the specific cytokine of interest, Flt3 ligand, produced results.

Pubmed:

1. CDX-301 = 0 hits
2. Flt3 ligand + ionizing radiation = 13 hits. These include Flt3 ligand as a biomarker, therapeutic against UV and gamma radiation (alone and in combination), role in stem cell expansion. These studies all use the full length form of Flt3 ligand. Our studies use the truncated form of Flt3 ligand, CDX-301.
3. Flt3 ligand + radiation = 73 hits. These include Flt3 ligand as a biomarker, as a therapeutic against radiation using in vitro and *in vivo* methods, effect of Flt3 ligand on bone marrow and hematopoietic recovery. These studies use the full length form of Flt3 ligand. Our studies use the truncated form of Fl3 ligand, CDX-301.
4. Flt3 ligand + gamma radiation = 12 hits. These include previously described studies as well as the effects of Flt3 ligand on tumor models. Note: Flt3 ligand + gamma alone yielded 140 hits but this search was too broad. It included correlations with Flt3 ligand and interferon gamma as well as immune cell development via interactions with receptor gamma chains for specific cytokines.
5. Flt3 ligand + neutron = 0 hits
6. Flt3 ligand + neutron radiation = 0 hits
7. 7. Flt3 ligand + protracted radiation = 1 hit. This described the use of Flt3 ligand as a rapid and simple method of triage, using human data from a radiation accident.
8. Flt3 ligand + chronic radiation = 1 hit. This described the use of serum Flt3 ligand as a biomarker after chronic ingestion of radiation in a mouse model.
9. Flt3 ligand + low dose rate = 4 hits.

Note: These describe Flt3 ligand involvement in tumor models, either in human or mouse studies.

III. OBJECTIVE / HYPOTHESIS The objective of this protocol is to develop CDX-301 as a countermeasure against gamma radiation and mixed neutron (MF)/gamma-radiation. This work involves optimizing CDX-301 administration (concentration and time of injection), as well investigating the effects on hematopoietic cells and tissues. In addition, our work will address the feasibility of CDX-301 as a countermeasure against prolonged exposure to gamma irradiation and address potential mechanisms of protection.

IV. MILITARY RELEVANCE Work performed under this protocol would directly affect the military response to a nuclear detonation. Development of CDX-301 as a countermeasure would provide radiation protection to first responders, those in zones of high danger where prompt radiation exposure would consist of neutrons and photons, as well as those exposed during radiation fallout. It is essential to understand the efficacy of this agent in these different scenarios, with the ultimate goal of making a responsible recommendation to our military personnel and the civilian population.

V. MATERIALS AND METHODS

V.1. Experimental Design and General Procedures

Male CD2F1 mice will be used in all experiments. Irradiations in the AFRRI reactor and Cobalt-60 facility will be performed according to previously published methods, following AFRRI standard operating procedures (12-16). Irradiations in the Low Level facility will be performed in collaboration with AFRRI dosimetrists and based on consultation with AFRRI VSD. Mice irradiated in the reactor will be inserted into aluminum holders and placed onto a carousel that rotates the mice within the exposure beam to ensure uniform exposures to all subjects. Mice irradiated at the Cobalt-60 facility will be placed into well-ventilated Plexiglas boxes and irradiated bilaterally. Mice irradiated in the Low Level Cobalt facility will be housed in modified cages (3 animals/cage) approved for long-term housing. Food and water will be available *ad libitum*. Temperature, humidity, and standard 12 h light/dark cycles will be maintained during chronic exposure. Sham-irradiated mice will undergo the same procedures as the irradiated mice (transport to radiation facility, placement into aluminum cylinder, Plexiglas box, or modified cages), minus the radiation exposure. In the reactor, non-neutron components of the exposure are controlled by shielding outside of the reactor core area within the exposure room. All reactor-irradiated mice, their tissues, and their bedding will be considered radioactive unless declared otherwise as a result of environmental Health Services (EHS) surveys.

V. 1. 1. Experiment 1 Drug dose and schedule optimization studies with CDX-301 as measured by 30 day post-irradiation survival

Two concentrations of CDX-301 (400 μg/kg and 800 μg/kg) will be administered by subcutaneous (SC) injection using 25-30 gauge needles (17) at 0.1 ml/injection site. A 400 μg/kg dose of CDX-301 protected mice against MF radiation, and 800 μg/kg provided protection against gamma-radiation. Because of these results, both doses were selected for Experiment 1. Six drug dosing schedules at times between -24 h and +48 h after radiation will be studied using both radiation sources and qualities. Table 1 summarizes animal numbers. Animals will be monitored for 30 days for survival.

Table 1: Animal requirements for experiment 1 (30 day survival study)

3 sc drug doses:	0 (sterile saline vehicle), 400, or 800 μg/kg
6 drug schedules:	Schedule1: pre-irradiation (-24 h) Schedules 2-5: post-irradiation: +4 h; +12 h; +4 and +48 h; +12 and +48 h Schedule 6: pre-, and post-irradiation -24 h, and +48 h

2 radiation qualities:	MF (2:1 neutron:gamma); pure gamma
Mice/Group:	24
Iterations:	2

Total # of animals	1728

*5.71 Gy MF and 9.2 Gy gamma radiation

3 drug groups (0, 400, 800 µg/kg) x 6 drug administration schedules x 1 radiation dose x 2 radiation qualities (MF and gamma) x 24 animals/group x 2 iterations = 1728 mice

V. 1. 2. Experiment 2 Determine the DRF of CDX-301 on MF-irradiated mice

Five radiation doses will be chosen to establish probit curves ranging from near 5% mortality to near 95% mortality with CDX-301 administration. Table 2 summarizes animal numbers. The endpoint will be 30-day survival. (Note: DRF studies with Cobalt 60 gamma radiation will not be done since this has been completed (b)(6) (b)(6)

Table 2: Animal requirements for experiment 2 (DRF, only for MF, 30 day survival)

5 radiation doses	4.0 4.5, 5.0, 5.5, 6.0 Gy
2 sc drug doses	0 (sterile saline vehicle), optimal concentration (See Table 1)
2 drug schedules	-24 h before radiation; optimal dosing schedule given after radiation (See Table 1)
1 radiation quality	MF (2:1 neutron:gamma)
Mice/group	16
Iterations	1
Total # of animals	320

5 radiation dose x 2 drug doses (vehicle, drug) x 2 drug administration schedules (pre- and post-irradiation) x 1 radiation quality (MF) x 16 animals/group x 1 iteration = 320

V. 1. 3. Experiment 3 Conduct hematopoietic and functional studies

Determine the effect of CDX-301, administered after a sublethal dose of MF or gamma-irradiation on hematopoietic cells in circulation, circulating cytokine levels, bone marrow cellularity, morphology, and function, and hematopoietic cells populations and function from spleen, lung, and liver.

Mice will be exposed to a sublethal dose of gamma or MF radiation appropriate for hematopoietic syndrome hematology studies where measurable numbers of blood elements are desired throughout the experiment (3 Gy MF; 7 Gy gamma) (b)(4) Using a sublethal dose makes it possible to carry out a time course of hematological parameters undistorted by data censoring due to mortality, and to allow a sufficient number of surviving cells for analysis during the first two weeks. Previous experiments have shown that detection of radioactivity is below background in 24 h or less in mice administered a 3 Gy dose of MF in the AFRRI TRIGA. This allows samples to be collected at day +1 after MF radiation. Sublethally-irradiated mice, or non-irradiated controls, will be treated with CDX-301 at the optimal concentration and administration schedule (determined in Experiment 1). Blood for CBC/diff and cytokine studies, femurs for GM-CFC studies, and spleen, lung, and liver for analysis of cell populations will all be collected from the same mice, according to standard protocols (b)(4) Briefly, mice will be anaesthetized using Isoflurane at days 1, 3, 7, and 14 after radiation (20 mice/timepoint) and blood will be collected by cardiac puncture. An optimal volume of collection will be 1.0 ml, which will be divided into tubes for CBC/diff and serum collection. Removal of this volume of blood is exsanguination and will be done only on anesthetized mice (18). Mice will be euthanized humanely by cervical dislocation after

blood collection. Both femurs will be dissected from the adhering tissues and flushed with sterile IMDM to obtain bone marrow single cell suspension. Spleen, lung, and liver will be removed and placed on ice in sterile dishes containing appropriate media. The day of irradiation is considered day 0. Table 3 summarizes animal numbers. Please note that only one optimum drug dose post-irradiation will be used in the study.

Table 3: Animal requirements for Experiment 3 (hematology)

2 sc drug doses	0 (sterile saline vehicle), optimal drug concentration (determined in Expt. 1)
1 drug schedule	optimal dosing schedule (post-irradiation) (determined in Expt. 1)
2 radiation doses	sublethal dose (0 and 3 Gy MF; 0 and 7 Gy gamma)
2 radiation qualities	MF (2:1 neutron:gamma) and pure gamma
Mice/Group	20
4 collection time points	+1, +3, +7, +14 day after radiation
Iterations	2
Total # animals	**1280**

2 drug doses (vehicle, drug) x 1 drug administration schedule (post-irradiation) x 2 radiation doses x 2 radiation qualities (MF and gamma) x 4 time points x 20 animals/group x 2 iterations = 1280

V. 1. 4. Experiment 4: Low dose Cobalt 60 studies
NOTE: The proposed studies will not be performed without a feasibility study and detailed SOP, followed by an approved IACUC Amendment. Experimental details are for informational purposes.

Determine the effect of CDX-301, administered sc after chronic total body gamma-irradiation given at a low dose rate, on circulating blood cells, cells within blood forming tissues, circulating cytokines, and markers of oxidative stress in serum.

Facility: AFRRI Low Dose Cobalt facility is unique and will allow housing both animals to be irradiated (on a protracted basis) as well as appropriate controls in a shielded area but subjected to the same housing conditions. The macroenvironment will include a temperature range of 20-26°C (68-79°F), 30-70% relative humidity, and a 12 hour light/dark cycle as spelled out in *The Guide*. Radiation Safety personnel are on call 24 h in the Low Dose Facility, and the room is monitored by a camera which can be visualized outside the exposure area. Prior to performing any animal experiments, a feasibility study will be performed where the room itself will be monitored for 72 h to ensure proper environmental conditions (temperature, humidity, lighting). This will also involve testing the capability of the facility's current camera, to determine the level of monitoring that can be accomplished on camera. The results of this preliminary experiment (without animals) will be provided to IACUC for review. An SOP will be written based on this feasibility study. Upon completion of the feasibility study as suggested by AFRRI veterinary staff, an initial test experiment will be performed using 2 cages (6 mice) to monitor mice in the facility under non-irradiated conditions as well as irradiated conditions at the lowest dose for the study (3 Gy). Mice will be housed during irradiation (for extended period-initially 48 ± 4 h) in well-ventilated cages made specifically for chronic mouse irradiation (Appendix 1). Each cage holds 3 mice; each

animal compartmentalized in a space of 15 in^2 with food and water freely available in each compartment of the cage. Non-irradiated control mice will be housed in the Low Level facility in a shielded area to protect mice from radiation. These animals will be transferred to these specialized cages in the vivarium for a minimum of 72 h before being transported to the Low Dose Cobalt facility for radiation or sham exposure to allow acclimatization. During the acclimatization period we will monitor environmental enrichment, particularly nestlet size, to determine if further adjustments are necessary.
Irradiation: CD2F1 male mice will be subjected to irradiation doses up to 7 Gy at a low dose rate, which will be determined by the Operational Dosimetry Division prior to the commencement of animal exposure (total dose being delivered over 48 ± 4 h). This includes 48 h of radiation exposure and additional time (up to 4 h) that it may take to pause radiation and enter the facility for monitoring and husbandry. The objective of this experiment is chronic radiation exposure, so the "pause" time will be kept minimal. Investigators will temporarily pause the radiation once daily to monitor the mice. This includes replenishing food and water, and closely monitoring the animals for injury related or non-related to radiation. In addition, investigators will request that the radiation be temporarily paused to enter the exposure room if additional monitoring is required.
Drug Administration: CDX-301 will be administered at the optimal concentration determined in Experiment 1, 24 h before radiation and at the optimal dosing schedule determined in Experiment 1. If the optimal injection schedule coincides with the length of time that mice will be irradiated (i.e. time less than or equal to 48 h), a portable procedure hood will be transported to the facility, radiation paused, and injections administered in the Low Level facility as opposed to transporting animals back to VSD.
Table 4 summarizes animal numbers. At the end of the radiation period blood will be removed by cardiac puncture from isoflurane anesthetized mice, and after death is confirmed by cervical dislocation, femurs and organs (lung, liver, and spleen) will be removed from these mice as in the previous experiment (Experiment 3), as well as organs for fixation and possible histopathology, (femurs, trachea, thymus, esophagus, lungs, heart, liver, spleen, kidney, stomach, pancreas, small intestine, cecum, colon, urinary bladder, reproductive organs, endocrine organs, head). Blood and tissue harvest will be 1, 2, 4, 7, 10, 14, 21, 28, 35 and 42 d after completion of the irradiation.

Table 4: Projected animal requirements for experiment 4 (Low Dose Gamma Radiation Facility)*

NOTE: This is not included in V.4.1.1.1. Number of Animals or V.4.1.1.1.4. Pain Category Assignments

4 radiation doses	0, 3, 5, 7 Gy
2 sc drug doses	0 (sterile saline vehicle), optimal concentration
2 drug schedules	-24 h before radiation; optimal schedule after radiation
1 radiation quality	Gamma
Mice/timepoint	5
10 time points	1, 2, 4, 7, 10, 14, 21, 28, 35, 42 d after radiation
Iterations	1
Trial mice	6 (3 irradiated + 3 non-irradiated)

Total # of animals required	**6* (approved in this protocol)**

*Low dose radiation is not expected to lead to lethality and hence should be considered as "hematology"

~~4 radiation doses x 2 drug doses (vehicle, drug) x 2 drug administration schedule (pre- and post-irradiation) x 1 radiation quality (gamma) x 10 time points x 5 animals/group x 1 iteration = 800 + 6 trial mice, total = 806~~ (see Note in the beginning of this section).

V.2. Data Analysis

Means with standard errors, or percentages, will be reported if applicable. The significance level will be set at 5% for each test. All statistical tests will be two-sided. Multiple comparison tests will be used when appropriate. Drugs will be compared to vehicle injections, and irradiation will be compare to sham irradiation where appropriate. Statistical software, PC SAS, will be used for statistical analyses.

Experiment 1, 2: Log-rank tests will be used in comparing survival curves for each experiment. Fisher's exact tests will be used for comparisons of percent survival among groups. If those are significant, pair-wise comparisons will be done by Fisher's exact tests

Experiment 3: Probit analysis will be used. The DRF will be calculated as the ratio of the radiation LD50/30 for drug-treated and vehicle-treated groups; standard errors and 95% confidence intervals will be derived.

Experiment 4: Analysis of variance (ANOVA) will be used to detect significant differences among groups. If significant, then Tukey-Kramer pair-wise comparisons will be used to identify which groups are different from each other. These experiments involve multiple time points, and since the parameters are being followed over a period of time, in consultation with statistician, 5 animals/time point has been included in the protocol.

Note on requirement to repeat some experiments: It is a generally accepted principle of the scientific method that results must be repeated to evaluate a hypothesis. Scientific journals (e.g., Endocrinology) state that experiments must be repeated to qualify for publication.

V.3. Laboratory Animals Required and Justification

V.3.1. Non-animal Alternatives Considered We considered computer models and tissue culture as alternatives to animals. Both alternatives lack the knowledge base and complexity needed to evaluate the effects of radiation and countermeasures on the hematological and immune systems. The phenomena under study involve complex information-processing networks comprising hundreds of cell types and biological signaling molecules. Responses to irradiation and drugs involve interactions between the central nervous system, the peripheral nervous system including the enteric nervous system, endocrine glands, the immune and inflammatory systems, hematopoietic organs, etc. We do not know all of the cell types and tissues involved and many of the signaling molecules have not been discovered yet. Even if all of the tissues, cell types and signaling molecules were known, the present state of the art of tissue culture would be incapable of reproducing the *in vivo* relationships. One would have to reproduce much of an entire mammalian organism in culture to study these phenomena in *vitro*, a scenario that would have its own ethical issues. As for computer models, the most

powerful supercomputers available in the foreseeable future would be incapable of analyzing interactions between so many elements in the network. Drugs and formulations will have to be evaluated as countermeasures in whole animal models. The purpose of the proposed research is to prove the efficacy of a countermeasure, as well as to begin to identify the cells and signaling molecules necessary to construct a model of radiation injury and countermeasure mechanisms.

V.3.2. Animal Model and Species Justification Evaluation of countermeasures in the animal model is the only option for identifying potential safe and efficacious countermeasures. The murine model is the most well-defined immunological animal model for this type of research. In addition, this model is preferred over other species due to readily available immunological reagents. Mice have significant hematological and immunological similarity to higher animals and humans. AFRRI staff has had extensive experience with mice, including male CD2F1 mice, in radiation injury and countermeasure research.

V.3.3. Laboratory Animals

V.3.3.1. Genus / Species: Mice (*Mus musculus*)

V.3.3.2. Strain / Stock: CD2F1

V.3.3.3. Source / Vendor: VSD approved multiple vendors.

V.3.3.4. Age: 10-14 weeks

V.3.3.5. Weight: 24-32 g

V.3.3.6. Sex: male

V.3.3.7. Special Considerations: The vendor's animal husbandry, breeding, and shipping practices will be in accordance with the Animal Welfare Act P.L. 89-544 and The "Guide" for the Care and Use of Laboratory Animals.

The animals must be adventitious disease free. All animals should be raised with restricted access and strict entry and exit policy in caging that reduces the exposure to pathogens such as in barrier condition, microisolation caging or isolators. They must be free of pathological lesions as assessed by gross exam.

Health surveillance monitoring must be performed regularly on the colonies and verified by an outside source. Health Surveillance reports should be sent with the animal shipments and must be current as well as accurate.

The mice must be pathogen-free, specifically for the following agents: Pseudomonas aeruginosa, Proteus morgani and Pasteurella. In addition, all mice need to be free of the following viral agents: Sendai, Pneumonia Virus of Mice (PVM), Reovirus-3 (Reo 3), Mouse Adenovirus (MAD-1, MAD-2), Mouse Cytomegalovirus Virus (MCMV), Ectromelia, K virus, Lymphocytic Choriomeningitis Virus (LCM), Epizootic Diarrhea of Infant Mice (EDIM), Hantaan virus, Rotavirus, Mouse Parvovirus (MPV), Polyoma Virus, Mouse Minute Virus (MMV), Mouse Thymic Virus (MTV), Theiler's

Mouse Encephalomyelitis Virus (TMEV/GDVII), Encephalitozoon cuniculi, CAR bacillus, Mycoplasma pulmonis, and Clostridium piliforme. Endoparasite- and ectoparasite-free.

Genetic monitoring should be used to detect possible contamination and policies and procedures must be in place to reduce genetic drift.

Mice used in chronic radiation experiment (Expt 4) will be housed 3 per cage in special compartmentalized cages constructed specifically for the AFRRI Low Level Cobalt facility (please see the design attached as an enclosure to the protocol). Each compartment is 15 in^2, in accordance with AALAS regulations on space/animal and The Guide (48). Each compartment will contain standard bedding and free access to food and water.

V.3.4. Number of Animals Required (by species) Mice = 3334

V.3.5. Refinement, Reduction, Replacement (3 R's)

V.3.5.1. Refinement In the mortality studies, in order to minimize discomfort when animals become morbid, investigators and animal care staff will examine the mice at least twice daily, including early morning and late afternoon with increased frequency of observations when animals are in the critical phase. Moribund animals will be considered to have arrived at the study endpoint and will be euthanized. Criteria for identifying morbidity and moribundity will be based on the current IACUC Operating Policy #10 with the accompanying Appendix A clinical observations score sheet (August 2014). This Policy is under review and an amendment will be submitted in the event of any policy changes. Analgesics were considered as a way of minimizing discomfort during the onset of opportunistic infections, which will occur during the survival experiments. However, analgesics and anesthetics are well-known to alter the functional properties of the immune system and resistance to infection (19-43), which would defeat the purpose of the study.

V.3.5.2. Reduction We will use the same mice for peripheral blood counts, analysis of cytokines in serum, and tissue collection for clonogenic and immune organ studies. We will determine the optimal dose of CDX-301 to administer in Expt 1, thus reducing the number of mice used for our studies.

V.3.5.3. Replacement None

V.4. Technical Methods

V.4.1. Pain / Distress Assessment

V.4.1.1. APHIS Form 7023 Information

V.4.1.1.1. Number of Animals

V.4.1.1.1.1. Column C 3 (# of animals)

V.4.1.1.1.2. Column D 83 (# of animals)

V.4.1.1.1.3. Column E 3248 (# of animals)

V.4.1.1.1.4. Pain Category Assignments

Exp. #	Experimental/Control Group	C	D	E	Totals
1	Survival experiment – all irradiated			1728	1728
2	DRF study – all irradiated			320	320
3	Hematology		80	1200	1280
4	Hematology	3	3		
Totals:		3	83	3248	3334

V.4.1.2. Pain Relief / Prevention

V.4.1.2.1. Anesthesia / Analgesia / Tranquilization Mice will be anesthetized as part of euthanasia (in cases of moribundity or for sample collection) using a portable metered Isoflurane system. There will be no recovery from anesthesia in this case and death confirmed by cervical dislocation. All euthanasia will be according to AVMA guidelines and performed by trained and technically proficient personnel (44).

V.4.1.2.2. Pre- and Post-procedural Provisions Mice will be housed and monitored in accordance with VSD standard operating procedures both before and after irradiation procedures (see Section V.5. "Veterinary Care"). For special Husbandry considerations post-procedural (see Section V.5.1.2)

V.4.1.2.3. Paralytics N/A

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures

V.4.1.3.1. Sources Searched AGRICOLA

V.4.1.3.2. Date of Search May 8, 2014

V.4.1.3.3. Period of Search All dates available

V.4.1.3.4. Key Words of Search ionizing radiation AND pain, injection AND pain, CDX-301 AND pain, Flt3L AND pain, neutron AND pain, gamma AND pain

V.4.1.3.5. Results of Search Agricola: Ionizing radiation and pain resulted in 0 hits. Radiation and pain resulted in 20 hits. These encompassed articles where radiation was used as a therapeutic against a number of tumors, mainly in dogs. Several studies address skin dermatitis in response to radiation and suggested increased monitoring. We propose to monitor all animals at least twice/day for any signs, including changes/roughness of fur.

To study the efficacy of any radiation countermeasure in modulating survival, and to investigate its mechanism of action, one needs to irradiate animals. A search using radiation related terms neutron AND pain and gamma AND pain yielded no relevant results. Irradiation itself is not a painful process, in fact, it can be analgesic (45), but it induces various changes in the body, and kills hematopoietic cells. In irradiated animals, the immune response is compromised, and opportunistic infections may ensue. As discussed earlier, anesthetic or analgesic drugs cannot be used. All drug injections will be administered by sc injection. A search on subcutaneous AND injection AND pain

yielded 51 hits. Most were irrelevant to the scope of this proposal. Gurney et al. demonstrated that an sc injection of an agent of interest was as effective as and less painful than an intramuscular injection (46). Subcutaneous injections also proved to be painless and most effective in a dog model (47). No references were found suggesting any effect of CDX-301 or Flt3L on pain or distress. Since the drug under investigation is being developed to enhance survival, and we believe the mechanisms involve modulating complex signaling in hemato-immune-endocrine networks, we do not believe alternatives to the use of whole animals are feasible. As discussed earlier, in vitro experiments do not serve our purpose. See section V.3.1.

V.**4.1.4. Unalleviated Painful or Distressful Procedure Justification** Irradiated animals die due to compromised immune responses and opportunistic infections. The percentage of surviving animals is the indicator of the efficacy of a countermeasure. As discussed above, we cannot give anesthetic and/or analgesic agents to animals since they are known to interact with the immune system, and would confound the interpretation, resulting in a waste of animals.

V.4.2. Prolonged Restraint N/A

V.4.3. Surgery N/A

V.4.3.1. Pre-surgical Provisions N/A

V.4.3.2. Procedure(s) N/A

V.4.3.3. Post-surgical Provisions N/A

V.4.3.4. Location N/A

V.4.3.5. Surgeon N/A

V.4.3.6. Multiple Major Survival Operative Procedures N/A

V.4.3.6.1. Procedures N/A

V.4.3.6.2 Scientific Justification N/A

V.4.4. Animal Manipulations Subcutaneous injections will be performed as described in V.4.4.1. Blood will be removed from anesthetized mice as described in V.4.4.2. Tissues required for the study will be removed after euthanasia, described in V.4.4.2.

V.4.4.1. Injections We will use 25-30 gauge needles for SC injections in the nape of the neck. Injections will consist of CDX-301 diluted in PBS, or PBS alone in a 0.1 ml volume.

V.4.4.1.1. Pharmaceutical Grade Drugs N/A

V.4.4.1.2. Non-Pharmaceutical Grade Drugs

CDX-301 will be provided by Celldex Therapeutics, Inc. (Needham MA) in sterilized form. It was produced under GMP conditions and with GLP toxicology studies. There is no detectible endotoxin or mycoplasma contamination.

V.4.4.2. Biosamples Blood will be drawn from the caudal vena cava or by cardiac puncture using a 23 gauge needle in mice anesthetized by Isoflurane inhalation. A maximum of 1 ml of blood will be collected, and approximately 0.5 ml will be sent to hematology while 0.5 ml will be used for cytokine analysis after serum separation. After Isoflurane anesthesia and blood collection, animals immediately will be euthanized by cervical dislocation. Femur marrow for clonogenic assays, tissues processed for cell isolation (spleen, lung, liver, heart) and/or for fixation and possible histopathology, (femurs, trachea, thymus, esophagus, lungs, heart, liver, spleen, kidney, stomach, pancreas, small intestine, cecum, colon, urinary bladder, reproductive organs, endocrine organs, head), or bodies for disposal, will be collected after euthanasia as described under Euthanasia (V.4.6). All euthanasia will be according to AVMA 2013 guidelines by trained and technically proficient personnel (44).

V.4.4.3. Adjuvants N/A

V.4.4.4. Monoclonal Antibody (MAb) Production N/A

V.4.4.5. Animal Identification Cage cards

V.4.4.6. Behavioral Studies N/A

V.4.4.7. Other Procedures N/A

V.4.4.8. Tissue Sharing N/A

V.4.4.9. Animal By-Products N/A

V.4.5. Study Endpoint In Experiments 1, and 2 the endpoints are euthanasia of moribund animals. A score sheet provided in IACUC Policy #10 (attached) will be part of the criteria for euthanasia in the 30-day survival experiments. In Experiments 3 and 4, the endpoints are blood and tissue collection for further studies.

V.4.6. Euthanasia For sample collection, mice first will be anesthetized with Isoflurane and then cervical dislocation will be performed to cause death under a portable fume hood with charcoal filter. Mice to be euthanized at the end of the experiment will be exposed to CO_2 by investigative or VSD staff followed by cervical dislocation.

V.5. Veterinary Care

V.5.1. Husbandry Considerations No more than 4 mice will be placed in a cage during experiments. Animals will receive Harlan Teklad Rodent Diet (w) 8604 and water *ad libitum*. Acidified water (pH 2.5 – 3.0) is routinely provided to AFRRI mice. Cages will be regularly changed and cleaned by VSD staff in accordance with Standard Operating

Procedures and the most recent edition of the *Guide for the Care and Use of Laboratory Animals*. Animal rooms will be maintained under a 12 h light/dark cycle.

Animals housed in the Low Level Facility will receive identical care, diet, and water to those housed in VSD. Husbandry during this time will be provided by research staff. Husbandry for animals irradiated in the TRIGA Reactor will be provided by research staff until the study room is cleared by members of the AFRRI Radiation Safety Office.

V.5.1.1. Study Room Experiments 1-3: As assigned by VSD in the vivarium. Experiment 4: The radiation will occur over 48 h +/- 4 h in the Low Level Facility. A feasibility study will be done in the room prior to the actual experiments. This study will monitor the timing of the light dark cycle, temperature and humidity of the room over 48 h +/- 4 h It will also determine the feasibility of using the current monitoring camera (used to monitor the radiation source) to visualize cages, and to what level of detail. The results of this study will be presented to IACUC before animal research in this room will begin. Upon completion of the radiation, animals will be housed in a room assigned by VSD in the vivarium.

V.5.1.2. Special Husbandry Provisions Reactor-irradiated animals will be monitored for radiation levels by the Radiation Safety staff. (b)(6) (b)(6) The activated animals, room, and bedding will be considered radioactive until levels of radiation are not distinguishable from background. This is estimated to be one day when doses below an LD50/30 are given (less than 4.92 Gy) and no more than two days when doses above an LD50/30 (4.92 Gy and higher) are given. This estimate is based on past experience of investigators at AFRRI.

The room housing the irradiated mice will be designated a "radiation room" by RSD and EHS, labeled as such, and access will be restricted to properly trained staff until declared clear by RSD/EHS radiological surveys. Standard radiological room operating procedures will require removal of all PPE before exiting the room and surveying all equipment and materials for radioactivity with a hand held Fluke 451-B detector before allowing them to be removed from the room.

No irradiated, live mice will be moved out of VSD. Samples will be collected in VSD prep areas after mice have been declared non-radioactive by EHS. Following standard operating procedures, gloves will be worn at all times when handling the irradiated mice. Finger ring dosimeters will be worn by all personnel handling irradiated mice until they have been declared non-radioactive by Safety. Before mice have been declared non-radioactive by Safety, carcasses and bedding will be disposed of in the Rad Waste Facility area designated for such material. Irradiated mice remains will be disposed of in the Radiation Safety Storage area designated for such material until the mice can be surveyed for radiation hazard level before final disposal.

All personnel involved in these neutron irradiation experiments will remain current with respect to radiation safety training and will continue to receive annual radiation worker training. They will also undergo all required specialized training provided by SHD and RSD, including AFRRI reactor exposure room training given by the reactor facility staff. Appropriate dosimetry will be worn at all times when working with the reactor. This includes the standard TLD along with a self-reading pocket chamber to serve as a backup. Source accountability and ALARA principles will be adhered to at all times, and the SWIMS procedure will be followed in case of any spills of potentially radioactive materials.

Animals involved in Experiment 4 will be housed in the Low Level Cobalt Facility during chronic irradiation. During this time the temperature, humidity, and light cycle will be maintained as per The Guide for the Care and Use of Laboratory Animals.
V.5.1.3. Exceptions None

V.5.2. Veterinary Medical Care

V.5.2.1. Routine Veterinary Medical Care The animals will be observed twice daily by research staff of this protocol (morning and late afternoon). Animals in a critical phase (period of study when animals begin to show clinical signs of morbidity and increased mortality is expected) will be monitored three times/day, including a late evening check. Any moribund mice will be euthanized as soon as possible. If needed, a VSD veterinarian will be contacted for the decision to euthanize. The most current approved IACUC Policy Letter #10 will serve as a reference for the criteria for health evaluation/euthanasia.

V.5.2.2. Emergency Veterinary Medical Care AFRRI veterinary staff will be consulted as needed in an emergency veterinary medical care scenario.

V.5.3. Environmental Enrichment

V.5.3.1. Enrichment Strategy Nestlets and other enrichment items may be allowed in animals that have been separated for experimentation.

V.5.3.2. Enrichment Restrictions Nestlets will be allowed in experimental cages.

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING

NAME	DEGREE	TRAINING	DATE	PROCEDURES	YRS/MOS EXPERIENCE
(b)(6)				1, 3, 4b, 5	(b)(6)
				1, 3, 4a, 5	
				7 – tail vein	
				1, 3, 3d, 4a, 4b, 5, 7	
				1, 2, 3, 4a, 5	
				7 – tail vein	

Procedure and manipulation codes:
Code 1= Animal handling and euthanasia
Code 2= Surgery (aseptic technique) pre- and post-operative care
Code 3= Injections (3a–ip, 3b-sc, 3c-gavage) - can say 3 if trained in all manipulations or add 3d-iv
Code 4= Blood collection under anesthesia (4a-cardiac, 4b-posterior vena cava)
Code 5= Tissue collection (after euthanasia) - doesn't need to be specific
Code 6 = Implantation (provide details)
Code 7 = Others - (provide protocol specific manipulations or procedures for e.g., retro-orbital bleeding, tail vein injection, or drug delivery)

VII. BIOHAZARDS/SAFETY N/A

X. ASSURANCES

Protocol Title: Evaluation of CDX-301 as a radiation countermeasure in the laboratory mouse (Mus musculus); effects of neutrons, gamma photons, and rate of exposure.

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made every effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with a qualified individual who evaluated the experimental design with respect to the statistical analysis, and that the minimum number of animals needed for scientific validity will be used.

D. Biohazard / Safety: I have taken into consideration and made the proper coordinations regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R", namely, "Responsibility," which the DOD has embraced for implementing animal use alternatives where feasible and conducting humane and lawful research.

G. Scientific Review: This proposed animal use protocol has received appropriate peer scientific review and is consistent with good scientific research practice.

H. Painful Procedure(s): I **AM** / **AM NOT** conducting biomedical experiments, which may potentially cause more than momentary or slight pain or distress to animals. If applicable, potential pain and/or distress **WILL** / **WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

DOD ANIMAL CARE AND USE STANDARDIZED PROTOCOL FORMAT WITH EMBEDDED INSTRUCTIONS (December 2013)

Reference DOD Instruction 3216.01 & AFRRI Instruction 3216.2H

****

Information requested in the following animal use protocol template reflects the requirements of the Animal Welfare Act Regulations (AWAR), the Guide for the Care and Use of Laboratory Animals, and other applicable Federal regulations and DOD instructions.

****

This document is intended to be an aid in the preparation of DOD-sponsored animal use protocols. It is a companion document to an identical protocol template that does not have embedded instructions. Either template may be used to format DOD-sponsored animal research proposals; however, reference to the instructions during protocol preparation is highly recommended. If using the template with instructions, the instructions should be deleted prior to submitting the finished protocol for IACUC review. Please use Arial, regular, size 12, black font to prepare the protocol. With the exception of section headings, all paragraphs require a response. Paragraphs that do not apply should be marked N/A. There is no space limitation for responses to the information requested.

Approved standard operating procedures (SOPs) promulgated by the AFRRI Veterinary Sciences Department (VSD) or similar VSD-validated documents that describe specific procedures may be referenced by SOP number and title in lieu of repeating the details in the protocol. However, it is essential to include general descriptions of all animal manipulations to be carried out under the IACUC-approved protocol and to provide details where no approved references are cited. To do otherwise would constitute a breach of statutory regulations. Manipulations not covered in the originally approved protocol can be initiated only after IACUC approval of a formal amendment adding the new procedures. Additionally, Principal Investigators (PIs), or other delegated research personnel, should maintain accurate experimental records and be able to provide an audit trail of animal expenditures and use that correlates with their approved protocol. Protocol PIs will be required to provide this and other information during annual protocol reviews.

Any supporting information that may be of use to the IACUC during its review may be attached to the completed protocol. Adding subparagraphs within the body of the protocol template is permissible, *provided that the numbering sequence of paragraphs in the original standard format is maintained.* In other words, all of the labeled paragraphs and subparagraphs in this template must be retained, with additional information being presented as sub-numbered paragraphs containing information that supports or complements what is requested.

INTELLECTUAL PROPERTY STATEMENT

Research protocols drafted by Government scientists include intellectual property (e.g., concepts, ideas, experimental approaches, etc.), some of which is innovative or original and therefore considered proprietary to the investigators and/or the sponsoring agency. All Government and non-Government personnel handling this protocol shall exercise EXTREME CARE, to ensure that the information contained herein is NOT DUPLICATED OR DISCLOSED, in whole or part, for any purpose other than to evaluate the protocol, without the written permission of the principal investigator or the sponsoring agency.

I. NON-TECHNICAL SYNOPSIS Nuclear proliferation, terrorist activity, and the distribution of nuclear and radioactive materials through underground networks make incidents involving radiation injuries increasingly likely. Scenarios involving radiological hazards include nuclear detonations, covert placement of radioactive substances, and dirty bombs. Depending upon the exposure dose, radiation can cause extensive damage to the rapidly dividing cell populations of the hematopoietic and the gastrointestinal systems leading to secondary infections and hemorrhage resulting in fatalities. At doses of 8 Gy and above in humans, there is severe damage of the gastrointestinal system, with accompanying weight loss, diarrhea, dehydration, and disruption of the gastrointestinal mucosa allowing large numbers of gut microorganism to enter the systemic circulation, causing opportunistic infections and mortality. The outcome is collectively termed Gastrointestinal Acute Radiation Syndrome (GI-ARS). Currently, there is no effective treatment for GI-ARS consequent to accidental radiation exposure.

The current protocol is funded by the (b)(4) (b)(4) to develop a rodent model with 5% shielding of the bone marrow, and to evaluate potential radiation countermeasures that can delay mortality and increase survival of lethally irradiated mice when administered after irradiation. We propose to 1) establish the baseline for GI injury using total body irradiation [TBI], 2) develop a radiation model for GI-ARS with 5% shielding of the bone marrow [partial body irradiation, PBI], 3) evaluate the efficacy of pharmacological countermeasures (CM) in both TBI and PBI, and 4) to study the pathophysiology of radiation-induced gastrointestinal injury and its time-course, as well as the effect of CM on these parameters.

II. BACKGROUND

II.1. Background

Gastrointestinal Syndrome

The three biological systems most affected by high levels of radiation are (1) the vascular system in the brain; (2) the mucosal cells lining the gastrointestinal tract, and (3) the hematopoietic (HP)/immune system. Damage to the brain's vasculature, which occurs only at the very highest levels of radiation exposure, is irreversible and lethal.

Gastrointestinal damage, including lesions within the gut followed by sepsis, is induced by high levels of radiation and is known as gastrointestinal acute radiation syndrome (GI-ARS). Exposure to high doses of radiation exceeding 10-12 Gy causes GI-ARS, which can result in death in 5-10 days. The extent of injury to the bone marrow and the GI tract are the principal determinants of survival after exposure to total body irradiation (TBI).

The classical radiobiological view presents radiation-induced tissue injury as the direct consequence of DNA damage and cell death induction in target cells, meaning that the severity of tissue damage would be directly related to cell depletion during the acute phase. In mouse models of the gastrointestinal syndrome, acute injury has been mainly attributed to apoptosis of epithelial stem cells and microvascular endothelial cells. The pathophysiological mechanisms of GI-ARS is complex and involves loss of clonogenic crypt cells with eventual depopulation of the intestinal villi, defective regeneration of the irradiated intestinal stem cells and a systemic inflammatory response syndrome from a host of cytokines and growth factors released in the serum, following exposure to radiation and gut microbes (Marxhman *et al* 2002, Potten *et al*, 1998). Survival from GI-ARS depends on the rate of the crypt depopulation and the efficiency and number of the residual clonogens, capable of regenerating crypt-villus units.

Partial body irradiation for GI-ARS

(b)(4)

(b)(4) has been in the forefront (MacVittie 2012) in developing animal models for evaluation of various countermeasures which are organ specific. One such model is the Partial body Irradiation with 5% bone marrow shielding (PBI/BM5 or PBI). In a bioterrorism event, typical victims would receive a nonhomogeneous radiation dose that preserves roughly 5% or more of their marrow. The PBI model protects approximately 5% of bone marrow [BM] and is sufficient to separate the effects of BM collapse from those of GI toxicity and to spare 100% of mice from death (LD100/30) at the hematological doses (Zhang *et al* 2010). (b)(4) has requested AFRRI to develop a PBI model to evaluate countermeasures for GI-ARS in mice at AFRRI). The current proposal addresses this request. It is necessary to develop specific jigs suitable to our radiation sources to isolate/shield one hind leg form exposure to irradiation. It is anticipated that 5% shielding of the BM will increase survival by a factor of 1.2 to 1.3.

Countermeasures against GI-ARS

An intense area of research in radiopathology involves the prophylactic use of trophic growth factors such as keratinocyte growth factor (Dorr *et al*, 2002, Terry *et al*, 2004) and glucagon-like peptide 2 (Booth *et al* 2004). Keratinocyte growth factor and interleukin-11 and growth facts that inhibit cell cycle in regenerating crypts, such as, transforming growth factor-β1 (TGFβ1) promote radioresistance of crypt cells when administered prophylactically (Booth and Potten 2001, Booth *et al* 2000, Khan *et al* 1997).

Besides the intestinal crypts where the putative intestinal stem cell (ISC) reside, the stroma or the ISC niche has also been postulated to be a target in GI-ARS. Thus, endothelial cells residing in the ISC niche, is particularly vulnerable to radiation. Growth factors, such as, basic fibroblast growth factor (bFGF) that prevented radiation-induced endothelial (Okunieff *et al* 1998, Zhang *et al* 2010) cell death, also conferred radioprotection from GI-ARS. Recently, a peptide derived from Salmonella Flagellin, which is a ligand for TLR5, was found to be radioprotective against GI-ARS in murine and primate models, possibly via NFkB activation (Saha *et al* 2012).
Work at AFRRI is currently focused on the prophylactic use of vitamin isomers; Li *et al* (2013) reported that DT3 administered 24 h prior to 10-12 Gy irradiated CD2F1 mice improved survival, and protected the intestinal tissue by reducing inflammatory process. Singh *et al* (2012) reported alpha-tocopherol succinate protected against GI-ARS by inhibiting apoptosis, promoting regeneration of crypt cells, and inhibiting translocation of gut bacteria.

Currently, there are no reports of CMs effective when administered post-irradiation.

III. OBJECTIVE / HYPOTHESIS The objective of this protocol is to develop a rodent model for acute gastrointestinal syndrome with 5% shielding of the bone marrow tissue and to evaluate various drugs as radiation protectants and mitigators, as recommended by (b)(4) using survival as the endpoint. Further, we will determine the pathophysiology of GI-ARS following irradiation and the effect of countermeasures on these markers of GI injury to understand the mechanism of GI-ARS.

IV. MILITARY RELEVANCE In the event of a mass casualty event involving radiological/nuclear material, military personnel and first responders can be exposed to radiation doses ranging from mild, moderate to very high. At 6-8 Gy exposures (mild to moderate), GI-ARS or the gastrointestinal syndrome occurs, for which there is currently no FDA approved pharmacological intervention. GI-ARS cannot be managed with supportive care including antibiotics, hydration or cell therapies; eventually leading to mortality. Progress in understanding the differences in the mechanisms involved in response of the GI to high doses of radiation has led to the development of new rationales for selective protection of the normal cells, by suppressing death signals and increasing radioresistance of the normal cells. This protocol will address the critical gap in knowledge regarding GI-ARS and to develop strategies to protect, ameliorate, or treat armed personnel.

V. MATERIALS AND METHODS

V.1. Experimental Design and General Procedures

V.1.1. Experiment 1.

V1.1.a Establish LD-30/10, LD-50/10, LD-70/10 and LD-100/10 for CD2F1 mice following total body irradiation.

1. We will use 6 radiation doses to determine the LD-50/10 for CD2F1 mice [radiation dose that results in 50% mortality of CD2F1 mice within 10 days post-TBI].
2. We will use n=10 mice per radiation dose for the preliminary study. The study will be reiterated prior to start of countermeasure screening.
3. Probit analyses will determine the LD-30, LD-50 and LD-70 radiation doses for the model.

6 radiation doses (10, 11, 12, 13, 14 and 15 Gy, 0.6 Gy/min)* x 10 mice x 2 iteration

Subtotal = 120 mice

*The radiation doses are based on literature. We will refine the dose based on preliminary data to arrive at the correct GI dose.

V.1.1.b. Determine the pathophysiology of GI-injury in mice irradiated with different GI total body radiation doses (TBI) to establish a radiation-dose response for GI injury.
4 radiation doses *x 4 time points post TBI (4 d, 6 d, 8 d and 10 d post-TBI) x 10 mice

Subtotal = 160 mice

* *Radiation doses will be determined based on V.1.1.a.*

Note: V.1.2. Experiment 2 has been shelved

V.1.3. Experiment 3

V.1.3.a. Test a promising radiation countermeasure against radiation injury (GI-ARS) after exposure to total body irradiation (TBI).

1. There will be 3 arms for the survival study: Prophylaxis (24 h pre-TBI), and two mitigation arms (post-TBI) starting at 4 h and 24 h post-TBI.
2. The radiation dose resulting in 100% mortality on day 10 will be selected for testing radiation countermeasures based on results from V.1.1.a.
3. Delay in mortality and improvement in survival (30% over vehicle) is the 'pass' criteria for a successful radiation countermeasure.
4. The countermeasure identified for preliminary screening in the GI model is (b)(4) [50 mg/kg, 4 doses, once a day by oral gavage].

For each drug, the animal requirement is calculated as follows:

Drug + vehicle (2 groups) x 3 regimen (one pre- and two post-TBI) x 1 rad dose (LD-100/10) x 1 route (*po*) x 24 CD2F1 mice per group **Subtotal = 144 mice/drug**.

Pilot study (Partial body radiation): It appears from conversation with JIG manufacturers for partial body radiation that Cobalt 60 gamma radiation cannot be used for such studies due to the scattering of the radiation. The alternate option is to use X-ray source. PI has identified the source as the unit available (b)(4) Additional discussions are in progress and hence PI is not requesting any animals for even a pilot study. **Subtotal = 0 mice**

Shelved experiments V1.2., V1.3.b, V1.4.,V.1.5., and V.1.6

Partial body radiation studies (place holder- no animals requested)

V.1.2. Experiment 2 [The details pertaining to partial body irradiation is under active discussion between the PI, VSD, and radiation dosimetry lead. We will submit an amendment at a later date describing the precise methodologies].

V.1.2.a. Establish LD-50/10 for CD2F1 mice following 5% shielding of bone marrow.
6 radiation doses (12, 13, 14, 15, 16 and 17 Gy, 0.6 Gy/min) x 10 mice x 2 iteration*

Subtotal = 0 mice^

**These radiation doses are projected based on a DRF of 1.3 for survival following 5% bone marrow shielding reported in literature. These will likely change based on the AFRRI model, radiation source, dose-rate and other variables.*

V.1.2.b. Determine the pathophysiology of GI-injury in mice irradiated with different GI partial body radiation doses (PBI) to establish a radiation dose response for GI injury.
4 radiation doses x 4 time points post TBI (4 d, 6 d, 8 d and 10 d post-TBI) x 10 mice*

Subtotal = 0 mice^

**Radiation doses will be determined based on V.1.2.a.*
^Mice will be requested for PBI studies in the amendment detailing methodologies for irradiation, anesthesia, and other logistics.

V.1.3.b. Test a promising** radiation countermeasure for GI efficacy after exposure to partial body irradiation (PBI). **[Details for anesthesia and irradiation will be submitted as an amendment once the details are determined by the PI, VSD and Radiation Department].

1. *As before, there will be 3 arms for the survival study: Prophylaxis (24 h pre-TBI), and two mitigation arms (post-TBI) starting at 4 h and 24 h post-TBI.*

2. *The radiation dose resulting in 100% mortality on day 10 with 5% bone marrow shielding will be selected for testing radiation countermeasures based on results from V.1.2.a.*
3. *Delay in mortality and improvement in survival (30% over vehicle) is the 'pass' criteria for a successful radiation countermeasure.*
4. (b)(4) *is the first countermeasure to be tested in the PBI model [50 mg/kg, 4 doses, once a day by oral gavage].*

For each drug, the animal requirement is calculated as follows:
Drug + vehicle (2 groups) x 3 regimen (one pre- and two post-TBI) x 1 rad dose (LD-100/10) x 1 route (po) x 24 CD2F1 mice per group **Subtotal = 0 mice/drug^**

^Mice will be requested for PBI studies in the amendment detailing methodologies for irradiation, anesthesia, and other logistics.

V.1.4. Experiment 4
***Optimization studies**: Optimization studies will be initiated in CD2F1 mice only if any of the drugs tested meets the AFRRI criteria of >30% survival than vehicle in the preliminary radiation survival screen. As a reduction strategy, we will use only PBI. Drug dose and schedule will be selected based on optimum survival by* (b)(4) *We project initiating the optimization studies with 50 mg/kg* (b)(4) *administered once a day by oral gavage for 10 days [see background].*

***Drug dose optimization study**: 6 groups (Five drug doses + 1 vehicle) x 1 radiation dose (LD-100/10) x 2 regimen (pre- and post-exposure) x 1 route x 20 animals per group* **Subtotal = 0 CD2F1 mice^**

***Time optimization study**: 4 different time points x 1 optimum dose + 1 vehicle (2 groups) x 1 radiation dose (LD-100/10) x 1 route x 20 animals per group* **Subtotal = 0 CD2F1 mice^**
^Mice will be requested for PBI studies in the amendment detailing methodologies for irradiation, anesthesia, and other logistics.

V.1.5. Experiment 5
Dose reduction factor study (DRF)
The dose reduction factor (DRF) studies will use the optimum drug dose and times determined by the optimization studies to evaluate the effectiveness of the drug against a range of GI radiation doses in CD2F1 mice for both TBI and PBI conditions.

DRF for total body irradiation (TBI)

6 TBI-irradiated vehicle groups (0.6 Gy/min) + 6 TBI-irradiated drug groups* x 24 mice per group*

Subtotal = 0 CD2F1 mice

**These radiation doses will be determined based on experiment V.1.1 and V.1.2 and are considered a guidance. The appropriate radiation doses will be determined using experiment V.1.1.*

DRF for partial body irradiation (PBI)

6 PBI-irradiated vehicle groups (0.6 Gy/min) + 6 PBI-irradiated drug groups* x 24 mice per group*

Subtotal = 0 CD2F1 mice^

**As above, data generated from experiment V.1.2 will determine the radiation dose range.*

^Mice will be requested for PBI studies in the amendment detailing methodologies for irradiation, anesthesia, and other logistics.

V.1.6. Experiment 6
*V.1.6.a. Determine the pathophysiology of GI-injury in mice irradiated with GI radiation doses (**PBI**) and treated with a countermeasure. Data from these studies will form the basis of understanding the mode of action of the drug. Experiment V.1.4. will determine the optimum dose and schedule for these studies.*

Naïve + vehicle + drug alone (3 groups) x 4 time-points x 10 mice per group x 1 route of administration x 1 drug **Subtotal = 0 CD2F1 mice^**

^Mice will be requested for PBI studies in the amendment detailing methodologies for irradiation, anesthesia, and other logistics.

2 experimental groups (vehicle-irradiated, Drug-irradiated) X 4 time-points X 10 mice per group x 1 route of administration X 2 radiation doses ***Subtotal = 0 CD2F1 mice^***
^Mice will be requested for PBI studies in the amendment detailing methodologies for irradiation, anesthesia, and other logistics.

V.2. Data Analysis

Note: THIS SECTION HAS NOT BEEN REVISED in the light of shelving certain experiments as shown above, because ultimately similar type of statistics will be used.

All data will be reported as means with standards errors or percentages where applicable.

Experiment V.1.1 and V.1.2: A 6 dose probit model to determine LD-50 will have a>80% power to detect significant difference if the effect size is 1.0 standard deviations and the sample size per dose is 10 animals. We request an iteration for each of these experiments to
Allow for additional radiation doses if the preliminary study fails to achieve the LD-5/10 to LD-100/10 range for survival.

Experiment V.1.3 and V.1.4: Assumptions for 30% improvement in 10-d survival in the radiation countermeasure group compared to none in the vehicle group. Based on a log-rank test with 80% power and 5% two-sided significance, we determined that this design has adequate power for screening countermeasures using a 10-day survival and N of 20 (Kodell *et al*, 2010).

Experiment V.1.5. 20 animals per dose with six radiation doses is sufficient to determine a probit line fit to mortality data for DRF calculations. At least three out of the six doses should sustain survival other than 100 or 0 percent. Finney's methods will be adhered to in making probit fits and estimating DRF.

Experiment V.1.6. For testing the overall difference between groups (averaging over time points), two-way ANOVA with 10 animals per group measured at 4 time points will have 80% power to detect a difference of 0.91 standard deviations if the within-subject correlation is 0.2. For comparisons between groups at a single time point, the proposed sample size will have 80% power to detect a difference of 1.8 standard deviations between groups, based on a t-test for independent samples with a 5%, two-sided significance level.
Prasanna and Devi (1993) observed standard deviations of ~35 crypts. A sample size of 8-10 per group will have 80% power to detect a difference of 3 crypts (2.38 std. dev) based on a 2 group t-test with 5%, 2-sided significance level. Observed differences are expected to exceed 10 crypts.

Kodell *et al*. Determination of sample size for demonstrating efficacy of radiation countermeasures. Biometrics. 2010.
Prasanna and Devi, Modification of WR-2721 radiation protection from gastrointestinal injury and death in mice by 2-mercaptopropionylglycine. Rad Res. 1993.

V.3. Laboratory Animals Required and Justification

V.3.1. Non-animal Alternatives Considered: Although high throughput screening and computer modeling have advanced significantly in recent years in identification of promising drugs, it would be simplistic to assume that cell systems or artificial intelligence modeling can replace the data that can be generated by using an animal model. Irradiation of animals will result in a cascade of changes including death of stem and progenitor cells in bone marrow, alterations in signal transduction pathways, multiple organ dysfunctions etc. due to differing radiosensitivities of organs. Currently, there are no alternatives in existence that can predict or compute the complexity of the response to total body irradiation. The US FDA recognizes the ethical considerations involved in testing the efficacy of radioprotective drugs in humans. The FDA regulations concerning the approval of new drugs or biological products when human efficacy studies are not ethical or feasible are known as the "Animal Rule" (Crawford 2002). Therefore, FDA requires preclinical drug assessments (safety and efficacy) to be performed using both small and large animal models (FDA 2002) prior to granting approval for safety testing in humans. These regulations state that the pathophysiological mechanism of radiotoxicity and its prevention or substantial reduction by the product must be well understood and demonstrated in more than one animal species expected to react with a response predictive for humans. Further, the endpoint in such studies must be clearly related to the desired benefit in humans, generally the enhancement of survival or prevention of major morbidity. Finally, there must be supporting pharmacokinetic (pK) and pharmacodynamic (pD) data (USFDA 2009).

Crawford. New drug and biological drug products; evidence needed to demonstrate effectiveness of new drugs when human efficacy studies are not ethical or feasible. Federal Register 67: 37988<37998; 21 CFR parts 314 and 601.FDA, HHS; ACTION: Final Rule; 2002.
U.S. Food and Drug Administration. Guidance for industry:animal models, essential elements to address efficacy under the Animal Rule. Silver Spring, MD: CBER; 2009.

V.3.2. Animal Model and Species Justification Recent advances in molecular techniques have allowed significant improvements in understanding the cellular and biochemical processes. These advances are possible only due to whole animal modeling of human ailments. The mouse, in particular, has high sequence homology to humans at a genomic level as well as similar hematological and immunological response to radiation. Mouse models not only confirm primary pathological processes but have also provided a venue for studying basic molecular, cellular, biochemical, and cytological processes. Further, there are extensive data on the mouse for comparison, review and analysis. The practicalities of breeding and housing these small mammals have made the mouse model invaluable. The Principal Investigator's group at AFRRI has significant training and experience in handling mice in radiation countermeasure studies.

V.3.3. Laboratory Animals

V.3.3.1. Genus / Species Mouse, *Mus musculus*

V.3.3.2. Strain / Stock CD2F1

V.3.3.3. Source / Vendor CD2F1 from VSD approved vendors (Harlan Inc., Charles Rive laboratories, or Jackson Laboratories).

V.3.3.4. Age 7-8 weeks on purchase.

V.3.3.5. Weight 25-30 grams

V.3.3.6. Sex Males have been used historically and will continue to be used in this study. Females may be included as per the Program Manager's directive. In this case, an amendment will be submitted detailing the reason for inclusion of females.

V.3.3.7. Special Considerations Commercially procured animals must be adventitious disease free. Specific pathogen-free, including *Pseudomonas aeruginosa,* and *Pasteurella*: All mice need to be free of the following agents: Sendai, Pneumonia Virus of Mice (PVM), Reovirus-3 (Reo 3), Mouse Adenovirus (MAD-1, MAD-2), Mouse Cytomegalovirus Virus (MCMV), Ectromelia, K virus, Lymphocytic Choriomeningitis Virus (LCM), Epidemic Diarrhea of Infant Mice (EDIM), Hantaan virus, Rotavirus, Mouse Parvovirus (MPV), Polyoma Virus, Mouse Minute Virus (MMV), Mouse Thymic Virus (MTV), Theiler's Mouse Encephalomyelitis Virus (TMEV/GDVII), *Encephalitozoon cuniculi,* CAR bacillus, *Mycoplasma pulmonis*, and *Clostridium piliforme.*
Endoparasite- and ectoparasite-free.

V.3.4. Number of Animals Required (by species) 424 CD2F1 mice

V.3.5. Refinement, Reduction, Replacement (3 R's)

V.3.5.1. Refinement The PI will take necessary steps to assure that all personnel in the project are rigorously trained in handling techniques (ear-punch, injections, oral gavage, intraperitoneal and subcutaneous injections, and routine cage-side observations) to minimize distress and pain to the animals. Specifically, during capture and restraint of the rodents, care will be taken to ensure that handling does not contribute to distress. Topical ointment/lubrication gel will be used, if necessary, to prevent drying of the cornea as well as at the site of drug injection in consultation with attending veterinarian and veterinary staff.

V.3.5.2. Reduction The protocol will use a tiered approach to reduce the number of animals. In preliminary studies, if we achieve the LD-50 in the first attempt, we will repeat the study with 5 radiation doses and an n of 5 each to validate the data. Wherever possible we will reduce the number of repeats planned for the experiments above.

V.3.5.3. Replacement It is not feasible to use non-animal systems in place of actual animal models to address the questions in this project. Rodents are considered sentient and hence rodents will be used for screening large number of potential radiation countermeasures. Only those drugs that pass the AFRRI criteria for significant survival benefit will advance to studies in higher mammals.

V.4. Technical Methods
V.4.1. Pain / Distress Assessment

V.4.1.1. APHIS Form 7023 Information

V.4.1.1.1. Number of Animals 424

V.4.1.1.1.1. Column C __ (# of animals).

V.4.1.1.1.2. Column D __160___ (# of animals). These mice will not be irradiated. They will be deeply anesthetized, euthanized, and their tissue harvested as a terminal procedure.

V.4.1.1.1.3. Column E __264 (# of animals). These mice will be irradiated and will not receive any intervention for pain relief. However, they will be euthanized if found moribund.

V.4.1.1.1.4. Pain Category Assignments

Exp. #	Experimental/Control Group	C	D	E	Totals
1	TBI probit			120	120

Totals:			160	264	424

** experiments shelved (all crossed out experiments)*

V.4.1.2. Pain Relief / Prevention

V.4.1.2.1. Anesthesia / Analgesia / Tranquilization The protocol will not use analgesics during radiation since they will adversely affect the outcome of the experiments. The proposed study is to determine the effects of radiation and countermeasures on the function of the immune and blood forming systems; use of any analgesics and anesthetics would interfere with the function of the immune system and therefore compromise the interpretation of the results. It is anticipated that at high radiation doses, animals will demonstrate varying degrees of morbidity and moribund, which makes it critical to define the criteria for euthanizing the animals without undermining the study objective. Euthanasia will be performed by trained personnel in accordance to the current AVMA guidelines (AMVA Guidelines on Euthanasia, 2013).

For Experiment 6, mice will be placed in the Isoflurane chamber and delivered a metered amount of 5% Isoflurane mixed with 100% oxygen until all voluntary motor movement ceases and the animal is recumbent for 10 seconds. Animal's respiration rate will be closely monitored through the Plexiglas chamber during induction of anesthesia. When animals are recumbent, they will be removed from the chamber and their nose/mouth placed in the anesthesia apparatus breathing/gas administration cone for maintenance of anesthesia at 3% Isoflurane and 100% O_2. Blood will be collected by cardiac stick or from the inferior vena cava (as described under procedures). All

personnel will be extensively trained for efficient administration of the agents as well as to minimize handling stress.

Anesthesia for partial body irradiation [PBI]: This is under discussion with VSD based on the time projection for radiation at high doses (12-15 Gy; approximately 30 min). The PI will submit a detailed description for the procedure after preliminary studies under the aegis of VSD.

Association AVM. AMVA Guidelines on Euthanasia. http://www.avmaorg/issues/animal_welfare/euthanasiapdf; 2013.

V.4.1.2.2. Pre- and Post-procedural Provisions Mice will be housed under standard conditions both before and after radiation procedures in accordance with current VSD rodent husbandry Standard Operating Procedures (see section V.5).

V.4.1.2.3. Paralytics N/A

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures
V.4.1.3.1. Sources Searched AGRICOLA, PubMed, EMBASE

V.4.1.3.2. Date of Search: 05/30/2014

V.4.1.3.3. Period of Search AGRICOLA: 1975-2004, EMBASE 1974-present PubMed~1950 to present.

V.4.1.3.4. Key Words of Search Gastrointestinal Radiation Syndrome and pain, (b)(4) and pain, anesthesia and radiation, analgesia, distress, humane.

V.4.1.3.5. Results of Search There are no alternatives to irradiation. While radiation itself does not cause pain or distress, it induces a number of changes in the body that alters immune response and destroys hematological and gastrointestinal tissues, resulting in opportunistic infections, and multiorgan dysfunction leading to death. It is anticipated that animals exposed to high lethal radiation doses will become moribund. Unfortunately, literature clearly demonstrates that use of analgesics alters radiation response and therefore leads to increase in animal number for better statistical results or for iteration of entire experiments. No references were found suggesting distress due to (b)(4) though some changes associated with the pathophysiology of biological response to the drug is expected, such as increase in fiber content of GI and therefore more stool formation.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification Because exposure to irradiation is potentially lethal or causes debilitating effects in humans, it is ethically impermissible to test the effectiveness of radiation countermeasures on human volunteers. Irradiation compromises the immune and blood forming systems leading to mortality. The radiation-induced mortality and potential percentage increase of survivors over 30 days using potential radiation countermeasures are study endpoints for this protocol. Administration of drugs and analgesics is not an option since it is well documented that they interact with the immune system which will

confuse data interpretation (Galley *et al*, 1997, 1998). Pain relieving measures are not used because such measures may compromise the experimental integrity of the study.

Galley *et al*., The effect of midazolam and propofol on interleukin-8 from human polymorphonuclear leukocytes. Anesth Analg 1998.
Galley and Webster. Effects of propofol and thiopentone on the immune response. Anaesthesia 1997.

V.4.2. Prolonged Restraint The experimental animals will receive radiation at a dose rate 0.6 Gy per/min in the AFRRI Cobalt 60 gamma radiation facility. Animals will be irradiated in Lucite boxes (8 animals/box) and arranged in an array (dosimetry 02/28/2013;or the latest dosimetry map) using plastic racks. Mice will be inserted into the standard radiation boxes just prior to irradiation (~15-30 min of exposure time) and taken to the cobalt facility for irradiation. Animals will be restrained for no more than 60 min and returned to cages at the end of the irradiation period. They will be monitored daily (twice a day when necessary) for 30 days and euthanized at the completion of the observational period. Although the radiation dose results in mortality on day 10 post-irradiation, all surviving mice will be monitored for 30 day, to determine the effect of the countermeasure.

V.4.3. Surgery N/A
V.4.3.1. Pre-surgical Provisions
V.4.3.2. Procedure(s)
V.4.3.3. Post-surgical Provisions
V.4.3.4. Location
V.4.3.5. Surgeon
V.4.3.6. Multiple Major Survival Operative Procedures
V.4.3.6.1. Procedures
V.4.3.6.2 Scientific Justification

V.4.4. Animal Manipulations
V.4.4.1 Animal Identification: Individual animals will be identified by either ear punch or tattoos as per VSD policy.

V.4.4.1. Injections For the oral route, drug(s) will be administered using a 20 G gavage needle (Fisherbrand-Animal feeding needles, disposable-sterile, non-toxic and nonpyrogenic-20 G, 1 ½" length). Non-disposable, metal ball ended, oral gavage needles are included as an alternative to the disposable needles. Drug volume will be 0.2 ml (with a maximum of 0.5 ml). The animal will be restrained in a vertical position to align the spine straight. The bulb will be introduced into the mouth horizontally. Using the needle as lever, the syringe will be moved into a vertical position and the needle dropped down the esophagus into the stomach. The needle contents will be administered when the needle hub touches the animal's mouth. All precautions will be taken to ensure that the placement of the needle is properly positioned and that the animal is not struggling severely. No forceful feeding will be done to prevent perforation of the esophagus.

Irradiation: These will follow the standard AFRRI protocol with mice placed in restrainers shortly prior to exposure, irradiation at the cobalt facility and return to VSD for further monitoring. Briefly, the experimental animals will receive radiation at a dose

rate 0.6 Gy per/min in the AFRRI Cobalt 60 gamma radiation facility. Animals will be irradiated in Lucite boxes (8 animals/box) and arranged in an array (dosimetry 02/28/2013 or current dosimetry map) using plastic racks. Animals will be restrained for no more than 60 min and returned to cages at the end of the irradiation period. They will be monitored daily (twice a day when necessary) for 30 days and euthanized at the completion of the observational period. In case of non-lethal exposures, mice will be harvested at specific time-points after irradiation, and tissues collected after terminal blood draw.

Irradiation for PBI is under discussion with (b)(6) Once the details are determined, the PI will submit an amendment describing the procedure for PBI.

V.4.4.1.1. Pharmaceutical Grade Drugs N/A

V.4.4.1.2. Non-Pharmaceutical Grade Drugs (b)(4) will be tested for endotoxin levels if this information is not supplied by the manufacturers. Physical characterization, including osmolality and pH of final solutions will be in the range stipulated by IACUC by its policy letter on testing non-pharmaceutical grade drugs (policy #9). We do not anticipate filtering the test agent due to the limited availability of drugs, and uncertainty as to how much of the drug will be filtered out. However, we will ensure that drug preparation is carried out under hygienic conditions (use of PPE, clean surface area for drug preparation, use of clinical grade solvents, sterile needles and syringes) to preclude contamination of test samples.

V.4.4.2. Biosamples

Blood collection: Mice will be anesthetized as described under section V.4.1.2.1 (anesthesia). Blood draw for hematology is collected either by cardiac stick or from the inferior vena cava (IVC). The animals will be deeply anesthetized in the rodent anesthesia machine; the tail will be pinched for reflexive movement, indicative of insufficient anesthesia. If there is no response, the animal will be moved to the station with individual nose cone for continued anesthesia. An incision will be made on the right side below the abdomen of the animal, closest to the IVC, the vein exposed and blood drawn with a 23 G needle. Similarly, cardiac stick will be performed on the animal positioned at the platform under anesthesia. The animals will be placed on the back, and the skin wet with 70% alcohol. The needle will be inserted under the sterum towards the mouse head, and negative pressure applied to the plunger very gently. If not blood appears, the needle will be slowly withdrawn so that the needle remains under the skin and then redirected in a slightly different direction. In both cases, the animals will be immediately euthanized on completion of blood draw by cervical dislocation.

V.4.4.3. Adjuvants N/A

V.4.4.4. Monoclonal Antibody (MAb) Production N/A

V.4.4.5. Animal Identification Generally, cage cards will be used to distinguish drug-treated and control groups. Some experiments might necessitate ear punch or tattooing by personnel to identify individual animals in a cage. This will be done as per VSD policy.

V.4.4.6. Behavioral Studies N/A

V.4.4.7. Other Procedures N/A

V.4.4.8. Tissue Sharing On approval by IACUC.

V.4.4.9. Animal By-Products N/A

V.4.5. Study Endpoint The study end-point for experiments 1-5 is 10 day mortality following irradiation. However, if the mice survive past 10-d post-TBI, we will monitor survival for 30 days to determine mortality at different radiation doses.

Since this is a screening protocol, the PI requests modification of policy#10 (revised July 2014)to score morbidity and determine mortality. The revised scoring sheet for the current study has been included as an appendix.

All scores (5, 6 and 9 from the "appearance" clinical signs) and the amended respiratory score are removed following consultation with the AV, because the former have never been observed in our studies and the latter, because we do see lowered respiratory rates. Mice will only be euthanized if there is a score of 12 in a single category. Body weights are not included since there is no clear correlation between body weight loss and mortality. Further, we do not anticipate significant body weight loss during the course of the study [10 days post-TBI]. Previous publications (b)(4) (b)(4) describing survival studies did not use body weight as a parameter to determine survival (b)(4) Further, other radiation researchers do not use body weight loss as a mortality criterion either (Plett *et al*, 2012).

However, to adhere to the policy of preventing animal suffering, the PI will facilitate the late PM and early AM checks (not more than 10 h apart) in addition to the twice a day checks during the critical lethality period. All morbid mice will be monitored carefully and their conditions scored for documentation.

The critical period spans between day 5 and 10 post-TBI.

(b)(4)

Plett *et al., 201*, Establishing a murine model of the hematopoietic syndrome of the acute radiation syndrome. Health Physics, Vol. 103, 343-355.

Animals will be will be immediately euthanized when they display abnormal breathing, are recumbent, or unable to respond to mild external stimulus by the research staff and scored as dead on removal, while recorded as euthanized in the medical records. VSD veterinarians will be consulted for all matters regarding the animal welfare.

V.4.6. Euthanasia Mice found moribund will be euthanized by CO_2 inhalation plus confirmatory cervical dislocation by investigator/ technician according to the directives of the VSD-SOP [Rodent Euthanasia Guidelines] and in accordance with current AVMA Guidelines on Euthanasia (AMVA 2013). At the conclusion of the experimental time frame, all animals that survived the procedures of irradiation, drug intervention and controls, will be sacrificed by CO_2 inhalation plus confirmatory cervical dislocation and their carcasses disposed of according to VSD regulations.

V.5. Veterinary Care

V.5.1. Husbandry Considerations Husbandary practices will be performed as per standard AFRRI VSD SOPs.

V.5.1.1. Study Room As assigned by VSD

V.5.1.2. Special Husbandry Provisions N/A

V.5.1.3. Exceptions Mice will be socially (group) housed as described above, except when there is a possibility that during survival studies cage mates may be lost through attrition and for a period of time the sole surviving mouse may remain singly housed until the end of the 30-day study.

V.5.2. Veterinary Medical Care We do not project routine veterinary medical care. However, in case of minor injuries arising from fighting, topical application of antibiotics is acceptable with consensus from the PI and VSD.

V.5.2.1. Routine Veterinary Medical Care Experimental animals will be observed daily by either the investigator or technician or both. VSD personnel will monitor all animals during their routine rounds as per VSD SOPs. In the course of the study, as animals approach morbidity, the research staff observations will be increased to a minimum of twice a day, early morning and late afternoon (includes weekends and holidays). There is no supportive therapy contemplated since this would compromise the experimental results (described earlier in the end point and pain category sections).

V.5.2.2. Emergency Veterinary Medical Care Moribund animals (gasping, recumbent, non-responsive to mild stimulus), will be euthanized by trained personnel.

V.5.3. Environmental Enrichment

V.5.3.1. Enrichment Strategy: Igloos and huts may be provided to animals but not on active experiments. Nestling pads will be provided in each cage during bedding changes as per AFRRI-VSD SOPs.

V.5.3.2. Enrichment Restrictions For active experiments, no igloos or huts will be provided, but nestlets will be used. Irradiated animals are considered immunosuppressed and hence PI is of the opinion that Igloos will not be appropriate.

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING

NAME	DEGREE	TRAINING	DATE	PROCEDURES	YRS/MOS EXPERIENCE
(b)(6)				1, 3, 4b, 5	(b)(6)
				1, 3, 4a, 5	
				1, 3, 4a, 5	
				1, 3, 4a, 5	
				1,3,4a,4b, 5	
				1,3,4a,4b, 5	
				1,3,4a,4b, 5	

Procedure and manipulation codes:

Code 1= Animal handling and euthanasia
Code 2= Surgery (aseptic technique) pre- and post-operative care
Code 3= Injections (3a–ip, 3b-sc, 3c-gavage) - can say 3 if trained in all manipulations or add 3d-iv
Code 4= Blood collection under anesthesia (4a-cardiac, 4b-posterior vena cava)
Code 5= Tissue collection (after euthanasia) - doesn't need to be specific
Code 6 = Implantation (provide details)
Code 7 = Others - (provide protocol specific manipulations or procedures for e.g., retro-orbital bleeding, tail vein injection, or drug delivery)

VII. BIOHAZARDS/SAFETY All personnel working in the protocol have undergone necessary training in handling experimental animals. The amount of drug used will be small and standard safety precautions will be taken while handling them in the laboratory and in the vivarium. All personnel listed in the present protocol have been trained as general radiation users on a regular basis. All investigators and personnel will use appropriate protective gear while in the vivarium as described by the VSD. All listed personnel are current in safety training and medical surveillance.

VIII. ENCLOSURES None

X. ASSURANCES

Protocol Title: Screening Radiation Countermeasures for prophylaxis and mitigation of gastrointestinal syndrome ((GI-ARS) in the lab mouse, *Mus musculus*.

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made every effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with a qualified individual who evaluated the experimental design with respect to the statistical analysis, and that the minimum number of animals needed for scientific validity will be used.

D. Biohazard / Safety: I have taken into consideration and made the proper coordinations regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R", namely, "Responsibility," which the DOD has embraced for implementing animal use alternatives where feasible and conducting humane and lawful research.

G. Scientific Review: This proposed animal use protocol has received appropriate peer scientific review and is consistent with good scientific research practice.

H. Painful Procedure(s): [**AM**] / **AM NOT** conducting biomedical experiments, which may potentially cause more than momentary or slight pain or distress to animals. If applicable, potential pain and/or distress **WILL** / [**WILL**] **NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

Any single criteria of 12* euthanize immediately; consider as 'found dead.'

DOD ANIMAL CARE AND USE STANDARDIZED PROTOCOL FORMAT WITH EMBEDDED INSTRUCTIONS (December 2013)

Reference DOD Instruction 3216.01 & AFRRI Instruction 3216.2H

****

Information requested in the following animal use protocol template reflects the requirements of the Animal Welfare Act Regulations (AWAR), the Guide for the Care and Use of Laboratory Animals, and other applicable Federal regulations and DOD instructions.

****

This document is intended to be an aid in the preparation of DOD-sponsored animal use protocols. It is a companion document to an identical protocol template that does not have embedded instructions. Either template may be used to format DOD-sponsored animal research proposals; however, reference to the instructions during protocol preparation is highly recommended. If using the template with instructions, the instructions should be deleted prior to submitting the finished protocol for IACUC review. Please use Arial, regular, size 12, black font to prepare the protocol. With the exception of section headings, all paragraphs require a response. Paragraphs that do not apply should be marked N/A. There is no space limitation for responses to the information requested.

Approved standard operating procedures (SOPs) promulgated by the AFRRI Veterinary Sciences Department (VSD) or similar VSD-validated documents that describe specific procedures may be referenced by SOP number and title in lieu of repeating the details in the protocol. However, it is essential to include general descriptions of all animal manipulations to be carried out under the IACUC-approved protocol and to provide details where no approved references are cited. To do otherwise would constitute a breach of statutory regulations. Manipulations not covered in the originally approved protocol can be initiated only after IACUC approval of a formal amendment adding the new procedures. Additionally, Principal Investigators (PIs), or other delegated research personnel, should maintain accurate experimental records and be able to provide an audit trail of animal expenditures and use that correlates with their approved protocol. Protocol PIs will be required to provide this and other information during annual protocol reviews.

Any supporting information that may be of use to the IACUC during its review may be attached to the completed protocol. Adding subparagraphs within the body of the protocol template is permissible, *provided that the numbering sequence of paragraphs in the original standard format is maintained.* In other words, all of the labeled paragraphs and subparagraphs in this template must be retained, with additional information being presented as sub-numbered paragraphs containing information that supports or complements what is requested.

INTELLECTUAL PROPERTY STATEMENT

Research protocols drafted by Government scientists include intellectual property (e.g., concepts, ideas, experimental approaches, etc.), some of which is innovative or original and therefore considered proprietary to the investigators and/or the sponsoring agency. All Government and non-Government personnel handling this protocol shall exercise EXTREME CARE, to ensure that the information contained herein is NOT DUPLICATED OR DISCLOSED, in whole or part, for any purpose other than to evaluate the protocol, without the written permission of the principal investigator or the sponsoring agency.

I. NON-TECHNICAL SYNOPSIS

Radiation mitigators are needed to protect military personnel from adverse effects of radiation exposure in the event of a nuclear weapon disaster or in a terrorist attack employing a dirty bomb. A safe and efficacious material that can be delivered after *radiation* exposure is needed and a variety of agents are being evaluated for their effectiveness (b)(4),(b)(6) (b)(4),(b)(6) (b)(4),(b)(6) is in the process of developing a medical counter measure mitigator, (R)-3-Hydroxybutyl (R)-3-hydroxybutyrate, a ketone ester or more simply called "R3-KE". Thus far R3-KE has been shown to be highly effective in preventing radiation-induced cell death and decreasing radiation-induced chromosomal damage in *in vitro* radiation studies when delivered pre or post exposure. An *in vivo* radiation lethality study is needed to confirm R3-KE's radiation damage mitigation ability. R3-KE is currently being studied in other laboratories for its potential to treat Alzheimer's disease (AD) and Parkinson's disease (PD) and its use resulted in an increase in mental acuity and physical performance in tested Special Operations soldiers. It has been categorized as generally regarded as safe (GRAS) by the FDA and possesses very low clinical toxicity in human clinical trials. Its low toxicity in humans and preliminary *in vitro* radiation results make it an excellent radiation mitigation candidate.

II. BACKGROUND

II.1. Background

Radiation mitigators are needed to protect military personnel from adverse effects of radiation exposure in the event of a nuclear weapon disaster or in a terrorist attack employing a dirty bomb. A safe and efficacious material that can be delivered rapidly and easily after radiation exposure is needed (b)(4),(b)(6) (b)(4),(b)(6) is in the process of developing a medical counter measure mitigator, (R)-3-Hydroxybutyl (R)-3-hydroxybutyrate, a ketone ester or more simply called "R3-KE". Thus far R3-KE has been shown to be highly effective in preventing radiation-induced cell death and decreasing radiation-induced chromosomal damage *in vitro* radiation studies when delivered pre or post exposure. An *in vivo* radiation lethality study is needed to confirm R3-KE's radiation damage mitigation ability.

History of R3-KE and Military Use

R3-KE is an organic ester product comprised of one unit of β-hydroxybutyrate and 1, 3-butane-diol. In the liver the 1, 3-butane-diol is rapidly converted to β-hydroxybutyrate. R3-KE has undergone a battery of safety tests in both human subjects and in animals (1, 2). It is a safe and efficacious compound and has received FDA approval and determined to be Generally Regarded As Safe (GRAS). R3-KE was developed for a specific intended military purpose. (b)(4) (b)(4)

(b)(4)

Metabolism of Ketone Bodies

Ketone bodies, in particular, 3-hydroxybutyrate and acetoacetate are intermediary metabolites typically produced from beta-oxidation of fatty acids in the liver. During periods of extended fast, as carbohydrate reserves become exhausted, fatty acids released from adipose tissue become partially oxidized in the liver and ketones, 3-hydroxy butyrate and acetoacetate are released into the blood. Generally blood ketones rise to a few millimolar (3-7 millimolar) during an extended fast. Aside from the liver, many physiological systems (e.g. skeletal and heart muscle, and particularly the nervous system) are capable of utilizing ketones effectively for highly efficient energy production (4). Unlike glucose, ketone metabolism is independent of blood insulin levels. Ketones are transported in the blood and enter into various tissues via the mono-carboxylate transporter (MCT) sparing glucose utilization and thereby aide in maintaining blood glucose levels. This allows ketones a notable metabolic advantage for maintaining system homeostasis during periods of heightened physiological stress (i.e. traumatic somatic wounds or burn injuries) as the glucose-insulin signaling becomes compromised.

Medical Uses of Ketones

Decades of independent medical research have shown that the metabolism of ketones, through administration of a ketogenic diet (very high in fat and devoid of carbohydrate), has had significant therapeutic advantage in treating cases of juvenile epilepsy (5). One possible mechanism is hypothesized to involve a form of modulating energy pathways (5). Ketones have also shown significant benefit in a Parkinson's disease model by limiting cellular damage through mitigating free radical injury (6). (b)(4)

(b)(4)

Ketone metabolism and the antioxidant environment.

Radiation is well known to involve the production of oxidant species to create reactive oxygen species leading to an oxidized cellular environment and oxidative phosphorylation. The metabolism of ketones enhances several metabolic outcomes increasing acetyl-coA and mitochondria NADH formation while at the same time restoring the NADPH/NADP+, ratio for the regeneration of GSH (8, 9). As an electron donor reduced glutathione (GSH) is a major cellular antioxidant which can neutralize oxygen radicals producing the oxidized GSSG. GSH is regenerated from GSSG via glutathione reductase and the reductant, NADPH. It is well known that ionizing radiation ionizes water and organic oxygen compounds producing oxygen free radicals. Organic oxygen radicals are the primary initiators of biochemical events leading to lipid and protein oxidation, and aberrations in nucleic acid structure in connection with radiation exposure. Therefore a compound like R3-KE should be tested for its ability to alter radiation-induced damage since mechanistically it appears to have significant benefit to increasing the anti-oxidant environment

Furthermore, the metabolism of ketones has recently been shown to increase both catalase and manganese super-oxide dismutase (MnSOD) in tissues, two noted enzymes that are important in

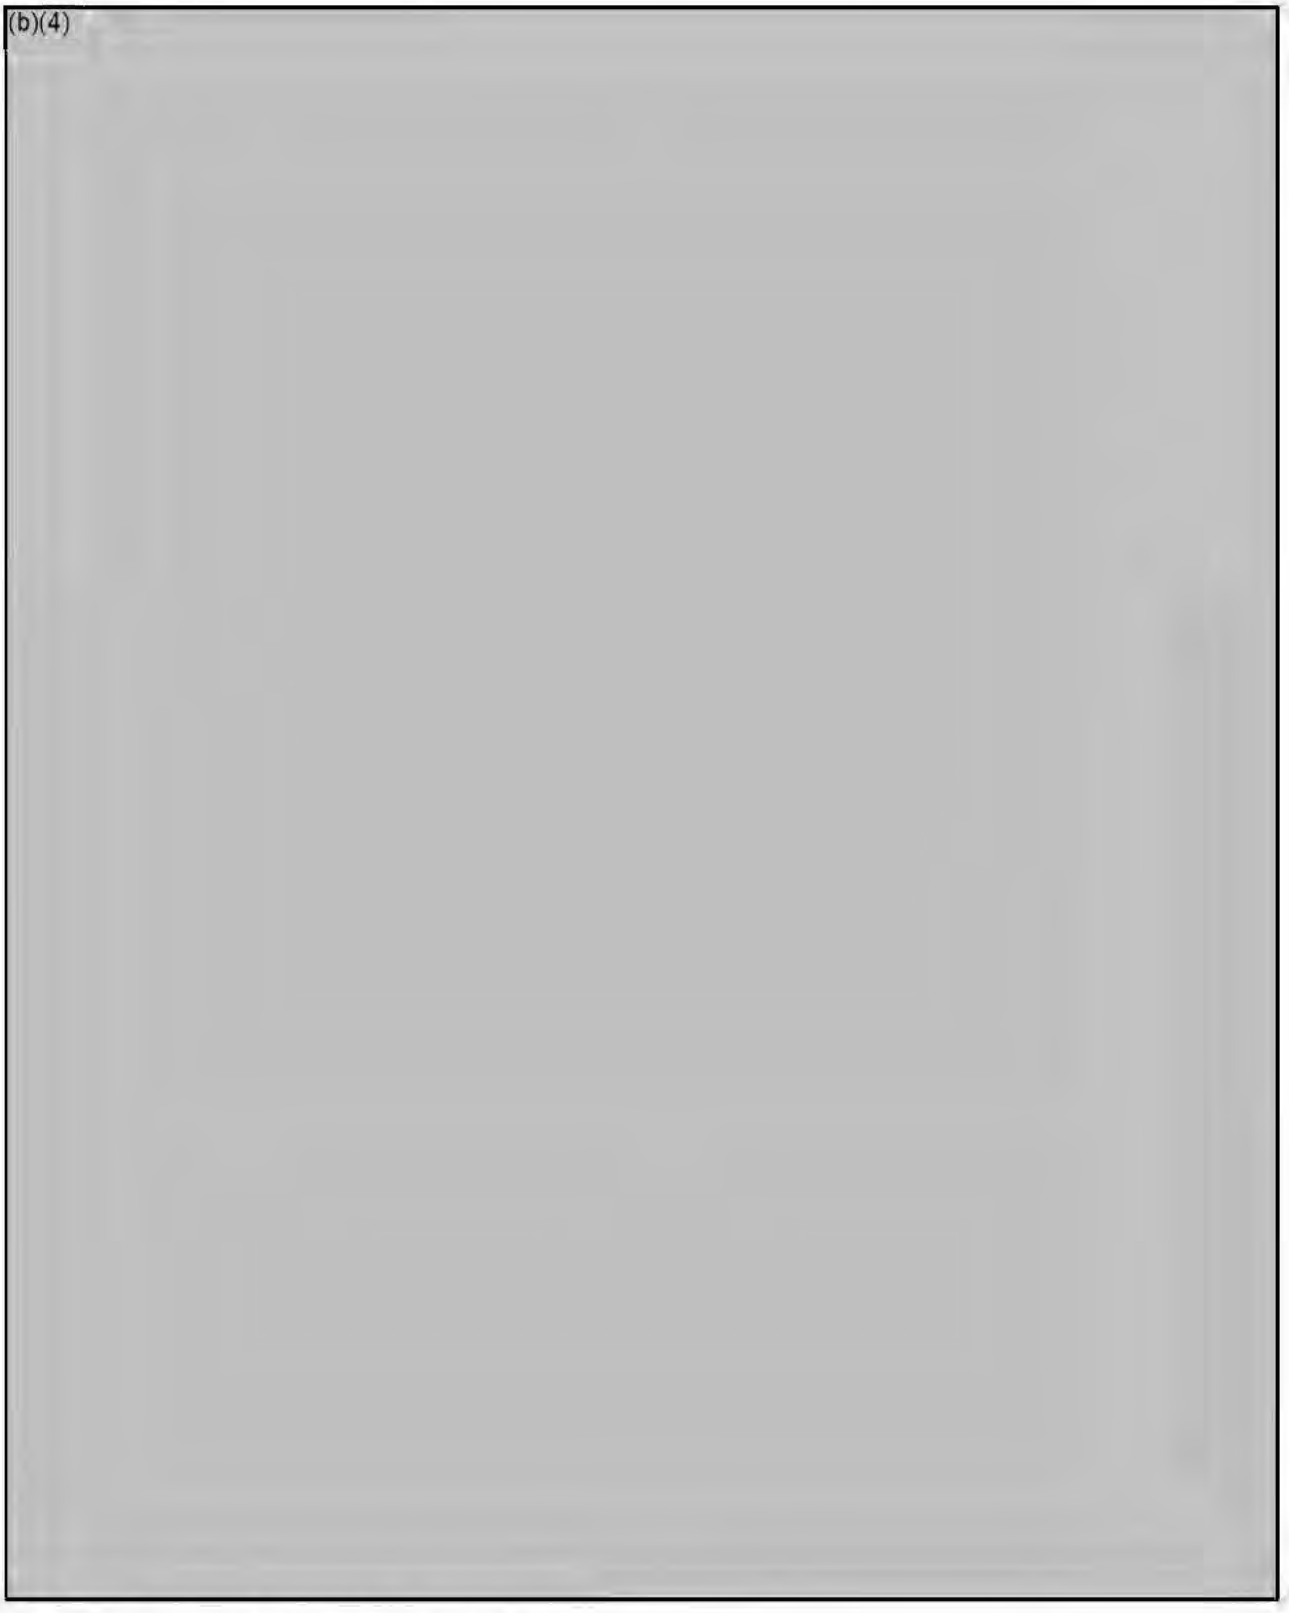
resolving oxygen free radicals (10). These increases have been attributed to increased levels of the transcription factor FOXO3A in cells treated with β-Hydroxybutyrate (10). Ketones have also been demonstrated to have histone deacetylase (HDAC) activity *in vitro* and *in vivo* (10).

(b)(4)

(b)(4) In addition to being formed by ionizing radiation, free radicals can be formed by the mitochondrial electron transport system, the quantitatively most important reaction being the non-enzymatic reaction of the free radical co-enzyme Q semi-quinone (13). A final mechanism of action may involve a decrease in the amount of Q semi-quinone by ketones, thus decreasing the baseline formation of free radicals (14).

(b)(4)

(b)(4)



II.2. Literature Search for Duplication

II.2.1. Literature Sources Searched

II.2.2. Date of Search Biomedical Research Database Jun 24, Jun 27 2014
Projectreporter: Jun 24, Jun 27 2014
PubMed; Jul 22, 2013; Aug 6, 2013; Jun 24 2014; Jun 27, 2014

II.2.3. Period of Search Biomedical Research Database 1998-2009
ProjectReporter 2009-2014
PubMed 2000-2014

II.2.4. Key Words of Search
Radiation, ketone ester, mitigator, protector, mouse, rodent, oral administration, injection, R3-KE, (R)-3-Hydroxyhutyl (R)-3-hydroxyhutyrate

II.2.5. Results of Search
BRD A search of the BDR database did not reveal any queries regarding the combination of the keywords, radiation, ketone, ester, and rodent. A search of the word radiation alone resulted in 325 entries but the combination of radiation and ketone yielded none. A search of the word ketone alone resulted in 14 entries. Several of these involved the studies I referred to in my background regarding the use of ketone ester as a means to increase physical efficiency and preserve cognitive function during extended periods of extreme stress.
Project Reporter: A search of the Project Reporter database showed that there are no studies funded to evaluate the ketone ester and radiation. There is one project in which a ketogenic diet is used to modify chemo and radio- tumor responses (based on tumor cell requirements for oxidants) but there are no publications on this new study in the PubMed database. As expected there are multiple studies to evaluate radiation countermeasures although none involve the ketone ester or ketone compounds.
PubMed: PubMed has been searched numerous times; these searches were conducted during the preparation of the grant proposal to DMRDP last summer and fall. However, I did conduct another PubMed search on Jun 24 and 27th. The recent searches again indicated that there are no publications on the use of ketone ester to modify radiation response in vivo or in clinical trials. The ketone ester is being tested in a clinical trial for Alzheimer's disease (AD) and Parkinson's disease (PD) based on the hypothesis that it could enhance cellular antioxidant capability. As stated in the background, ketone ester has been tested in rodent models for AD and PD. It was also tested in special operations soldiers for its ability to increase physical endurance and mental acuity.

III. OBJECTIVE / HYPOTHESIS
This project intends to determine whether R3-KE via oral administration post-radiation can mitigate radiation lethality in a mouse model, protect against radiation-induced chromosomal damage, ameliorate adverse radiation-induced hematopoietic system changes, and increase protective cytokine levels and expression. An *in vitro* study of the effects of R3-KE on gene expression using a microarray genomics approach will be done to investigate which gene pathways are affected by R3-KE but does not involve animal use.

IV. MILITARY RELEVANCE
Military personnel could be exposed to radiation due to nuclear weapons use, accidental exposure, or a terrorist attack. This type of radiation exposure could lead to the development of

acute radiation syndrome (ARS) and possibly result in death to an exposed individual. Currently the ability for medical treatment of personnel post-radiation injury is limited and there are no FDA-approved post-radiation countermeasures for ARS. The focus of this proposal is to test a candidate for post-exposure mitigation of radiation injury and would meet the Department of Defense need to test post-radiation countermeasures. The candidate R3-KE, is a safe, food supplement with a long shelf-life that could easily be disseminated to large numbers of potentially exposed military personnel and/or civilians. (b)(4)

(b)(4)

A two-fold approach to mitigation of radiation injury should be considered. The first approach involves the rapid and early delivery of a radiation mitigator to anyone suspected of being exposed; the second approach is undertaken after exposure-triage, in a hospital location of a second radiation therapeutic countermeasure. If this proposal is successful in determining that R3-KE is an effective radiation mitigator, this product could easily be distributed to large numbers of military personnel regardless of their radiation-exposure status but provide medical benefit to those actually exposed.

This proposal does not duplicate research that is being done in a BARDA or HHS funded project. (b)(4)

(b)(4)

Therefore the objective of this project is to progress the cell-based countermeasure studies (see preliminary results), to conduct animal-based radiation countermeasure and mitigation experiments. This will assist the development of safe and efficacious countermeasures for mitigation of radiation injury.

V. MATERIALS AND METHODS

V.1. Experimental Design and General Procedures

V.1.1. Pilot Study

(b)(4) we will first do a pilot study with the R3-KE alone at each dosage to monitor for any toxic effects. We do not expect any toxic effects from the R3-KE based on its GRAS approval by the FDA and the observations that in human trials and rat studies, there we no reported or observed toxic effects (1, 2). For our mouse study, we will start with the lowest dosage (140 mg/kg) and proceed to increasing dosage groups (350, 750 mg/kg). R3-KE will be administered via oral gavage using AFRRI SOP for oral gavage (see attached SOP). After gavage animals will be monitored for 3hr continuously and then again within 4 hrs (assumed to be approximately 4 pm the day of gavage). Then they will be

monitored twice daily for the next 6 days; this will be done at approximately 9 am and 4 pm daily. This study will be completed before any further animal studies are initiated. After the toxicity study is completed, an assessment of the results will be done to determine if the dosages need to be altered from what is in this protocol. After 7 days animals will be euthanized as described in section V.4.6 and tissues collected at necropsy. Adverse effects are not anticipated at these doses based on the human and rat studies (1, 2). Ten animals per dose will be used (0, 140, 350, 750 mg/kg). Toxicity is not expected as R3-KE has been tested in humans and rats without any adverse effects. However, evidence of toxicity would include shivering, motionless, lack of drinking and eating, and diarrhea. To assess for toxicity at the time of euthanasia, 7 days post R3-KE administration, we intend to conduct serum biochemistry and necropsy in the mice. Organ weight will be measured and histological examination of liver and kidney will be conducted.

PILOT STUDY Dosage Response of Oral KE (NO RADIATION)	
Saline	*10*
Control Group	
KE (140 mg/kg)	*10*
KE (350 mg/kg)	*10*
KE (750 mg/kg)	*10*

Total # mice: **40 mice**
Pain Category C: **40 mice**
Euthanasia by isoflurane overdose (1-4%) followed by confirmation with cervical dislocation.

Experiment 1

Determine whether R3-KE (orally administered post-radiation) treatment can mitigate radiation lethality in a mouse model. This experiment will assess the following, a) optimum R3-KE dosage required for maximum radiation mitigation at 8.5 Gy; b) post-radiation administration of R3-KE and radiation mitigation at varying doses of radiation; c) optimum timing of R3-KE administration for optimum radiation mitigation; and d) dose-reduction factor for R3-KE.

Aim 1 will focus on whether R3-KE has potential as a radio-mitigator of acute radiation damage. For this radiation lethality mitigation study, mice will be exposed to ^{60}Co gamma radiation total body irradiation (TBI) and then treated (post- radiation) with R3-KE (oral gavage) and the endpoint will be radiation lethality/survival at 30 days. Radiation dose response effects will be examined as well as optimization of dose, dosage level, and timing of administration. A dose reduction factor (DRF) analysis will be conducted. This aim is divided into four sub-Aims. All animals will be weighed before the experiments begin and will be weighed 3x weekly during the experiments; animal may be weighed more than 3X weekly if their health status indicates it is warranted.

Purpose Aim1: To determine if R3-KE orally administered post-radiation can protect total body irradiated (TBI) mice from acute radiation lethality.

Aim 1a: Assess radiation mitigation potential of varying dosages of R3-KE at 8.5 Gy (0.6 Gy/min) when administered orally. AFRRI SOP for oral gavage will be used (REF SOP). To achieve Aim1a, mice (n = 15) will be given R3-KE (oral gavage; 140, 350, or 750 mg/kg body weight) (SOP V.4.4) in saline 24 hr after 8.5 Gy ^{60}Co whole irradiation (0.6 Gy/min); after radiation mice will be observed for 30 days for survival. After 30 days, surviving mice will be euthanized and tissues collected for analysis. This radiation dose was chosen based on the LD50/30 radiation dose of 8.2-8.5 Gy for DBA mice. The experiment will be repeated for a total of 30 mice/group. The results are expected to show which dosage of R3-KE is most efficacious at increasing radiation survival. This dosage will be used in further experiments. The R3-KE dosages chosen to be tested in this aim will be chosen based on the pilot study. They were also tentatively selected based on the safety profile in healthy adult subjects (1) and oral administration in rats (2). Euthanasia by isoflurane overdose (3-5%) followed by confirmation with cervical dislocation will be used.

Aim 1 Radioprotection of Acute Lethality by KE
Aim 1a

Pain Category E: 120 mice
Euthanasia by isoflurane overdose (3-5%) followed by confirmation with cervical dislocation.

Aim 1b: Assess post-radiation administration of R3-KE and radiation mitigation at varying doses of radiation. The response of the most efficacious dosage of R3-KE determined in Aim 1a will be used. To achieve Aim 1b, mice will be irradiated with ^{60}Co radiation (8.0, 8.5, and 9.0 Gy; 0.6 Gy/min; TBI) and orally administered R3-KE (optimum dosage in saline) post-radiation. Mice will be observed for 30 days after radiation for survival. These results are expected to determine the range of R3-KE effectiveness at various radiation doses. Euthanasia by isoflurane overdose (3-5%) followed by confirmation with cervical dislocation.

Aim 1b

Oral Administration of KE and Radiation Mitigation at Varying Doses of Radiation			
	8.0 Gy	8.5 Gy	9.0 Gy
Radiation + Saline	15 (x2)	15 (x2)	15 (x2)
Radiation + KE (optimum mg/kg)	15 (x2)	15 (x2)	15 (x2)
Total mice	180		

Total # mice: 180 mice
Pain Category E: 180 mice
Euthanasia by isoflurane overdose (3-5%) followed by confirmation with cervical dislocation

Aim 1c. Determine the optimum timing of R3-KE administration after 8.5 Gy. The optimum timing of oral R3-KE administration post-radiation will be tested using the radiation lethality model. Using the optimum dosage of R3-KE determined in Aim 1a, mice will be irradiated (^{60}Co, 8.5 Gy, 0.6 Gy/min) and administered R3-KE at 1, 8, 12, 24, or 48 hr) post-radiation. Mice will be observed for 30 days after radiation for survival. These results are expected to determine the optimum administration time of R3-KE at 8.5 Gy. Euthanasia by isoflurane overdose (3-5%) followed by confirmation with cervical dislocation.

Aim 1c

Optimum Timing of KE Oral Administration After 8.5 Gy					
	1 hr	8 hr	12 hr	24 hr	48 hr
Rad + Saline	15 (x2)	15 (x2)	15 (x2)	15 (x2)	15 (x2)
Rad + KE (optimum dose mg/kg)	15 (x2)	15 (x2)	15 (x2)	15 (x2)	15 (x2)
Total mice	300				

Total # mice: 300 mice
Pain Category E: 300 mice
Euthanasia by isoflurane overdose (3-5%) followed by confirmation with cervical dislocation

Aim 1d. Determine the dose-reduction factor (DRF) for R3-KE. Information regarding DRF is crucial to evaluating a potential radiation mitigator and provides a standard by which a quantitative comparison to other known radiation mitigators can be done. The DRF will be determined using the optimum dosage of R3-KE (Aim 1a) and the optimum scheduling of R3-KE administration (Aim 1c). Mice will be divided into 10 groups (15 each); 5 groups will be treated with R3-KE (optimum dosage) and 5 groups of saline as control. Mice will be irradiated (7.5, 7.75, 8.0, 8.5, and 9.5 Gy) and at the optimum time post-radiation (Aim 1c) will be orally administered R3-KE. These doses are based on preliminary results that the lowest radiation dose will result in a significant number of survivors (>80%) and the highest dose 100% lethality (at 30 days) (41-42). Three doses were chosen between these extremes. After radiation/R3-KE treatment animals will be monitored for 30 days for survival. For calculation of the dose

reduction factor, percent mortality versus radiation dose will be fitted using probit analysis. The DRF will be calculated as a ratio of the radiation LD50/30 with and without administration of R3-KE; the standard error and 95% confidence interval will be derived using error propagation. These results are expected to determine what the DRF for R3-KE is.

DRF Study					
	7.5 Gy	7.75 Gy	8.0 Gy	8.25 Gy	9.0 Gy
Rad + Saline	15 (x2)	15 (x2)	15 (x2)	15 (x2)	15 (x2)
	7.5 Gy	8.0 Gy	8.5 Gy	9.0 Gy	9.5 Gy
Radiation + KE (optimum dose mg/kg)	15 (x2)	15 (x2)	15 (x2)	15 (x2)	15 (x2)
Total mice	300				

Total # mice: 300 mice
Pain Category E: 300 mice
Euthanasia by isoflurane overdose (3-5%) followed by confirmation with cervical dislocation

The DRF is an important measure of the efficacy of a putative radioprotective drug. As represented hy the designs of this experiment, establishing efficacy of such a compound like R3-KE by demonstrating a statistically significant DRF is generally accomplished using 5–7 radiation doses with the lowest dose giving mortality near 0% and the highest dose giving mortality near 100% (11). Since the R3-KE group is expected to result in increased survival, higher radiation doses are needed for the statistical analysis. Since the promulgation of the New Animal Rule (16), it is imperative that these efficacy determinations be robust because the final tests are done only in animals; human efficacy studies are not ethical or feasible.

All animals will be euthanized by an overdose of isoflurane anesthesia (3-5%) followed by cervical dislocation. Euthanasia will be conducted as described in section V.4.6.

Each sub-part of Aim 1 involves 15 mice per group and will be repeated for a total of 30 mice/group.

V.1.2. Experiment 2

Assess whether R3-KE (orally administered post-radiation) treatment can protect bone marrow against radiation-induced chromosomal damage.

Purpose of Aim 2: To determine whether R3-KE (post-radiation) can prevent radiation-induced chromosomal damage

Aim 2: It is well known that significant biological consequences of exposure to radiation include cell death, gene mutations, and chromosome aberrations. Radiation-induced chromosomal damage has implications for both acute radiation survival and development of radiation-induced late effects. This aim will assess whether R3-KE can protect bone marrow from radiation damage. Chromosomal aberrations in hone marrow cells will be studied at twenty-four hours after R3-KE treatment (optimum R3-KE dosage, optimum time of administration). Mice will be divided into four groups (5 per group) as follows: Group1) No radiation-No R3-KE; Group 2)

R3-KE optimum dosage in saline; Group 3) Gamma radiation (0, 0.5, 1.0, 2.0, 4.0, and 6.0 Gy) followed by saline (optimum R3-KE timing); and Group 4) Gamma radiation (0, 0.5, 1.0, 2.0, 4.0, and 6.0 Gy) followed by R3-KE (optimum dosage, timing post-radiation) in saline. Twenty-two hours after R3-KE treatment animals will be injected i.p. (see Section V.4.4.1) with 0.01ml/g body weight of 0.025% colchicine and euthanized after 2 hrs. The 22 hrs post-R3KE administration was chosen based on previous studies by others which showed that this was the optimum time to allow for chromosomal aberrations to form post-radiation (17). All animals will be euthanized as described in Section V.4.6. Euthanasia will be under deep isoflurane anesthesia (3-5%); exsanguination by cardiac puncture, followed by cervical dislocation.

Metaphase plates will be prepared from femur bone marrow and approximately 1000 metaphases (200/animal) will be counted for each group. The same number of metaphases per animal (200) will be prepared. Aberrant metaphases and different aberrations, chromatid and chromosome breaks, fragments, rings and dicentrics, will be scored under a light microscope. The PI hypothesizes that different doses of radiation will induce different numbers of aberrations and that R3-KE will decrease the number of aberrations. Results will be presented as percentage aberrant metaphases. Statistical analysis is described below. These results are expected to determine whether R3-KE can protect bone marrow cells from radiation-induced chromosomal damage.

Aim 2 Protection of Bone Marrow against Radiation-Induced Chromosome Damage

Radiation-Induced Chromosome Damage 24 hrs After Optimum KE Administration Post-Rad						
	0.0 Gy	0.5 Gy	1.0 Gy	2.0 Gy	4.0 Gy	6.0 Gy
No Rad/No R3-KE	5 (x2)					
R3-KE	5 (x2)

Rad + KE (optimum dose and timing)	5 (x2)	5 (x2)	5 (x2)	5 (x2)	5 (x2)	5 (x2)
Total Mice	140					

Total # mice: 140 mice
Pain Category D: 20 mice
Pain Category E: 120 mice
Euthanasia will be isoflurane anesthesia (3-5%) exsanguination by cardiac puncture, followed by cervical dislocation.
There will be 5 mice/group and the experiment will be repeated for a total of 10 mice per group.

V.1.3. Experiment 3

Measure the effect of R3-KE treatment (orally administered post-radiation) on hematological parameters including blood cell elements (circulating neutrophils, GM-CFC, and platelets) at times post radiation (8 hr to 28 days).

Purpose of Aim 3: To determine if R3-Ke treatment post-radiation can increase hematopoietic recovery from radiation.

This aim will assess if R3-Ke can enhance hematological cell recovery from radiation exposure. Mice will receive a sublethal radiation exposure (6.0 Gy) to increase survivability up to and at 30

days post-radiation. Mice will be divided into four groups: Group 1) No Radiation-No R3-KE; Group 2) R3-KE optimum dosage in saline; Group 3) Gamma radiation (6.0 Gy) + Saline; and Group 4) Gamma radiation (6.0 Gy) followed by R3-KE (optimum dosage, timing post-radiation) in saline. At the following times post-R3-KE treatment (0.3, 1, 3, 7, 14, 21, and 28 days) mice will be euthanized (10/group/day). Blood will be collected as described in Section V.4.4 and 4.4.2 using AFRRI SOP on Blood collection. Euthanasia will be under deep isoflurane anesthesia (3-5%); exsanguination by cardiac puncture, followed by cervical dislocation (section 4.4.6).

Hematological parameters (total and differential counts) will be determined using a Heska Hematology Analyzer (Heska, Boston, MA) which we have in our laboratory. Otherwise the VSD hematology lab may be used for total and differential counts.

Aim 3

Hematological Parameters Following R3-KE Treatment Post-Radiation: Blood Element Counts							
	0.3 d	1 d	3 d	7 d	14 d	21 d	28 d

Total Mice	560						

Total # mice: 560 mice
Pain Category D: 140 mice
Pain Category E: 420 mice
Euthanasia will be isoflurane anesthesia (3-5%) exsanguination by cardiac puncture, followed by cervical dislocation.
There will he 10 mice/group and the experiment will be repeated for a total of 20 mice/group.

V.1.4. Experiment 4

Investigate the cytokine profile *in vivo* indnced by R3-KE treatment (orally administered post-radiation) using a sandwich ELISA (serum) and multiplex Luminex (proteins) after radiation (6.0 Gy).

Purpose of Aim 4: To determine if R3-KE Treatment post-radiation has an effect on cytokines causing an increase in the levels of radiation-mitigating cytokines.

Cytokines and growth factors have shown efficacy against radiation injury. Therefore the effect of R3-KE administration on cytokines should be examined. Cytokine protein levels will be analyzed in mouse plasma at various time points in relation to R3-KE (optimum dosage) post oral administration (0, 4, 24, 48 hr) and/or radiation and will be quantified by multiplex Luminex. Cytokine gene expression will be evaluated by semi-quantitative RT-PCR in bone marrow and spleen cells at the same time points as well. These results will show whether R3-KE affects cytokine levels as a potential mechanism of its action in vivo. Mice will be sublethally irradiated with gamma radiation 6.0 Gy. At 4, 24, or 48 hr post oral R3-KE administration +/- radiation, blood will be collected as described in Section V.4.4 using AFRRI Blood collection SOP and mice will be euthanized as described in Section V.4.6. Controls (NO Rad NO R3-KE will be assessed as well. Euthanasia will be under deep isoflurane anesthesia (3-5%); exsanguination by cardiac puncture, followed by cervical dislocation.

Aim 4
Effect of R3-KE on Cytokines
(Cytokine Message and Serum Protein Levels)

	4 hr Post Injection	24 hr Post-Injection 48 hr Post-Rad	48 hr Post Injection 72 hr Post-Rad
No Rad No R3-KE	10 (x2)	10 (x2)	10 (x2)
R3-KE	10 (x2)	10 (x2)	10 (x2)
Rad (6.0 Gy)	10 (x2)	10 (x2)	10 (x2)
Rad + R3-KE (Optimum dosage/timing	10 (x2)	10 (x2)	10 (x2)
Total Mice	240		

Total # mice: **240 mice**
Pain Category D: **60 mice**
Pain Category E: **180 mice**
Euthanasia will be isoflurane anesthesia (3-5%) exsanguination by cardiac puncture, followed by cervical dislocation.
There will be 10 mice/group and the experiment will be repeated for a total of 20 mice per group.

For all aims, euthanasia will be confirmed by cessation of the heartbeat and breathing.

Total mice for all Aims/Experiments = 2000

V.2. Data Analysis

Statistical Analyses:

The statistical tests chosen were suggested by Dr. (b)(4),(b)(6) Means and SE with a significance level at 5% set for each test or aim has to be performed. In order to evaluate the hypothesis set forth and establish a comparison of significance of deviation from the hypothesis, Fisher Exact Test will be used. The test can provide the significance and deviation. The Fisher test for Variance or the ANOVA which provided the means to analyze the differences between group and their associated procedures is a suitable test to detect significance between sampling groups. ANOVA is a test of choice to compare group means and group variables. Bonferroni and Newman-Keuls methods (pairwise comparisons) and Tukey-Kramer comparison for unequal group size can be used for identifying which groups are different from each other. When inferential statistics is used such as t-test, F tests, ANOVA etc., to evaluate the outcome and comparisons, sample size (n) needs to be determined to provide sufficient statistical capability for performance. Based on the power analyses the sample size n=10 proposed by the investigator is appropriately sufficient to deliver more than 80%. Fisher's exact test will be used to detect if there is a significant difference across the groups in survival rates. For Aim1d to study the binomial response variables such as the drug efficacy or response for treated or non-treated groups studies, 'Probit analyses' can be used which is a powerful method to calculate probits, regression coefficient, and confidence intervals. Probit analysis is used to analyze many kinds of dose-response or binomial response experiments in a variety of fields. Here the probit can be used to record the response of the drug at various time points and concentrations and response is always binomial and the relation between response and concentration/time points is

sigmoidal. By plotting the response at different time points and doses. ORF can be calculated as the ratio of the radiation for drug-treated and vehicle-treated groups.

Pilot or Aim #	Number per group	Endpoint	Test Used
Pilot (Assess Toxicity)	10	Euthanasia	ANOVA
Aim 1a (Assess Dosage of R3KE on Single Dose Rad Survival)	15	Survival at 30 days	ANOVA, Fishers Test
Aim 1b (Assess Effect of Optimum Dosage on Varying Rad Doses)	15	Survival at 30 days	ANOVA, Fishers Test
Aim 1c (Assess Effect of Optimum Dosage on Timing of R3KE Administration on Rad Response)	15	Survival at 30 days	ANOVA, Fishers Test
Aim 1d (DRF study with optimum R3KE dosage and optimum timing)	15	Survival at 30 days	ANOVA, Fishers Test
Aim 2	5 (2 femurs per animal)	Planned euthanasia at 24 hrs post rad/R3KE	ANOVA, Fishers Test
Aim 3	10	Planned euthanasia	ANOVA, Fishers Test
Aim 4	10	Planned euthanasia	ANOVA, Fishers Test

V.3. Laboratory Animals Required and Justification

V.3.1. Non-animal Alternatives Considered

The development of a medical countermeasure requires that it be tested *in vitro* and *in vivo*. Prior to the development of this DMRDP funded project and this animal use proposal R3-Ke was tested in vitro for its potential effectiveness as a radiation mitigator (b)(4)

(b)(4)

(b)(4) *In vitro* studies do not consider physiological factors which could affect the response to a potential radiation mitigator. Therefore an animal model is necessary to test the effectiveness of R3-KE as a radiation mitigator. It is the goal of this project however to always keep animal welfare as a priority and to use as few as rodents as possible to achieve scientific and statistical accuracy.

V.3.2. Animal Model and Species Justification

The murine model has been widely used for radiation survival studies in my laboratory to evaluate radiation exposure and a variety of endpoints including survival, radioprotection, mitigation, carcinogenesis, and biomarker development. (b)(4)

(b)(4)

(b)(4) The rodent model is the least sentient model that can be used to assess the efficacy of a radiation biomarker. Use of an invertebrate model will not provide the

necessary information regarding physiological responses i.e. cytokine induction, that a mouse model will provide. (b)(4)

(b)(4)

V.3.3. Laboratory Animals
DBA/2 murine model

V.3.3.1. Genus / Species
Mus musculus

V.3.3.2. Strain / Stock
DBA/2

V.3.3.3. Source / Vendor
Taconic, or Charles River (USDA # 14-R-0144)
Multiple vendors available.

V.3.3.4. Age

V.3.3.5. Weight
15-30 g

V.3.3.6. Sex
Male and female.

V.3.3.7. Special Considerations
None

V.3.4. Number of Animals Required (by species) 1960

V.3.5. Refinement, Reduction, Replacement (3 R's)

V.3.5.1. Refinement

(b)(4)

V.3.5.2. Reduction (b)(4)

(b)(4) Previously published in vivo studies evaluating R3-KE delivered in a ketogenic diet to rodents has enabled us to assess the least toxic dosage of R3-KE

to deliver in our studies thus reducing the number of toxicology experiments that would need to be done. It is also important to note the FDA has already designated R3-KE as generally regarded as safe ("GRAS") which also supports the reduced use of animals to establish safety and toxicology. This information has enabled us to reduce the number of animals we need to use. This information also enables us to avoid dose-ranging experiments which would require the use of larger numbers of animals.

V.3.5.3. Replacement The use of an animal model is necessary to determine if a mitigating agent can protect against acute radiation effects and increase survival. We have already conducted *in vitro* experiments with immortalized human cell lines to better understand the mechanisms of how R3-KE works; however, tissue culture systems do not consider physiological factors which could affect survival. Using *in vitro* studies with the human cell lines has already replaced the use of some animals in this study as I described above.

V.4. Technical Methods

V.4.1. Pain / Distress Assessment

V.4.1.2. Pain Relief / Prevention

V.4.1.2.1. Anesthesia / Analgesia / Tranquilization

AFRRI SOP on blood collection via cardiac stick will be done for Aims 2, 3 and 4. First, mice will be deeply anesthetized for this procedure using isoflurane (3-5%). Their reflexes will be tested to ensure they are deeply anesthetized before proceeding. After blood collection, mice will be euthanized as described in Section V.4.6.

V.4.1.2.2. Pre- and Post-procedural Provisions
No surgery is being conducted.

V.4.1.2.3. Paralytics
None will be used.

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures

V.4.1.3.1. Sources Searched AltWeb
PubMed
Agricola

V.4.1.3.2. Date of Search
Jun 30 2014
Jun 30 2014
Sept 26, 2014

V.4.1.3.3. Period of Search

V.4.1.3.4. Key Words of Search Radiation, mitigator, pain, alternatives, death as an endpoint, survival study, DBA/2, lethality, survival, hematopoietic syndrome, LD50/30, mouse, model, pain, suffering, gavage, oral administration, ketone esters, R3-KE, (R)-3-Hydroxybutyl (R)-3-hydroxybutyrate

V.4.1.3.5. Results of Search
Acute radiation exposure can be a painful process due to the decrement of digestive and hematological systems based on human studies. The literature verifies that developing symptoms of radiation illness appears to be painful and is distressful in humans and animals. As was indicated in the justification of animal use section, development of a post radiation mitigator that is safe and efficacious in humans required testing an animal model. This is partially based on FDA regulations and the use of an animal model in testing a potential radio-mitigator is beyond our control and is necessary if we are to develop mitigators for humans. At the earliest sign that the animals are in pain or distress, they will be immediately be considered for a humane euthanized and the criteria for euthanasia will be carefully monitored. In this project we are assessing the animals multiple times daily to decrease the amount of time that they might be in distress; if we observe any animal assessed by the scoring sheet to be moribund, they will be euthanized. As was indicated earlier, we have exhausted all preliminary non-animal alternatives including *in vitro* survival and radioprotection studies using human cell models.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification
IACUC Policy 10 will be used to establish early endpoints in experiments with early mortality. Experiments 1(a, b, c, and d) are the acute radiation syndrome studies; the doses used in aims 2-4 (0.5-6 Gy) are not expected to induce death (b)(4) (b)(4) In experiment 1 a significant number of mice will be irradiated alone or will be

irradiated and then receive R3-KE to test its mitigation abilities. These radiation doses 7.5 to 9.5 are expected to cause death in approximately 50 to 100% of the animals by day 30 post radiation (without any R3-KE countermeasure). There is no pharmacological intervention/support planned for the radiation alone groups as these groups are needed to provide a radiation control for the experiment. With or without R3-KE administration, this exposure could cause more than momentary unalleviated pain or distress. To decrease any pain or period of distress, after the radiation or radiation + R3-KE, animals will be monitored multiple times daily with at least 3 planned monitoring times for 30 days; additional monitoring times are anticipated to include a monitoring time in the late evening so that the next monitoring time will be 10 hr or less after that late evening monitoring. Animals that appear morbid will be monitored 3-4X daily. Monitoring will include weighing the animals since baseline weights will have already been established at the start of the experiment. These animals cannot be given any prophylactic pain medication for two reasons. 1) There is no specific information indicating what dose of analgesic would be effective to alleviate the discomfort/distress/pain of hematopoietic ARS in mice and 2) Prophylactic analgesia could be contraindicated and detrimental to the protocol purpose.

V.4.2. Prolonged Restraint N/A

V.4.3. Surgery N/A

V.4.3.1. Pre-surgical Provisions No Surgery

V.4.3.2. Procedure(s) N/A

V.4.3.3. Post-surgical Provisions N/A

V.4.3.4. Location N/A

V.4.3.5. Surgeon N/A

V.4.3.6. Multiple Major Survival Operative Procedures N/A

V.4.3.6.1. Procedures N/A

V.4.3.6.2 Scientific Justification N/A

V.4.4. Animal Manipulations

1) Permanent individual identification for each rodent will be done prior to the start of any experiments. IF tattooing is available in VSD and is done by VSD in co-ordination with (b)(6) (b)(6) tattooing will be used. If tattooing is not available, permanent individual identification using the ear notching method will be used. This method require a special tool to punching or notching holes at various positions in the ears, this technique is commonly used in rodents. Procedure will take place under sterile conditions in VSD after released from quarantine. Manual restraining is required to perform this technique
2) Animals will receive either administration of sterilized R3-KE via gavage or an administration of sterile water via gavage. Administration will take place under sterile conditions in VSD. See next section for additional details.

3) Animals will be placed in a plastic holder for radiation. The time in the holder will be approximately ten minutes prior to radiation, ten to twenty minutes in the radiation facility, and ten minutes in the transfer back to VSD. The total time will be approximately 40 minutes. Previous experience indicates that this is a good time estimate. The radiation doses in this project range from 0.5 Gy to 9.5 Gy.
4) Oral gavage will be used to administer R3-KE. Prior to the initiation of oral gavage, a VSD veterinarian or designee will review the oral gavage technique of the staff person conducting the oral gavage. The AFRRI GLP oral gavage protocol will be used to administer the R3-KE. An 18-20 gauge feeding tube will be selected. Isoflurane anesthesia may be used after consultation with VSD staff. The volume of the R3-KE will be 0.15 ml.
5) Blood collection will be done using AFRRI SOP for cardiac puncture blood collection (see attached SOP).

V.4.4.1. Injections

The purpose of aim 2/experiment 2 is to measure chromosomal aberrations at 24 hrs post-radiation. In aim 2/experiment 2, at 22 hrs post-radiation +/- R3-KE, mice will be injected i.p. using a 26 gauge needle with 0.01ml/g body weight of 0.025% colchicine and euthanized as described above at 2 hr after colchicine injection. Colchicine is used to stop cell mitosis in the metaphase stage to allow for chromosomal assessment. It is during this stage of nuclear division that the chromosomes are most condensed and, as a result, visible with a light microscope.

V.4.4.1.1. Pharmaceutical Grade Drugs None

V.4.4.1.2. Non-Pharmaceutical Grade Drugs

(R)-3-Hydroxybutyl (R)-3-hydroxybutyrate, a Ketone ester (or R3-KE) is rated GRAS by the FDA and is available from the NIH, NIAAA. It will be sterilized by filter (0.2 micron filter) prior to gavage administration. R3-KE is solubilized in sterile water (pH 7.4).

Colchicine (Sigma-Aldrich Co.) will be used in Aim 2. It is solubilized in sterile water and is pH 7.2. It will be sterilized by filter (0.2 micron filter).

V.4.4.2. Biosamples

Blood and tissue collection in Pilot study:
The AFRRI GLP Blood collection SOP will be used. Animals will be deeply anesthetized using isoflurane 3-5%. Using a 23-25 gauge needle, the cardiac blood will be collected to exsanguination (1 ml expected). After exsanguination, the animal will undergo cervical dislocation as a secondary euthanasia method.

Blood collection in Aims 2-4.
The AFRRI GLP Blood collection SOP will be used. Animals will be deeply anesthetized using isoflurane 3-5%. Using a 23-25 gauge needle, the cardiac blood will be collected to exsanguination (1 ml expected). After exsanguination, the animal will undergo cervical dislocation as a secondary euthanasia method.

V.4.4.3. Adjuvants N/A

V.4.4.4. Monoclonal Antibody (MAb) Production N/A

V.4.4.5. Animal Identification Tattoo, Ear notch, and cage cards. Tattoo will be used if available in AFRRI VSD.

V.4.4.6. Behavioral Studies None

V.4.4.7. Other Procedures None

V.4.4.8. Tissue Sharing At necropsy, tissues will be shared with (b)(4),(b)(6) including brain and blood. A tissue sharing form will be completed.

V.4.4.9. Animal By-Products None

V.4.5. Study Endpoint -
This project is divided into 4 aims or experiments with different endpoints.

1) For the pilot study to evaluate R3-KE toxicity, the endpoint will be euthanasia at 7 days post R3-KE gavage administration. We do not expect to observe any signs of toxicity after R3-KE administration, however the animals will be euthanized upon observation of morbidity (not expected) or at 7 days. Criteria for toxicity include: shivering, motionless, lack of drinking and eating, diarrhea.
2) For aim1/experiment 1, the endpoint for the radioprotection parts of the study is survival at 30 days or euthanasia based upon morbidity and moribundity criteria at any point post-radiation for up to 30 days. The purpose of Aim 1/ experiment 1 is to determine optimum R3-KE dosage, optimum timing of R3-KE administration, and the DRF for R3-KE. The endpoint of experiment 1 is survival or euthanasia after 6.5 to 9.5 Gy gamma radiation +/- R3-KE. We hypothesize that a portion of the animals receiving the R3-KE (via gavage) will survive the radiation and will survive until 30 days post-radiation (8.1 Gy which is the LD50/30 for this strain). It is also expected that a portion (approximately 80%) of the animals that do not receive R3-KE (only sterile water via gavage) will not recover from radiation (8-9.5 Gy) and will not survive for 30 days post-radiation exposure. Any surviving animals will be eutbanized at 30 days post radiation for necropsy and tissue collection. It is our intention to euthanize any animal post-radiation at an earlier endpoint to minimize pain and distress. Research staff will be trained to differentiate between animals showing signs/symptoms of morbidity (affeeted with radiation syndrome) and those in a state of moribundity (an irreversible condition leading to death).
3) For aim 2/experiment 2 the endpoint is planned euthanasia at 24 hrs post-radiation. The purpose of aim 2 is to determine whether R3-KE (post-radiation) can prevent radiation-induced chromosomal damage. Chromosomal damage will be measured at 24 hrs post radiation after the i.p. administration of colchicine to arrest cellular mitosis. The doses used are 0, 0.5, 1.0, 2.0, 4.0, and 6.0 Gy +/- R3-KE and are not expected to induce morbidity/moribundity within 22-24 hrs. Animals will be closely monitored for the 24 hrs post-radiation (3 x during the 24 hr period).
4) For aim 3/ experiment 3 the endpoint is planned euthanasia at (0.3, 1, 3, 7, 14, 21, and 28 days) post-radiation +/- R3-KE treatment. The purpose of Aim 3 is to determine if R3-KE treatment post-radiation can increase hematopoietic recovery from radiation. A single sublethal radiation dose of 6.0 Gy will be used and it is not expected that any animals will

show morbidity or moribundity at that dose for the duration of the experiment 0 to 28 days post-radiation. However, animals will be monitored as previously detailed each day.

5) For aim 4/ experiment 4, the endpoint is planned euthanasia at (0, 4, 24, 48 hr) post-radiation +/- R3-KE treatment. The purpose of aim 4 is to determine if R3-KE Treatment post-radiation has an effect on cytokines causing an increase in the levels of radiation-mitigating cytokines. A single sublethal radiation dose of 6.0 Gy will be used and it is not expected that any animals will show morbidity or moribundity at that dose for the duration of the experiment 0 to 48 hr post-radiation. However, animals will be monitored as previously detailed each day.

V.4.6. Euthanasia

All animals in the Pilot study and Aim 1 will be euthanized by an overdose of isoflurane anesthesia (3-5%) given via chamber followed by secondary confirmation with cervical dislocation. For aims 2-4 animals will be deeply anesthetized with isoflurane (3-5%), then euthanized by exsanguination by intra-cardiac blood withdrawal followed by secondary confirmation with cervical dislocation. If necessary, euthanasia by CO_2 followed by cervical dislocation may he used as an alternative method. In all cases, death will be confirmed by cessation of the heart beat and breathing.

V.5. Veterinary Care

V.5.1. Husbandry Considerations

Animals will be housed no more than 4 per cage in a micro-isolator cage. Animals will receive food and water ad libitum. Cages are changed three times weekly in accordance with the current VSD Rodent Hushandry SOP. Animals will have a 12 hour/12 hour light and dark cycle.

V.5.1.1. Study Room

Study room is provided and assigned by AFRRI VSD.

V.5.1.2. Special Husbandry Provisions

None

V.5.1.3. Exceptions

None

V.5.2. Veterinary Medical Care

V.5.2.1. Routine Veterinary Medical Care

Research sStudy personnel will monitor all animals (Exps 1-4) 3X daily however as stated above, animals will be more frequently monitored during critical periods. The animals will be individually observed at each observation period and weighed three times weekly or daily during the critieal period. A necropsy will be performed by research study personnel and hematological and molecular assessment will be made.

If an animal becomes ill or debilitated during the course of the study (prior to a planned euthanasia), the principle investigator and study personnel will use the score sheet to assess condition of the animal. A determination of morbidity or moribundity will be made by study

personnel; VSD staff may be consulted. When an animal is determined to be moribund it will be euthanized by research study staff according to section "XI. C. 7 Euthanasia will be done as described in section V.4.6.\

Routine veterinary care will be provided by VSD as per the standard SOPs.

Animals will be evaluated as per the score sheet in Policy 10 and moribund mice will be euthanized as described in section V.4.6.

V.5.2.2. Emergency Veterinary Medical Care

Emergency veterinary medical care will include euthanasia (and necropsy) if the animal meets the criteria described in section V.5.2.1 after consultation with a member of the research study staff.

V.5.3. Environmental Enrichment

V.5.3.1. Enrichment Strategy

Animals can be given items in accordance with VSD/IACUC policy.

V.5.3.2. Enrichment Restrictions

None

X. ASSURANCES

Protocol Title: Re-Purposing (R)-3-Hydroxybutyl (R)-3-hydroxybutyrate, a Ketone ester (or R3-KE) as a Radiation Mitigator in mice (*Mus musculus*)

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made every effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with a qualified individual who evaluated the experimental design with respect to the statistical analysis, and that the minimum number of animals needed for scientific validity will be used.

D. Biohazard / Safety: I have taken into consideration and made the proper coordinations regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R", namely, "Responsibility," which the DOD has embraced for implementing animal use alternatives where feasible and conducting humane and lawful research.

G. Scientific Review: This proposed animal use protocol has received appropriate peer scientific review and is consistent with good scientific research practice.

H. Painful Procedure(s): I **AM / AM NOT** conducting biomedical experiments, which may potentially cause more than momentary or slight pain or distress to animals. If applicable, potential pain and/or distress **WILL / WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

I. NON-TECHNICAL SYNOPSIS

In the event of radiological or nuclear exposure (i.e. a "dirty" bomb, or a nuclear accident), medical care would be focused on treatment of acute radiation syndrome (ARS), also known as radiation toxicity or radiation sickness. Exposure of mammals to total body ionizing radiation (TBI) can lead to lethal ARS. The cause of death depends on the radiation dose. The lowest lethal doses cause death by severe hematopoietic injury which leads to increased risk of sepsis due to a suppressed immune system, and hemorrhagic events can occur due to depletion of platelets (thrombocytopenia). As the radiation dose escalates, symptoms of a compromised immune and coagulation system persist, along with addition of damage to gastrointestinal (GI) tract. The impaired integrity of the GI epithelium further increases the risk of bleeding, dehydration and sepsis. The increase in radiation dose involves injury to other tissues (lung, skin, kidney, etc.) making the situation less and less medically manageable, and ultimately incurable. We plan to assess gamma-tocotrienol (GT3) as a radiation countermeasure against the hematopoietic and GI syndromes of ARS. This study will employ a well-defined, nonhuman primate (NHP) model in order to assess the countermeasure's efficacy (increased survival) against different doses of radiation and mechanism(s) of action for hematopoietic and GI rescue.

II. BACKGROUND

II.1. Background

Although the search for radiation countermeasures for ARS was initiated more than half a century ago, no safe and effective radiation countermeasure has been approved by the United States Food and Drug Administration (US FDA) for the ARS (b)(4) (b)(4) Most recently, natural products have been investigated for prevention and therapy of human diseases because they are 'generally recognized as safe' and appropriate for medicinal purposes. Unlike their synthetic analogs, they are well tolerated and minimally toxic, even in the upper ranges of dietary intake (*3*,) Vitamin E represents a family of (b)(4) compounds that is divided into two subgroups called tocopherols and tocotrienols, which act as important antioxidants that regulate peroxidation reactions and control free-radical production within the body (*5, 6*). This family of compounds has eight

different isoforms that belong to two categories: four saturated analogues (α, β, γ, and δ) called tocopherols and four unsaturated analogues referred to as tocotrienols. These 8 components are collectively known as tocols. Tocopherols and tocotrienols share common structural features of a chromanol ring and a 15-carbon tail at the C-2 position derived from homogenistate and phytyl diphosphate, respectively. Tocotrienols differ structurally from tocopherols by the presence of three trans-double bonds in the hydrocarbon tail. The isomeric forms of tocopherol and tocotrienol are distinguished by the number and location of methyl groups on the chromanol rings. Recent studies suggest that both the molecular and therapeutic targets of the tocotrienols are distinct from those of the tocopherols. A number of studies have shown that tocotrienols are superior antioxidants compare to tocopherols (*1, 7-10*).

Gamma-tocotrienol (GT3), one of the eight isomers (tocols) of vitamin E, is a potent inhibitor of HMG-CoA (3-hydroxy-3-methylglutaryl-coenzyme A) reductase (*11, 12*). Its antioxidant activity was a compelling reason to evaluate it for radioprotective efficacy; in recent years, it has received a great deal of attention by researchers and appears to be one of the most promising radioprotective tocols tested to date. GT3 has been shown to increase survival in rodents, through the amelioration of the hematopoietic and GI syndromes. When administered 24 h before ^{60}Co γ-irradiation, GT3 significantly protected mice against radiation doses as high as 11.5 Gy, and its dose reduction factor (DRF) as a radioprotector (24 h before irradiation, 200 mg/kg, subcutaneous route, sc) was 1.29 (b)(4) GT3 demonstrated dose response against different doses of radiation used. GT3 treatment accelerated hematopoietic recovery as judged by higher numbers of total white blood cells, neutrophils, monocytes, platelets, and reticulocytes in peripheral blood (b)(4) and enhanced hematopoietic progenitors (b)(4) in the bone marrow (BM) of irradiated mice. Additionally, GT3-treated irradiated mice had higher numbers of colony-forming cells, more regenerative microfoci for myeloid and megakaryocytes, higher cellularity in BM, and reduced frequency of micronucleated erythrocytes compared to vehicle treated mice compared to irradiated vehicle controls (b)(4) Mouse survival studies with GT3 suggested the most efficacious time for drug administration was 24 h prior to irradiation, possibly due to the induction of key hematopoietic cytokines during that time frame. GT3 treatment resulted in significant induction of granulocyte colony-stimulating factor (G-CSF) and several other cytokines in mice; administration of G-CSF antibody completely abrogated the radioprotective efficacy of GT3 in mice (b)(4) GT3 mobilized progenitors in peripheral blood (b)(4) and transfusion of such blood, enriched progenitor cells also was capable of protecting mice against γ–irradiation (b)(4)

These results prompted us to evaluate GT3 against ionizing radiation in NHP model in a pilot study. We evaluated GT3 pharmacokinetics and efficacy using different doses of drug and radiation. Our results demonstrate promising radioprotective efficacy of GT3 in NHPs.

Three drug doses (9.375, 18.75 and 37.5 mg/kg, n = 4 for each group) were selected for pharmacokinetics (PK) studies based on earlier efficacy and toxicity studies conducted in the murine model. Each dose was administered sc to 4 NHPs and blood samples were collected at various time points following GT3 injection. Studies were terminated at the end of d 20 based on the previous observations with other drugs. PK study data are presented below displaying maximum blood plasma concentrations (C_{max}), the time at which C_{max} is obtained (T_{max}), half-life ($T_{1/2}$), area under the curve (AUC), clearance rate (Cl) and mean retention time (MRT) for the various doses of GT3 that were administered.

Pharmacokinetic parameters of GT3 in rhesus macaques

Dose (mg/kg)	C_{max} (ng/ml)	T_{max} (h)	$T_{1/2}$ (h)	AUC (µg*h/ml)	Cl (ml/h/kg)	MRT (h)	MRT (d)
9.375	734.9	2	30.4	26.192	0.358	48.6	2.0
18.75	997.4	8	34.6	43.714	0.429	48.0	2.0
37.5	1142	12	40.9	82.225	0.456	273.9	11.4

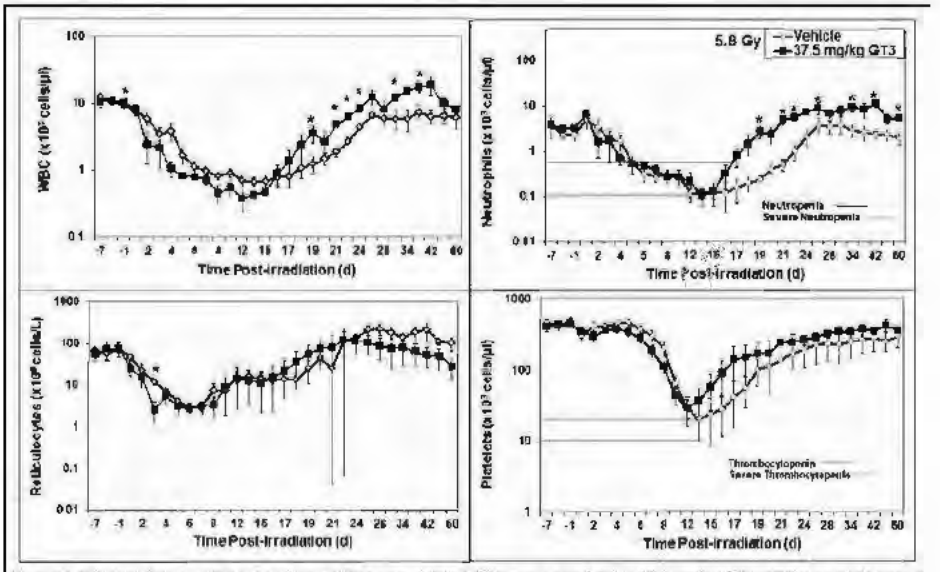

Figure 1. Effect of GT3 on CBC in irradiated NHPs exposed to 5.8 Gy and administered 37.5 mg/kg GT3. GT3 was administered sc 24 h prior to irradiation and blood samples were collected at various time points in relation to irradiation for CBC analysis.

Pilot efficacy study in NHP: The NHPs (n = 4) treated with 37.5 mg/kg GT3 had a higher level of WBCs beginning at d 16 post-irradiation compared with vehicle control, this difference became significant at d 21 post-irradiation and continued inconsistently until d 38, by which both groups average WBC levels returned to pre-exposure levels (figure 1). These same NHPs had a higher number of neutrophils beginning at 15 d post-irradiation and had a faster recovery from neutropenia. The GT3-treated group was considered neutropenic from d 6-16; the vehicle-treated group was neutropenic from d 6-20. The reticulocyte response curve for the 37.5mg/kg NHPs closely resembles the response curve for those treated with the vehicle. Only at 3 days post irradiation was there a significant difference between treatment groups. Though, the platelet counts for the GT3-treated NHPs were also higher, there was no significant difference between the two treatments.

NHPs treated with 75 mg/kg GT3 (n = 4), had higher levels of WBCs than the vehicle treated NHPs at day 14; this improvement was significant at day 15 and continued until day 24 when both groups' counts returned to normal levels (figure 2). Additionally, GT3-treated NHPs had an accelerated recovery from neutropenia and remained in a state of severe neutropenia for one day compared to the vehicle-treated NHPs (6 days). The GT3-treated group recovered from neutropenia on d 15 compared to the vehicle-treated NHPs recovery from neutropenia on d 20. NHPs treated with 75 mg/kg clearly had improved reticulocytes recovery compared to the vehicle treated group by d 16 post-irradiation; significant difference by treatments ranged from d 19 to 22 post-irradiation. The GT3-treated NHPs had significantly higher platelet counts than the vehicle-treated NHPs from d 15-28. The GT3-treated group did not become thrombocytopenic whereas the vehicle group was in a state of thrombocytopenia from d 12-16 post-irradiation.

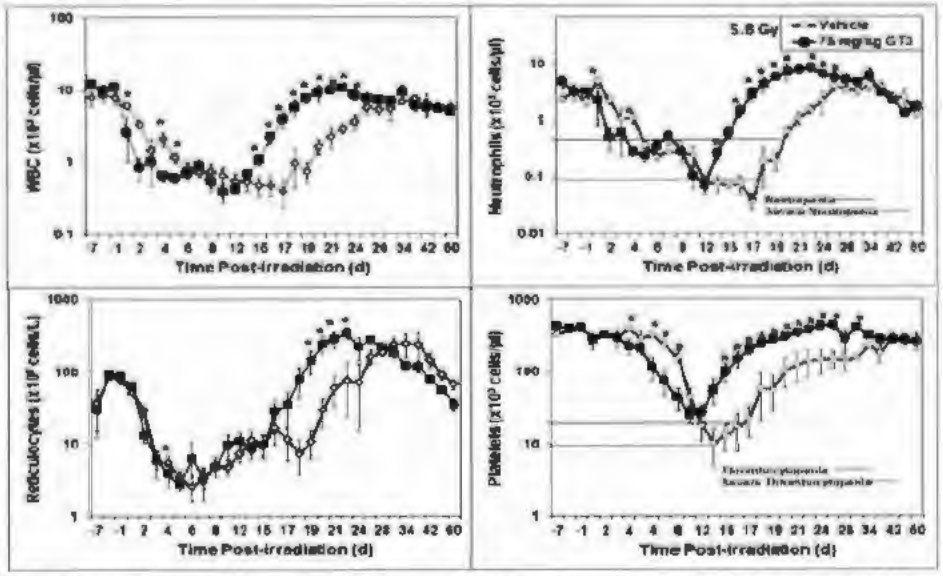

Figure 2. Effect of GT3 on CBC in irradiated NHPs exposed to 5.8 Gy and administered 75 mg/kg GT3. GT3 was administered sc 24 h prior to irradiation and blood samples were collected at various time points in relation to irradiation for CBC analysis.

The trend of accelerated recovery of GT3-treated NHPs at 5.8 Gy was also noted at the higher radiation dose, 6.5 Gy (n = 8). Figure 3 shows that WBC was significantly higher in GT3-treated animals from d 14 to 28 post-irradiation compared to vehicle group. GT3-treated NHPs had significantly higher neutrophil counts than the

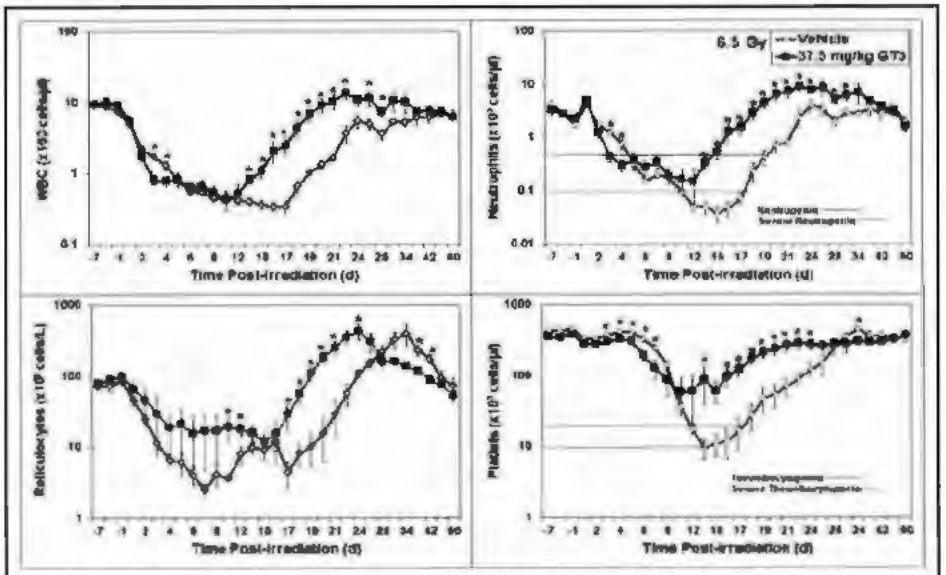

Figure 3. Effect of GT3 on CBC in irradiated NHPs exposed to 6.5 Gy and administered 37.5 mg/kg GT3. GT3 was administered sc 24 h prior to irradiation and blood samples were collected at various time points in relation to irradiation for CBC analysis.

vehicle-treated NHPs continuously from d 14-30. The GT3-treated group was considered neutropenic from d 3-14, whereas the vehicle-treated group was in a state of neutropenia from d 5-19 and was considered severely neutropenic from d 10-17.

These exciting preliminary results of the pilot study demonstrate an unprecedented promise of GT3 as safe, well-tolerated, highly effective radioprotector (i.e. given before irradiation). Therefore, we decided to develop GT3 as a FDA approved radiation countermeasure for human use. The ultimate goals of this proposal are (1) to characterize in detail the radioprotective potential of GT3 against radiation exposure in NHPs; (2) to evaluate GT3's capacity to accelerate hematopoietic and GI recovery in irradiated animals exposed whole-body as well as with partial-body exposures and, (3) to evaluate in the NHP model a select number of potential biomarkers for GT3's radioprotective efficacy.

None of these searched references address the questions to be tested in this protocol.				

Some related studies with GT3 have been conducted in mice however; none have been conducted with the refined formulation proposed in this protocol or using the NHP model. Studies in mice are helpful in that they have proven the principle that GT3 is prophylactically useful in managing morbidity and mortality in lethally irradiated animals. These results seem to demonstrate an unprecedented promise of GT3 as safe, well-tolerated, highly effective radioprotector (i.e. given before irradiation). Therefore, we decided to develop GT3 as a FDA approved radiation countermeasure for human use. There are no references of using gamma-tocotrienol in the NHP model for radiation protection.

III. OBJECTIVE / HYPOTHESIS Tocols protect mice against lethal γ-irradiation when administered by sc injection 24 h prior to irradiation. It is also found to be efficacious in a pilot study in NHPs against different doses of radiation when administered 24 h prior to radiation exposure. Specifically, we hypothesize that: 1) GT3 will enhance survival in NHPs exposed to different doses of radiation since we have observed significant improvement in neutropenia and thrombocytopenia in a pilot study using NHPs exposed to 5.8, 6.5, and 7.2 Gy whole body radiation. 2) GT3 is effective through sc route 3) GT3

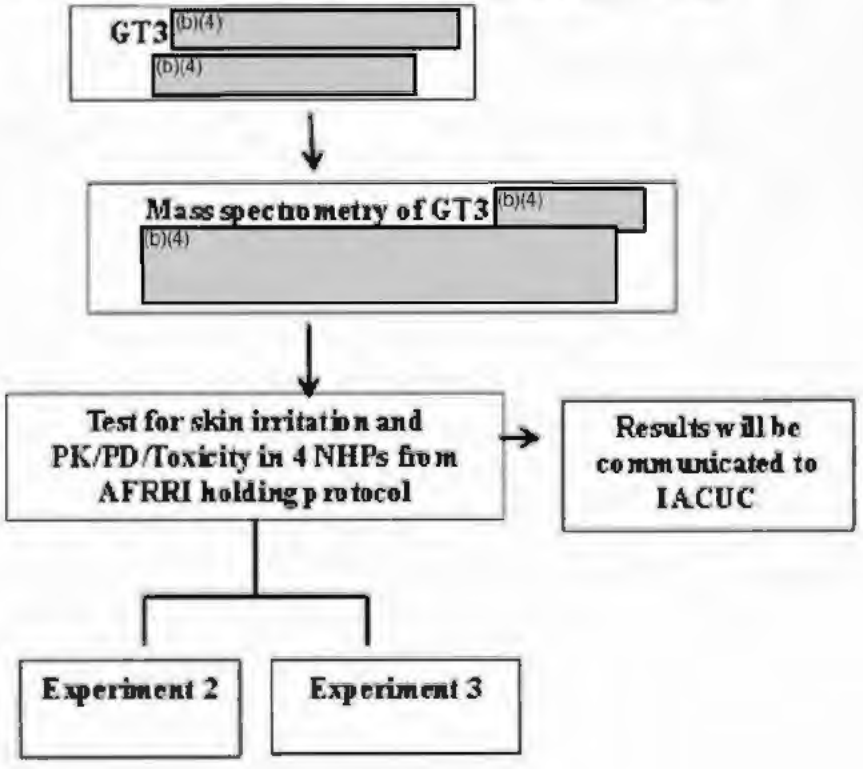
will be effective against partial-body radiation exposure similar to its efficacy against whole body radiation exposure. GT3 will accelerate recovery against radiation injury to hematopoietic as well as GI injury-induced by whole body and partial body radiation exposures. G-CSF (and interleukin-6; IL-6) in conjunction with CBC may serve as efficacy biomarkers for GT3 in NHP.

IV. MILITARY RELEVANCE

Currently, there are no FDA approved pharmaceutical agents that can prevent or treat injury from external ionizing radiation. The problem has become more acute in recent times due to the unpredictable nature of terrorist attacks. Recognizing this urgent need, the U.S. Department of Defense has assigned top priority to the "development of medical countermeasures to radiation exposure" against both early and late arising health effects. Advanced development of radiation countermeasures are currently an unfunded requirement. These concerns imply the urgent need to develop an appropriate countermeasure for radiation injuries potentially sustained by war fighters during combat operations and enable commanders to make judicious decisions in troop deployment. There are several drugs at different stages of the development. This study will perform essential research and development of a promising agent (gamma-tocotrienol (GT3), a component of vitamin E, also known as a tocol) as a prophylaxis for potential injuries sustained by military personnel who have been accidentally exposed to ionizing radiation.

V. MATERIALS AND METHODS

V.1. Experimental Design and General Procedures



We propose to carry-out the following experiments to test new preparation of GT3 from another vendor, identify biomarkers for GT3, investigate efficacy and also investigate hematopoietic and GI accelerated recovery of irradiated animals by treatment with GT3. Details of subsequent experiments will depend on results obtained in previous experiment.

V.1.1. Experiment 1. Investigate the pharmacokinetics/pharmacodynamics/toxicity of new batch of GT3 from (b)(4) when administered sc

The new batch of GT3 (prepared in 5% Tween 80 and saline) (b)(4) will be tested in four NHPs (obtained from Veterinary Science Department holding/training protocol) for PK/pharmacodynamics (PD)/toxicity before initiating efficacy study in next experiment. This study will be conducted in un-irradiated NHPs to determine the complete blood chemistry (CBC), biochemistry, cytokine and protein micro array (proteomics). Blood draw schedule for PK study has been given in table # 1. GT3 levels in blood will be determined by mass spec as performed earlier in our collaborator's laboratory. Skin irritation will be closely monitored. After the last bleed on day 20 and completion of experiment 1, animals will be transferred to the holding protocol of the Veterinary Science Department (VSD).

Table 1 Blood collection schedule for tests discussed above

GT3 dose mg/kg	Time of blood draw	For PK 0.5 ml	For CBC, 0.5ml	For Cyto 0.5 ml	For Chem 0.5 ml	For Gene array 0.5 ml	Total blood, ml
0	-7d	+	+				1.0
0	-3d	+	+		+	+	2.0
0	-1d	+		+			1.0
37.5	0 day of injection)						
	0.25 h	+		+			1.0
	0.5 h	+		+			1.0
	1.0 h	+		+			1.0
	2 h	+		+			1.0
	4.0 h	+		+			1.0
	8.0 h	+		+			1.0
	12.0 h	+		+			1.0
	1 d	+	+	+	+		2.0
	2 d	+	+	+		+	2.0
	3 d	+		+			1.0
	4 d	+	+	+			1.5
	5 d	+		+			1.0
	6 d	+		+			1.0
	7 d	+	+	+			1.5
	10 d	+	+	+			1.5
	14 d	+	+	+			1.5
	20 d	+	+	+	+		2.0
On day 0, the blood collection volume will be 7 ml, over 1% of the animal's total blood volume.							

We will be well within the acceptable published blood collection volumes (*19*) that are followed at AFRRI. According to these guidelines 1% blood (2.2 ml per day for 4 kg NHP – minimum body weight of experimental NHP) can be withdrawn every 24 h. Up to 15% of circulating blood volume can be drawn in

a single day repeated every 4 weeks in normal healthy animal. For the entire span of the study, the total blood drawn (26 ml) will be well below the recommended maximum limits (32 ml total, 15% of total blood volume in a 4 kg animal over a period of 28 days). Each NHP weight will be different and that fact will be kept in mind while blood drawing.

V.1.2. Experiment 2. Investigate the radioprotective efficacy of GT3 in NHPs using different doses of whole body radiation exposure using large sample size

Following experimental set up and NHP distribution scheme will be used:

Two groups of NHPs (16 NHP per treatment group; 8 males + 8 females, totaling 32 NHPs) will be irradiated with 5.8 Gy total body irradiation (expected to be $LD_{30/60}$) 24 h after single sc injection of either vehicle (5% Tween 80 in saline) or 37.5 mg/kg GT3. In another experiment, other two groups using, the same number of NHPs will be exposed to 6.5 Gy (expected to be $LD_{50/60}$) total body irradiation, 24 h after single sc injections of 37.5 mg/kg GT3 or vehicle. NHPs will be observed for 60 d following irradiation, while monitoring survival and multiple clinical and laboratory parameters such as CBC, blood chemistry, citrulline, and cytokine level. Total number of animals: 64 NHPs (16 NHPs in each group x 2 groups x 2 radiation doses).

Table 2. Efficacy of GT3 in NHPs using large sample size

NHP#	Drug	Route	Dose	Frequency	Irradiation dose (Gy)
16	GT3	sc	37.5 mg/kg	24 h prior to irradiation	5.8
16	Veh	sc	37.5 mg/kg	24 h prior to irradiation	5.8
16	GT3	sc	37.5 mg/kg	24 h prior to irradiation	6.5
16	Veh	sc	37.5 mg/kg	24 h prior to irradiation	6.5

For GT3 or vehicle, the administration volumes will be in accordance with Diehl et al, *(19)*, sc injection volume for rhesus macaques is 2 and 5 ml/kg (good practice and maximum volume, respectively). Exact dose will be calculated based on animal body weight and drug concentration. We expect that drug administration volume will be within good practice limits and we may not need to use maximum volume allowed.

Table 3. Blood collection schedule for experiment 2

GT3 dose mg/kg	Time of blood draw	CBC 0.5 ml	Cytokine/Bio markers 1.0 ml	Biochemis try 0.5 ml	Bacteremia 1.0 ml	Citrulline 0.5 ml	Total blood, ml
	-7d	+			+		1.5
	-3d	+	+	+			2.0
	-1d	+		+	+		2.0
37.5 mg/kg	GT3/vehicl e injection day -1						0
Radiation Dose 5.8 or 6.5 Gy	Day 0						(Total 2.0 ml on day 0, see below)
	4 h		+				1.0
	8 h		+				1.0
	12 h		+	+			1.5
	Day 1	+	+			+	2.0
	Day 2	+	+	+			2.0
	Day 4	+				+	1.0
	Day 6	+	+				1.5
	Day 8	+			+	+	2.0

	Day 10	+					0.5
	Day 12	+					0.5
	Day 14	+					0.5
	Day 16	+					0.5
	Day 18	+					0.5
	Day 20	+				+	1.0
	Day 22	+					0.5
	Day 24	+			+		1.5
	Day 26	+					0.5
	Day 28	+		+		+	1.5
	Day 30	+					0.5
	Day 34	+			+		1.5
	Day 38	+		+		+	1.5
	Day 42	+			+		1.5
	Day 50	+		+		+	1.5
	Day 60	+		+		+	1.5

We will be well within the acceptable published blood collection volumes (*19*) that are followed at AFRRI. According to these guidelines 1% blood (2.2 ml per day for 4 kg NHP – minimum body weight of experimental NHP) can be withdrawn every 24 h. Up to 15% of circulating blood volume can be drawn in a single day repeated every 4 weeks in a normal healthy animal. For the entire span of the study, the total blood drawn (33 ml) will be well below the recommended maximum limits.

V.1.3. Experiment 3. Study of hematopoietic and GI injury, accelerated recovery, and efficacy biomarkers in NHPs administered GT3

The GT3 used in experiment 2 will be used for this experiment. Two different experiments will be conducted for studying hematopoietic and GI injury accelerated recovery by GT3 administration. For both experiments, 8 NHPs will be used for each treatment (GT3 and vehicle: 5% Tween 80 in saline). These NHPs are being sub-distributed into smaller groups as stated in table 4. The experiment will be initially conducted using whole body exposure and then repeated with partial body exposure with LINAC. Total 64 NHPs for this specific aim (8 animals per group x 2 groups x 2 experiments for GI and hematopoietic injury models x 2 experiments for whole body and partial body radiation exposures).

Table 4.Hematopoietic and GI injury in NHPs administered GT3 or vehicle

Hematopoietic Study (Whole body irradiation)					
NHP#	Drug	Route	Dose	Frequency	Irradiation Dose (Gy)
4	GT3	Sc	37.5 mg/kg	24 h prior to irradiation	4.0
4	Veh	Sc	37.5 mg/kg	24 h prior to irradiation	4.0
4	GT3	Sc	37.5 mg/kg	24 h prior to irradiation	5.8
4	Veh	Sc	37.5 mg/kg	24 h prior to irradiation	5.8
Hematopoietic Study (Partial body irradiation)					
4	GT3	Sc	37.5 mg/kg	24 h prior to irradiation	4.0
4	Veh	Sc	37.5 mg/kg	24 h prior to irradiation	4.0

4	GT3	Sc	37.5 mg/kg	24 h prior to irradiation	5.8
4	Veh	Sc	37.5 mg/kg	24 h prior to irradiation	5.8
GI Study (Whole body irradiation)					
8*	GT3	Sc	37.5 mg/kg	24 h prior to irradiation	12.0
8*	Veh	Sc	37.5 mg/kg	24 h prior to irradiation	12.0
GI Study (Partial body irradiation)					
8*	GT3	Sc	37.5 mg/kg	24 h prior to irradiation	12.0
8*	Veh	Sc	37.5 mg/kg	24 h prior to irradiation	12.0

*Out of 8 NHPs in each group, 3 will be euthanized on day 4, 3 on day 7, and the remaining 2 will be euthanized on day 10 post-irradiation.

For GT3 or vehicle, the administration volumes will be in accordance with *Diehl et al, (19)*, sc injection volume for rhesus macaques is 2 and 5 ml/kg (good practice and maximum volume, respectively). Exact dose will be calculated based on animal body weight and drug concentration. Since GT3 is highly soluble in its proposed vehicle, we expect that drug administration volume will be within good practice limits and we may not need to use maximum volume allowed.

Hematopoietic injury and accelerated recovery by GT3 administration

To assess radiation damage and recovery by GT3 administration a total of 16 NHPs (8 receiving vehicle and 8 receiving GT3) will be exposed to either whole body or partial body radiation. Each treatment group will be split evenly in half. Each sub-group will then receive one of two radiation doses 4 Gy (sublethal) and 5.8 Gy ($LD_{30/60}$) for studying hematopoietic injury at two different radiation doses and accelerated recovery by GT3 administration.

BM aspiration

BM aspiration will be carried out on days -8, 2, 7, 14, and 30. BM cells will be used for various colony forming (CFU) assays as previously described (*20*) and the BM plasma will be used to obtain information about the BM microenvironment. The procedure for BM aspiration has been detailed under section V.4.3.2. 'Procedure(s)'. Cytokines/chemokines analysis by multiplex Luminex will also be carried out in each sample (the protein concentration in each sample will be measured with a modified Bradford reaction, Coomassie Plus Protein Assay, Thermo Scientific, Rockford, IL). It has been reported for mice that radiation and GT3 affect various cytokines/growth factors in BM plasma (*20, 21*). BM cells (mononuclear cells) will also be analyzed for apoptosis by TUNEL assay (b)(4)

For CBC, whole blood will be collected in EDTA coated tubes and complete blood count will be obtained to assess hematopoietic injury. Animals will be euthanized around 30 d post-irradiation (period when there is maximum hematologic difference between GT3- treated and control group) for necropsy, histopathology of various organ and additional BM analysis.

Table 5. BM and blood sample collection for hematopoietic recovery in irradiated animals treated with GT3

GT3 dose mg/kg	Time of blood collection/BM aspiration	BM 2 ml	Blood for CBC 0.5 ml	Total volume
	-8 d	+	+	2.5 ml
37.5 mg/kg (-24 h)				
	Radiation 5.8 or 6.5 Gy			
	Day 2	+	+	2.5 ml
	Day 7	+	+	2.5 ml
	Day 14	+	+	2.5 ml
	Day 16		+	0.5 ml
	Day 18		+	0.5 ml
	Day 20		+	0.5 ml
	Day 22		+	0.5 ml
	Day 24		+	0.5 ml
	Day 26		+	0.5 ml
	Day 28		+	0.5 ml
	Day 30	+	+	2.5 ml

This table will be applicable to both experiments (whole-body and partial-body irradiation) and two different radiation doses (4 and 5.8 Gy). We will be well within the acceptable published blood collection volumes (*19*) that are followed at AFRRI. According to these guidelines 1% blood (2.2 ml per day for 4 kg NHP – minimum body weight of experimental NHP) can be withdrawn every 24 h. Up to 15% of circulating blood volume can be drawn in a single day repeated every 4 weeks in a normal healthy animal. For the entire span of the study, the total blood drawn (16 ml) will be well below the recommended maximum limits.

GI injury and accelerated recovery by GT3 administration

This study will include evaluation of the crypt microcolony assay, where crypt survival will be quantified at 7 days after high-dose radiation exposure (rather than 3 days in mice), coupled with necropsy and histopathology of various organs. Our proposed experimental model is based upon those developed and published by MacVittie and colleagues, in which rhesus macaques were exposed bilaterally to 10.0-14.0 Gy at a 0.80 Gy/min (*23*). For this study, a high radiation dose of 12 Gy (approx. $LD_{75/15}$ for whole body, lethality will be lower with partial body) will be used as this dose induces a classic radiation GI syndrome consistent with depletion of GI stem cells and subsequent organ failure. Animals exposed to whole body radiation will duly succumb within the expected 20 day period to GI syndrome and hematopoietic injury. NHPs exposed to partial body radiation will experience GI injury and hematopoietic injury, however, due to residual BM cells in specific body area (5% sparing of BM – hind limbs fibula, tibia, and feet not irradiated – in LINAC shielding is not required for sparing) these animals are expected to rapidly recover.

Out of 8 NHPs in each group, 3 will be euthanized on day 4, 3 on day 7, and the remaining 2 will be euthanized on day 10 post-irradiation. Such study has been carried out in [redacted] with another radiation countermeasure with remarkable results.

GI study end points

The primary end point will be crypt count in jejunum samples on d 4, 7, and 10 post-irradiation. Samples of small and large intestine will be collected at necropsy and fixed in formalin, embedded in paraffin, cut, mounted, and stained with hematoxylin and eosin (H&E). Microcolony crypt cell survival assay will be performed as described by Withers and Elkins (*24*). The number of crypts will be calculated according to this method described by MacVittie (*23*).

Secondary endpoints will include key GI- and hematologic-associated parameters. These parameters will include a) histological analysis of radiation damage in the jejunum and colon, b) Ki-67 analysis of proliferating cells, c) mucosal surface area (measured in longitudinal H&E-stained sections of the jejunum using projection cycloid method described by Baddeley (*25*) which was validated in the [redacted] d) body weight loss, and e) the incidence, severity, and duration of diarrhea and dehydration. Hematologic analysis will include neutropenia and thrombocytopenia related parameters, incidence of febrile neutropenia, and incidence of positive blood cultures. Serum citrulline levels will be determined. Blood samples will also be tested for gut bacterial translocation.

Assessment of vascular oxidative stress

Pre-and post-irradiation peroxynitrite measurements provide information about the severity of radiation-induced oxidative/nitrosative stress. Peroxynitrite readily oxidizes dihydrorhodamine 123. The peritoneal aorta from NHPs euthanized on days 4 and 7 will be used for this assay to indicate the level of peroxynitrite production. It has been demonstrated in mouse model that vascular peroxynitrite production was increased by radiation exposure and administration of GT3 inhibited such radiation-induced peroxynitrite production (*21*).

Table 6. Euthanasia schedule of experiment for GI injury and accelerated recovery experiment

Groups	Day 4 post-irradiation	BM Day 7 post-irradiation	Day 10 post-irradiation	Total
GT3 + 12 Gy	3	3	2	8
Vehicle + 12 Gy	3	3	2	8

This table will be applicable to both experiments (whole-body and partial-body irradiation).

Table 7. Blood sample collection schedule for GI injury and accelerated recovery experiment

GT3 dose mg/kg	Time of blood draw	CBC 0.5 ml	Cytokine/Bio markers 1.0 ml	Biochemis try 0.5 ml	Bacteremia 1.0 ml	Citrulline 0.5 ml	Total blood, ml
	-7d	+			+	+	2.0
	-3d	+	+	+			2.0
37.5 mg/kg	GT3/vehicl e injection day -1						0
Radiation Dose 12 Gy	Day 0						(Total 2.0 ml on day 0, see below)
	4 h		+				1.0
	8 h		+				1.0
	12 h		+	+			1.5
	Day 1	+	+			+	2.0
	Day 2	+	+	+			2.0
	Day 4	+				+	1.0
	Day 6	+	+				1.5
	Day 7	+			+	+	2.0

This table will be applicable to both experiments (whole-body and partial-body irradiation). We will be well within the acceptable published blood collection volumes (*19*) that are followed at AFRRI. According to these guidelines 1% blood (2.2 ml per day for 4 kg NHP – minimum body weight of experimental NHP) can be withdrawn every 24 h. Up to 15% of circulating blood volume can be drawn in a single day repeated every 4 weeks in a normal healthy animal. For the entire span of the study, the total blood drawn (16 ml) will be well below the recommended maximum limits.

V.2. Data Analysis

In order to evaluate the hypothesis set forth and establish a comparison of significance of any deviation from the hypothesis, Fisher Exact Test will be performed. The test can provide the significance and deviation. The Fisher test for Variance or the ANOVA which provides the means to analyze the differences between group and their associated procedures is a suitable test to detect significance between sampling groups. ANOVA is a test of choice to compare group means and group variables. Means and standard deviations will be calculated. A $p<0.05$ will be considered statistically significant. When inferential statistics is used such as *t*-test, Fisher's tests, ANOVA etc, to evaluate the outcome and comparisons, sample size (n) needs to be determined to provide sufficient statistical capability for performance.

For experiment 2, to investigate the radioprotective efficacy of GT3 in NHPs using different doses of whole body radiation, we will be using n=16 (8 males and 8 females in each group) which should give more than 80% power for calculation (*27*). We expect a 30% difference (30% mortality in control and 0% mortality in drug treated group) at 5.8 Gy. Similarly at 6.5 Gy we would expect 50% mortality in control and 0% mortality in drug treated group.

For survival data, a Kaplan-Meier plot and log-rank test will be used to visualize and compare survival data, respectively. Fisher's exact test will be used to compare survival rates at the end of 60 d, with a Bonferroni correction used to control for type I error if multiple comparisons are made. For additional efficacy/mechanistic data, mean

values with standard errors (SE, when applicable) will be reported. Independent samples *t*-tests or analysis of variance (ANOVA) will be used to detect if there are significant differences between experimental groups. All statistical tests will be two-sided, with a 5% significance level. Statistical software SPSS version 22 (IBM, Armonk, NY, USA) and GraphPad Prism 5 (GraphPad Software, Inc., La Jolla, CA, USA) will be used for analyses.

V.3. Laboratory Animals Required and Justification

V.3.1. Non-animal Alternatives Considered

Both computer models and tissue culture have been considered as alternatives to animals. These alternatives lack the knowledge base and complexity needed to evaluate the effects of radiation and radiation countermeasures on the immune system. The phenomena under study involve complex information-processing networks comprising large number of cell types and biological signal transduction molecules. Responses to irradiation and radioprotective agents involve interactions between the central nervous system, the peripheral nervous system including the enteric nervous system, endocrine glands, the immune and inflammatory systems, hematopoietic system, GI system etc. We do not know all of the cell types and tissues involved and many of the signal transduction molecules have not been discovered yet. Even if all of the tissues, cell types and signaling molecules were known, the present state of tissue culture would be incapable of reproducing *in vivo* relationships. One would have to reproduce much of an entire mammalian organism in culture to study these phenomena *in vitro*. As for computer models, the most powerful supercomputers available in the near future would be incapable of analyzing interactions between so many elements in the network. Thus these drugs necessitate investigation in whole animal models to see overall outcome.

V.3.2. Animal Model and Species Justification

As described above, preliminary studies have shown that GT3 is effective in mice when administered sc as a radioprotector. Demonstrating efficacy in a large animal species (LAS) is a critical requirement of the FDA Animal Rule. *Rhesus macaque* has 95+% DNA sequence identity with humans. NHPs are necessary for the pre-clinical development of a drug candidate intended for use in humans, because drug metabolism and physiology are so similar between NHPs and humans. Rhesus macaques are the model of choice for investigations of toxicity, pharmacokinetics, biomarkers, radiation injury, and countermeasures, because the large database available from the existing literature. The FDA has accepted rhesus macaques as the appropriate animal model for pivotal efficacy testing of radiation countermeasures under the Animal Efficacy Rule, where efficacy testing cannot be performed in humans. The biomarker and efficacy of the drug to be tested in this protocol have already been demonstrated in mice. Previous experience with other radiation countermeasures (e.g. Neummune or HE 2100 or 5-AED) has shown that testing in dogs is not always relevant to pharmacokinetics and efficacy in primates. Metabolism of 5-AED in dog hepatocytes was much different than in NHPs and human hepatocytes. Animal model of pig (specifically Gottingen minipig) is currently under initial stage of the development for studying radiation injury. This model is not well defined and mature enough to evaluate radiation countermeasures. Our ultimate goal is to generate data which will be submitted to US FDA and our data should be acceptable to them for approval of this radiation countermeasure (GT3). Minipig

model has not reached to that stage of acceptance yet. (b)(4) Therefore, this study in rhesus macaque is being undertaken to guide future development of this class of radiation countermeasures. There are several reports for use of NHPs in radiation research and countermeasure development (*31-34*).

V.3.3. Laboratory Animals

V.3.3.1. Genus / Species

*Macaca mulatta (*Rhesus macaques*)*

V.3.3.2. Strain / Stock Chinese or Indian origin

V.3.3.3. Source / Vendor

AFRRI VSD will procure animals from vendors registered with the USDA or DoD.

V.3.3.4. Age 2.5 to 7 years

V.3.3.5. Weight 4 to 8 kg

V.3.3.6. Sex Male and female

V.3.3.7. Special Considerations

Animals should test antibody negative for Herpes B virus (aka *Macacine herpesvirus*), Simian T-cell leukemia virus type 1 (STLV-1), Simian Immunodeficiency virus (SIV) and Simian Retrovirus (SRV) Types 1, 2, 3, and 5. Animals shall also test negative by means of virus isolation or polymerase chain reaction (PCR) for SRV Type 2. NHPs will either be vaccinated for measles or, in the case of previously measles-vaccinated NHPs, tested for the presence of measles antibodies. NHPs shall come from the vendor colony negative for Salmonella, Shigella and Yersenia. Vendor must provide the health reports indicating the pathogen free status of the NHPs for the agents listed in this section. Animals will be pole and collar trained before use in experiment.

V.3.4. Number of Animals Required (by species)

Macaca mulatta: 132 (66 males and 66 females)

V.3.5. Refinement, Reduction, Replacement (3 R's)

V.3.5.1.

For biomarker and hematopoietic/GI injury recovery studies, end point will be measurement of BM cell and GI crypt cell analysis till predetermined days. For this purpose blood, BM, and GI samples (only from euthanized animals) samples will be collected at predetermined time points and analysis of relevant parameters will be carried out.

For efficacy study, the endpoint currently mandated by the FDA for approval of radiation countermeasures is mortality. Moribundity will be used as a surrogate for mortality, and euthanasia will be used in order to minimize pain and distress, using an extensive set of criteria (listed under section V.4.5). The actual irradiation procedure does not cause pain or distress. Animal care and use procedures will only be performed by trained and certified personnel.

V.3.5.2. Reduction

As we move forward with experiments, plans will be reevaluated at every stage of the experiments, in light of incoming data in an attempt to reduce the numbers of experiments and groups, if possible. If deemed not necessary based on incoming data, some investigations may not be carried out to optimize the use of experimental animals.

V.3.5.3. Replacement

There are no *in vitro* techniques available to demonstrate that this drug will counter the effects of whole-body irradiation in humans. Efficacy and safety have already been demonstrated in rodents. The preferred large animal model for preclinical evaluation of radiation countermeasures intended for use in humans is NHP. This study represents the next step necessary to develop this drug for FDA approval. According to FDA scientists and the radiobiology community, the large database of radiation studies in *Macaca mulatta* makes this the most useful large animal model to evaluate interactions of radiation injury and drugs intended for use in humans.

V.4. Technical Methods

V.4.1. Pain / Distress Assessment

V.4.1.1. APHIS Form 7023 Information

V.4.1.1.1. Number of Animals

V.4.1.1.1.1. Column C 0

V.4.1.1.1.2. Column D 4

V.4.1.1.1.3. Column E *128*

V.4.1.1.1.4. Pain Category Assignments

Exp. #	Experimental/Control Group	C	D	E	Totals
1	PK/PD/toxicity		4		4
2	Efficacy study			64	64
3	Accelerated hematopoietic /GI injury recovery			64	64
Totals:			4	128	132

V.4.1.2. Pain Relief / Prevention

V.4.1.2.1. Anesthesia / Analgesia / Tranquilization

Microchips will be implanted to animals during first sedation prior to irradiation (experiment 2 and 3) with the help of veterinary department staff. For experiment 1, microchips will be implanted before first blood draw on -8 d. BM will be collected under anesthesia in experiment 3. This procedure has been described in detail under section V.4.3.2 (not elaborated here to avoid duplication). Since anesthesia, analgesia, and tranquilizers are known to affect functions of the immune system of animals, we plan to minimize their use during course of the experiment after irradiation (*35-37*).

Pain is not expected from actual irradiation process. The sequelae of high dose of radiation may result in pain but the animals treated with GT3 will experience reduced infections observed in immunosuppressed animals. As observed in mice and a recent pilot study conducted in NHPs, we expect GT3 will enhance hematopoietic recovery

after radiation. This should lead to an accelerated recovery and improved health. Use of other bactericidal agents to combat unresolved infections during the experiments is not warranted in this study as the scientific end points identified above will be abridged. If pain and/or distress are observed, the PI and attending veterinarian staff will be notified to evaluate and determine the appropriate course of treatment. If pain and/or distress cannot be alleviated, the animal will be evaluated for euthanasia.

Some animals may feel temporary discomfort such as nausea, emesis, and diarrhea that may occur after irradiation. In such situation, administration of flavored fluids using a water bottle will be considered. No treatments for radiation-induced behavioral manifestations will be provided as they may interfere with the evaluation of GT3 in post-irradiation recovery.

Use of ketamine and Isoflurane for BM aspiration and LINAC partial body irradiation has been elaborated under section V.4.3.1. Pre-Surgical Provisions and V.4.4.7.

V.4.1.2.2. Pre- and Post-procedural Provisions

Animals will be observed for signs of pain and distress by either the veterinary or research staff at least twice daily. After surgical procedure (such as BM aspiration), NHPs will be monitored at least twice daily for signs of surgical site complication such as infection or trauma.

V.4.1.2.3. Paralytics

No paralytic agent will be used in this study.

No citations for pain were associated with exposure to ionizing radiation, the use of analgesia in conjunction with sub-lethal doses of ionizing radiation, or the use of analgesia in conjunction with GT3 in all of the searched databases. The use of GT3 was not associated with any reports of pain. Studies conducted in mice show GT3 to be well tolerated and low toxicity even when administered at a high dose (400 mg/kg). No alternatives were cited as being a replacement for irradiation. BM aspiration can be a painful procedure; however, appropriate pain management will be used to minimize the discomfort to animals undergoing BM aspiration.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification

(a): BM aspiration: Animals will get proper analgesics for this procedure and they will not be in a painful or distressful condition.

(b) Irradiation: As stated above, irradiated animals finally succumb due to a compromised immune response and microbial infections. In the event that there is pain and distress for animals, as we have already discussed under above headings, we cannot give anesthetic/analgesic agents to the animals (except at the time of BM aspiration which can't be performed without anesthesia) since these agents interact with the immune system, and in turn will affect experimental results.

There are conflicting reports regarding effects of buprenorphine on the immune system (*38-45*). A majority of reports suggest that buprenorphine influences immune response. Since buprenorphine has been shown to influence various arms of cellular and humoral immune response (*40, 43-45*), we have decided not to use it in our efficacy study. This agent will be administered to NHPs of experiment 3 for biomarker study as

stated above. Non-steroidal anti-inflammatory drugs are not suitable for use in survival study experiments (*46*). Such drugs are being used after BM aspiration.

V.4.2. Prolonged Restraint

Animals to be irradiated will be placed in restraint devices for irradiation in the cobalt facility. Animals will be sedated for this purpose (ketamine 10-20 mg/kg, im).

For blood collection, NHPs will be placed in a primate restraint chair. NHPs will not be left in the restraint chair for more than 30 minutes.

V.4.3. Surgery

V.4.3.1. Pre-surgical Provisions

BM aspiration proposed in experiment 3 is considered a surgical procedure. Animals will be assessed for signs of pain and distress by either the veterinary or research staff at least twice per day or as often as needed. Antibacterial prophylaxis may be administered: Cefazolin iv or sc (20 - 25 mg/kg, one time before BM aspiration) or ampicillin (15 - 20 mg/kg, iv or im one time before BM aspiration). Animals will be fasted for 8-12 h before sedation. Animals will be fed a snack (1 full banana or one apple or other fresh fruit) the night (around 8-9 pm) before BM aspiration is scheduled to avoid prolonged fasting Water will not be restricted and animals will have free access to water at all times. The NHPs will be chemically sedated with ketamine (5-15 mg/kg im) or Telazol (5-10 mg/kg im) with (needle 22-25 G). For induction, 3-5% isoflurane in 100% oxygen by mask will be used. For maintenance, 1-3% isoflurane will be administered in 100% oxygen via endotracheal tube or mask. While the animal is under the anesthesia, vital signs will be monitored including SpO_2, pulse, respiration rate and body temperature. Bair Hugger heated surgical table will be used for keeping animal warm. Animal body temperature will be recorded frequently using a rectal thermometer or via microchip during the procedure.

Before BM aspiration, a catheter (20-25 G, 1" long) will be placed in saphenous or cephalic vein. We will administer 100-200 ml bolus of 5% dextrose in normal saline through iv catheter during the procedure to take care of loss of appetite because of fasting, analgesia, and anesthesia.

V.4.3.2. Procedure(s)

The site of BM aspiration may be the iliac crest, scapula, ischial tuberosity, trochanteric fossa of the femur, tibial crest, or the proximal humerous. The site will be prepared as a surgical site: hair will be clipped using # 40 surgical blade and the site scrubbed at least 3 times using either betadine or chlorhexidine and 70% alcohol. Animal will be positioned appropriately (dorsal or ventral or lateral recumbency) depending on the site being used for the BM aspiration. A sterile drape will be used to cover the site. One dose of buprenorphine (0.005 – 0.03 mg/kg, im or sc or iv) will be administered before procedure. A small stab incision (just enough for a 16-20G needle to go through) will be made in the skin at the site of BM aspiration. We will infuse 0.1 - 0.2 ml analgesic (0.5% Marcaine or 2% lidocaine or 4% Articaine) at the BM aspiration site. Then, BM aspiration needle will be advanced through the incision into the cortex of the bone. The stylet is removed from the BM needle. A –5-10 ml syringe will be used to aspirate the BM. The needle will be removed and incision will be closed with tissue glue or a suture after BM aspiration. Either non absorbable nylon or absorbable monocryl

suture will be used to close the skin. Only autoclaved or disposable sterile instruments will be used. Only one attempt will be made per site and only two sites will be attempted at any one sampling point. No more than 3 ml of BM will be collected per animal.

V.4.3.3. Post-surgical Provisions

Animals will be monitored at least twice per day for signs of surgical complications such as infection or trauma. If treatment for such conditions is needed, a VSD veterinarian will provide the appropriate medical intervention: After the procedure Rimadyl (2-4 mg/kg, sc or po every 12-24 h for 1-2 d or longer as determined by the veterinarian) will be administered.

V.4.3.4. Location

The procedure will occur in the VSD surgical suite at the veterinarian's discretion.

V.4.3.5. Surgeon

VSD personnel trained in the specific procedure and aseptic technique will perform surgical procedures.

V.4.3.6. Multiple Major Survival Operative Procedures

V.4.3.6.1. Procedures

N/A

V.4.3.6.2 Scientific Justification

Though BM aspiration is not a major procedure per se, we are conducting repeated aspiration s which may make it fall into this section. Hematopoietic recovery is an important objective of this protocol. To accomplish these objectives, we need to collect BM and blood samplings at different time points in relation to radiation exposure. (stated above in table 5).

Same site can be used for BM aspiration again after a rest period of 14 days in a specific study. Same animal will be used to aspirate BM at specified time points (applicable only for experiment 3). We have identified several sites for BM aspiration in NHPs of experiment 3. There will be no BM aspiration in experiment 1 and 2.

V.4.4. Animal Manipulations

V.4.4.1. Injections

NHPs will be dosed with GT3 or vehicle in the dorsal scapular region (midline). Injections will be performed with a sterile 21 - 25 gauge needle. The site for GT3 injection will be prepared as a surgical site before the injection: hair will be clipped using # 40 surgical blade and the site scrubbed at least 3 times using either betadine or chlorhexidine and 70% alcohol. Injections will be performed by appropriately trained staff listed in this protocol under section VI. Injections for ketamine (5-15 mg/kg) will be administered *im* with 22-25 gauge needle length of ¾-1". The injection volume for this will be 0.1-1.0 ml.

V.4.4.1.1. Pharmaceutical Grade Drugs

N/A

V.4.4.1.2. Non-Pharmaceutical Grade Drugs

Gamma-tocotrienol will be purchased as a formulation in 5% Tween 80 (in saline) (b)(4),(b)(6) (b)(4) Since we are planning to obtain this product from another vendor, we plan to test this agent in 4 NHPs in experiment 1 before proceeding to efficacy study in experiment 2.

Excipient proposed (5% Tween 80 in saline) for the drug formulations is approved by FDA for animal oral and parenteral administration and has been supplied (b)(4) (b)(4) in the past. This excipient is used regularly in parenteral injections in animals at AFRRI. GT3 will be formulated in this sterilized excipient under aseptic conditions to deliver a dose of 200 mg/kg in 0.1 ml. Such formulation has been used parenterally in mice and in NHPs in the past. The supply of new GT3 batch will be tested for endotoxin before use. The pH and osmolality are within the acceptable range as discussed in the earlier protocols. The NHP protocol in which GT3 and this formulation was used is (b)(6) (b)(6)

V.4.4.2. Biosamples

Blood withdrawals will be carried out according to the schedule presented above in experiment 1. Blood will be collected from a peripheral vessel rather than a femoral vein with a 21-25 gauge sterile needle attached to a 2-3 ml syringe, to reduce the chances of bleeding after blood collection in irradiated animals.

The area for the blood draw (samples for bacterial culture) will be swabbed with providone-iodine twice before inserting the needle. Providone-iodine will be swabbed off to reduce irritation to the tissue. For samples collected for other tests, only alcohol swab will be used. The blood sample will be drawn as described above. While withdrawing needle, pressure will be applied at the same time with a sterile bandage to reduce bleeding from the blood draw site. While making regular routine observation of animals, the blood-draw site will be checked for bleeding. In the event the site becomes infected, topical triple antibiotics (bacitracin, neomycin, and polymyxin) or similar agent will be applied.

BM samples will be collected as stated above under section V.4.3.2. GI tissue and other organs will be collected from euthanized animals as discussed under experimental methods above.

V.4.4.3. Adjuvants

No adjuvants will be used.

V.4.4.4. Monoclonal Antibody (MAb) Production

N/A

V.4.4.5. Animal Identification

Animals arrive tattooed and such tattoo will be used for identification. Additionally cage tags or ID's written on cages with permanent markers are used for identification.

V.4.4.6. Behavioral Studies

No behavioral studies will be performed in this protocol.

V.4.4.7. Other Procedures

Management of skin irritation following sc administration

Before the GT3 injection, the site will be prepared as a surgical site: hair will be clipped using # 40 surgical blade and the site scrubbed at least 3 times using either betadine or chlorhexidine and 70% alcohol. Following the sc administration of GT3, the injection site will be closely monitored (manually palpating the site to ascertain any increased sensitivity or mild increases in swelling that aren't visually readily apparent). A VSD veterinarian will be notified if mild redness, skin wrinkling, alopecia or other abnormal clinical signs are observed. If severe redness, irritation, or ulceration of the skin develops, the VSD veterinarian will initiate treatment. Treatment may include topical antibiotics and/or topical anti-inflammatory drugs. The veterinarian will be notified immediately, if the injection site develops into an abscess. If the abscess is less than 1 cm in diameter and remains the same or regresses in size and the NHP exhibits no other adverse clinical signs, continued monitoring is all that is needed. If the abscess continues to increase in size, then the animal may be restrained in a chair, sedated, and the abscess drained then flushed with betadine/chlorhexidine. A diagnostic culture swab will be taken prior to draining the site. The treatment regimen may include lancing the abscess and/or surgical placement of a penrose drain. Additional treatment may include local/oral/parenteral analgesics as suggested by veterinarian. Development of recurring abscess: Animal will be sedated for a more surgically invasive procedure including debridement of the dead necrotic infected tissue (antibiotics and/or anti-inflammatories may be used as suggested by veterinarian).

Transport plan

For whole body irradiation, the sedated animals will be placed in positioning aide devices and will be transported inside a cart to the High Level Gamma Radiation (HLGR) facility or LINAC facility. HEPA filtered transport carts will be used for transportation of animals through common hallways/areas. At no time will the animals be removed from the restraint boxes while outside of the VSD vivarium. At least two personnel will accompany the animals. Additional ketamine may be administered as needed for chemical restraint (animals are not awake during irradiation), and provide animal handling support. After irradiation, the NHPs in their restraint boxes will be removed from the irradiation platform, returned to the transport cart and returned to the vivarium.

For partial body irradiation with LINAC, there will be no shielding since irradiation is carried out after CT scan. Both legs will not be irradiated. This procedure has not been executed at AFRRI before. It is our best guess that it will take 30-45 min. Animals will be sedated with ketamine (details given under section V.4.4.1. Injections) and maintained with isoflurane (3-5%) via mask and they will be intubated with endotracheal tube of appropriate size. Animals will be transportated to LINAC. Then they will be maintained with isoflurane (1-3%) during irradiation procedure. Anesthesia will be monitored as stated under V.4.2.1. Anesthesia/Analgesia/Tranquilization throughout the procedure. During entire procedure veterinarian/veterinarian designee will be available.

V.4.4.8. Tissue Sharing

This is a collaborative research project between AFRRI PI and (b)(6) (b)(6) Tissue samples will be shared (b)(6) (b)(6) and for this purpose tissue sharing form will be completed after approval of the protocol and prior to tissue sharing. Unused biological samples will be retained for additional studies and stored in the PI's laboratory. Studies planned will depend upon additional funding for supplies and staff in future.

V.4.4.9. Animal By-Products

No animal by-products will be used in the proposed study.

V.4.5. Study Endpoint

The primary endpoint used in the efficacy study will be mortality. Moribundity will be used as a surrogate for mortality, and euthanasia will be used in order to minimize pain and distress. Moribundity will be used as the endpoint (tracking the symptoms listed in this section) as a surrogate for mortality. Euthanasia will be carried out when one or more of the following signs and symptoms of moribundity are observed as determined by or in consultation with AFRRI veterinarians. Necropsy and histopathological analysis will be performed on all euthanized animals. The following parameters will provide the guidelines for moribundity (all signs will be taken together along with the recommendation of a veterinary science department veterinarian for euthanasia decision):

1. Weight loss: loss of more than 20% body weight from the baseline (NHPs will be weighed whenever we will put animal on the restraint chair attached to scale for blood collection),

2. Inappetance: complete anorexia for 2 days with deteriorating conditions based on clinical examination,

3. Weakness/inability to obtain feed or water: Inability or extreme reluctance to stand which persists for 1 h,

4. Minimal or absence of response to stimuli (animal does not move when prodded),

5. Core body temperature: Below 96.6 ºF following a period of febrile neutropenia (such as >103 0F and <500 neutrophils/ml),

6. Severe acute anemia: <13% hematocrit or <40 g/L hemoglobin (decision in consultation with AFRRI veterinarians),

7. Severe thrombocytopenia (<10,000 platelets/µl) (decision in consultation with AFRRI veterinarians),

8. Other signs of severe organ system dysfunction with a poor prognosis as determined by a veterinarian:
   - 8.1 Respiratory: any dyspnea or severe cyanosis.
   - 8.2 Gastrointestinal: sustained vomiting or diarrhea, obstruction, intussusceptions; peritonitis (transient vomiting and diarrhea are expected results of whole-body gamma irradiation, therefore, as criteria for euthanasia, these symptoms should be severe and life-threatening per se, i.e., hemorrhagic diarrhea to the point of causing anemia as listed above or severe uncompensated dehydration).
   - 8.3 Urogenital: renal failure

8.4 Nervous: sustained CNS depression, seizures, paralysis of one or more extremities.
8.5 Integumentary: non-healing wounds, repeated self-trauma, severe skin infections, indicating severe organ system dysfunction with a poor prognosis.

Surviving animals at the end of the study (60 d post-irradiation) will be euthanized for gross necropsy and tissue collection as described under section V.4.6. Histopathology of various organs will be conducted to study the effects of radiation and drug.

Endpoint for hematopoietic recovery will be analysis of BM cells and endpoint for GI recovery will be analysis of crypt in GI tissue.

V.4.6. Euthanasia

Animals will be humanely euthanized using American Veterinary Medical Association (2012 AVMA) guidelines. These animals will be given sodium pentobarbital intravenously (saphenous or cephalic), needle size 20-25 gauge ¾-1" length, (100 mg/kg, 1-5 ml). Prior to pentobarbital administration, animal will be sedated using ketamine (5-15 mg/kg im). Intracardiac administration will be performed if unable to administer sodium pentobarbital through peripheral veins. The animal will be deeply anesthetized by Isoflurane (1-5%) via mask before giving intracardiac injection. The animals will be euthanized only under the guidance of a staff veterinarian. After sodium pentobarbital administration, the animals will be examined (heart auscultation and pulse) to confirm death. A full body necropsy and histopathology analysis will be performed, after confirmation of the death.

V.5. Veterinary Care

V.5.1. Husbandry Considerations

All non-human primates will be housed individually in cages with at least 4.3 square feet of floor space per NHP in accordance with the Guide for the Care and Use of Laboratory Animals. In addition, every cage will be equipped with built in perches. Excreta and food waste will be removed from inside each indoor primary enclosure, once per day, to prevent the primates from becoming soiled, and to reduce disease hazards, insects, pests, and odors. Care will be exercised when washing the primary enclosure so that the animals remain dry at all times. Primary enclosures will be sanitized every two weeks. The secondary enclosure (room) will be sanitized once per month. Foraging boards as well as other enrichment devices will follow the same schedule as the primary enclosures of the primate.

Special care will be given to animals that have been irradiated as their natural immunity will be suppressed (more prone to infections). Irradiation boxes will be sanitized after every use or more often as needed.

V.5.1.1. Study Room

Study rooms will be assigned by VSD.

V.5.1.2. Special Husbandry Provisions

None

V.5.1.3. Exceptions

None

V.5.2. Veterinary Medical Care

V.5.2.1. Routine Veterinary Medical Care

All animals will be quarantined for 45 days prior to any experiment. For this study, NHPs will arrive at AFRRI after completing quarantine at suppliers's facility. As per Standard Operating Procedures, VSD staff will monitor all animals at least twice daily during morning and afternoon rounds. Any abnormalities will be reported immediately to the on-call veterinarian and PI. In addition, animals will be observed daily by this protocol's research staff. Any sick animal will be observed at least twice a day (early morning and late afternoon/night) by the research staff. When animals become ill or debilitated, a veterinarian will be contacted immediately to assess the animal and provide adequate/emergency care. If the animal becomes moribund, it will be euthanized via intravenous administration of pentobarbital sodium at a dose of 100 mg/kg body weight under the guidance of the veterinarian. Prior to pentobarbital administration, animal will be sedated using Ketamine (5-15 mg/kg intramuscularly) (needle 25 G).

V.5.2.2. Emergency Veterinary Medical Care

The on-call veterinary officer will be available via telephone 24 hours a day. The on-call roster is located outside the VSD conference room (Room # (b)(6) on the bulletin board and at the security watch desk. These procedures are in accordance with VSD SOPs

V.5.3. Environmental Enrichment

V.5.3.1. Enrichment Strategy

In these studies, all primates will receive regular enrichment [IAW VSDM SOP VS0226 (Environmental Enhancement Plan for NHP)]. Enrichment provided will include sanitizable plastic toys, contact with husbandry and research workers, and visualization of conspecifics. To facilitate the consumption of food post-irradiation, the primates may be provided with an array of drinking and food products that will heighten their interest. Such items will be kool-aid type drinks, jello and yogurt as examples of soft type foods, and bananas, sweet potatoes, and celery with peanut butter as examples of harder type foods. This brief listing is not meant to exclude any drink or food product that will aid in the consumption of diet designated for the animals.

V.5.3.2. Enrichment Restrictions

Fruits or vegetables containing citrulline such as watermelons, cantaloupes, curcubits (squash, pumpkin, zucchini) or cucumbers will be avoided since it will interfere with the study objective (citrulline will be measured in experiment 2 and 3).

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING

On-the-job training for AFRRI employees is completed and assessed by the supervisor or designee and documented. When a trainee is judged competent in a given function, a training certification describing on-the-job training is completed by the person responsible for the training and approved by the supervisor or appropriate level of

departmental management. This training is documented in each individual employee's training record at AFRRI. The qualifications indicated below are only applicable for NHP procedures. The personnel listed have also been trained and have experience working with rodents.

NAME	DEGREE	TRAINING	DATE	PROCEDURES	YRS/MOS EXPERIENCE
(b)(6)				7 (off-hour observations)	(b)(6)
				1,3 (b,d),4,5,7 (off-hour observation	
				1,3 (b,d),4,5,7 (off-hour observation	
				7 (off-hour observations)	
				7 (off-hour observations)	

The training indicated in the above table represents training that has been completed, (b)(6) will be trained further for performing injections and blood draws. All staff members have received annual training including refresher for 2015. In the table above, initial training years have been listed.

Procedure and manipulation codes:
Code 1= Animal handling and euthanasia
Code 2= Surgery (aseptic technique) pre- and post-operative care
Code 3= Injections (3a–ip, 3b-sc, 3c-gavage) - can say 3 if trained in all manipulations or add 3d-iv
Code 4= Blood collection under anesthesia (4a-cardiac, 4b-posterior vena cava)
Code 5= Tissue collection (after euthanasia) - doesn't need to be specific
Code 6 = Implantation (provide details)
Code 7 = Others - (provide protocol specific manipulations or procedures for e.g., retro-orbital bleeding, tail vein injection, or drug delivery)

VII. BIOHAZARDS/SAFETY

There is no plan to use any potential biohazard. Standard laboratory safety precautions will be observed throughout this study.

VIII. ENCLOSURES

Form 310

List of references

X. ASSURANCES

Protocol Title: Advanced Development of Gamma-tocotrienol as a Radiation Countermeasure in Nonhuman Primates (*Macaca mulatta*)

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made every effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with a qualified individual who evaluated the experimental design with respect to the statistical analysis, and that the minimum number of animals needed for scientific validity will be used.

D. Biohazard / Safety: I have taken into consideration and made the proper coordinations regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R", namely, "Responsibility," which the DOD has embraced for implementing animal use alternatives where feasible and conducting humane and lawful research.

G. Scientific Review: This proposed animal use protocol has received appropriate peer scientific review and is consistent with good scientific research practice.

H. Painful Procedure(s): (**AM**) / **AM NOT** conducting biomedical experiments, which may potentially cause more than momentary or slight pain or distress to animals. If applicable, potential pain and/or distress **WILL** / (**WILL NOT**) be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

- For each section and subsection, enter your text into the underlined data field ( ) only. Do not make entries into the red-text instruction text. Single-click your mouse cursor in the data field, then begin typing.

I. NAME OF FACILITY: Armed Forces Radiobiology Research Institute

II. PROTOCOL NUMBER: (b)(6)

III. PROTOCOL TITLE: Radioprotective efficacy of new formulations of tocotrienols in mice, *Mus musculus*

IV. PRINCIPAL INVESTIGATOR:

(b)(6) **Ph. D**
Research Biologist, AFRRI-SRD
Office: (b)(6) Fax: (b)(6)
(b)(6)

V. DEPARTMENT HEAD: This animal use proposal received appropriate peer scientific review and is consistent with good scientific research practice.

(b)(6) **PhD, LTC, USA** Date

Head, Scientific Research Department, AFRRI
Telephone: (b)(6)
(b)(6)

- Or –

(b)(6) **PhD, CDR, USN** Date

Head, Scientific Research Department, AFRRI
Telephone: (b)(6)
(b)(6)

VI. STATISTICAL REVIEW: A person knowledgeable in biostatistics reviewed this proposal and ensures that the number of animals used is appropriate to obtain sufficient data and/or is not excessive, and the statistical design is appropriate for the intent of the study

(b)(6) **PhD** Date

Statistician
Telephone: (b)(6) Fax: (b)(6)
(b)(6)

VII. ATTENDING VETERINARIAN: In accordance with Animal Welfare Regulations, the Attending Veterinarian was consulted in the planning of procedures and manipulations that may cause more than slight or momentary pain or distress, even if relieved by anesthetics or analgesics.

(b)(6) **DVM, DACVPM, DACLAM** Date

Head, Veterinary Sciences Department
Armed Forces Radiobiology Research Institute
(b)(6)
Office: (b)(6)
Fax: (b)(6)
Email: (b)(6)

VIII. SAFETY OFFICER: This animal use protocol received appropriate review for safety and biohazards. *(Attach copy of completed AFRRI Form 310, EHS Research Protocol Hazard Analysis)*

(b)(6) Date

Safety and Occupational Health Specialist, USUHS
Telephone: (b)(6) Fax: (b)(6)
(b)(6)

IX. IACUC APPROVAL: This protocol was reviewed and approved by the Institute Animal Care and Use Committee on _____.
(Date)

(b)(6) **Ph.D.**
IACUC Chair, (b)(6) Scientific Research Department, AFRRI
Telephone (b)(6) Fax: (b)(6)

AFRRI SCIENTIFIC RESEARCH PROTOCOL NUMBERS: (b)(6)

I. NON-TECHNICAL SYNOPSIS

Protection of first responders and military personnel deployed in a radiation scenario is a major concern for both the military and the homeland defense. We have shown that various analogs of vitamin E (tocopherol and tocotrienol), also designated as tocols protect and enhance survival in mice exposed to lethal doses of irradiation. The present proposal will compare the beneficial effects of delta- and gamma-tocotrienol (DT3 and GT3) with a commercially available dietary supplement (b)(4) (b)(4) (b)(4) We will compare the 30 day survival efficacy of three specially formulated emulsions in (b)(4) DT3 and GT3 in mice exposed to gamma-radiation (Cobalt-60). We will conduct basic toxicity studies after a subcutaneous injection of the drugs, followed by survival studies. Depending on experimental results, additional studies such as a. optimization studies (drug route, concentration, multiple administrations and time of drug administration), b. Dose reduction factors (DRF) studies (testing efficacy of promising candidates using various radiation doses), and c. hematological and mechanistic studies (to elucidate drug response) will be conducted with (b)(4) representing mostly DT3) and GT3 formulations.

II. BACKGROUND

II.1. Background: Threat characterization for radiologic and nuclear events (intentional or accidental) is defined by the nature of the incident [1]. Threat devices or sources include radiologic dispersal devices, radiologic exposure devices, a sophisticated nuclear weapon, improvised nuclear devices, nuclear power plants, and stolen or mishandled medical radiologic sources [2-5]. AFRRI has been in the forefront in evaluating radiation countermeasures against the deleterious effects of ionizing radiation (b)(4)

Tocols as radiation countermeasures: AFRRI investigators and their collaborators have extensively studied tocols including tocopherols, tocotrienols, esters such as tocopherol succinate, and found those to be radioprotective when administered prior to the total body radiation exposure (b)(4) The current protocol will allow us to test several formulations of tocols with the support of a commercial partner (b)(4) As mentioned in the nontechnical summary, (b)(4) and the company has interest in advancing tocols as radiation countermeasure.

Product Development Considerations:

T3 Sources/Manufacture: DT3 and GT3 are both derived from natural plant sources, the three most common sources being palm, rice bran, and annatto seeds [13, 14].

(b)(4)

(b)(4) is manufactured through a molecular distillation process. As a dietary supplement for oral use, it has a Technology Readiness Level (TRL) of 9 using the Portfolio Tracking Tool used by the Public Health Emergency Medical Countermeasures (PHEMCE), the Dept. of Health and Human Services (HHS), the department of Defense (DoD), and other United State government agencies (b)(4),(b)(6) Acquiring highly purified single T3s from the available natural sources requires a more complicated manufacturing process. This could have significant fiscal impacts in product development for bulk-level manufacturing (b)(4),(b)(6) (b)(4),(b)(6) is already commercially available as an oral dietary supplement and food additive, manufactured under cGMP conditions. Neither highly purified DT3 nor GT3 has been produced at bulk-scale to date (b)(4) has a Generally Regarded as Safe (GRAS) status (GRAS notice # (b)(4) with a letter from the U.S. Food and Drug Administration (FDA) dated May 13, 2014 stating that there were no questions about the product regarding its intended use "as a source of vitamin E in food at a level of up to 100 milligrams of tocotrienols per serving". There is one IND on file for oral use of (b)(4) in a clinical trial for osteoporosis at up to 600 mg/day.

(b)(4)

Tocols in the clinic: Tocotrienols are being tested for multiple medical indications. Promising results have been demonstrated for these vitamin E isomers (or vitamers) for multiple chronic diseases or conditions including cardiovascular disease, hypertension, hypercholesterolemia, diabetes, osteoporosis and in cancer prevention and treatment [16-26].

(b)(4) as well as to pursue additional funds from (b)(4) (b)(4) has been in consultation with the (b)(4) (b)(4) (use of GRAS emulsifiers) for human use. These formulations

(proprietary) based on [redacted] on behalf of [redacted] and will be tested at AFRRI using the current protocol.

II.2. Literature Search for Duplication

II.2.1. Literature Sources Searched BRD, NIHRePORTER, PUBMED , Embase
II.2.2. Date of Search 02-02-2015 to 02-06-2015
II.2.3. Period of Search The search period extended from 1998 to 2005 for BRD, 2009-present for NIHReporter, 1970 to present for PubMed, 2006 to present for Embase.

II.2.4. Key Words of Search Each individual term Gamma-tocotrienol, Delta-tocotrienol, [redacted] + (emulsifier) + (radiation), + (radioprotection), + (radioprotection+mice)

II.2.5. Results of Search
Table 1. Literature search resulted the following hits as tabulated below:

KEY WORDS	PUBMED	NIHRePORTER	BRD	Embase
Gamma tocotrienol + emulsifier	310	408	30	418
Gamma tocotrienol +radiation	31	366	26	41
Gamma tocotrienol + radioprotection+mice	8	358	9	5
Delta tocotrienol + emulsifier	161	372	17	192
Delta tocotrienol +radiation	8	166	13	16
Delta tocotrienol +radioprotection+mice	2	363	5	4
[redacted] + emulsifier	0	0	0	0
[redacted] + radiation	0	0	0	0
[redacted] + radioprotection+mice	0	0	0	0

Table 2 provides a summary of these searches from NIHRePORTER database

Table1. Project Title	Project Number	Contact PI / Project Leader

Summary of the Search: None of these published references are duplicative of the current protocol. (b)(4) (b)(4)

III. OBJECTIVE / HYPOTHESIS: The objective of the present protocol is to compare the radioprotective efficacy of the following compounds with GT3 in Tween-80 used previously at AFRRI:
a. (b)(4) in a formulation containing emulsifying and stabilizing agents,
b. DT3 formulation containing (b)(4) and emulsifying agents,
c. GT3 formulation in (b)(4) and emulsifying agents
It is hypothesized that (b)(4) (b)(4)

IV. MILITARY RELEVANCE: In the event of a nuclear related accident or terrorist activity, the first responders including military, fire and police personnel will be at risk for exposure. The risks include mortality at higher doses such as 10 Gy and above, while exposure to 2-8 Gy may result in severe hematopoietic ablation, GI injury and ensuing infectious diseases (b)(4) Additional constraints in a mass casualty scenario such as significant delays in transport, disruption of communication and overfilling of limited hospital resources would increase the risk associated with exposure to ionizing radiation (b)(4) The availability of safe and effective countermeasures would greatly reduce the radiation risk. The efficacy of tocols, administered prophylactically in mice will allow us to advance one of the tocols (to be recommended after comparing the efficacy data from this study and programmatic hurdles) in large animals for FDA approval and national stock pile.

V. MATERIALS AND METHODS

V.1. Experimental Design and General Procedures

General experimental design: The experimental design for this protocol is divided in to 5 subsections and each subsection covers a specific area:

Section v.1.1.: Basic toxicity
Section v.1.2.: Proof of principle - survival studies
Section v.1.3.: Drug optimization – survival studies
Section v.1.4.: Dose reduction factor - survival studies
Section v.1.5.: Hematological studies - sublethal dose of radiation

Section V.1.1.: Basic toxicity

We will adopt the modified toxicity protocol Optimal (non-toxic) Drug Dose for screening (ODDS) which has been used in our previous protocols (b)(6) (b)(6) at AFRRI to determine maximum tolerated dose (MTD). The purpose of using the ODDS method is that it allows testing in one gender (males in the present protocol) and requires fewer animals when compared to the FDA protocol. If the drug doesn't show any signs of basic toxicity (using the clinical sign discussed in Policy#10, Appendix 1), then the drug dose will be escalated 2 to 3 fold. However, if toxicity is observed, then the drug dose will be reduced by 2 to 3 fold (b)(4) Finally, for survival studies we will use $1/4^{th}$ of the observed non-toxic dose.

In our previous experiments using a protocol P# (b)(6) tocols in 5% Tween-80 did not show systemic toxicity although injection site inflammation was noted at a dose of 800 mg/kg (b)(4) Here we propose to start the toxicity study with 400 mg/kg dose (4 times the dose proposed for survival studies, section V.1.2). The dose will be reduced to 200 mg/kg if we observe inflammation in local injection site. However, if there are no observable inflammation in the injection site with 400 mg/kg drug, we will scale up the dose to 800 mg/kg (the new formulation with better emulsification of fat soluble tocols, may still be non- toxic at this high dose). We do not intend to increase the drug dose any further (b)(4)

The drug will be administered as a single subcutaneous (sc) administration under the nape of the neck. A vehicle with a similar composition but without the drug will be used as control. A maximum of six animals per drug dose will be used to evaluate toxicity. Animals will be monitored daily following IACUC Policy#10 for acute (first hour and then every hour up to 4 h) and chronic (up to 14 days) signs of toxicity using the observation codes listed in Appendix 1. Signs of acute toxicity include decreased activity, squinting eyes, hunching, labored breathing or injection site swelling [29]. If there is a sign of toxicity, the PI will facilitate the late PM and early AM checks (not more than 10 h apart) in addition to two times a day checks following Policy#10 to prevent animal distress. All morbid mice will be monitored carefully and their conditions scored for documentation (Please see section V.4.5). If animals treated with the 400 mg/kg dose show any sign of skin inflammation, one group of mice will be euthanized on day 14 and the other group of mice will be monitored up to day 30 after drug administration to allow the skin inflammation site to recover (Table 3). However,

animals treated with either 200 or 800 mg/kg of the test articles (TA) will be euthanized on day 14 after drug administration.

Table 3: Acute toxicity study (14 and 30 day) after a single sc drug administration

Drug Dose (mg/kg)	Groups (day 14 after drug administration)	Groups (day 30 after drug administration)	# of groups	# of animals per group	End point (whole blood)
400	Vehicle (AO + E), (b)(4) GT3(AO+E), DT3(AO+E), and GT3 (5% Tween-80 in PBS)	Vehicle (AO + E), (b)(4) GT3(AO+E), DT3(AO+E), and GT3 (5% Tween-80 in PBS)	10	6	CBC & Serum chemistry
200 or 800	(b)(4) GT3(AO+E), DT3(AO+E)	None	3	6	CBC & Serum chemistry
	Total no. of animals required = 13 groups x 6				78

AO+E-(b)(4) + emulsifying agents

Note: Injection site skin will be stored in formalin for histopathological analysis if needed.

Body weight changes: Each animal in the study will be weighed prior to drug treatment and weight loss/gain will be followed individually on days 2, 4, 7, 10, and 14 for groups terminated on day 14 and on day 21 and 30 for animals to be euthanized on day 30 (b)(4) Animals will be weighed at a specific time of the day (will be determined later). It should be noted that ODDS method only uses day 14, however, for this study, based on discussions with the supplier and the tocol team at AFRRI, an additional time point of 30 day is included in order to observe any delayed recovery of hematological parameters, body weight changes and recovery (if any) of the injection site inflammation. However, for an additional dose, 200 or 800 mg/kg, animals will be monitored only for 14 days (b)(4) following the standard protocol.

Hematological parameters and serum biochemical analysis: Blood will be collected under anesthesia by cardiac stick or inferior vena cavae (see section V.4.4.1 for more description about the procedure) on either day 14 or 30 after drug administration. Syringes will be wetted with Heparin (1000 units/ml solution). Part of the collected blood will be transferred to EDTA tubes (200 µl) for hematological analysis. The rest of the blood will be transferred to serum tubes (300-400 µl) for serum samples, and will be stored at -20C until analysis (b)(4) Hematological parameters (CBC/differential) and serum biochemistry will be analyzed using an Advia 2120 hematology system from Siemens Corporation or any other validated system at AFRRI.

Procedure: There will be six animals per group, and will be housed three per box. Each mouse will be identified by standard ear punch or tattoo system. Each cage will have an animal with a right ear punch, left ear punch and no punch. In the case of tattoo system, each animal will be tattooed on the tail prior to starting the experiment. The procedure is described under section V.4.4.1 (surgical methods or procedures). Individual mouse will be monitored for body weight loss and clinical signs of morbidity.

All formulations will be tested via subcutaneous route.

Dose 1 (400 mg/kg)
Day 14: 5 groups (Table 1) x 1 route (*sc*) x 6 mice per group = 30
Day 30: 5 groups (Table 1) x 1 route (*sc*) x 6 mice per group = 30

Dose 2 (200 or 800 mg/kg)
Day 14: 3 groups (Table 1) x 1 route (*sc*) x 6 mice per group = 18

Subtotal = 78

All mice will be placed in Column E (V.4.1.1.1.4. Pain Category Assignments, Table 6) since they might experience unalleviated experimental pain or distress due to drug or vehicle administration.

Section V.1.2. Radiation survival study:

There will be16 animals per group. Drug will be administered (sc) prophylactically 24 hour prior to irradiation. Animals will be exposed to Cobalt 60 gamma radiation (9.75 Gy at 0.6 Gy/min). This dose represents the LD90/30 dose for CD2F1 male mice (12-14 weeks old). Table 2 provides details of the experimental design. There will be four test article-treated (TA) groups and one control group (CA). 100 mg/kg will be used because it will be the ¼ MTD if 400 mg/kg is found to be non-toxic. GT3 in Tween-80 will be considered the positive control for this study. Animals will be monitored for 30 days post-irradiation.

Table 4: Survival efficacy of (b)(4) DT3 and GT3 in special formulation as compared to GT3 in Tween-80

Radiation dose 9.75 Gy (app. $LD_{90/30}$)	1 rad dose
Vehicle (AO+E), (b)(4) GT3(AO+E), DT3(AO+E), and GT3 (5% Tween-80 in PBS)	5 groups
Drug administration, -24 h, sc	1 treatment
Drug dose ~100 mg/kg*	1 drug dose
Mice/group	16
30 day survival	1 time point
Iterations	2
Total no. of animals required	1 X 5 x1 x 1 x 16 x 1 x 2 = 160
AO+E=(b)(4) + emulsifying agent(s)	
*The dose was selected based on our previous published work on DT3 and GT3. This may change based on the toxicity data of (b)(4) GT3 and DT3 formulations	

Sub-Total CD2F1 mice for efficacy studies = 160

All mice will be placed in Column E (V.4.1.1.1.4. Pain Category Assignments, Table 6) since they might experience unalleviated experimental pain or distress due to exposure to radiation.

Section V.1.3.

Optimization studies: Optimization studies will be initiated with all three new formulations (b)(4) DT3 in AO+E, and GT3 in AO+E). A vehicle group (AO+E) will be included in the study as required. Animals for three vehicle groups are included since each experiment may consist of only one formulation. All drug doses (3

per formulation, 50,100 and 200 mg/kg, please note that these doses were selected based on our previous published work on DT3 and GT3, these may change based on the toxicity data of (b)(4) GT3 and DT3 formulations) will be administered at -24 h for the drug optimization study. An amendment will be submitted to the IACUC if doses other than 50, 100, 200 mg/kg are to be used. However, for time optimization study only one of the drug doses from the drug optimization study will be used. The time optimization will include 3 different pre-irradiation time points (-24 h, -12 h, and -4 h). The radiation dose will be 9.75 Gy at 0.6 Gy/min for all of these optimization studies. Survival will be monitored for 30-day post-irradiation.

Drug dose optimization study:

Three (3) experimental groups (new formulations of (b)(4) DT3, and GT3) X 3 drug doses (50, 100, and 200 mg/kg) x 1 radiation dose (LD 90/30) x 1 route (*sc*) x 16 animals/ group Subtotal = **144**

Three (3) vehicle groups (assuming each formulation is tested separately (on different days) x 1 dose (original formulation) x 1 radiation dose x 1 route x 16 animals/group Subtotal = **48**

Time optimization study:

Three (3) different time points (-24 h, -12 h, -4 h) x 4 treatment groups (1 optimum drug dose for 3 drugs + 1 vehicle) x 1 radiation dose (LD90/30) x 1 route (*sc*) x 16 animals per group
Subtotal = **192**

All mice will be placed in Column E (V.4.1.1.1.4. Pain Category Assignments, Table 6) since they might experience unalleviated experimental pain or distress due to exposure to radiation.

Section V.1.4. Determination of Dose reduction factor (DRF):

Among the new formulations, two will be used for the DRF study. Since the (b)(4) formulation (b)(4) either (b)(4) formulation (b)(4) or DT3 (100% DT3) along with the GT3 formulation (100% GT3) will be used to conduct DRF studies, since these formulations may be advanced to large animal studies. Another group that will be included for comparison will be the vehicle (AO+E) group. Drug or vehicle will be administered 24 h prior to radiation (time of administration based on our (b)(4) administration time may change if the proposed time is not the optimum time in experiment V.1.3 Time Optimization Study). Six radiation doses will be selected for the drug groups. Similarly 6 radiation doses will be chosen for the vehicle group, but these may change depending on the survival profile of vehicle groups at higher radiation doses. Radiation doses will be selected so that the lowest dose will give 100% protection and the highest dose will give 100% mortality. Four additional intermediate doses will be selected, which will provide varying degrees of protection. From the probit analysis, LD50/30 radiation dose will be calculated for (b)(4) vehicle and tocols From these data, the DRF will be calculated as follows:
DRF = LD50/30 radiation dose for tocol / LD50/30 radiation dose for vehicle

Six radiation doses (9, 10, 10.5, 11, 11.5 and 12Gy)* x 2 drug groups (b)(4) DT3, or GT3) x 16 animals/rad dose Sub total (6 x 2 x 16) = **192**

Six radiation doses (8.5, 9, 9.5, 9.75, 10 and 10.5 Gy)* x 1 vehicle group (AO +E) x 16 animals/group Subtotal = (6 x 1 x16) = **96**

*These radiation doses are projected based on an earlier probit study and are considered a guidance. The appropriate radiation doses will be determined using the new dosimetry map (07/09/2014). An amendment will be submitted to the IACUC if the radiation doses change from what is stated here.

All mice will be placed in Column E (V.4.1.1.1.4. Pain Category Assignments, Table 6) since they might experience unalleviated experimental pain or distress due to exposure to radiation.

Section V.1.5. Amelioration of peripheral blood pancytopenia.
One of the earliest expressions of radiation effects is pancytopenia in peripheral blood as a result of shut-down of cell production in the bone marrow. Particular attention will be given to radiation-induced neutropenia (innate immunity and infectious complications) and thrombocytopenia (hemorrhagic complications).In this experiment one radiation dose will be used – 7Gy (hematopoietic range). The experimental design (b)(4) will be followed as described previously (b)(4) Drug or vehicle will be administered SC 24 h prior to radiation (time of administration based on our published data on GT3 and DT3, administration time may change if the proposed time is not the optimum time in experiment V.1.3 Time Optimization Study). An amendment will be submitted to the IACUC for any proposed changes to the time of drug administration. Blood will be drawn from deeply anesthetized mice at 0 time, 1 day, 4 days, 7 days, 10 days, 20 days, and 30 days after irradiation. Blood will be collected from the inferior vena cava or cardiac stick (as described in section V.4.4) into heparinized syringes, transferred to EDTA tubes, and total leukocytes, erythrocytes, neutrophils, platelets, lymphocytes, and monocytes will be counted using Advia 2120 cell counter (Siemens) (b)(4)

Without radiation:
Three drug formulations (b)(4) or DT3, GT3, vehicle (AO+E)) x 7 time-points x 6 mice/ group x 1 route of administration x no radiation Subtotal (3 x7 x 6) = **126**

With radiation
Three drug formulations (b)(4) or DT3, GT3, vehicle (AO+E)) x 7 time points x 6 mice/group X 7 time-points X 6 mice/group x 1 route of administration 1 radiation (7 Gy)

Subtotal (3 x7 x6) = **126**

All mice will be placed in Column E (V.4.1.1.1.4. Pain Category Assignments, Table 6) since they might experience unalleviated experimental pain or distress either due to exposure to radiation or deep anesthesia during blood draw.

V.2. Data Analysis All data will be reported as means with standards errors or percentages where applicable.

Experiment V.1.1 (ODDS) – This is a qualitative study so no additional statistics will be conducted.
Experiments V.1.2 (preliminary survival study) and V.1.3 (Optimization study)- Using calculations based on log rank test with 80% power and 5% two-sided significance level, we have determined that this protocol design has adequate power based on our previously published studies [redacted] Differences in 30-day survival (Experiments V.1.2 and V.1.3) will be analyzed using Fisher's exact test. Experiments V.1.2 will be repeated a maximum of 2 times with 16 mice per group, thus providing adequate statistical power for any conclusions. (b)(4)
Experiment V.1.4. (Dose Reduction Factor study) - Probit analysis will be used to generate the LD50 of the drugs under study using PASW Statistics (version 18). In our past experience, 16 animals per dose with six radiation doses has been sufficient to determine a probit line fit to mortality data for DRF calculations [redacted] At least three out of the six doses should sustain survival other than 100 or 0 percent. Finney's methods will be used to make probit fits and estimating DRF [redacted] 30]. (b)(4)
Experiment V.1.5: For testing the overall difference between groups (averaging over time points), a repeated measures ANOVA with 6 animals per group measured at 7 time points will have 80% power to detect a difference of 0.91 standard deviations if the within-subject correlation is 0.2. For comparisons between groups at a single time point, the proposed sample size will have 80% power to detect a difference of 1.8 standard deviations between groups, based on a t-test for independent samples with a 5%, two-sided significance level. Previous studies have yielded differences of this magnitude [redacted] (b)(4)

V.3. Laboratory Animals Required and Justification

V.3.1. Non-animal Alternatives Considered Although high throughput screening and computer modeling have advanced significantly in recent years in identification of promising drugs, it would be simplistic to assume that cell systems or artificial intelligence modeling can replace the data that can be generated by using an animal model. Irradiation of animals will result in a cascade of changes including death of stem and progenitor cells in bone marrow, alterations in signal transduction pathways, multiple organ dysfunctions etc. due to differing radiosensitivities of organs. Currently, there are no alternatives in existence that can predict or compute the complexity of the response to total body irradiation. The US FDA recognizes the ethical considerations involved in testing the efficacy of radioprotective drugs in humans. Therefore FDA requires preclinical drug assessments (safety and efficacy) to be performed using both small and large animal models [31] prior to granting approval for safety testing in humans.

V.3.2. Animal Model and Species Justification Recent advances in molecular techniques have allowed significant improvements in understanding the cellular and biochemical processes. These advances are possible only due to whole animal modeling of human ailments. The mouse, in particular, has high sequence homology to humans at a genomic level as well as similar hematological and immunological response to radiation. Mouse models not only confirm primary pathological processes

but have also provided a venue for studying basic molecular, cellular, biochemical, and cytological processes. Furthermore, there are extensive data on the mouse for comparison, review and analysis. The practicalities of breeding and housing these small mammals have made the mouse model invaluable. The Principal Investigator's group at AFRRI has significant training and experience in handling mice in radiation countermeasure studies. In this protocol, we will use male CD2F1 mice since this a historical strain AFRRI has been using for last 30 years. The PI also has used this strain in previous studies. To compare the previous data with this study, PI will use only male CD2F1 mice.

V.3.3. Laboratory Animals

V.3.3.1. Genus / Species: Mouse, *Mus musculus*

V.3.3.2. Strain / Stock: CD2F1,

V.3.3.3. Source / Vendor: CD2F1 from Harlan Inc. or any other approved vendors

V.3.3.4. Age: (procurement) 7-8 weeks

V.3.3.5. Weight (delivery) 22-26 grams

V.3.3.6. Sex Males have been used historically and will continue to be used in this study.

V.3.3.7. Special Considerations Commercially procured animals must be adventitious disease free. Specific pathogen-free, including *Pseudomonas aeruginosa*, and pasteuralla sp. All mice need to be free of the following agents: Sendai, Pneumonia Virus of Mice (PVM), Reovirus-3 (Reo 3), Mouse Adenovirus (MAD-1, MAD-2), Mouse Cytomegalovirus Virus (MCMV), Ectromelia, K virus, Lymphocytic Choriomeningitis Virus (LCM), Epidemic Diarrhea of Infant Mice (EDIM), Hantaan virus, Rotavirus, Mouse Parvovirus (MPV), Polyoma Virus, Mouse Minute Virus (MMV), Mouse Thymic Virus (MTV), Theiler's Mouse Encephalomyelitis Virus (TMEV/GDVII), *Encephalitozoon cuniculi*, CAR bacillus, *Mycoplasma pulmonis*, and *Clostridium piliforme*. Endoparasite- and ectoparasite-free.

V.3.4. Number of Animals Required (by species) (Table 5)

Animal (genus, species and common names)	**Original**
CD2F1	1162

V.3.5. Refinement, Reduction, Replacement (3 R's)

V.3.5.1. Refinement: PI will take necessary steps for all personnel in the project to be rigorously trained in handling techniques (ear-punch, injections, and routine cage-side observations) to minimize distress and pain to the animals. Specifically, during capture and restraint of the rodents, care will be taken to ensure that handling does not

contribute to distress. Topical ointment/lubrication gel will be used, if necessary, to prevent drying of the cornea as well as at the site of drug injection in consultation with attending veterinarian and veterinary staff.

V.3.5.2. Reduction Although basic toxicity and survival will be carried out on all three formulations, additional studies will be done with the best formulation. Positive controls and negative controls will be used to confirm robustness of experimental conditions. In addition, control groups (such as vehicle) will be shared whenever possible between formulations that are dissolved in similar vehicles. In classical toxicology testing, groups of 10-20 mice of both sexes are routinely used. In using the ODDS method (current protocol), we will reduce the number of animals to 6 per group, and use only males, thereby reducing animal numbers significantly.

V.3.5.3. Replacement It is not feasible to use non-animal systems in place of actual animal models to address the questions in this project. Rodents are considered sentient and hence rodents will be used for screening large number of potential radiation countermeasures.

V.4. Technical Methods
V.4.1. Pain / Distress Assessment
V.4.1.1. APHIS Form 7023 Information
V.4.1.1.1. Number of Animals 1162

V.4.1.1.1.1. Column C 0 (# of animals)

V.4.1.1.1.2. Column D 0 (# of animals)

V.4.1.1.1.3. Column E 1162 (# of animals). These mice will be either treated with drug or vehicle or irradiated and will not receive any intervention for pain relief. However, they will be euthanized if found moribund. The mice (#126, expt V.1.5) not receiving any radiation, will be under deep anesthesia for blood collection.

V.4.1.1.1.4. Pain Category Assignments: (Table 6)

Exp. #	Experimental/Control Group	C	D	E	Totals
V.1.1.	ODDS safety/toxicity study			78	78
V.1.2.	Radiation survival studies			160	160
V.1.3.	Optimization studies			384	384
V.1.4.	Dose reduction factor studies			288	288
V.1.5.	Hematology			252	252
Totals:				1162	1162

V.4.1.2. Pain Relief / Prevention. Animals can experience pain and distress. Minimizing and alleviating pain in laboratory animals without compromising the methodological integrity of a research project is important both ethically and legally. Mice often exhibit pain and distress with only subtle changes in their behavior [32]. Potential signs associated with pain and distress in mice includes decreased food and water consumption, weight loss, self-imposed isolation/hiding rapid breathing, opened-

Mouth Breathing, abdominal Breathing, decreased movement, abnormal posture, muscle rigidity, twitching, trembling, tremor etc as included in Appendix 1 (sample scoring sheet for clinical observations with criteria for rodent euthanasia) in IACUC policy#10. PI and her staffs are trained to assess the presence or absence of pain or distress in animal and score them appropriately.

V.4.1.2.1. Anesthesia / Analgesia / Tranquilization The protocol will not use anesthetics or analgesics during radiation since they will adversely affect the outcome of the experiments. The proposed study is to determine the effects of radiation and countermeasures on the function of the immune and blood forming systems. Use of any analgesics and anesthetics would interfere with the function of the immune system and therefore compromise the interpretation of the results [33]. Topical antibiotics will be applied if wounding occurs via in-cage fighting, under the guidance of the clinical veterinarian in accordance with standard treatment measures.

Anesthesia using standard Isoflurane apparatus under the guidance of the VSD will be carried out in mice for blood collection. All personnel will be extensively trained for efficient administration of the agents as well as to minimize handling stress.

Animals will be placed in the Isoflurane chamber and delivered a metered amount of 3-5% Isoflurane mixed with 100% oxygen until all voluntary motor movement ceases and the animal is recumbent for 10 seconds. Animal's respiration rate will be closely monitored through the Plexiglas chamber during induction of anesthesia. When animals are recumbent, they will be removed from the chamber and their nose/mouth placed in the anesthesia apparatus breathing/gas administration cone for maintenance of anesthesia at 1-3% Isoflurane and 100% O_2.

V.4.1.2.2. Pre- and Post-procedural Provisions Mice will be housed under standard conditions both before and after radiation procedures in accordance with current VSD rodent husbandry Standard Operating Procedures (see section V.5).

V.4.1.2.3. Paralytics: N/A

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures

There are no alternatives to irradiation. While radiation itself does not cause pain or distress, it induces a number of changes in the body that alters immune response and destroys hematological tissues, resulting in opportunistic infections, and multiorgan dysfunction leading to death. It is anticipated that animals exposed to high lethal radiation doses will become moribund. Unfortunately, literature clearly demonstrates that use of analgesics alters radiation response and therefore leads to increase in animal number for better statistical results or for iteration of entire experiments. Since the purpose here is to compare the efficacy of the three experimental drugs we will be unable to use analgesics and anesthetics because they may interfere with the innate system [33].

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification: Because exposure to irradiation is potentially lethal or causes debilitating effects in humans, it is ethically impermissible to test the effectiveness of radiation countermeasures on human volunteers. Irradiation compromises the immune and blood forming systems leading to mortality. The radiation-induced mortality and potential percentage increase of survivors over 30 days using potential radiation countermeasures are study endpoints for this protocol. Administration of drugs and analgesics is not an option since it is well documented that they interact with the immune system which will confuse the interpretation [34-36]. Pain relieving measures are not used because such measures may compromise the experimental integrity of the study. All moribund animals will be euthanized by overdose of CO_2 inhalation and cervical dislocation.

V.4.2. Prolonged Restraint : The experimental animals will receive radiation at a dose rate 0.6 Gy per/min in the AFRRI Cobalt 60 gamma radiation facility. Animals will be irradiated in Lucite boxes (8 animals/box) and arranged in an array (dosimetry 07/09/2014; or the latest dosimetry map) using plastic racks. Mice will be inserted into

the standard radiation boxes just prior to irradiation (~15 min of exposure time) and taken to the cobalt facility for irradiation. Animals will be restrained for no more than 60 min and returned to cages at the end of the irradiation period. They will be monitored daily following policy 10 (3-4 times a day during critical period with no more than 10 h interval between late night and morning check and at least twice a day during non-critical period) for 30 days and euthanized at the completion of the observational period.

V.4.3. Surgery: N/A
V.4.3.1. Pre-surgical Provisions: N/A

V.4.3.2. Procedure(s): N/A

V.4.3.3. Post-surgical Provisions: N/A

V.4.3.4. Location: N/A

V.4.3.5. Surgeon : N/A

V.4.3.6. Multiple Major Survival Operative Procedures: N/A

V.4.4. **Animal Manipulations:**
V.4.4.1 Ear punch: Three animals/group will be housed per shoe box during the toxicity study (section V.1.1.). They will be identified by ear punch (one animal will have a right punch, the second will have a left punch and the third will have no punch).

Procedure for ear-punch
a. Soak the ear punch (Fine Science Tools, Cat# 24212) in a disinfectant (100% ethanol) before use and between animals.
b. Place the device on the pinna of the ear (external ear) where the skin is thin avoiding the cartilage.
Press firmly to punch a circular hole through the ear

Tattoo procedure: VSD SOP will be used.

Irradiation: These will follow the standard AFRRI protocol with mice placed in restrainers shortly prior to exposure, irradiation at the cobalt facility and return to VSD for further monitoring. Briefly, the experimental animals will receive radiation at a dose rate of 0.6 Gy per/min in the AFRRI Cobalt 60 gamma radiation facility. Animals will be irradiated in Lucite boxes (8 animals/box) and arranged in an array (dosimetry 07/09/2014) using plastic racks. Animals will be restrained for no more than 60 min and returned to cages at the end of the irradiation period. They will be monitored daily following policy 10 (3-4 times a day during critical period with no more than 10 h interval between late night and morning check and at least twice a day during non-critical period) for 30 days and euthanized at the completion of the observational period. In case of non-lethal exposures, mice will be harvested at specific time-points after irradiation, and tissues collected after terminal blood draw.

Blood collection: Mice will be anesthetized as described under section V.4.1.2.1 (anesthesia). Blood draw for hematology is collected either by cardiac stick or from the inferior vena cava (IVC). The animals will be deeply anesthetized in the rodent anesthesia machine; the tail will be pinched for reflexive movement, indicative of insufficient anesthesia. If there is no response, the animal will be moved to the station with individual nose cone for continued anesthesia. An incision will be made on the right side below the abdomen of the animal, closest to the IVC, the vein exposed and blood drawn with a 1 ml syringe with 23 G needles. Similarly, cardiac stick will be performed on the animal positioned at the platform under anesthesia. An one ml syringe with 23 G needle will be inserted underneath the Xyphoid at a 45 degree angle towards the left side of the thoracic cavity into the heart and blood will be drawn. In both cases, the animals will be immediately euthanized on completion of blood draw by cervical dislocation.

V.4.4.2. Injections: Subcutaneous injections will be given with either a 23 or 25 G needle to the nape of the neck of 0.1 ml (maximum volume 1 ml for 25 to 38 g animals). A disposable sterile needle will be used for all *sc* injections. One needle will be used per cage containing generally 4 animals. Endotoxin testing for all drugs will be completed prior to any animal testing at AFRRI and a report submitted for IACUC/VSD review and approval. The endotoxin tests are conducted by Charles River Laboratories. At the same time, pH will be tested to ensure that it falls in the range (6-8 for sc administration) stipulated by IACUC. It is expected that the osmolarity will not be more than AFRRI IACUC's recommended levels (Policy#9).

V.4.4.1.1. Pharmaceutical Grade Drugs

V.4.4.1.2. Non-Pharmaceutical Grade Drugs

Research grade DT3, GT3, and (b)(4) formulations will be supplied by (b)(4) These (b)(4) (b)(4) and will be tested at AFRRI using the current protocol (using AFRRI intramural funds for animal studies). All formulations will be tested for endotoxin by Charles River Laboratory before using in the animals. pH and osmolality will be tested at AFRRI. Pure GT3 also will be supplied by (b)(4) and will be used as positive control (formulated in 5% Tween-80 at AFRRI) based on our previously published studies. We are not expecting any toxic effects in animals for any of the formulations. The following formulations will be supplied by (b)(4)

(b)(4)

V.4.4.2. Biosamples: N/A

V.4.4.3. Adjuvants: N/A

V.4.4.4. Monoclonal Antibody (MAb) Production : N/A

V.4.4.5. Animal Identification Generally, cage cards will be used to distinguish drug-treated and control groups. This will be a blinded study. Three drug groups will be designated as X, Y, and Z. Only vehicle group will be identified. Animals will be randomly distributed in groups. Some experiments might necessitate ear punch or notch or tattoos by personnel to identify individual animals in a cage. Ear punch will be performed as described in V.4.4.1.

V.4.4.6. Behavioral Studies: N/A

V.4.4.7. Other Procedures: N/A

V.4.4.8. Tissue Sharing All tissues from the animals used in toxicity study will be preserved for histopathological analysis by the VSD pathologist. The pluck method will be used to harvest all the organs from tongue to rectum, brain, sternum, femur and blood may be collected at euthanasia. Tissue from irradiated mice (brain, GI, spleen, lung, liver, kidney) will be collected for histopathology at intervals.

V.4.4.9. Animal By-Products: N/A

V.4.5. Study Endpoint: The time frame for experiment V.1.1 (basic toxicity) will be 14 and 30 days after final drug dose administration.
The radiation survival studies will span 30 days after radiation exposure (experiments V.1.2, V.1.3. and V.1.4.). Serial sampling by terminal procedures is projected on 7 different time points after drug or irradiation for experiment V.1.5.
It is anticipated that the animals involved in these studies may succumb to death either due to a drug administration or radiation or a combination of the two. To maintain a suitable baseline for humane treatment of the animals while adhering to the study objective, the IACUC recommendations stipulated in Policy Letter #10 with some minor modification (as stated later in the paragraph) will be implemented for judging morbidity and moribundity. The moribund condition is defined as a clinically irreversible condition leading inevitably to death. Signs of morbidity in the mouse include difficulty in breathing, ruffling of hair, drying of lacrimal fluid, fall in body temperature, loss of appetite with/without diarrhea. A modified IACUC policy #10 will be used to record the scoring of clinical signs of pain in animals (attached Appendix 1). PI would like to modify the "Increased breathing" to "Changes in breathing" under "Respiratory rate" and change the score as 3 as used in the ongoing NIAID screening protocol P#(b)(6) Body weights are not included since there is no clear correlation between body weight loss and mortality. The objective of the present protocol is to compare the radioprotective efficacy of(b)(4) with GT3 in Tween-80 studied previously at AFRRI for last 8 years in five protocols(b)(6) (b)(6) . The PI is concerned that if the morbidity scoring, particularly weight loss scoring (which was not used in previous experiments) in combination with other morbidity criteria will lead to increased euthanasia and hence potentially affect the outcome of the results.(b)(4)

(b)(4) [redacted] Further, other radiation researchers do not use body weight loss as a mortality criterion [37]. However, body weights will be recoded and action for humane endpoints will be taken as follows (please see attached modified score sheet):
a) Body weights will be recorded prior to radiation.
b) Once animals reach a score of 6, weights will be recorded and monitored with each subsequent scoring change.
c) Animals who exceed 35% body weight loss with any other clinical signs are scored at a 12 and will be euthanized immediately.
To adhere to the policy of preventing animal distress, the PI will facilitate the late PM and early AM checks (not more than 10 h apart) in addition to two times a day checks during the critical lethality period (early morning, late morning, and late afternoon and evening). During non-critical periods, we will continue to check animals except late night. All morbid mice will be monitored carefully and their conditions scored for documentation (Appendix 1, revised scoring sheet).
PI will use a scoring card for each animal in the critical period and scored in each observation. Scores below 6 will not be recorded in the scoring sheet. Mice will be euthanized if there is a score of 12 in a single category or a cumulative score of 12 in multiple categories.

No supportive care is proposed, however, moribund animals will be immediately euthanized. VSD veterinarians will be consulted for all matters regarding the animal welfare.

V.4.6. Euthanasia
It is anticipated that at high radiation doses, animals will demonstrate varying degrees of morbidity and moribund, which makes it critical to define the criteria for euthanizing the animals without undermining the study objective.
In toxicity studies, if any animal shows discomfort (hunching, decreased activity, inappetence, separation from cage-mates), that animal will be under careful observation on consultation with the attending VSD veterinarian. Mice found moribund (defined in V.4.5.) or meeting the criteria for euthanasia following IAUC poloicy#10 (score sheet attached) will be euthanized by CO_2 inhalation plus confirmatory cervical dislocation by investigator/technician according to the directives of the VSD-SOP and in accordance with current AVMA Guidelines on Euthanasia [38, 39]. At the conclusion of the experimental time frame, all animals that survived the procedures of irradiation, drug intervention and controls, will be euthanized by CO_2 inhalation plus confirmatory cervical dislocation and their carcasses disposed of according to VSD regulations. An alternate method of euthanasia by cervical dislocation after exsanguination (by cardiac stick or inferior vena cava) under Isoflurane will be applied in experiment V.1.5.

V.5. Veterinary Care
V.5.1. Husbandry Considerations The AFRRI vivarium follows stringent protocols for the housing and care of all animals. The PI and designated team members will adhere to all the policy and guidelines set forth by standard operating protocols of the VSD.

The specific requirements for mice housing should meet the following criteria of opportunity for social interaction, opportunity to carry out normal behavior and the opportunity to rest and withdraw from each other [40]. Mice are social animals and hence will be caged together in groups of 4 or 8. For ODDS testing, mice will be housed in groups of 3 or 5 mice per cage and identified individually as described. Nestling pads will be provided in each cage during bedding changes. In cage shelters will also be provided as an enrichment strategy at the discretion of the PI depending on experimental conditions. Animals will receive Harlan Teklad Rodent Diet (w) 8604 and water *ad libitum*. Acidified water (pH 2.5 – 3.0) is routinely provided to AFRRI mice used in radiological experiments. Cages will be regularly changed and cleaned by VSD staff in accordance with Standard Operating Procedure. Animals will have 12 h light/dark cycle. Animals will be habituated to their surroundings and routine procedures prior to experimentation. In the event of procedures that last into the night cycle, care will be taken to minimize exposure to light.

V.5.1.1. Study Room As assigned by VSD

V.5.1.2. Special Husbandry Provisions N/A

V.5.1.3. Exceptions Mice will be socially (group) housed as described above, except when there is a possibility that during survival studies cage mates may be lost through attrition and for a period of time the sole surviving mouse may remain singly housed until the end of the 30-day study.

V.5.2. Veterinary Medical Care We do not project routine veterinary medical care of animals for injuries/inflammation related to injection site inflammation. In case of minor injuries arising from fighting, topical application of antibiotics is acceptable with consensus from the PI and VSD

.

V.5.2.1. Routine Veterinary Medical Care Experimental animals will be observed daily by either the investigator or technician or both. VSD personnel will monitor all animals during their routine rounds as per VSD SOPs. In the course of the study, as animals approach morbidity, the research staff observations will be increased to a minimum of at least three times a day, early morning and late afternoon (includes weekends and holidays). The timing between the late evening and early morning check will not exceed ten hours during the critical period. There is no supportive therapy contemplated since this would compromise the experimental results (described earlier in the end point and pain category sections).

V.5.2.2. Emergency Veterinary Medical Care. Moribund animals (gasping, recumbent, non-responsive to mild stimulus) will be euthanized by trained personnel.

V.5.3. Environmental Enrichment: As provided by the husbandry staff to animals not on active experiments.

V.5.3.1. Enrichment Strategy Nestling pads will be provided in each cage during bedding changes as per AFRRI-VSD SOPs.

V.5.3.2. Enrichment Restrictions

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING (Table 10)

NAME	DEGREE	TRAINING	DATE	PROCEDURES	YRS/MOS EXPERIENCE
(b)(6)				1, 3, 4b, 5	(b)(6)
				1, 3, 4b, 5	
				1, 3, 4b, 5	
				1, 3, 4b, 5	
				1, 3, 4b, 5	
				1, 3, 4b, 5	
				1, 3, 4b, 5	
				1, 3, 4a, 5	

Procedure and manipulation codes:
Code 1 = Animal handling and euthanasia
Code 2 = Surgery (aseptic technique) pre- and post-operative care
Code 3 = Injections (3a–*ip*, 3b-*sc*, 3c-gavage) - can say 3 if trained in all manipulations or add 3d-*iv*
Code 4 = Blood collection under anesthesia (4a-cardiac, 4b-posterior vena cava)
Code 5 = Tissue collection (after euthanasia) - doesn't need to be specific
Code 6 = Implantation (provide details)
Code 7 = Others - (provide protocol specific manipulations or procedures for e.g., retro-orbital bleeding, tail vein injection, or drug delivery)
*Trained in retro-orbital injection, tail vein injection and tumor implantation.

VII. BIOHAZARDS/SAFETY All personnel working in the protocol have undergone necessary training in handling experimental animals. The amount of drug used will be small and standard safety precautions will be taken while handling them in the laboratory and in the vivarium. All personnel listed in the present protocol have been trained as general radiation users on a regular basis. All investigators and personnel will use appropriate protective gear while in the vivarium as described by the VSD. All listed personnel are current in safety training and medical surveillance.

X. ASSURANCES

Protocol Title: Radiation Countermeasure Screening for Protection and Mitigation in the lab Mouse, *Mus musculus*.

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made every effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with a qualified individual who evaluated the experimental design with respect to the statistical analysis, and that the minimum number of animals needed for scientific validity will be used.

D. Biohazard / Safety: I have taken into consideration and made the proper coordination regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R", namely, "Responsibility," which the DOD has embraced for implementing animal use alternatives where feasible and conducting humane and lawful research.

G. Scientific Review: This proposed animal use protocol has received appropriate peer scientific review and is consistent with good scientific research practice.

H. Painful Procedure(s): **I AM** / **AM NOT** conducting biomedical experiments, which may potentially cause more than momentary or slight pain or distress to animals. If applicable, potential pain and/or distress **WILL** / **WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

Appendix 1.
Clinical Observations with Criteria for Euthanasia (Rodent)

Criteria:	Description:	Score
Appearance:		
	Normal (smooth coat, clear eyes/nose)	0
	Hunched and/or fluffed	1
	Ocular discharge, and/or edema	3
	Soft stools (fecal matter around anus)	5
	Pale, white mucus membranes/skin	6
	Bloody diarrhea	9
	Blue mucus membranes/skin (cyanosis)*	12
Respiratory Rate:		
	Normal breathing	0
	Change in breathing (an increase or decrease in respiratory rate from normal baseline)	3
	Abdominal breathing (gasping +/- open mouth breathing)*	12
General Behavior:		
	Normal (based on baseline observations)	0
	Stretching of hind limbs with abdominal motion (writhe) or grimace (App. B and C)	1
	Decreased mobility	2
	Ataxia, wobbly, weak	6
	Inability to stand*	12
Provoked Behavior:		
	Normal (moves when cage is disturbed, runs from hand (mice) or investigates (rat))	0
	Subdued; responds to stimulation (moves away briskly)	1
	Subdued even to stimulation (moves away slowly)	3
	Unresponsive to gentle prodding	6
	Does not right when placed gently on side within 5 seconds*	12
Weight loss		
	0-35% with no other clinical signs	0
	≥35% weight loss	12

*** Regardless of score, immediately euthanize (death is imminent)**

Individual or Cumulative Score:

< 6	Normal
6 - 11	Morbid: See VI.D.2 and VI.D.4 in IACUC Policy #10 for guidelines
≥ 12	Moribund: Notify responsible personnel immediately for euthanasia (if no single criteria is 12*). Any single criteria of 12* euthanize immediately; consider as 'found dead.'

DOD ANIMAL CARE AND USE STANDARDIZED PROTOCOL FORMAT WITH EMBEDDED INSTRUCTIONS (April 2015)

Reference DOD Instruction 3216.01 & AFRRI Instruction 3216.2H

****

Information requested in the following animal use protocol template reflects the requirements of the Animal Welfare Act Regulations (AWAR), the Guide for the Care and Use of Laboratory Animals, and other applicable Federal regulations and DOD instructions.

****

This document is intended to be an aid in the preparation of DOD-sponsored animal use protocols. It is a companion document to an identical protocol template that does not have embedded instructions. Either template may be used to format DOD-sponsored animal research proposals; however, reference to the instructions during protocol preparation is highly recommended. If using the template with instructions, the instructions should be deleted prior to submitting the finished protocol for IACUC review. Please use Arial, regular, size 12, black font to prepare the protocol. With the exception of section headings, all paragraphs require a response. Paragraphs that do not apply should be marked N/A. There is no space limitation for responses to the information requested.

Approved standard operating procedures (SOPs) promulgated by the AFRRI Veterinary Sciences Department (VSD) or similar VSD-validated documents that describe specific procedures may be referenced by SOP number and title in lieu of repeating the details in the protocol. However, it is essential to include general descriptions of all animal manipulations to be carried out under the IACUC-approved protocol and to provide details where no approved references are cited. To do otherwise would constitute a breach of statutory regulations. Manipulations not covered in the originally approved protocol can be initiated only after IACUC approval of a formal amendment adding the new procedures. Additionally, Principal Investigators (PIs), or other delegated research personnel, should maintain accurate experimental records and be able to provide an audit trail of animal expenditures and use that correlates with their approved protocol. Protocol PIs will be required to provide this and other information during annual protocol reviews.

Any supporting information that may be of use to the IACUC during its review may be attached to the completed protocol. Adding subparagraphs within the body of the protocol template is permissible, *provided that the numbering sequence of paragraphs in the original standard format is maintained.* In other words, all of the labeled paragraphs and subparagraphs in this template must be retained, with additional information being presented as sub-numbered paragraphs containing information that supports or complements what is requested.

INTELLECTUAL PROPERTY STATEMENT

Research protocols drafted by Government scientists include intellectual property (e.g., concepts, ideas, experimental approaches, etc.), some of which is innovative or original and therefore considered proprietary to the investigators and/or the sponsoring agency. All Government and non-Government personnel handling this protocol shall exercise EXTREME CARE, to ensure that the information contained herein is NOT DUPLICATED OR DISCLOSED, in whole or part, for any purpose other than to evaluate the protocol, without the written permission of the principal investigator or the sponsoring agency.

AFRRI SCIENTIFIC RESEARCH PROTOCOL NUMBER: (b)(6)

I. NON-TECHNICAL SYNOPSIS Ionizing radiation exposure presents an increasing threat to the global population. Therefore, it is critical that we develop drugs against ionizing radiation. One of the AFRRI missions is to develop radiation countermeasures to shield first responders, military personnel and civilians who are exposed to high amounts of radiation. Over the past few years, several promising drugs from AFRRI have already been advanced to Investigation New Drug (IND) status. We have extensively evaluated Gamma tocotrienol (GT3), a vitamin E isomer, in mice previously at AFRRI for last 8 years in five protocols (P# (b)(6) (b)(6) .Another drug of interest is (b)(4) (currently active in (b)(6) , a modified cytokine that acts as a growth factor for regenerating bone marrow after exposure to ionizing radiation. This drug has advanced to the clinic (successful phase 1 trials) and is promising against both low linear energy transfer (LET), as represented by Cobalt-60 γ-radiation, and high LET mixed-field radiation (neutron and gamma from AFRRI reactor). In recent years, micro Ribonucleic acids (miRNAs) have been implicated in cellular differentiation, carcinogenesis, and modulation of signaling pathways. Thus, to characterize the underlying mechanism of radioprotection, we studied the miRNA profile in spleen from irradiated mice with or without GT3 treatment. Our studies indicate that several miRNAs are differentially regulated in mice spleen after radiation exposure. Specifically, miR-34a is significantly increased (15-fold on day 15) in spleen after 8 Gy exposure. We have also shown that a single dose of GT3 administration 24 h prior to irradiation suppresses miR-34a expression. Therefore, we propose to extend our preliminary observations to blood, bone marrow, kidney, thymus, and liver. Network analysis in molecular biology can predict signaling pathways, molecular networks, and biological functions for genes. Such analysis of our preliminary data suggests that ERK and p38MAPK pathways may play a significant role in the mechanism of radioprotection. We will use CD2F1 male mice as *in vivo* models to study this signaling pathway. Our broad objective is to understand radiation-induced damage regulation by GT3 and (b)(4) modulated miRNAs. The study will involve: **a.** Confirmation of the effect of GT3 on ERK/p38MAPK in spleen, bone marrow, kidney, thymus, and liver and **b.** Evaluation of signaling pathways of the promising (b)(4) radiation countermeasure.

II. BACKGROUND

II.1. Background Ionizing radiation exposure presents an increasing threat to the global population. Therefore, it is critical that we develop drugs against ionizing radiation. One of the AFRRI missions is to develop radiation countermeasures to shield first responders, military personnel and civilians who are exposed to high amounts of radiation. Over the past few years, several promising drugs from AFRRI have already been advanced to Investigation New Drug (IND) status (b)(4) We have extensively evaluated Gamma tocotrienol (GT3), a vitamin E isomer, in mice. Another drug of interest is (b)(4) (b)(4) after exposure to ionizing radiation (b)(4) This drug has advanced to the clinic (successful phase 1 trials) and is promising against both low linear energy transfer (LET), as represented by Cobalt-60 γ-radiation, and high LET mixed-field radiation (neutron and gamma from AFRRI reactor). To meet the Food and Drug Administration's (FDA) animal rule for radiation countermeasures, it is essential to carry out studies to understand the mechanisms of radiation protection.

Survival from radiation lethality by GT3 and possible mechanism

We reported that gamma-tocotrienol, a naturally occurring vitamin E analog, protects mice from radiation-induced pancytopenia, restores bone marrow progenitor cells (b)(4) reduces intestinal and vascular oxidative stress, and protects 100% mice exposed to lethal dose of whole body γ-radiation (b)(4) CD2F1 mice treated with GT3 showed increased numbers of spleen colonies compared to vehicle treated animals at 12 days after 8.5 Gy of γ-radiation (b)(4) GT3 reduces radiation-induced vascular oxidative stress in mice through an HMG-CoA reductase dependent manner post-radiation treatment [4]. GT3 may exert its beneficial inhibitory effects on post-irradiation free-radical production by improving the availability of the endothelial nitric oxide synthase (eNOS) cofactor BH4 through downregulation of GTP-cyclohydrolase 1 regulatory protein (GFRP), thereby enhancing the production of NO (nitric oxide) and reducing the production of ONOO- (peroxynitrite) by eNOS [5]. GT3 has also been shown to improve the post-irradiation recovery of plasma markers of endothelial function, an effect that is not dependent on HMG-CoA reductase inhibition [5]. However, the signaling pathway through which GT3 protects mice from hematopoietic damage is not known. We propose here to study the molecular pathways involved in radioprotection by GT3.

Survival from radiation lethality by (b)(4) and possible mechanism

Recently a preliminary study by an (b)(4) (b)(4) (b)(4) in the CD2F1 mouse model when administered sc 24 before or 4 h after exposure to Co-60 γ-radiation. (b)(4) (800 μg/kg) demonstrated 100 % survival administered 24 h before total-body irradiation to CD2F1 mice and protected ~50% of the animals when administered 4 h after radiation. In another preliminary study an (b)(4) (b)(4) demonstrated ~80-100% survival in mice administered 4 h or 4 h and 48 h after mixed-field (65% neutron and 35% gamma) radiation. Based on this novel finding, (b)(4) approved funding to develop

this drug for mixed-field radiation, which has been accepted as a more realistic scenario for a nuclear accident or terrorist activity using an enhanced radiation weapon (ERW). In a preliminary study, (b)(4) mice from radiation-induced neutropenia and thrombocytopenia, and bone marrow cellularity after exposure to total-body radiation. However, the mechanism of radioprotection by (b)(4) (b)(4) is unknown. Previously authors have demonstrated that (b)(4) (b)(4)

Since GT3 and (b)(4) were found to be promising radiation countermeasures in mice models exposed to γ-radiation (preliminary studies), it is essential to understand the mechanism of action of these drugs according to Food and Drug Administration's (FDA) animal guidelines for the Investigational New Drug (IND) application process. This project will provide valuable information on microRNA and mRNA regulation by GT3 and (b)(4) in protecting mice from hematopoietic damage after radiation.

II.2. Literature Search for Duplication

II.2.1. Literature Sources Searched

To find any possibility for duplication, the following databases have been searched:
PubMed
BRD - Biomedical Research Database
Reporter (CRISP) - Computer Retrieval of Information on Scientific Projects, now known as 'Reporter'

II.2.2. Date of Search PubMed – 06/12/2015
BRD - 06/12/2015
Reporter (CRISP) - 06/12/2015

II.2.3. Period of Search

PubMed – 1960-2015
BRD – 1998-2015
Reporter (CRISP) – 1972-2015

II.2.4. Key Words of Search

1. Micro RNA AND Radiation
2. Gamma-tocotrienol AND micro RNA
3. (b)(4) AND micro RNA
4. Gamma-tocotrienol AND Radiation
5. (b)(4) AND Radiation

II.2.5. Results of Search

Table 1 includes a summary of the keywords and keyword combinations used for searching the RePORTer, BRD, and PubMed databases.

Table 1. Summary of Database Keyword Searches

Keywords	PubMed	BRD	RePORTer
Micro RNA AND radiation	852	1312	154
Gamma-tocotrienol AND micro RNA	1	2	1

(b)(4) AND micro RNA	0	0	0
Gamma-tocotrienol AND Radiation	32	83	399
(b)(4) And Radiation	0	20	0

The searches indicated that there have been no previous or current studies have been done on the role of microRNA in the regulation of DNA damage after radiation injury. Therefore, the proposed study to determine the mechanism of radioprotection by (b)(4) (b)(4) or GT3 and the role of microRNA in regulating DNA damage in mouse after whole body radiation is not a duplication of a previous experiment. While there were some hits, the studies were not relevant to the mechanism of radiation protection involving microRNA and GT3 or (b)(4)

III. OBJECTIVE / HYPOTHESIS The overall objective of this study is to decipher the molecular pathways involved in the protection from radiation-induced hematopoietic failure by two promising radiation countermeasures, Gamma tocotrienol (GT3) and (b)(4)

Specific Aim 1: Determine radiation-induced differential mRNA expression modulated by GT3 and confirm activation of ERK/p38MAPK signaling by GT3 in mice exposed to Cobalt-60 γ-radiation

In a preliminary study, we have shown that miR-34a, miR-15b, miR-150, miR-99a, miR-99b, miR-130, miR-143, and miR-145 were differentially regulated post-irradiation from day 1 to day 14 in spleen of GT3 treated mice compared to vehicle treated ones. Ingenuity pathway analysis (IPA) with these miRNAs identified predicted mRNAs and target signaling pathways of GT3 through ERK/p38MAPK. We propose to identify radiation induced mRNA targets that are regulated by GT3, and confirm the predicted target pathway of action of GT3 using pathway analysis. Mice will be treated with GT3 and total-body irradiated (TBI) to a sublethal dose of 7 Gy and spleen, bone marrow and blood will be harvested after irradiation. Whole genome expression will be done using the Illumina BeadChip array.

Specific Aim 2: Identify the signaling pathways modulated by (b)(4) through differential regulation of miRNAs and target mRNAs in irradiated mice

We hypothesize that mice exposed to a sublethal dose of TBI will produce a time-dependent differential expression of miRNAs during hematopoietic recovery, and pre-treatment with (b)(4) will significantly modulate these genes to rescue mice from radiation injury. Preliminary studies show that (b)(4) was found to be an effective radiation countermeasure administered before or after radiation, protecting mice from radiation-induced pancytopenia and lethality. MiRNA and mRNA analysis will be done in circulating blood, as well as in bone marrow and spleen. This data will determine the role of miRNAs in (b)(4) irradiated tissues and organs. To further understand the signaling pathway involved in the mechanism of action of (b)(4) we will identify and validate the predicted signaling targets of the (b)(4) regulated miRNAs.

This project will deliver a systematic approach to identifying signaling targets of radiation countermeasures using the complex network interactions of radiation induced mRNA and miRNA.

IV. MILITARY RELEVANCE Military operations are seriously impaired by radiation exposures depending on the dose and dose rate. Currently, there is no FDA approved preventive measure available for military personnel to protect them from the hazards of radiation exposure. The problem is more acute in recent times due to the unpredictable nature of terrorist attacks. Recognizing this urgent need, United States Department of Defense has assigned top priority in "Defense Technology Objectives (DTO)" to the "development of medical countermeasures to radiation exposure" against both early effects and late arising health effects. These concerns address the urgent need to develop an appropriate radiation protective agent (prophylactic or therapeutic) to sustain immediate warfighter capabilities and to enable the commanders to make judicious decisions in troop deployment. Currently, there are several drugs at various stages of development. This study will focus on revealing the mechanism of action of a prophylactic radiation countermeasure, gamma tocotrienol (GT3) and (b)(4) (b)(4)

V. MATERIALS AND METHODS

V.1. Experimental Design and General Procedures

General Experimental Design for animal studies: **Experiments 1 and 2:** Ten to twelve weeks old male CD2F1 mice (Harlan Labs, Indianapolis, Indiana) will be used in this experiment. GT3 will be supplied by (b)(4) (b)(4)

Mice will be injected subcutaneously (see section V.4.4.1) with either vehicle (5% Tween-80 for GT3 or PBS for (b)(4) or GT3 (100 mg/kg) or (b)(4) (400 µg/kg) administered 24 h before exposure to Co-60 radiation (0.6 Gy/min). Mice will be irradiated to 7 Gy resulted in the hematopoietic syndrome where measurable numbers of blood elements are desired throughout the experiment. Animals will be euthanized (see section V.4.5 and 6) from each experimental group on days 1, 4, 7, 14, and 21 and blood will be collected from anesthetized mice while they are alive from the inferior vena cava in serum separator tubes (see section V.4.4). Serum will be separated and stored at -80C. Bone marrow will be harvested following a standard protocol [3]. Spleen and other tissues (kidney, liver, and thymus) will be collected and snap frozen for storage at -80C. Both the drugs have been tested for 30-day survival in various protocols at AFRRI. There was no reaction observed at the injection site for the doses proposed in this protocol.

Table 2. Experimental design

Groups	Drug	Collection days	Radiation dose (Gy)	No. of mice/day	Total no. of mice
1	0 (naïve control)	1,4,7,14,21	0	5	25
2	PBS/GT3 veh	1,4,7,14,21	0	5	50

3	(b)(4) GT3	1,4,7,14,21	0	5	50
4	PBS/GT3 veh	1,4,7,14,21	7	5	50
5	(b)(4) GT3	1,4,7,14,21	7	5	50

We will repeat the study to confirm the data. Total no. of mice that will be used in this proposed study = 450. Tissues from naïve control animals will be shared between the two experiments.

V.1.1. Experiment 1. ***Determine radiation-induced differential mRNA expressions modulated by GT3 and confirm activation of ERK/p38MAPK/p53 signaling by GT3 in mice exposed to Cobalt-60 γ-radiation***

Total RNA will be extracted from blood, bone marrow and spleen collected at days 1, 4, 7, 14, and 21 post-radiation by a standard protocol (miRVana isolation kit, Ambion). Whole genome expression will be determined using Illumina Beadarray (MouseRef-8 version 2.0) BeadChips using the iscan system and BeadScan software, Illumina, San Diego) [7]. Data will be validated using RT-PCR and western blot analyses.

A total of 250 mice will be used for this experiment.
Groups = 5 (Naïve, 0 Gy Veh, 0 Gy GT3, 7 Gy Veh, 7 Gy GT3)
No. of time points = 5
No. of animals per group = 5
No. of repeat = 2

V.1.2. Experiment 2. Identify the signaling pathways modulated by (b)(4) through differential regulation of miRNAs and target mRNAs in irradiated mice

Total RNA will be extracted from blood, bone marrow and spleen collected at days 1, 4, 7, 14, and 21 post-radiation. RNA will be extracted using mirVana total RNA isolation kits (Life Technologies) following the manufacturer's protocol. Microarray hybridization and data analyses will be performed by a commercial service provider, LC Sciences in Houston, TX (www.lcsciences.com) and miRbase version 19.0 (http://mirbase.org/) will be used to study the expression profiling of 1265 unique mature mouse miRNAs using a µParaflo® microfluidic technology [8, 9]. Data will be analyzed and computed by first subtracting the background and then normalizing the signals using a LOWESS filter (Locally-weighted Regression methods) [10] by LC Sciences, Houston TX. Array will be performed only using spleen RNA. Data will be validated using RT-PCR and western blot analysis.

A total of 200 mice will be used for this experiment.
Groups = 5 (0 Gy Veh, 0 Gy CDX-301, 7 Gy Veh, 7 Gy (b)(4)
No. of time points = 5
No. of animals per group = 5
No. of repeat = 2

A grand total of 450 animals will be used in this study.

Rationale for selecting the time of collecting spleen after radiation: Our published data demonstrate that regeneration of bone marrow progenitor cells starts after day 4 post-irradiation and the cells are recovered by day 13 (100%) with GT3 compared to vehicle (40%) (b)(4) Peripheral blood cells recovery was observed by day 21 after

radiation for both GT3 and (b)(4) Therefore, we chose five time points, days 1, 4, 7, 14, and 21 post-irradiation to study the miRNA regulations after radiation and its modulation by GT3 or (b)(4) during hematopoietic injury and consequent recovery.

Rationale of selecting sublethal dose (7 Gy): LD50/30 (lethal dose of radiation that results in the lethality of 50% of the exposed animals in 30 days) of CD2F1 mice that will be used in this study is 8.6 Gy (b)(4) A sublethal dose of 7 Gy will be used in order to keep the mice alive in vehicle-treated group to collect samples on specific time points after irradiation. These samples will be compared to the samples collected from either (b)(4) or GT3 treated mice.

V.2. Data Analysis

Statistical software PC SAS will be used for statistical data analysis. Ten animals per group will be used to provide statistical power >90% for two-tailed student's T-Test. We will report the mean with standard error or percentage when applicable. ANOVA (Analyses of Variance) with mixed-effect model will be used when testing one dependent variable and Multivariate analysis of variance (MANOVA) will be used when testing more than one dependent variable to detect if there is significant difference among the groups.

V.3. Laboratory Animals Required and Justification

V.3.1. Non-animal Alternatives Considered Our ultimate goal is to find a suitable radioprotectant for human use. We have already established that GT3 can be good prophylactic radiation countermeasures in male CD2F1 mice, protecting both the hematopoietic and GI systems from radiation injury. (b)(4) was also found to protect mice from lethal dose of radiation and protect mice from hematopoietic damage. To advance the drug to clinical trial, we have to understand the mechanism of action of these radiation countermeasures. For this purpose, we want to know the role of microRNA in regulating DNA damage after radiation injury. For that purpose we have to use an animal model as proof-of-concept.

V.3.2. Animal Model and Species Justification As discussed in the previous section, animals must be used to study the mechanism of action of a radioprotectant *in vivo*. Mouse model will be used as a proof-of-concept because approximately 99% of human DNA is similar to that of mice, and mouse models are well characterized to study the mechanism of action of a radioprotectant (b)(4) Zebrafish and Drosophila is not considered for this study because their physiology is largely different from mammalian systems.

V.3.3. Laboratory Animals

V.3.3.1. Genus / Species Mus musculus

V.3.3.2. Strain / Stock CD2F1

V.3.3.3. Source / Vendor Harlan Labs, Indianapolis, Indiana or similar approved vendors (Ph# 800-793-7287)

V.3.3.4. Age 7 - 8 wks old

V.3.3.5. Weight 22-30 g

V.3.3.6. Sex Male
Justification of using only male mice: Previous studies have been conducted with male mice, so male mice are needed for data comparison. Although, it is important to confirm observations in females, such studies may be carried out at a later date.

V.3.3.7. Special Considerations Commercially procured animals must be adventitious, disease free, and pathogen-free—including *Pseudomonas aeruginosa,* and *Pasteurella.* All mice need to be free of the following agents: Sendai, Pneumonia Virus of Mice (PVM), Reovirus-3 (Reo 3), Mouse Adenovirus (MAD-1, MAD-2), Mouse Cytomegalovirus Virus (MCMV), Ectromelia, K virus, Lymphocytic Choriomeningitis Virus (LCM), Epidemic Diarrhea of Infant Mice (EDIM), Hantan virus, Rotavirus, Mouse Parvovirus (MPV), Polyoma Virus, Mouse Minute Virus (MMV), Mouse Thymic Virus (MTV), Theiler's Mouse Encephalomyelitis Virus (TMEV/GDVII), *Encephalitozoon cuniculi*, CAR bacillus, *Mycoplasma pulmonis*, and *Clostridium piliforme.* They must also be endoparasite and ectoparasite-free.

V.3.4. Number of Animals Required (by species)

V.3.5. Refinement, Reduction, Replacement (3 R's)
V.3.5.1. Refinement PI will take necessary steps to all personnel in the project to be rigorously trained in handling techniques (injections, and routine cage monitoring) to minimize distress and pain to the animals. Specifically, during capture and restraint of the rodents before and after radiation, care will be taken to ensure that handling does not contribute to distress.
Animals will be irradiated at a sublethal dose of 7 Gy. We do not expect to see morbidity in the course of the study. However, for any reason, if we observe morbid animals, we will increase monitoring and euthanize animals following policy 10 at early time points.

V.3.5.2. Reduction Previously published and unpublished data have established which radiation dose and time points are important to get the information for hematopoietic regeneration after radiation injury. This information has enabled us to reduce the number of animals needed for this study. We are also reducing the animal numbers (n = 10) by sharing tissues for determining different parameters from the same experiment. Based on our previous experiments, we will use the minimum required number of animals for statistical validity. This will reduce the number of animals used in this protocol.

V.3.5.3. Replacement None

V.4. Technical Methods

V.4.1. Pain / Distress Assessment

Expt 2	0 Gy Veh, 0 Gy (b)(4) 7 Gy Veh, 7 Gy (b)(4)	0	0	200	200
Totals:			50	400	450

V.4.1.2. Pain Relief / Prevention

V.4.1.2.1. Anesthesia / Analgesia / Tranquilization The protocol will not use anesthetics or analgesics during radiation since they will adversely affect the outcome of the experiments. The proposed study is to determine the effects of irradiation and countermeasures on the function of the immune and blood forming systems. Use of any analgesics and anesthetics would interfere with the function of the immune system and therefore compromise the interpretation of the results [10]. Topical antibiotics will be applied if wounding occurs via in-cage fighting, under the guidance of the clinical veterinarian in accordance with standard treatment measures.

Anesthesia using standard Isoflurane apparatus under the guidance of the VSD will be carried out in mice for blood collection. All personnel will be extensively trained for efficient administration of the agents as well as to minimize handling stress. Animals will be placed in the Isoflurane chamber and delivered a metered amount of 3-5% Isoflurane mixed with 100% oxygen until all voluntary motor movement ceases and the animal is recumbent for 10 seconds. Animal's respiration rate will be closely monitored through the Plexiglas chamber during induction of anesthesia. When animals are recumbent, they will be removed from the chamber and their nose/mouth placed in the anesthesia apparatus breathing/gas administration cone for maintenance of anesthesia at 1-3% Isoflurane and 100% O_2.

V.4.1.2.2. Pre- and Post-procedural Provisions Mice will be housed under standard conditions both before and after radiation procedures in accordance with current VSD rodent husbandry Standard Operating Procedures (see section V.5).

V.4.1.2.3. Paralytics No paralytic agents will be administered

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures

V.4.1.3.3. Period of Search
1970-2015

V.4.1.3.4. Key Words of Search
Pain, analgesia, anesthesia, radiation, radioprotection, mouse, humane, alternative, gamma-tocotrienol, (b)(4)

V.4.1.3.5. Results of Search
We are studying the mechanism of radioprotection of (b)(4) and GT3 in this protocol. We will be using a subletha**l** dose 7 Gy in this study based on results from our previous studies. Irradiation itself is not a painful process but it induces various changes in the body (i.e., vomiting and nausea, changes in hematology cells numbers, etc.). Although radiation does not induce pain, animals in these experiments might experience pain and distress prior to death because of sequelae. Radiation compromises the immune system. As a result of a compromised immune response, various types of infections can initiate and become painful. Table 3 includes a summary of the keyword combinations used for searching and the results of the search. While the literature indicates that cell models have been used to study radiation damage, such models cannot alone predict mechanism of radioprotection of a specific drug. Although radiation-induced pain was alleviated during some studies [11-13], such pain relief was the aim of the studies in question, which focused on patients receiving radiotherapy for cancer treatment. We do not have the option of using alternatives such as a cell culture model. If animals show sign of pain or distress (please see section V.4.1), all moribund animals will be euthanized immediately to minimize potential pain or distress following policy#10.

Table 3. Summary of Database Keyword Searches

Radioprotection AND pain	0	0	154
Radiation AND humane	1	38	12
Pain AND analgesia AND mice	49	26	1904
Radiation AND mouse AND pain	0	9	239
Radiation AND mouse AND pain AND alternative	0	9	6

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification Since the purpose of these studies is to determine the mechanism of radioprotection of the immune system by (b)(4) or GT3, we will be unable to use analgesics and anesthetics because they may interfere with the innate system [14].

V.4.2. Prolonged Restraint
The experimental animals will receive radiation at a dose rate 0.6 Gy per/min in the AFRRI Cobalt 60 gamma radiation facility. Animals will be irradiated in Lucite boxes (8 animals/box) and arranged in an array (dosimetry 07/09/2014; or the latest dosimetry map) using plastic racks. Mice will be inserted into the standard radiation boxes just prior to irradiation (~15 min of exposure time) and taken to the cobalt facility for irradiation. Animals will be restrained for no more than 60 min and returned to cages at the end of the irradiation period.

V.4.4. Animal Manipulations

Irradiation: These will follow the standard AFRRI protocol with mice placed in restrainers shortly prior to exposure, irradiation at the cobalt facility and return to VSD

for further monitoring. Briefly, the experimental animals will receive radiation at a dose rate of 0.6 Gy per/min in the AFRRI Cobalt 60 gamma radiation facility. Animals will be irradiated in Lucite boxes (8 animals/box) and arranged in an array (dosimetry 07/09/2014) using plastic racks. Animals will be restrained for no more than 60 min and returned to cages at the end of the irradiation period. They will be monitored daily following policy#10. There is no critical period for the animals in this protocol since all animals irradiated at 7 Gy (sublethal dose) are expected to survive based on our published manuscript on peripheral blood recovery post-irradiation at 7 Gy[(b)(4)] Tissue from mice will be harvested at specific time-points after irradiation after terminal blood draw.

Blood collection: Mice will be anesthetized as described under section V.4.1.2.1 (anesthesia). Blood will be collected from anesthetized mice while they are alive from the inferior vena cava (IVC). The animals will be deeply anesthetized in the rodent anesthesia machine induction chamber; the tail will be pinched for reflexive movement, indicative of insufficient anesthesia. If anesthesia is insufficient, animal will be replaced in induction chamber. If there is no response, the animal will be moved to the station with individual nose cone for continued anesthesia. An incision will be made on the right side below the abdomen of the animal, closest to the IVC. This will expose the vein and blood will be drawn with a 1 ml-syringe with 23 G needles. Animals will have cervical dislocation performed immediately upon completion of blood draw to confirm euthanasia.

V.4.4.1. Injections
Subcutaneous (SC) injections will be given with either a 23 or 25 G sterile needle to the nape of the neck. Animals will be injected once 24 h before radiation.

V.4.4.1.1. Pharmaceutical Grade Drugs

V.4.4.1.2. Non-Pharmaceutical Grade Drugs
[(b)(4)] is formulated as a sterile buffered solution (pH 7) intended for single-use parenteral administration under GMP conditions. The drug will be provided to AFRRI via an MTA[(b)(4)] GT3 formulation will be supplied by [(b)(4)] Endotoxin testing for all drugs will be completed prior to any animal testing at AFRRI and a report submitted for IACUC/VSD review and approval. The endotoxin tests are conducted by Charles River Laboratories. At the same time, pH will be tested to ensure that it falls in the range (6-8 for SQ administration) stipulated by IACUC. It is expected that the osmolarity will not be more than AFRRI IACUC's recommended levels (Policy#9). Both [(b)(4)] and GT3 have been tested previously in other protocols at AFRRI. PBS will be used as diluent foir [(b)(4)] A diluent (developed by [(b)(4)] will be used for GT3.

V.4.4.2. Biosamples Animals will be euthanized from each experimental group on days 1, 4, 7, 14, and 21 and blood will be collected from anesthetized mice while they are alive from the inferior vena cava (using a 23 G needle) in serum separator tubes. Serum will be separated and stored at -80C. Bone marrow will be harvested following a standard protocol. Spleen and other tissues (kidney, liver, and thymus) will be collected and snap frozen for storage at -80C.

V.4.4.3. Adjuvants

V.4.4.4. Monoclonal Antibody (MAb) Production

V.4.4.5. Animal Identification Generally, cage cards will be used to distinguish drug-treated and control groups. Animals will be randomly distributed in groups.

V.4.4.6. Behavioral Studies N/A

V.4.4.7. Other Procedures N/A

V.4.4.8. Tissue Sharing At present there are no plans for tissue sharing.

V.4.4.9. Animal By-Products N/A

V.4.5. Study Endpoint In experiments 1 and 2, at specific time points, experimental mice will be euthanized before tissue collection. Different tissues will be used for different experiments. If we see any morbidity or moribundity, frequency of examinations including late-night checks will be increased and animals will be scored following policy 10 (score sheet attached, appendix 1).

V.4.6. Euthanasia All moribund animals (see section V.4.5) (if any) will be euthanized by overdose of CO_2 inhalation as described in VSD SOP VS0211, by trained investigators or technicians in accordance with current AVMA Guidelines on Euthanasia. Compressed CO_2 gas in a cylinder with a regulator will be used for euthanasia in a euthanasia chamber. After blood draw (please see section V.4.4), animals will have cervical dislocation performed immediately to confirm euthanasia.

V.5. Veterinary Care

V.5.1. Husbandry Considerations The AFRRI vivarium follows stringent protocols for the housing and care of all animals. The PI and designated team members will adhere to all the policy and guidelines set forth by standard operating protocols of the VSD. The specific requirements for mice housing should meet the following criteria of opportunity for social interaction, opportunity to carry out normal behavior and the opportunity to rest and withdraw from each other [15]. Mice are social animals and hence will be caged together in groups of 4 or 8. For ODDS testing, mice will be housed in groups of 3 or 5 mice per cage and identified individually as described. Nestling pads will be provided in each cage during bedding changes. In cage shelters will also be provided as an enrichment strategy at the discretion of the PI depending on experimental conditions. Animals will receive Harlan Teklad Rodent Diet (w) 8604 and water *ad libitum*. Acidified water (pH 2.5 – 3.0) is routinely provided to AFRRI mice used in radiological experiments. Cages will be regularly changed and cleaned by VSD staff in accordance with Standard Operating Procedure. Animals will have 12 h light/dark cycle. Animals will be habituated to their surroundings and routine procedures prior to experimentation. In

the event of procedures that last into the night cycle, care will be taken to minimize exposure to light.

V.5.1.1. Study Room As assigned by VSD

V.5.1.2. Special Husbandry Provisions N/A

V.5.1.3. Exceptions Mice will be socially (group) housed as described above, except there might be time when few animals from the cage will be removed for blood and tissue collection.

V.5.2. Veterinary Medical Care

V.5.2.1. Routine Veterinary Medical Care Experimental animals will be observed daily by either the investigator or technician or both. VSD personnel will monitor all animals during their routine rounds as per VSD SOPs.

V.5.2.2. Emergency Veterinary Medical Care We do not expect animals will be moribund in this protocol. If moribund animals (gasping, recumbent, non-responsive to mild stimulus) are found, those will be euthanized by trained personnel.

V.5.3. Environmental Enrichment

V.5.3.1. Enrichment Strategy The enrichment strategy for mice will be according to VSD Standard Operating Procedure, which involves socially grouped housing and providing nestlets and hiding tubes in the cage.

V.5.3.2. Enrichment Restrictions

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING

NAME	DEGREE	TRAINING	DATE	PROCEDURES	YRS/MOS EXPERIENCE
(b)(6)				1, 3, 4b, 5	(b)(6)
				1, 3, 4b, 5	
				1, 3, 4b, 5	
				1, 3, 4b, 5	
				1, 3, 4b, 5	

Procedure and manipulation codes:
Code 1= Animal handling and euthanasia
Code 2= Surgery (aseptic technique) pre- and post-operative care
Code 3= Injections (3a–ip, 3b-sc, 3c-gavage) - can say 3 if trained in all manipulations or add 3d-iv
Code 4= Blood collection under anesthesia (4a-cardiac, 4b-posterior vena cava)
Code 5= Tissue collection (after euthanasia) - doesn't need to be specific
Code 6 = Implantation (provide details)
Code 7 = Others - (provide protocol specific manipulations or procedures for e.g., retro-orbital bleeding, tail vein injection, or drug delivery)

VII. BIOHAZARDS/SAFETY

All personnel working in the protocol have undergone necessary training in handling experimental animals. The amount of drug used will be small and standard safety precautions will be taken while handling them in the laboratory and in the vivarium. All personnel listed in the present protocol have been trained as general radiation users on a regular basis. All investigators and personnel will use appropriate protective gear while in the vivarium as described by the VSD. All listed personnel are current in safety training and medical surveillance.

X. ASSURANCES

Protocol Title: Regulation of radiation-induced damage by microRNAs in laboratory mice, *Mus musculus*

As the Principal Investigator on this protocol, **I** acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made every effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with a qualified individual who evaluated the experimental design with respect to the statistical analysis, and that the minimum number of animals needed for scientific validity will be used.

D. Biohazard / Safety: I have taken into consideration and made the proper coordinations regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R", namely, "Responsibility," which the DOD has embraced for implementing animal use alternatives where feasible and conducting humane and lawful research.

G. Scientific Review: This proposed animal use protocol has received appropriate peer scientific review and is consistent with good scientific research practice.

H. Painful Procedure(s): I **AM / AM NOT** conducting biomedical experiments, which may potentially cause more than momentary or slight pain or distress to animals. If applicable, potential pain and/or distress **WILL / WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

Appendix 1.
Clinical Observations with Criteria for Euthanasia (Rodent)

Criteria:	Description:	Score
Appearance:		
	Normal (smooth coat, clear eyes/nose)	0
	Hunched and/or fluffed	1
	Ocular discharge, and/or edema	3
	Soft stools (fecal matter around anus)	5
	Pale, white mucus membranes/skin	6
	Bloody diarrhea	9
	Blue mucus membranes/skin (cyanosis)*	12
Respiratory Rate:		
	Normal breathing	0
	Change in breathing (an increase or decrease in respiratory rate from normal baseline)	3

	Abdominal breathing (gasping +/- open mouth breathing)*	12
General Behavior:		
	Normal (based on baseline observations)	0
	Stretching of hind limbs with abdominal motion (writhe) or grimace (App. B and C)	1
	Decreased mobility	2
	Ataxia, wobbly, weak	6
	Inability to stand*	12
Provoked Behavior:		
	Normal (moves when cage is disturbed, runs from hand (mice) or investigates (rat))	0
	Subdued; responds to stimulation (moves away briskly)	1
	Subdued even to stimulation (moves away slowly)	3
	Unresponsive to gentle prodding	6
	Does not right when placed gently on side within 5 seconds*	12
Weight loss		
	0-35% with no other clinical signs	0
	≥35% weight loss	12

*** Regardless of score, immediately euthanize (death is imminent)**

Individual or Cumulative Score:

< 6	Normal
6 - 11	Morbid: See VI.D.2 and VI.D.4 in IACUC Policy #10 for guidelines
≥ 12	Moribund: Notify responsible personnel immediately for euthanasia (if no single criteria is 12*). Any single criteria of 12* euthanize immediately; consider as 'found dead.'

DOD ANIMAL CARE AND USE STANDARDIZED PROTOCOL FORMAT WITH EMBEDDED INSTRUCTIONS (April 2015)

Reference DOD Instruction 3216.01 & AFRRI Instruction 3216.2H

****

Information requested in the following animal use protocol template reflects the requirements of the Animal Welfare Act Regulations (AWAR), the Guide for the Care and Use of Laboratory Animals, and other applicable Federal regulations and DOD instructions.

****

This document is intended to be an aid in the preparation of DOD-sponsored animal use protocols. It is a companion document to an identical protocol template that does not have embedded instructions. Either template may be used to format DOD-sponsored animal research proposals; however, reference to the instructions during protocol preparation is highly recommended. If using the template with instructions, the instructions should be deleted prior to submitting the finished protocol for IACUC review. Please use Arial, regular, size 12, black font to prepare the protocol. With the exception of section headings, all paragraphs require a response. Paragraphs that do not apply should be marked N/A. There is no space limitation for responses to the information requested.

Approved standard operating procedures (SOPs) promulgated by the AFRRI Veterinary Sciences Department (VSD) or similar VSD-validated documents that describe specific procedures may be referenced by SOP number and title in lieu of repeating the details in the protocol. However, it is essential to include general descriptions of all animal manipulations to be carried out under the IACUC-approved protocol and to provide details where no approved references are cited. To do otherwise would constitute a breach of statutory regulations. Manipulations not covered in the originally approved protocol can be initiated only after IACUC approval of a formal amendment adding the new procedures. Additionally, Principal Investigators (PIs), or other delegated research personnel, should maintain accurate experimental records and be able to provide an audit trail of animal expenditures and use that correlates with their approved protocol. Protocol PIs will be required to provide this and other information during annual protocol reviews.

Any supporting information that may be of use to the IACUC during its review may be attached to the completed protocol. Adding subparagraphs within the body of the protocol template is permissible, *provided that the numbering sequence of paragraphs in the original standard format is maintained.* In other words, all of the labeled paragraphs and subparagraphs in this template must be retained, with additional information being presented as sub-numbered paragraphs containing information that supports or complements what is requested.

INTELLECTUAL PROPERTY STATEMENT

Research protocols drafted by Government scientists include intellectual property (e.g., concepts, ideas, experimental approaches, etc.), some of which is innovative or original and therefore considered proprietary to the investigators and/or the sponsoring agency. All Government and non-Government personnel handling this protocol shall exercise EXTREME CARE, to ensure that the information contained herein is NOT DUPLICATED OR DISCLOSED, in whole or part, for any purpose other than to evaluate the protocol, without the written permission of the principal investigator or the sponsoring agency.

AFRRI SCIENTIFIC RESEARCH PROTOCOL NUMBER:

I. NON-TECHNICAL SYNOPSIS The terrorist attack of September 11, 2001 against the United States has increased the concern that terrorists may acquire and use radioactive sources (e.g. dirty radioactive bombs) to expose military and civilian populations to ionizing radiation. However, despite this concern, there are currently no FDA approved drugs that can be used for the general population to prevent death that is likely to result from exposure to ionizing radiation. (b)(4) rradiation in humans can result in both (b)(4) (b)(4) injuries. However, because rodents are more resistant to (b)(4) injuries than *humans*, there is currently no murine model that has been developed to study both (b)(4) (b)(4) radiation injuries in the same animal.
(b)(4),(b)(6)

II. BACKGROUND

II.1. Background The acute toxic effects of exposure to high doses of ionizing radiation in humans have been shown to occur due to two sequential effects: first the ablation of immune cells, resulting in loss of immune function and increasing likelihood of pathogenic infection (b)(4) (b)(4) and subsequently the loss of epithelial progenitor cells of the gastrointestinal (GI) crypt (b)(4) Both of these events have been shown to be due to the loss of fast-growing pluripotent and/or progenitor cell types. The time course of the acute injuries correlates with the life span of the mature cell types of the tissue, which are not replaced because of radiation damage to the adult pluripotent cells and adult stem cells. There is currently no FDA approved prophylactic or treatment for prevention of acute radiation injuries following high-dose (b)(4) radiation exposure.

In some cases supportive measures can be used to treat acute radiation syndrome, and survival from (b)(4) radiation exposure is now possible (b)(4) This results in current efforts to mitigate or treat later stage effects of ionizing radiation exposure. (b)(4)

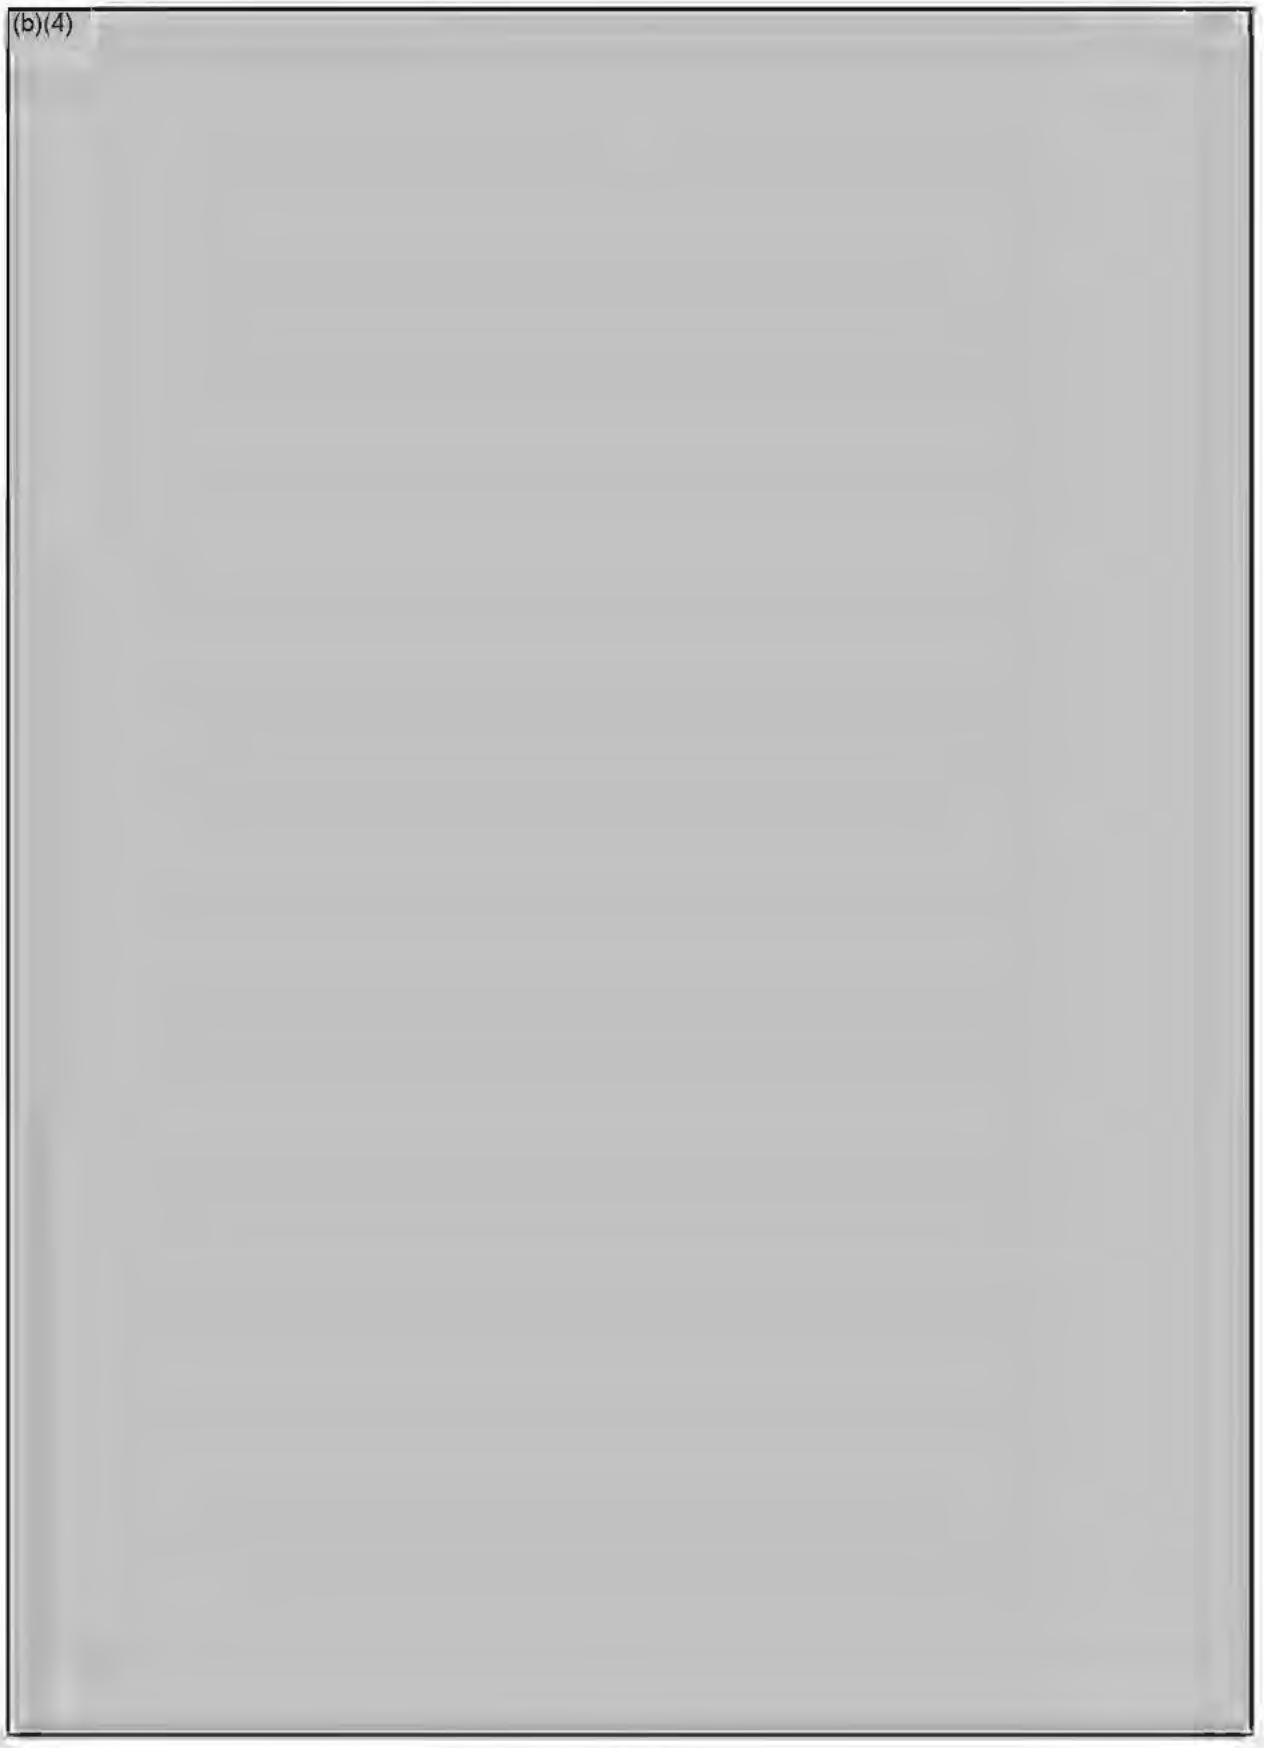
(b)(4)

In humans, death from (b)(4) can occur following survival from (b)(4) Cumulative evidence from a number of laboratories, including our own, shows that there is a threshold dose of radiation of (b)(4) to induce sufficient (b)(4) for the (b)(4) (b)(4) phases to occur in mice; below these doses, no permanent injury manifests, although some short-term effects are observed (b)(4) However, in humans, there is currently no accepted protocol for preventative treatment of radiation-induced (b)(4) and morbiditiy as high as 50% is associated with each phase (b)(4) (b)(4) (b)(4) injuries from radiation is considered to be a serious problem in the field for the development of agents to prevent these radiation injuries.

(b)(4) **as a radioprotectant and an antifibrotic agent:** (b)(4) (b)(4) and its proteolytic product (b)(4) are believed to have their primary biological functions in blood pressure homeostasis. However (b)(4) have been demonstrated to be upregulated in fibrotic tissues. Inhibition of (b)(4) or blockade of the (b)(4) receptors on cells has been shown to ameliorate drug-induced (b)(4) in murine and rat models (b)(4) (b)(4) receptor antagonists also prevent cardiac remodeling following ischaemia/reperfusion in rat models of cardiac remodeling diseases (b)(4) Several studies have also shown that inhibition of (b)(4) (b)(4) signaling mitigates radiation-induced injuries, including to the heart and (b)(4) (b)(4) One study shows that the (b)(4) reduces acute damage to the jejunal mucosa in mice following exposure to (b)(4) This work examined only initial tissue injury and did not extend findings past 5 days, and did not examine mortality. A second study found a reduction in (b)(4) and (b)(4) in rats exposed to (b)(4) (b)(4) radiation (b)(4)

Preliminary Studies:

(b)(4)



(b)(4)

(b)(4)

II.2. Literature Search for Duplication

II.2.1. Literature Sources Searched 1) Biomedical Research Database (BRD) (http://www.dtic.mil/biosys/org/brd/)
2) Computer Retrieval of Information of Scientific Projects (RePORTER) database (http://projectreporter.nih.gov/reporter.cfm)
3) PubMed (http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed)

II.2.2. Date of Search Data base searches conducted on 6/03/15.

II.2.3. Period of Search Searches conducted for the entire time periods available in each data base. For BRD, 1998-2015; for RePorter, 1979-2015. For PubMed, 1970-2015.

II.2.4. Key Words of Search Searches were performed using the following key word combinations:

(b)(4)

II.2.5. Results of Search 1) BRD: (b)(4)
Two grants were funded to examine the activity of (b)(4)

(b)(4)

2) A RePORTER search revealed 2 current grants studying the effects of (b)(4) radiation induced injuries for (b)(4)

(b)(4)

(b)(4)

None of the funded studies duplicate our research (b)(4)
(b)(4)

3) PUBMED Search *6/3/15*
None of the publications available described a murine model for both (b)(4)
(b)(4) injuries from radiation.

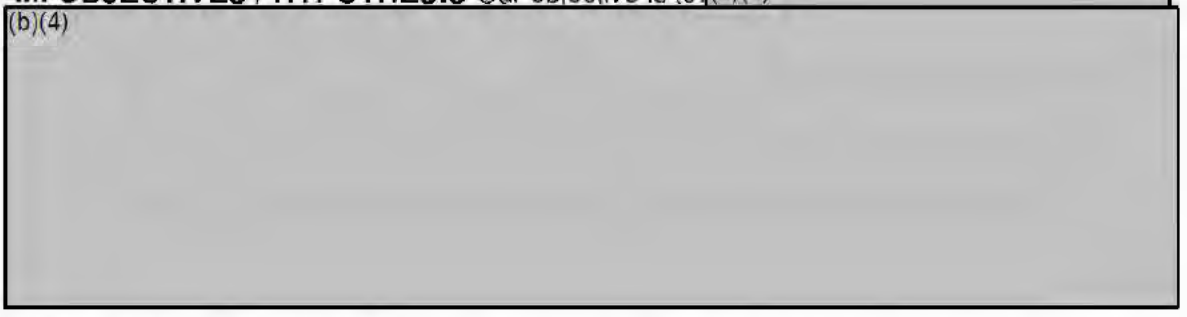
III. OBJECTIVES / HYPOTHESIS Our objective is to: (b)(4)



IV. MILITARY RELEVANCE The Department of Defense is prepared to execute military missions within radiation environments, to manage radiation crises associated with terrorist activities, and to manage consequences in the event of nuclear weapons detonation. Recent studies indicate that there is an increasing risk of exposure to ionizing radiation (IR) to military personnel due to increasing terrorist activities, including potential use of stolen nuclear weapons or dispersal of radioactive material in a "dirty bomb" (b)(4) Because of potential exposure of military personnel to radiation, the DoD is committed to protect members of the Armed Services from the adverse health effects of ionizing radiation. High dose IR causes short term, acute injuries including hematopoetic and GI syndromes. However, both high and low dose IR (as may result from a radiation dispersal device) can cause (b)(4) as demonstrated by Japanese atomic bomb survivor data as well as accidental exposures to Russian populations (b)(4) While early effects of radiation injury now have treatment/ prophylactic strategies, the delayed effects currently have no treatment. Lack of

treatment for late effects of radiation, including (b)(4) will likely lead to delayed morbidity and mortality for personnel exposed to IR.

The Department of Defense (DoD) Chemical and Biological Defense Program 2007 Annual Report to Congress, Chapter 2.7.6 Medical Radiological Defense, addresses the requirements for the development of radioprotectants. This priority is outlined for the development of protectants for both acute and delayed radiation injuries, with an emphasis on (b)(4) (b)(4) According to *this* report, the mitigation of (b)(4) is a major research thrust area. (b)(4) (b)(4)

V. MATERIALS AND METHODS

V.1. Experimental Design and General Procedures

(b)(4)

V.1.1. Experiment 1 Examine the mechanism of radioprotection from (b)(4) (b)(4) (b)(4) An understanding of the mechanism(s) of both sensitization and protection will help in the rational design of radioprotectants in the future.

1.1. Mature and progenitor blood cell effects of (b)(4) after (b)(4) irradiation

One dose of radiation will be used (b)(4) (b)(4) Groups will be: Radiation only, (b)(4)

(b)(4) Time points will be (b)(4) (b)(4) days postirradiation for euthanasia to obtain (b)(4) Mice needed for experiment: need (b) to reach statistical significance for (b)(4) Note: the effects of (b)(4) (b)(4) (b)(4) The sham group will receive no treatment, and will be euthanized on day 0 to establish normal (b)(4) levels.

(b)(4) mice/group) x (3 conditions) x (6 time points) = (b)(4)
(b)(4) nice/group x sham group, no treatment = (b)(4)

(b)(4)

One dose of radiation will be used (b)(4) (b)(4) Groups will be: Radiation only, (b)(4) (b)(4) (b)(4) Time points will be: (b)(4) (b)(4) postirradiation. Mice needed for experiment: need to reach (b)(4) statistical significance for (b)(4) (b)(4) (b)(4) The sham group will receive no treatment, and will be euthanized on day 0 to establish normal (b)(4) levels.

(b)(4) mice/group) x (3 conditions) x (4 time points) = (b)(4)
(b)(4) mice/group x sham group, no treatment = (b)(4)

Endpoint: Endpoints for the experiment will be taken at (b)(4) days postirradiation for experiment 1a, and (b)(4) days postirradiation for experiment 1b. . Early time points will be if any animal exhibits signs or symptoms of morbidity or moribundity in accordance with AFRRI IACUC Policy #10. Our score sheet is also attached. Such animals will be euthanized at the time of observation.

V.1.2. Experiment 2 (b)(4)

(b)(4)

(b)(4) Mice needed for experiments: group to reach statistical significance for survival. (2 regimens of (b)(4) administration) x (5 doses of radiation) x mice/group) x (2 (b)(4) expt) (b)(4)

(b)(4)

(1 no treatment group) x (5 doses of radiation) x [redacted] mice/group) x (2 expt) = (b)(4) [redacted]

(b)(4) [redacted]

Endpoint: Endpoint for the experiment will be survival at [redacted] days. Animals suriving at (b)(4)

(b)(4) [redacted] days will be euthanized. Early time points will be if any animal exhibits signs or symptoms of morbidity or moribundity in accordance with AFRRI IACUC Policy #10. Our score sheet is also attached. Such animals will be euthanized at the time of observation.

V.1.3. Experiment 3 (b)(4) [redacted]

(b)(4) [redacted]

(b)(4) [redacted] mice/group) x (3 doses of (b)(4) [redacted] x (2 times of administration) = (b)(4) [redacted]

(b)(4) [redacted]

Endpoint: Endpoint for the experiment will be survival at [redacted] days. Animals surviving to (b)(4)

(b)(4) [redacted] days will be euthanized and tissue will be obtained. Early time points will be if any animal exhibits signs or symptoms of morbidity or moribundity in accordance with AFRRI IACUC Policy #10. Our score sheet is also attached. Such animals will be euthanized at the time of observation.

V.2. Data Analysis Experiment 1: Analysis of variance (ANOVA) will be used to detect significant difference among the groups. If significant, then the pair-wise comparison by Tukey-Kramer will be used to identify which group is different from the other. For experiment 1.1, N =

(b)(4) [redacted] mice per group could have 80% power to detect any significant difference between groups if any, given type I error of 5% and delta/sigma has at least 1.4, where the delta is the estimated mean differences between the two groups and sigma is the pooled standard deviation of the two groups (b)(4) [redacted] For experiment 3, we only need N = [redacted] based on our current data from (b)(4)

radiation experiments and induction of apoptotic and senescence markers.

Experiment: 2 and 3: Log-Rank test will be used for comparison among groups. If significant, Fisher's exact test will be used to detect significant differences across the groups in

(b)(4) survival rates at day [redacted] Kaplan Meier curves will be displayed. N = [redacted] mice per group will (b)(4) have 80% power in detecting a significant difference between two groups if any, given type I error of 5% where the treatment group survival rate is at least 68%, compared to a control group survival rate of 20%. Similar statements would apply, if the treatment group survival rates are at least 83%, 78%, or 73%, compared to vehicle group survival rates of 35%, 30%, and 25%, respectively [redacted]

V.3. Laboratory Animals Required and Justification

V.3.1. Non-animal Alternatives Considered For the last 9 years, we have utilized primary cell culture systems to examine anti-apoptotic mechanisms; however, we must determine whether our culture findings are relevant in whole animals. We will continue to use primary cell culture whenever possible to avoid unnecessary use of animals. We have also considered computer models as alternatives to animals. However, this alternative also lacks the knowledge base and complexity needed to evaluate radioprotective and radiotherapeutic agents.

V.3.2. Animal Model and Species Justification Tissue culture conditions cannot fully substitute for the complexities of whole organisms in response to radiation injury. Such injury involves the interactions between the [redacted] system and other organ systems. In order to develop viable treatments for humans, we find that our research must be conducted in whole animals.

[redacted] also advocates the mouse as the best species to use for radiation protection and radiotherapy protocols: 1) mice provide the least sentient species available whose response to radiation has been clearly identified, with physiological responses to radiation and radioprotectants that are similar to human physiology, 2) extensive literature is available on responses of mice to radiation and countermeasures, 3) more reagents are available to study the relevant cell types and molecules in mice than in any other species except humans, and the availability of transgenic and knockout mice make this model extremely attractive for further research into molecular mechanisms, and 4) [redacted] have extensive experience with this model in radiation injury and radioprotection research [redacted]

V.3.3. Laboratory Animals

V.3.3.1. Genus / Species *Mus musculus*

V.3.3.2. Strain / Stock C57BL/6 mice, female. C57BL/6 mice have been used by [redacted] for the study of radiation-induced [redacted] injuries. These mice are also used by other laboratories. They provide consistent, reliable data for [redacted] injury and recovery.

CBA, female. CBA mice have previously been demonstrated to be sensitive to radiation-induced [redacted] in a shorter time course than C57BL/6 mice, and in a pattern that more closely resembles [redacted] in humans [redacted]

V.3.3.3. Source / Vendor [redacted] for both C57BL/6 and CBA (fully accredited by AAALAC Int)

V.3.3.4. Age 6-10 weeks (mice are ordered 6-10 weeks of age and irradiated from 12-14 weeks of age)

V.3.3.5. Weight Normal adult weight range for these strains: 17-21 g

V.3.3.6. Sex Female. Only females will be used in this study for the following reasons: 1) we have so far utilized female mice to lay the foundation of our studies for radiation-induced (b)(4) (b)(4) injuries; 2) because of long housing periods, it is advantageous to use female mice that are less aggressive toward each other.

V.3.3.7. Special Considerations Commercially procured animals must be adventitious disease free. Mice- Pathogen-free, including *Pseudomonas aeruginosa*, and Pasteurella: All mice need to be free of the following agents: Sendai, Pneumonia Virus of Mice (PVM), Reovirus-3 (Reo 3), Mouse Adenovirus (MAD-1, MAD-2), Mouse Cytomegalovirus Virus (MCMV), Ectromelia, K virus, Lymphocytic Choriomeningitis Virus (LCM), Epidemic Diarrhea of Infant Mice (EDIM), Hantaan virus, Rotavirus, Mouse Parvovirus (MPV), Polyoma Virus, Mouse Minute Virus (MMV), Mouse Thymic Virus (MTV), Theiler's Mouse Encephalomyelitis Virus (TMEV/GDVII), *Encephalitozoon cuniculi*, CAR bacillus; *Helicobacter* spp. *Mycoplasma pulmonis*, and *Clostridium piliforme*. Endoparasite- and ectoparasite-free.

V.3.4. Number of Animals Required (by species)

Mice C57BL/6 strain (b)(4)
Mice CBA strain
Total mice: (b)(4)

V.3.5. Refinement, Reduction, Replacement (3 R's)

V.3.5.1. Refinement Animals demonstrating moribundity due to radiation exposure (b)(4) will be considered to have arrived at the study endpoint and will be immediately euthanized (See sections V.4.5 Study Endpoint and V.4.6 Euthanasia). The literature search revealed that, at present, there are no alternative procedures for irradiation because its effects cannot be otherwise duplicated. In some cases radiation has been demonstrated to reduce pain in laboratory mice (b)(4) and has been in humans reported to alleviate cancer related bone pain (b)(4) (b)(4) A recent report showed that administration of botulinum toxin A was effective for reduction of pain and muscle spasms after clinical radiation for treatment of tumors (b)(4) (b)(4) Application of natural honey 20 min prior to radiation exposure was also shown to reduce mucositis with associated pain in humans following head/neck radiotherapy (b)(4) it has not been determined whether honey acts as a local radioprotectant. Spinal cord stimulation has also been reported in humans to alleviate pain resulting from radiotherapy (b)(4) however, this method would not be practical for use in mice because of the extensive spinal cord manipulation required. Human administration of morphine also relieves pain (b)(4) but again this would not be practical for mice in our experiments because of side effects of the drug. In humans, exposure to (b)(4) irradiation may induce vomiting and diarrhea, causing pain and distress. However, mice are not susceptible to vomiting.

V.3.5.2. Reduction Whenever possible our laboratory used shared control groups between experiments. Tissues will be collected for multiple assays from the same animals further reducing the total number of animals needed. At every stage of the research, planned experiments will be reevaluated, in an attempt to reduce the numbers of experiments and eliminate repeats of experiments where statistical significance has already been obtained. We also plan to take as many tissues as we can reasonably analyze for experiments examining protein oxidation.

V.3.5.3. Replacement Our laboratory has made extensive use of tissue culture techniques to study the effects of captopril, Ang II, and radiation on cells. While these studies have provided valuable data, it is not feasible to use non-animal systems in place of animal models to address the research questions in this protocol.

V.4. Technical Methods

V.4.1. Pain / Distress Assessment

V.4.1.1. APHIS Form 7023 Information

V.4.1.1.1. Number of Animals

V.4.1.1.1.1. Column C (b)(4) # of animals)

V.4.1.1.1.2. Column D (# of animals)

V.4.1.1.1.3. Column E _ (# of animals)

V.4.1.1.1.4. Pain Category Assignments

(b)(4)

V.4.1.2. Pain Relief / Prevention

V.4.1.2.1. Anesthesia / Analgesia / Tranquilization We will be unable to use analgesics since they have effects on (b)(4) function that would interfere with the interpretation of our results (b)(4) Some anesthetics and sedatives have been reported to contribute to postoperative (b)(4) which likely reduce some functions of radiation. Additionally, it has been shown that the biometabolism of analgesics can induce protein oxidation, which would interfere with sample analysis (b)(4)

(b)(4)

Animals in experiments involving blood collection will be deeply anaesthetized immediately prior to sample collection. For euthanasia, animals will be given 0.1-0.2 ml/mouse pentobarbital (Fatal Plus 50 mg/ml) given i.p. with a 25 G needle.

An anesthesia protocol has been developed for use during the SARRP irradiation. Mice will first be placed in a chamber to deliver isoflorane (3-5% isoflurane in 100% oxygen), until deep anesthesia is obtained. Animals will then be placed in position in the SARRP with a nose cone properly positioned to deliver inhaled isoflurane (1-3% isoflurane in 100% oxygen). During irradiaition, animals will be monitored in real time by camera. If any animal appears to be out of alignment, experiments will be paused to allow repositioning of the animal.

V.4.1.2.2. Pre- and Post-procedural Provisions Animals will be housed and cared for as described in Section V.5. Veterinary Care both before and after dose administrations and irradiation procedures.

V.4.1.2.3. Paralytics None

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures
V.4.1.3.1. Sources Searched Sources searched: DoD Bioedical Research Data Base (BRD), CRISP, PubMED

V.4.1.3.2. Date of Search 6/03/2015

V.4.1.3.3. Period of Search Search covered published manuscripts from ~1965-present. (BRD search included all available years 1998 -2015).

V.4.1.3.4. Key Words of Search Pain, analgesia, mice, radiation, ionizing radiation, humane

V.4.1.3.5. Results of Search The literature search revealed that, at present, there are no alternative procedures for irradiation because its effects cannot be otherwise duplicated. In some cases radiation has been demonstrated to induce opioid-mediated analgesia in laboratory mice (b)(4) and has been in humans reported to alleviate cancer related bone pain (b)(4) A report showed that administration of botulinum toxin A was effective for reduction of pain and muscle spasms after clinical radiation for treatment of tumors (b)(4) Application of natural honey 20 min prior to radiation exposure was also shown to reduce mucositis with associated pain in humans following head/neck radiotherapy (b)(4) it has not been determined whether honey acts as a local radioprotectant. Spinal cord stimulation has also been reported in humans to alleviate pain resulting from radiotherapy (b)(4) (b)(4) however, this method would not be practical for use in mice because of the extensive spinal cord manipulation required. However in a separate study in mice, low dose focal irradiation in a mouse model of bone cancer was associated with spinal changes in neuro-mediators of nociception, the sensory neurons that respond to potentially damaging stimuli by sending pain signals (b)(4) Human administration of morphine also relieves pain (b)(4) but again this would not be practical for mice in our experiments because of side effects of the drug. In humans, exposure to (b)(4) irradiation may induce vomiting and diarrhea, causing pain and distress. However, mice are not susceptible to vomiting.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification The literature search revealed that, at present, there are no alternative procedures for irradiation because its effects cannot be otherwise duplicated. In some cases radiation has been demonstrated to reduce pain in laboratory mice (b)(4) and has been in humans reported to alleviate cancer related bone pain (b)(4) A recent report showed that administration of botulinum toxin A was effective for reduction of pain and muscle spasms after clinical radiation for treatment of tumors (b)(4) (b)(4) Application of natural honey 20 min prior to radiation exposure was also shown to reduce mucositis with associated pain in humans following head/neck radiotherapy (b)(4) it has not been determined whether honey acts as a local radioprotectant. Spinal cord stimulation has also been reported in humans to alleviate pain resulting from radiotherapy (b)(4) however, this method would not be practical for use in mice because of the extensive spinal cord manipulation required. Human administration of morphine also relieves pain (b)(4) but again this would not be

practical for mice in our experiments because of side effects of the drug. In humans, exposure to (b)(4) irradiation may induce vomiting and diarrhea, causing pain and distress.

V.4.2. Prolonged Restraint
No prolonged restraint is required for (b)(4) irradiation (b)(4) irradiation will require restraint in the SARRP for 20-45 min to receive X-ray exposure (b)(4) (b)(4) animals will be anesthetized using inhaled isoflurane during this period (see Anesthesia above).

V.4.3. Surgery

V.4.3.1. Pre-surgical Provisions Not applicable

V.4.3.2. Procedure(s) None

V.4.3.3. Post-surgical Provisions Not applicable

V.4.3.4. Location Not applicable

V.4.3.5. Surgeon

V.4.3.6. Multiple Major Survival Operative Procedures Not applicable

V.4.3.6.1. Procedures Not applicable

V.4.3.6.2 Scientific Justification Not applicable

V.4.4. Animal Manipulations

V.4.4.1. Injections Intra-peritoneal injections of pentobarbital for euthanasia 0.1-0.2 ml/mouse Fatal Plus (39-78 mg pentobarbital/mouse), will be performed with a 25 G needle.

V.4.4.1.1. Pharmaceutical Grade (b)(4) (b)(4)

V.4.4.1.2. Non-Pharmaceutical Grade Drugs Not applicable

V.4.4.2. Biosamples
Blood will be taken under deep anesthesia with pentoparbital. All other biosamples will be taken after euthanasia (b)(4) or analysis will removed *en bloc*. Intestinal tissue will be taken in smaller amounts (the first segment of the small intestine). All other tissues will be available to other researchers for tissue sharing.

For some experiments, blood will be obtained from the animals. Blood will be taken by percutaneous intra-cardiac collection using a 23 – 22 g needle. All other tissues will be available for tissue sharing with other investigators. Intra-cardiac puncture must be performed under deep anesthesia and is considered a non-survival procedure. The mouse is deeply anesthetized and toe pinch response will be used to determine the depth of anesthesia. The ventral chest will be wiped with 70% ethanol. A 23 – 22 g needle will then be inserted at the base of the sternum, bevel up (b)(4) at a 15-20^0 angle directed to the left of the midline. Once the needle is inserted, the blood is slowly aspirated. If no blood is observed, the needle is repositioned with slow aspiration. Once the blood

volume is collected, the mouse is euthanized by cervical dislocation while still under deep anesthesia. Typically 0.5-0.75 ml of blood is collected; sometimes less blood is available after radiation exposure.

V.4.4.3. Adjuvants Not applicable

V.4.4.4. Monoclonal Antibody (MAb) Production Not applicable

V.4.4.5. Animal Identification
All cages will have cage cards identifying the treatment groups for each experiment. For experiment 3, each animal within a cage will receive ear punches for individual identification (1 = no cut; 2 = right ear upper corner; 3 = left ear upper corner; 4 = both ears). For experiments 1 and 2, we have found that tails can be marked with an indelible marker that remains visible for the duration of the experiment for the purpose of scoring pain on each individual animal (1 = 1 line; 2 = 2 lines; 3 = 3 lines; 4 = no lines.).

V.4.4.6. Behavioral Studies Not applicable.

V.4.4.7. Other Procedures
(b)(4) (b)(4) Mice will be placed in well-ventilated Plexiglas boxes (standardized for the cobalt irradiation facility) for up to 45 min, but usually less time, during acute irradiation procedures. Following radiation exposures mice will be immediately moved to standard sized cages that house either 4-8 animals per cage. Holders will be sanitized after each use.

(b)(4) (b)(4) this dose of radiation is currently under determination in another experiment. Mice will first be placed in a chamber to deliver isoflurane (3-5% isoflurane in 100% oxygen), until deep anesthesia is obtained. Animals will then be placed in position in the SARRP with a nose cone properly positioned to deliver inhaled isoflurane (1-3% isoflurane in 100% oxygen). During irradiaition, animals will be monitored in real time by camera. If any animal appears to be out of alignment, experiments will be paused to allow repositioning of the animal. Following radiation exposure, mice will be allowed to recover from anesthesia under supervision, with heating pads. Immediately upon recovery, animals will be returned to standard cages that house 4-8 animals per cage. Holders will be sanitized after each use.

V.4.4.8. Tissue Sharing For most studies (b)(4) will be removed *en bloc*, and (b)(4) (b)(4) will be obtained. (b)(4)
All other tissues will be available for tissue sharing with other investigators. Our laboratory has made extensive use of shared tissues for training and technique development for (b)(4 tissue.

V.4.4.9. Animal By-Products Not applicable

V.4.5. Study Endpoint Endpoints will be taken at (b)(4) days postirradiation for experiment 1a, and at (b)(4) days postirradiation for experiment 1b. Animals will be

euthanized at the endpoints and tissues will be obtained. Early time points will be taken if any animal exhibits signs or symptoms of morbidity or moribundity in accordance with AFRRI IACUC Policy #10. (b)(4) (b)(4) (b)(4) Early endpoints will be used in the case of morbidity and morbundity. Specific health assessment criteria including rapid weight loss, ruffled fur, dried lacrimal fluid accumulated in the cul-de-sac of their eyes, are cool to the touch, decreased appetite, diarrhea, difficulty breathing or panting (b)(4) (b)(4) will used to determine early study endpoints for euthanasia. Mice exhibiting these signs will be considered morbid and will be monitored by the PI or other members of the investigative team at least twice daily, early morning and late afternoon. Mice will be considered moribund when, in addition to showing some or all of the signs of morbidity, they exhibit labored breathing plus either an inability to remain upright or are unmotivated to move. Morbid or moribund mice will be automatically euthanized as described in accordance with IACUC Policy 10. As mice will be checked twice daily, the longest period of time that any animal may exhibit signs of moribundity is ~16 h (the overnight period).

V.4.6. Euthanasia Moribund animals, as defined by AFRRI Policy #10, and animals at the stated endpoints of experiment 2 will be euthanized using CO_2, followed by cervical dislocation to confirm euthanasia. Animals at the stated endpoints of experiments 1 and 3 will be euthanized by injection of 0.1-0.2 ml/mouse Fatal Plus (39-78 mg pentobarbital/mouse), i.p. using a 25 G needle. Euthanasia will be confirmed by cervical dislocation. Animals which appear to be experiencing pain or distress as a result of radiation exposure or are found moribund will also be euthanized by pentobarbitol and necropsied. Animals used for blood collection will be deeply anesthetized with pentobarbital and after blood draw will be euthanized by cervical dislocation or by thoracotomy. At the end of experiments, unused animals will be transferred to other protocols or euthanized by exposure to 100% CO_2 from a compressed gas cylinder in accordance with the current American Veterinary Medical Association (AVMA) Guidelines for Euthanasia. Exsanguination, cervical dislocation, and/or (b)(4) will be used as a secondary measure to ensure euthanasia.

V.5. Veterinary Care

V.5.1. Husbandry Considerations All of the animals used in this study will be housed in the VSD facility in cages of 4-8 mice. Food and acidified (2.5 – 3.0 pH) water (to minimize *Pseudomonas* infection) and Harlan Teklad Rodent Diet #8604 will be available *ad libitum*. The 12:12 hr (lights off at 6 pm) VSD room light cycle is fine for all the studies. (b)(4) (b)(4) Additional medicated water will be present in the room, in a labeled and dated bottle in case a bottle needs to be refilled and staff cannot be reached.

V.5.1.1. Study Room (b)(4),(b)(6) (b)(4),(b)(6)

(b)(4),(b)(6)

V.5.1.2. Special Husbandry Provisions (b)(4)
(b)(4)
(b)(4) Additional medicated water will be present in the room, in a labeled and dated bottle in case a bottle needs to be refilled and staff cannot be reached. No food or fluid restrictions are required.

V.5.1.3. Exceptions Mice will be group housed except during the irradiation exposure as described above or in the event that their cage mates have had to be removed from the study. Under these circumstances they may be housed individually.

V.5.2. Veterinary Medical

V.5.2.1. Routine Veterinary Medical Care Experimental animals will be observed twice a day during the critical period by one of the study investigators or technicians and scored according to Policy 10. Animals will be observed once a day during the critical period by VSD personnel, for a total of three visits a day during the critical period in accordance with AFRRI Policy 10. VSD personnel will also monitor the animals twice a day during their rounds. As described in another section (study endpoint) morbid animals will be monitored at least twice daily, morning and afternoon. The experimental design does not contemplate supportive therapy. The justification for not providing supportive care has been described in the study end point section as well as in the pain category section. Criteria to be used for health evaluation while the animals are on study are as stated in Policy 10: weight loss, appearance, general behavior, provoked behavior, and respiratory rate. Animals exhibiting adverse signs may be euthanized, and considered to be at the study endpoint.

V.5.2.2. Emergency Veterinary Medical Care Emergency veterinary medical care is available 24 hours a day, 7 days a week, including weekends and holidays.

V.5.3. Environmental Enrichment

V.5.3.1. Enrichment Strategy Environment enrichment for the mice will be provided with the addition of nestlets and/or hiding tubes to each cage. Group housing of the mice also provides social enrichment.

V.5.3.2. Enrichment Restrictions None

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING

NAME	DEGREE	TRAINING	DATE	PROCEDURES	YRS/MOS EXPERIENCE
(b)(6)	M.S.	AFRRI	Multiple dates	1,3a,4,5,7a, 7b, 7c	8+yrs
	Ph.D.	USUHS/AFRRI	(b)(6)	1, 3a, 5	5 yr
	Ph.D.	AFRRI		1, 3a, 5	<1 yr
	B.S.	AFRRI		1, 3a, 5	5 yr
	Ph.D.	USUHS/AFRRI		1, 3a, 5, 7b	<1 yr

Procedure and manipulation codes:
Code 1= Animal handling and euthanasia
Code 2= Surgery (aseptic technique) pre- and post-operative care
Code 3= Injections (3a–ip, 3b-sc, 3c-gavage) - can say 3 if trained in all manipulations or add 3d-iv
Code 4= Blood collection under anesthesia (4a-cardiac, 4b-posterior vena cava)
Code 5= Tissue collection (after euthanasia) - doesn't need to be specific
Code 6 = Implantation (provide details)
Code 7 = Others

7a. Ear punch for animal identification
7b.. Cobalt irradiation
7c. SARRP irradiation

VII. BIOHAZARDS/SAFETY

All the personnel will be trained as radiation users on a regular basis. All investigators and technicians while in the vivarium will use appropriate procedures as described by VSD, include the wearing of mask and gloves during observation of mice. No additional biohazards will be used for these experiments.

X. ASSURANCES

Protocol Title: (b)(4) Protection from Radiation-Induced (b)(4) (b)(4) Injuries in a Murine Model (*Mus musculus*)

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made every effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with a qualified individual who evaluated the experimental design with respect to the statistical analysis, and that the minimum number of animals needed for scientific validity will be used.

D. Biohazard / Safety: I have taken into consideration and made the proper coordinations regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R", namely, "Responsibility," which the DOD has embraced for implementing animal use alternatives where feasible and conducting humane and lawful research.

G. Scientific Review: This proposed animal use protocol has received appropriate peer scientific review and is consistent with good scientific research practice.

H. Painful Procedure(s): I **AM / AM NOT** conducting biomedical experiments, which may potentially cause more than momentary or slight pain or distress to animals. If applicable, potential pain and/or distress **WILL / WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

DOD ANIMAL CARE AND USE STANDARDIZED PROTOCOL FORMAT WITH EMBEDDED INSTRUCTIONS (August 2015)

Reference DOD Instruction 3216.01 & AFRRI Instruction 3216.2H

****

Information requested in the following animal use protocol template reflects the requirements of the Animal Welfare Act Regulations (AWAR), the Guide for the Care and Use of Laboratory Animals, and other applicable Federal regulations and DOD instructions.

****

This document is intended to be an aid in the preparation of DOD-sponsored animal use protocols. It is a companion document to an identical protocol template that does not have embedded instructions. Either template may be used to format DOD-sponsored animal research proposals; however, reference to the instructions during protocol preparation is highly recommended. If using the template with instructions, the instructions should be deleted prior to submitting the finished protocol for IACUC review. Please use Arial, regular, size 12, black font to prepare the protocol. With the exception of section headings, all paragraphs require a response. Paragraphs that do not apply should be marked N/A. There is no space limitation for responses to the information requested.

Approved standard operating procedures (SOPs) promulgated by the AFRRI Veterinary Sciences Department (VSD) or similar VSD-validated documents that describe specific procedures may be referenced by SOP number and title in lieu of repeating the details in the protocol. However, it is essential to include general descriptions of all animal manipulations to be carried out under the IACUC-approved protocol and to provide details where no approved references are cited. To do otherwise would constitute a breach of statutory regulations. Manipulations not covered in the originally approved protocol can be initiated only after IACUC approval of a formal amendment adding the new procedures. Additionally, Principal Investigators (PIs), or other delegated research personnel, should maintain accurate experimental records and be able to provide an audit trail of animal expenditures and use that correlates with their approved protocol. Protocol PIs will be required to provide this and other information during annual protocol reviews.

Any supporting information that may be of use to the IACUC during its review may be attached to the completed protocol. Adding subparagraphs within the body of the protocol template is permissible, *provided that the numbering sequence of paragraphs in the original standard format is maintained.* In other words, all of the labeled paragraphs and subparagraphs in this template must be retained, with additional information being presented as sub-numbered paragraphs containing information that supports or complements what is requested.

INTELLECTUAL PROPERTY STATEMENT

Research protocols drafted by Government scientists include intellectual property (e.g., concepts, ideas, experimental approaches, etc.), some of which is innovative or original and therefore considered proprietary to the investigators and/or the sponsoring agency. All Government and non-Government personnel handling this protocol shall exercise EXTREME CARE, to ensure that the information contained herein is NOT DUPLICATED OR DISCLOSED, in whole or part, for any purpose other than to evaluate the protocol, without the written permission of the principal investigator or the sponsoring agency.

I. NON-TECHNICAL SYNOPSIS

II. BACKGROUND

II.1. Background

Acute Radiation Syndromes (ARS) and Delayed Effects of Acute Radiation Exposure (DEARE)

Exposure to ionizing radiation from nuclear events or radiological accidents often leads to major harmful consequences to human health. Therefore, a critical need exists in the area of radiation countermeasures to diagnose and treat victims of radiation exposure. To this end, lack of reliable biomarkers that provide organ specific readout of biological response to radiation poses a major problem in identifying individuals who might be at risk for developing Acute Radiation Syndromes (ARS) and Delayed Effects of Acute Radiation Exposure (DEARE) following a radiological event. Depending on the dose, the symptoms of ARS can appear within hours to weeks. It is a challenge to triage individuals who are minimally exposed compared to those who received high radiation dose and need immediate treatment [1-4]. As such, ARS follows a deterministic effect whereby dose effects have distinct clinical outcomes: generally <2 Gy exhibit mild symptoms, hematologic effects (HE) are prominent at doses between 2 and 6 Gy, and gastrointestinal (GI) effects are prominent at doses >5 Gy and progress more rapidly at higher doses of >10 Gy where neurovascular collapse and death occur promptly [5]. Rapid diagnosis is essential as demonstrated by the dramatic increase in survival rates if treatments are administered early [6]. Currently, three criteria are mainly used to determine radiation exposure levels: clinical observation, lymphocyte depletion kinetics, and the dicentric chromosome (DC) assay [7, 8]. Patient to patient variability greatly decreases the accuracy of clinical diagnosis, lymphocyte depletion kinetics requires 3

days of analysis for a crude dosimetry reading. Moreover, the DC assay is highly technical and labor intensive.
A major issue that impacts the decision making in triage after radiation accidents is the heterogeneity due to variations in exposures [1, 3, 8, 9]. Depending on the geography of exposure, one or more organs may be affected at varying degrees. Damage to the GI system should be evident within days, which, however, requires a relatively higher dose than that needed to affect the HE system. The lung is a relatively sensitive organ; but the effects will not be apparent for weeks or even months [10, 11]. So far, there are no biomarkers that can accurately identify the levels of damage to the individual organs and the overlapping effects and multi-organ dysfunction. Current biodosimeters (lymphocyte depletion kinetics/dicentric chromosome assays) read only the response in the hematopoietic system. Because of the differences in the kinetics and latency period, it is difficult to detect and/or distinguish the effects on non-HE systems. In addition, the threshold and latency period could differ due to differences in immune status, inherent differences in the radiation sensitivity of the individual and other underlying conditions. Unfortunately, available diagnostics do not adequately meet these requirements, particularly in the case of partial body exposure scenario. This study addresses this critical gap of knowledge in the field through discovery and development of biomarkers that could be easily measured providing the readout of distinct organ specific and physiological response to radiation.

Circulating microRNAs (miRNAs) as radiation biodosimeters, biomarkers of organ injury/damage and early predictors of delayed effects:
miRNAs are small RNA molecules of 18-24 nucleotide length, originally identified as regulators of gene expression [12]. They are abundant in body fluids such as plasma, urine, tears, and breast milk. They are protected in exosomes, stable at room temperature for days, and ensure stability for long-term preservation and multiple freeze-thaw cycles [13]. Levels of specific miRNAs in blood can change after radiation, as do the expression levels of mRNAs [14, 15]. miRNAs can be released as exosomes and apoptotic bodies and/or by active secretary pathways. It has been shown that processing of the precursors of miRNAs can directly or indirectly be regulated by cytokines like TNFα and TGFβ1 [16-18] that are altered after radiation. Moreover, reduction in particular radiosensitive cell population (e.g. lymphocytes) will result in reduced circulating cell-free exosomes derived from those cells. There are specific signatures with regard to miRNA expression in different cells and their changes in circulating system can provide readout of organ-specific responses [19, 20]. Particularly, the HE system and lung constantly release exosomes associated with their respective signatures. We propose to exploit this unique tissue specific signature that can be read in exosomes released to the circulating system for evaluating the tissue responses. This can provide readout of changes in organs such as lung for which no biomarkers are currently available.

Survival from radiation lethality by gamma-tocotrienol (GT3)
We reported that gamma-tocotrienol, a naturally occurring vitamin E analog, protects mice from radiation-induced pancytopenia, restores bone marrow progenitor cells (b)(4) reduces intestinal and vascular oxidative stress, and protects 100% mice exposed to lethal dose of whole body γ-radiation (b)(4) CD2F1 mice treated with GT3 showed increased numbers of spleen colonies compared to vehicle treated animals at 12 days

after 8.5 Gy of γ-radiation (b)(4) GT3 reduces radiation-induced vascular oxidative stress *in* mice through an HMG-CoA reductase dependent manner post-radiation treatment (b)(4) GT3 has also been shown to improve the post-irradiation recovery of plasma markers of endothelial function, an effect that is not dependent on HMG-CoA reductase inhibition [24].

The proposed studies will allow us to develop a panel of circulating miRNAs for evaluation of organ responses/damages following partial body exposure and test the effect of GT3 on tissue-specific miRNA. miRNA biomarkers have several advantages over protein and metabolite biomarkers.

II.2. Literature Search for Duplication

II.2.1. Literature Sources Searched

To find any possibility for duplication, the following databases have been searched:
PubMed
Reporter (CRISP) - Computer Retrieval of Information on Scientific Projects, now known as 'Reporter'

II.2.2. Date of Search PubMed – 08/12/2015
Reporter (CRISP) - 08/13/2015

II.2.3. Period of Search
PubMed – 1960-2015
Reporter (CRISP) – 1972-2015

II.2.4. Key Words of Search
1. Micro RNA AND Radiation
2. Gamma-tocotrienol AND micro RNA
3. Gamma-tocotrienol AND Radiation
4. Lung and Radiation
5. Gastrointestinal system and Radiation

II.2.5. Results of Search
Table 1 includes a summary of the keywords and keyword combinations used for searching the RePORTer and PubMed databases.

Keywords	PubMed	RePORTer
Micro RNA AND radiation	852	154
Gamma-tocotrienol AND micro RNA	1	1
Gamma-tocotrienol AND Radiation	32	399
Lung and Radiation	30557	293
Gastrointestinal system and Radiation	25659	297

The searches indicated that there have been no previous or current studies have been done on developing a panel of microRNA biomarkers and to study the effect of GT3 in response to lung and gut injury. Therefore, the proposed study to develop a panel of circulating miRNAs for evaluation of organ responses/damages following partial body

exposure is not a duplication of a previous experiment. While there were some hits, the studies were not relevant to study the effect of GT3 following radiation.

III. OBJECTIVE / HYPOTHESIS

The objective of the project is to understand the acute, delayed and late effect of ionizing radiation and test the effects of radioprotectors and mitigators.

One of the major challenges in radiation countermeasure development is lack of biomarkers that provide minimally invasive and rapid readout of the recovery of the acute and delayed effects. As a proof-of-the-concept, we plan to compare the changes in multi-marker panel in mice treated with the tested agent, GT3, a novel prophylactics radiation countermeasure effective for HE-ARS and possibly for GI-ARS and lung DEARE. The vitamin E analogue, GT3 has been shown to exhibit significant radio-protective activities on hematopoietic stem cells and progenitors in multiple animal models [25].

(b)(4)

(b)(4) We will investigate the tissue versus plasma miRNA responses in evaluating the effect of gamma-tocotrienol (GT3), a novel radiation countermeasure in the mouse model.

IV. MILITARY RELEVANCE

Military operations are seriously impaired by radiation exposures depending on the dose and dose rate. Currently, there is no FDA approved preventive measure available for military personnel to protect them from the hazards of radiation exposure. The problem is more acute in recent times due to the unpredictable nature of terrorist attacks. Recognizing this urgent need, United States Department of Defense has assigned top priority in "Defense Technology Objectives (DTO)" to the "development of medical countermeasures to radiation exposure" against both early effects and late arising health effects. These concerns address the urgent need to develop an appropriate radiation protective agent (prophylactic or therapeutic) to sustain immediate warfighter capabilities and to enable the commanders to make judicious decisions in troop deployment. Currently, there are several drugs at various stages of development. This study will focus on comparing the changes in multi-marker panel in mice treated with the tested agent, GT3, a novel prophylactics radiation countermeasure effective for HE-ARS and possibly for GI-ARS and lung DEARE.

V. MATERIALS AND METHODS

V.1. Experimental Design and General Procedures

V.1.1. Experiment 1

(b)(4)

Experimental Design: We will use C3H mice exposed to two sub-lethal doses of gamma-rays (4 and 7 Gy) (TBI from Cobalt-60), which will ensure that the mice will be

available for studies throughout the period of study, and the biomarkers will have dose response (LD 50/30 is 7.6 Gy) [27]. We will use 12-14 weeks old male C3H mice. We will collect plasma and tissues (spleen, bone marrow sternum and intestine) at the indicated time points and (b)(4) (b)(4) Tissues and blood will be collected at acute (day 1) and delayed (day 14 and 30) post-radiation. A part of the tissue spleen, bone marrow sternum and jejunum will be fixed in formalin for histopathological analysis. (b)(4) (b)(4)

V.1.2. Experiment 2

(b)(4) (b)(4) A next generation microirradiator, SARRP (small animal radiation research platform) X-ray with real time CT imaging [28, 29] will be used for organ targeted irradiation. Lung and blood will be collected at acute (day 1) and delayed (days 14, 30, and 90) post-radiation from animals exposed for lung radiation; and jejunum and blood will be collected at 3.5 and 14 days from animals exposed for gut radiation. A part of the tissue will be fixed in formalin for histopathological analysis; (b)(4)

Experimental Design: Cumulative evidence from a number of laboratories shows that a threshold dose of radiation (10-20 Gy) induces significant lung injury [30, 31]. Depending on the mice strains, radiation induced delayed and late effects on lung (alveolitis, pneumonitis and subsequent fibrosis) occur between 3 to 12 weeks [30, 31]. (b)(4)

General Methods: A single dose of 200 mg/kg GT3 (b)(4) or vehicle (80% Miglyol 812, 9% Span 80, 1% Solutol HS-15, 10% Phosphate Buffered Saline, pH 7.4) or saline will be injected subcutaneously in a volume of 0.1 ml per mouse at the nape of the neck [22] 24 hours before irradiation. Organ/tissue specific partial body exposure to lung, and intestine in mice will be done with SARRP radiation facility at AFRRI to accurately deliver low LET radiation very specifically to tissue as established at the Johns Hopkins University. It will provide orthovoltage X-ray irradiation of mice with beams that can be as narrow as 0.5 mm in diameter [29]. Real-time CT imaging of animals positioned on the exposure table immediately before the radiation will provide reliable pinpoint targeting of organs of interest. Whole blood will be collected under anesthesia and plasma will be prepared, aliquoted and stored in -80C. A part of the tissues (lung and jejunum) will be collected and transferred to 10% formalin for

histopathology analysis and residual tissues will be flash frozen in liquid nitrogen. (b)(4) [redacted]

Histological and Biochemical Assays: Tissue (jejunum and lung) histopathology (e.g. H & E) will be evaluated by a veterinary pathologist at AFRRI. Since several of the (b)(4) [redacted] are linked to immune responses, the effects of the agent in reducing lung toxicity will be evaluated by comparing changes in pro- *versus* anti-inflammatory cytokines in plasma samples (Millipore mouse 32-plex kit, Luminex bead-based assay).

Mice Needed for Experiment 1 (Co-60 whole body radiation):

Radiation doses: 4 and 7 Gy
Groups = 3 (saline, vehicle, GT3)
No. of time points = 3 (Day 1, 14, and 30)
No. of animals per group = 6
Naïve control = 10
No. of repeat = 2

Total no. of mice: (2 x 3 x 3 x 6 +10) x 2 = 236

Mice Needed for Experiment 2 (SARRP partial body body radiation):

Radiation doses: 12 and 16 Gy
Parts of the body: Lung and gut
Groups = 3 (saline, vehicle, GT3)
No. of time points for lung = 4 (Days 1, 14, 30, and 90)
No. of time points for gut = 2 (Days 3.5 and 14)
No. of animals per group = 6
No. of repeat = 2

Total no. of mice for lung: (2 x 3 x 4 x 6) x 2 = 288

Total no. of mice for gut: (2 x 3 x 2 x 6) x 2 = 144

Naïve control will be shared between experiment 1 and 2.

Total number of mice requesting for this protocol = 236+288+144 = 668

Adding a 10% increase to the total number of mice requested to account for unexpected losses = 70

Grand total = 668+70 = 738

V.2. Data Analysis

All analysis will be done by our collaborator (Ohio State University). Six animals per group (N=6) will be used for both experiments 1 and 2. Six animals per group would have 80% power to detect a significant difference between two groups if any, given type I error of 5% and delta/sigma of the differences between two group at least 2.4, where sigma is the common standard deviation, and delta is the mean difference [34].

V.3. Laboratory Animals Required and Justification

V.3.1. Non-animal Alternatives Considered

In vitro studies using cell culture models have established the radioprotective and radiomitigating effect of certain anti-oxidents. However, animals study is required for understanding the systemic and tissue specific effects of radiation and counter effects of these agents. These studies will potentially lead to development of novel non-invasive assays to evaluate risk of ionizing radiation, therapeutic response as well as prevention of cancers and fibrosis in human beings. These can be achieved only by prior studies in live animals.

V.3.2. Animal Model and Species Justification

As discussed in the previous section, animals must be used to study the mechanism of action of a radioprotectant *in vivo*. Mouse model will be used as a proof-of-concept because approximately 99% of human DNA is similar to that of mice, and mouse models are well characterized to study the mechanism of action of a radioprotectant [22, (b)(4) [redacted] Zebrafish and Drosophila are not considered for this study because their physiology is largely different from mammalian systems.

V.3.3. Laboratory Animals

V.3.3.1. Genus / Species *Mus musculus*

V.3.3.2. Strain / Stock
C3H

V.3.3.3. Source / Vendor
Harlan Labs, Indianapolis, Indiana or similar approved vendors

V.3.3.4. Age
7 - 10 wks (age at acquisition). 12-14 weeks will be used in experiment.

V.3.3.5. Weight
22-30 g

V.3.3.6. Sex
Male

Justification of using only male mice: Previous studies have been conducted with male mice, so male mice are needed for data comparison. Although, it is important to confirm observations in females, such studies may be carried out at a later date.

V.3.3.7. Special Considerations
Commercially procured animals must be adventitious, disease free, and pathogen-free—including *Pseudomonas aeruginosa*, and *Pasteurella*. All mice need to be free of the following agents: Sendai, Pneumonia Virus of Mice (PVM), Reovirus-3 (Reo 3), Mouse Adenovirus (MAD-1, MAD-2), Mouse Cytomegalovirus Virus (MCMV), Ectromelia, K virus, Lymphocytic Choriomeningitis Virus (LCM), Epidemic Diarrhea of Infant Mice (EDIM), Hantan virus, Rotavirus, Mouse Parvovirus (MPV), Polyoma Virus, Mouse Minute Virus (MMV), Mouse Thymic Virus (MTV), Theiler's Mouse

Encephalomyelitis Virus (TMEV/GDVII), *Encephalitozoon cuniculi*, CAR bacillus, *Mycoplasma pulmonis*, and *Clostridium piliforme*. They must also be endoparasite and ectoparasite-free.

V.3.4. Number of Animals Required (by species)
C3H mice, 738
V.3.5. Refinement, Reduction, Replacement (3 R's)
V.3.5.1. Refinement
Animals will be irradiated at sublethal doses of 4 and 7 Gy for whole body Co-60 radiation. For SARRP exposure, animals will be irradiated at 12 and 16 Gy. We do not expect to see morbidity in the course of the study. However, if we observe morbid animals, we will increase monitoring and euthanize animals following policy 10 (score sheet attached, appendix 1) at early time points. PI will take necessary steps for all personnel in the project to be rigorously trained in handling techniques (injections, and routine cage-side observations) to minimize distress and pain to the animals. Specifically, during capture and restraint of the rodents, care will be taken to ensure that handling does not contribute to distress.

V.3.5.2. Reduction
Previously published and unpublished data have established which radiation dose and time points are important to get the information for miRNA after radiation injury. This information has enabled us to reduce the number of animals needed for this study. We are also reducing the animal numbers (n = 6) by sharing tissues for determining different parameters from the same experiment. Based on our previous experiments, we will use the minimum required number of animals for statistical validity. This will reduce the number of animals used in this protocol.

V.3.5.3. Replacement
N/A

V.4. Technical Methods

V.4.1.1.1.4. Pain Category Assignments
Table 2.

Exp. #	Experimental/Control Group	C	D	E	Totals
1.	Naïve, 4 Gy veh, 4 Gy GT3, 7 Gy veh, 7 Gy GT3		20	216	236
2.	12 Gy veh, 12 Gy GT3, 16 Gy veh, 16 Gy GT3			432	432

Exp. #	Experimental/Control Group	C	D	E	Totals
	10% animals added due to unexpected loss			70	70
Totals:			20	718	738

V.4.1.2. Pain Relief / Prevention

V.4.1.2.1. Anesthesia / Analgesia / Tranquilization

The protocol will not use anesthetics or analgesics during whole body Co-60 radiation (Experiment 1) since they will adversely affect the outcome of the experiments. The proposed study is to determine the effects of irradiation and countermeasures on the function of the immune and blood forming systems. Use of any analgesics and anesthetics would interfere with the function of the immune system and therefore compromise the interpretation of the results [36]. Topical antibiotics will be applied if wounding occurs via in-cage fighting, under the guidance of the clinical veterinarian in accordance with standard treatment measures.

For partial body SARRP exposure (Experiment 2), inhaled isoflurane anesthesia will be used. Anesthesia will be induced in an induction chamber using 3-5% Isoflurane in 100% oxygen (flow rate 1000 cc/min initially and then reduced to 500 cc/min). The tail and hind paw will be pinched for reflexive movement, indicative of insufficient anesthesia. If anesthesia is insufficient, animal will be returned to the induction chamber. Once the mice are deeply anesthetized as indicated by slow and deep respiration, they will be transferred to a mouse platform. On the platform, the isoflurane (1-3%) will be delivered by a nose cone. The top incisors of the mouse will be positioned in a small hole of the nose cone for the proper delivery of the anesthesia. During the SARRP exposure, the mice will be continuously monitored via a camera. If the mice seem to be getting lighter or deeper as indicated by the breathing or movement, the exposure will be stopped to adjust the anesthesia rate.
A heating pad will be provided to keep mice warm during the period of recovery from anesthesia. The temperature in room where the mice will be irradiated will be measured, and if the temperature gets below 68-70 F, an alternate heating device (such as Bair hugger to blow warm air into the room) will be used to increase the temperature.

Anesthesia of mice will be carried out for blood collection using standard Isoflurane apparatus. All personnel will be extensively trained for efficient administration of the agents as well as to minimize handling stress. Animals will be placed in the Isoflurane chamber and delivered a metered amount of 3-5% Isoflurane mixed with 100% oxygen until all voluntary motor movement ceases and the animal is recumbent for 10 seconds. The tail and hind paw will be pinched for reflexive movement, indicative of insufficient anesthesia. If anesthesia is insufficient, animal will be returned to the induction chamber. Animal's respiration rate will be closely monitored through the Plexiglas chamber during induction of anesthesia. When animals are recumbent, they will be removed from the chamber and their nose/mouth placed in the anesthesia apparatus breathing/gas administration cone for maintenance of anesthesia at 1-3% Isoflurane and 100% O_2.

V.4.1.2.2. Pre- and Post-procedural Provisions

Mice will be housed under standard conditions both before and after radiation procedures in accordance with current VSD rodent husbandry Standard Operating Procedures (see section V.5).

V.4.1.2.3. Paralytics

No paralytic agents will be administered

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures

Pain, analgesia, anesthesia, radiation, radioprotection, mouse, humane, alternative, gamma-tocotrienol, SARRP, Cobalt-60

V.4.1.3.5. Results of Search

Table 3 includes a summary of the keyword combinations used for searching and the results of the search. While the literature indicates that cell models have been used to study radiation damage, such models cannot alone predict mechanism of radioprotection of a specific drug. Although radiation-induced pain was alleviated during some studies [37-39], such pain relief was the aim of the studies in question, which focused on patients receiving radiotherapy for cancer treatment. We do not have the option of using alternatives such as a cell culture model.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification

Since the purpose of these studies is to determine the (b)(4) (b)(4) (b)(4) (spleen, bone marrow sternum, jejunum and lung), we will be unable to use analgesics and anesthetics because they may interfere with the innate immune system [40]. If we see any morbidity or moribundity, frequency of examinations including late-night checks will be increased and animals will be scored and euthanized following policy 10 (score sheet attached, appendix 1).

V.4.2. Prolonged Restraint

The experimental animals (Experiment 1) will receive radiation at a dose rate 0.6 Gy per/min in the AFRRI Cobalt 60 gamma radiation facility. Animals will be irradiated in Lucite boxes (8 animals/box) and arranged in an array (dosimetry 07/09/2014; or the latest dosimetry map) using plastic racks. Mice will be inserted into the standard radiation boxes just prior to irradiation (~15 min of exposure time) and taken to the cobalt facility for irradiation. Animals will be restrained for no more than 60 min and returned to cages at the end of the irradiation period.
For partial body SARRP exposure (Experiment 2), mice will not be restrained since inhaled isoflurane anesthesia will be used during exposure.

V.4.4. Animal Manipulations
Irradiation:
Experiment 1. These will follow the standard AFRRI protocol with mice placed in restrainers shortly prior to exposure, irradiation at the cobalt facility and return to VSD for further monitoring. Briefly, the experimental animals will receive radiation at a dose rate of 0.6 Gy per/min in the AFRRI Cobalt 60 gamma radiation facility. Animals will be irradiated in Lucite boxes (8 animals/box) and arranged in an array (dosimetry 07/09/2014) using plastic racks. Animals will be restrained for no more than 60 min and returned to cages at the end of the irradiation period. They will be monitored daily following policy#10. There is no critical period for the animals in this protocol since all animals irradiated at 4 and 7 Gy (sublethal doses) are expected to survive based on our published manuscript on peripheral blood recovery post-irradiation at 7 Gy (b)(4) Tissue from mice will be harvested at specific time-points after irradiation after terminal blood draw. Bilateral irradiation will be delivered in the cobalt-60 facility of AFRRI at a dose rate of 0.6 Gy/minute using established protocol. Dose rate will be determined with the alanine/EPR system (b)(4) directly traceable to national standards of the US (NIST) and UK (NPL).

Experiment 2. A next-generation microirradiator for small animals, SARRP (Johns Hopkins Univ. and Gulmay, Inc.) will be used for partial body radiation in gut and thorax. It will provide orthovoltage x-ray irradiation of mice with beams that can be as narrow as 0.5 mm in diameter. Real-time CT imaging of animals positioned on the exposure table immediately before the irradiation will provide reliable pinpoint targeting of organs of interest. The SARRP uses a dual-focal spot. constant voltage X-ray source mounted on a gantry with a source-to-isocenter distance of 35 cm. X-rays of 80–100 kVp from the smaller 0.4-mm focal spot are used for imaging. Both 0.4-mm and 3.0-mm focal spots operate at 225 kVp for irradiation. Robotic translate/rotate stages are used to position the animal. Cone-beam computed tomography is achieved by rotating the horizontal animal between the stationary X-ray source and a flat-panel detector.The radiation beams range from 0.5 mm in diameter to 60 x 60 mm^2.

Blood collection: Mice will be anesthetized as described under section V.4.1.2.1 (anesthesia). Blood will be collected from anesthetized mice while they are alive from the inferior vena cava (IVC). The animals will be deeply anesthetized in the rodent anesthesia machine induction chamber; the tail and hind paw will be pinched for reflexive movement, indicative of insufficient anesthesia. If anesthesia is insufficient, animal will be returned to the induction chamber. If there is no response, the animal will be moved to the station with individual nose cone for continued anesthesia. An abdominal incision will be made on the right side of the animal, closest to the IVC, the vein exposed and blood drawn with a 23 – 25 G needle. Animals will have cervical dislocation performed immediately upon completion of blood draw to confirm euthanasia. All tissues such as bone marrow sternum, spleen and other tissues (lung and jejunum) will then be harvested from the animals after euthanasia.

V.4.4.1. Injections
Subcutaneous (SC) injections will be given with a 23 – 25 G sterile needle to the nape of the neck. Animals will be injected once 24 h before radiation. There will be 4 animals per cage. One needle will be used to puncture the vial once to draw the drug for 4 animals per cage and it will be injected to 4 animals.

V.4.4.1.1. Pharmaceutical Grade Drugs

V.4.4.1.2. Non-Pharmaceutical Grade Drugs
Research grade GT3 formulations will be supplied by (b)(4) All formulations will be tested for endotoxin by Charles River Laboratory before using in the animals. pH and osmolality will be tested at AFRRI. We are not expecting any toxic effects in animals for any of the formulations since we have tested the toxicity of the drug at 400 mg/kg dose (2 times higher than the proposed dose in this protocol) previously at AFRRI.

V.4.4.2. Biosamples
Animals will be euthanized from each experimental group on days 1, 3.5, 14, 30, and 90 as specified in section V.1 and blood will be collected from anesthetized mice while they are alive from the inferior vena cava (using a 23 – 25 G sterile needle) in EDTA tubes for plasma separation. Plasma will be separated and stored at -80C. Bone marrow will be harvested following a standard protocol. Spleen and other tissues (lung and jejunum) will be collected from the carcasses and snap frozen for storage at -80C.

V.4.4.3. Adjuvants

V.4.4.4. Monoclonal Antibody (MAb) Production

V.4.4.5. Animal Identification
Generally, cage cards will be used to distinguish drug-treated and control groups. Animals will be randomly distributed in groups. Some experiments might necessitate ear punch or notch or tattoos by personnel to identify individual animals in a cage. Tattoo will be done by VSD personnel using labstamp.

V.4.4.6. Behavioral Studies
N/A
V.4.4.7. Other Procedures
N/A
V.4.4.8. Tissue Sharing
We will be sharing tissues (plasma and all tissues collected in the protocol) with Dr. (b)(6)
V.4.4.9. Animal By-Products
N/A
V.4.5. Study Endpoint
1. The endpoint for experiment 1 using whole body Co-60 radiation will be day 1, 14, and 30 after radiation.
2. The end point for experiment 2 using SARRP partial body radiation in thorax will be day 1, 14, 30, and 90 after irradiation.

3. The end point for experiment 2 using SARRP partial body radiation in gut will be day 3.5 and 14 after irradiation.

In experiments 1 and 2, at specific time points, experimental mice will be euthanized before tissue collection. Different tissues will be used for different experiments. If we see any morbidity or moribundity, frequency of examinations including late-night checks will be increased and animals will be scored and euthanized following policy 10 (score sheet attached, appendix 1). Animals will be weighed the day prior to injection, animals outside ±10% of the mean weight excluded, and randomized into groups of four animals per box. Morbid animals will be weighed, if the weight loss is 35% or more, animals will be euthanized immediately according to policy 10 (Appendix 1).

V.4.6. Euthanasia

All moribund animals (see section V.4.5) (if any) will be euthanized by overdose of CO_2 inhalation as described in VSD SOP VS0211, by trained investigators or technicians in accordance with current AVMA Guidelines on Euthanasia. We will follow the same method in weekends and after hours. Compressed CO_2 gas in a cylinder with a regulator will be used for euthanasia in a euthanasia chamber. Blood will be collected from anesthetized mice while they are alive from the inferior vena cava (IVC). The animals will be deeply anesthetized in the rodent anesthesia machine induction chamber; the tail and hind paw will be pinched for reflexive movement, indicative of insufficient anesthesia. If anesthesia is insufficient, animal will be returned to the induction chamber. If there is no response, the animal will be moved to the station with individual nose cone for continued anesthesia. An abdominal incision will be made on the right side of the animal, closest to the IVC, the vein exposed and blood drawn with a 23 – 25 G needle. Animals will have cervical dislocation performed immediately upon completion of blood draw to confirm euthanasia. All tissues such as bone marrow sternum, spleen and other tissues (lung and jejunum) will then be harvested from the animals after euthanasia.

V.5. Veterinary Care

V.5.1. Husbandry Considerations

The AFRRI vivarium follows stringent protocols for the housing and care of all animals. The PI and designated team members will adhere to all the policy and guidelines set forth by standard operating protocols of the VSD. The specific requirements for mice housing should meet the following criteria of opportunity for social interaction, opportunity to carry out normal behavior and the opportunity to rest and withdraw from each other [41]. Mice are social animals and hence will be caged together in groups of 4 or 8. Nestling pads will be provided in each cage during bedding changes. In cage shelters will also be provided as an enrichment strategy at the discretion of the PI depending on experimental conditions. Animals will receive Harlan Teklad Rodent Diet (w) 8604 and water *ad libitum*. Acidified water (pH 2.5 – 3.0) is routinely provided to AFRRI mice used in radiological experiments. Cages will be regularly changed and cleaned by VSD staff in accordance with Standard Operating Procedure. Animals will have 12 h light/dark cycle. Animals will be habituated to their surroundings and routine procedures prior to experimentation. In the event of procedures that last into the night cycle, care will be taken to minimize exposure to light.

V.5.1.1. Study Room
As assigned by VSD

V.5.1.2. Special Husbandry Provisions
N/A

V.5.1.3. Exceptions
Mice will be socially (group) housed as described above, except there might be a time when few animals from the cage will be removed for blood and tissue collection. Animals may be singly housed if all the co-housed animals are euthanized because of moribund status.

V.5.2. Veterinary Medical Care

V.5.2.1. Routine Veterinary Medical Care
Experimental animals will be observed daily by either the investigator or technician or both. VSD personnel will monitor all animals during their routine rounds as per VSD SOPs.

V.5.2.2. Emergency Veterinary Medical Care
We do not expect animals will be moribund in this protocol. If moribund animals (gasping, recumbent, non-responsive to mild stimulus) are found, those will be euthanized by trained personnel.

V.5.3. Environmental Enrichment

V.5.3.1. Enrichment Strategy
The enrichment strategy for mice will be according to VSD Standard Operating Procedure, which involves socially grouped housing and providing nestlets and hiding tubes in the cage.

V.5.3.2. Enrichment Restrictions

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING

NAME	DEGREE	TRAINING	DATE	PROCEDURES	YRS/MOS EXPERIENCE
(b)(6)				1, 3, 4b, 5	(b)(6)
				1, 3, 4b, 5	
				1, 3, 4b, 5	
				1, 3, 4b, 5	

Procedure and manipulation codes:
Code 1= Animal handling and euthanasia
Code 2= Surgery (aseptic technique) pre- and post-operative care
Code 3= Injections (3a-ip, 3b-sc, 3c-gavage) - can say 3 if trained in all manipulations or add 3d-iv
Code 4= Blood collection under anesthesia (4a-cardiac, 4b-inferior vena cava)
Code 5= Tissue collection (after euthanasia) - doesn't need to be specific
Code 6 = Implantation (provide details)
Code 7 = Others - (provide protocol specific manipulations or procedures for e.g., retro-orbital bleeding, tail vein injection, or drug delivery)

VII. BIOHAZARDS/SAFETY

All personnel working in the protocol have undergone necessary training in handling experimental animals. The amount of drug used will be small and standard safety precautions will be taken while handling them in the laboratory and in the vivarium. All personnel listed in the present protocol have been trained as general radiation users on a regular basis. All investigators and personnel will use appropriate protective gear while in the vivarium as described by the VSD. All listed personnel are current in safety training and medical surveillance.

X. ASSURANCES

Protocol Title:

As the Principal Investigator on this protocol, **I** acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made every effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that **I** have consulted with a qualified individual who evaluated the experimental design with respect to the statistical analysis, and that the minimum number of animals needed for scientific validity will be used.

D. Biohazard / Safety: I have taken into consideration and made the proper coordinations regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R", namely, "Responsibility," which the DOD has embraced for implementing animal use alternatives where feasible and conducting humane and lawful research.

G. Scientific Review: This proposed animal use protocol has received appropriate peer scientific review and is consistent with good scientific research practice.

H. Painful Procedure(s): I **AM / AM NOT** conducting biomedical experiments, which may potentially cause more than momentary or slight pain or distress to animals. If applicable, potential pain and/or distress **WILL / WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

Clinical Observations with Criteria for Euthanasia (Rodent)

Criteria:	Description:	Score
Appearance:		
	Normal (smooth coat, clear eyes/nose)	0
	Hunched and/or fluffed	1
	Ocular discharge, and/or edema	3
	Soft stools (fecal matter around anus)	5
	Pale, white mucus membranes/skin	6
	Bloody diarrhea	9
	Blue mucus membranes/skin (cyanosis)*	12
Respiratory Rate:		
	Normal breathing	0
	Change in breathing (an increase or decrease in respiratory rate from normal baseline)	3
	Abdominal breathing (gasping +/- open mouth breathing)*	12
General Behavior:		
	Normal (based on baseline observations)	0
	Stretching of hind limbs with abdominal motion (writhe) or grimace (App. B and C)	1
	Decreased mobility	2
	Ataxia, wobbly, weak	6
	Inability to stand*	12
Provoked Behavior:		
	Normal (moves when cage is disturbed, runs from hand (mice) or investigates (rat))	0
	Subdued; responds to stimulation (moves away briskly)	1
	Subdued even to stimulation (moves away slowly)	3
	Unresponsive to gentle prodding	6
	Does not right when placed gently on side within 5 seconds*	12
Weight loss		
	0-35% with no other clinical signs	0
	≥35% weight loss	12

*** Regardless of score, immediately euthanize (death is imminent)**

Individual or Cumulative Score:

< 6	Normal
6 - 11	Morbid: See VI.D.2 and VI.D.4 in IACUC Policy #10 for guidelines
≥ 12	Moribund: Notify responsible personnel immediately for euthanasia (if no single criteria is 12*). Any single criteria of 12* euthanize immediately; consider as 'found dead.'

I. NON-TECHNICAL SYNOPSIS

More animal models are required to screen candidates for radiation countermeasures. We have extensively characterized the Gottingen minipig as a model of hematopoietic Acute Radiation Syndrome (H-ARS) and Gastrointestinal Acute Radiation Syndrome (GI-ARS). The model has proven to be more sensitive to irradiation than other minipig strains.
The FDA states that animal models must be well-characterized to be used for testing efficacy of drugs under the Animal Rule. Understanding the reason behind the sensitivity of the Gottingen minipig is critical for the development and use of this model, as well as for an informed choice of different miniature strains. We propose here to compare two strains of minipigs, the Gottingen minipig and the Sinclair minipig (supposedly more resistant to radiation damage than the Gottingen minipig), and to investigate potential mechanism of radiation injury that leads to the extensive, severe hemorrhaging and bleeding observed in the Gottingen minipig. In addition, we will further characterize the Gottingen minipig for development of late effects of irradiation in the cardiovascular system, following partial body irradiation (PBI). To provide PBI, a linear accelerator (LINAC) similar to those used in the clinic to target precise tissue and organ areas must be used. Late effects of irradiation in humans may manifest several months after exposure in several organs. In the heart, evidence of coronary artery atherosclerosis leading to myocardial infarct, microvascular damage, fibrosis leading to congestive heart failure, pericardial disease, and cardiomyopathy has been found in patients exposed to radiation therapy, as well as in the H-bomb survivors (Armenian et al, 2015, Stewart et al, 2013; Waler et al, 2013, Yamada et al, 2005). Preliminary data indicate that the Gottingen minipig irradiated at clinically relevant doses (*i.e.* 2 Gy) displays a rapid reduction in HDL cholesterol level after irradiation, which may lead to development of coronary heart diseases and microvascular damage.

II. BACKGROUND

II.1. Background

The FDA states that animal models must be well-characterized to be used for testing efficacy of drugs under the Animal Rule. In parallel to the development of radiation countermeasures to increase survival to acute radiation doses, the issue of late effects of irradiation after exposure to survivable doses becomes relevant and an integral part of the model characterization.
We have extensively characterized the Gottingen minipig as a model of hematopoietic Acute Radiation Syndrome (H-ARS) and Gastrointestinal Acute Radiation Syndrome (GI-ARS). The model has proven to be more sensitive to irradiation than other minipig strains (Mandel et al, 1980; [(b)(4),(b)(6)]. It is characterized by widespread edema and hemorrhages affecting mainly heart, lungs and intestine, as well as by dyslipidemia [(b)(4),(b)(6)]. Damage to the vasculature is expected to be one of the main mediators of the radiation sensitivity of the Gottingen. Development of a PBI minipig model which can maintain the sensitivity of the cardiovascular system to irradiation but is capable to

overcome the acute lethality of the syndrome, will greatly aid our understanding of late effects of radiation. The cardiovascular features of the Gottingen minipig might be exploited to establish a model of late cardiovascular effects that requires relatively short period (months) to develop, as opposed to years. Cardiovascular late effect can manifest as arrhythmia, cardiomyopathy (affecting mainly the left ventricle of the heart, the mitral and aortic valve, and developing into congestive heart failure and infarction), premature coronary artery disease (*i.e.* atherosclerosis), and inflammation (pericarditis and pericardial fibrosis) (Keene & Oeffinger, n.d.).Understanding the reason behind the sensitivity of the Gottingen is critical for the short- and long-term use of this model, as well as for the choice of a different miniature strain.
The minipig model developed at AFRRI has utilized gamma photons from a Cobalt-60 source to irradiate the animals. This setup can be used for total body irradiation, but not for PBI. In order to irradiate only a portion of the animal, a linear accelerator (LINAC) similar to those used in the clinic to target precise tissue and organ areas must be used. AFRRI has an Elekta Linear Accelerator (LINAC) that can be used for partial body irradiation.
For total body irradiation, both Cobalt-60 sources and LINAC can be used. Survival is impacted by the type of radiation used. This study will compare side by side two minipig strains for two radiation doses, and will use Gottingen minipig historical data for two additional doses. We may use either Cobalt-60 or LINAC when comparing strain sensitivity to total body irradiation, for all animals in the protocol. Alternatively, we may deliver some of the doses with Cobalt-60 and some other with LINAC; however all animals in this protocol receiving the same dose will be exposed to the same source, for comparison purposes. Choice of radiation source will depend on availability of the source and in consultation with funding agency.

The insulin-like growth factor 1 (IGF-1) is an important hormone that plays pivotal roles in all phases of human growth and endocrine metabolism (Livingstone, 2013). It is induced following tissue or cellular injury to stimulate repair and homeostasis of tissues (blood vessels, skeletal muscles, heart, brain, intestine), and replication of cells (hematopoietic and intestinal crypt cells). IGF-1 expression changes over the course of the life span in humans, with the highest levels present in the pre-pubertal phase and early adulthood, and the lowest levels at early and late stages in life (Lamberts et al. 1997; Mayo Clinic, n.d). Gender and menopausal state also affect expression of IGF-1 (Roelfsema & Veldhuis, 2015). Low levels of IGF-1 have been associated to increased risk of atherosclerosis and other cardiovascular diseases (Ruidavets et al. 2011).

Alterations in IGF-1 levels (both deficiencies and excess) are associated with several human pathologies (Kim, 2015; Puche, 2012). Cardiovascular mortality, insulin resistance, high blood pressure and dysregulation of vascular tone are associated with both low and high IGF-1 concentration, suggesting the existence of a U-shape relationship between IGF-1 and pathologies, or the onset of IGF-1 resistance at high concentration of IGF-1 (Schutte, 2014). Studies from our lab with the Gottingen minipig suggest that IGF-1 levels are altered as a function of radiation exposure. IGF-1 is induced shortly after irradiation, peaks a few days before the animal becomes moribund, or declines over the course of weeks in surviving animals (Figure 1).

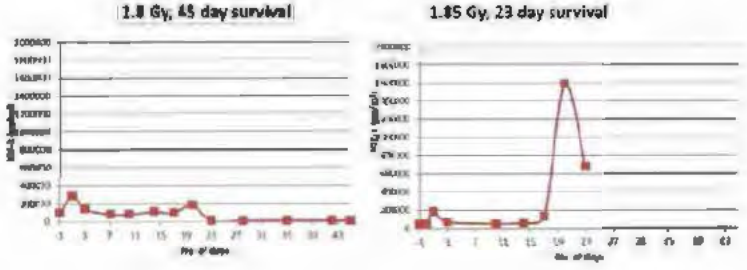

Figure 1: IGF-1 in the plasma of irradiated G. minipigs. The animal on the left survived the entire observation period (45 days), while the animal on the right survived only 23 days.

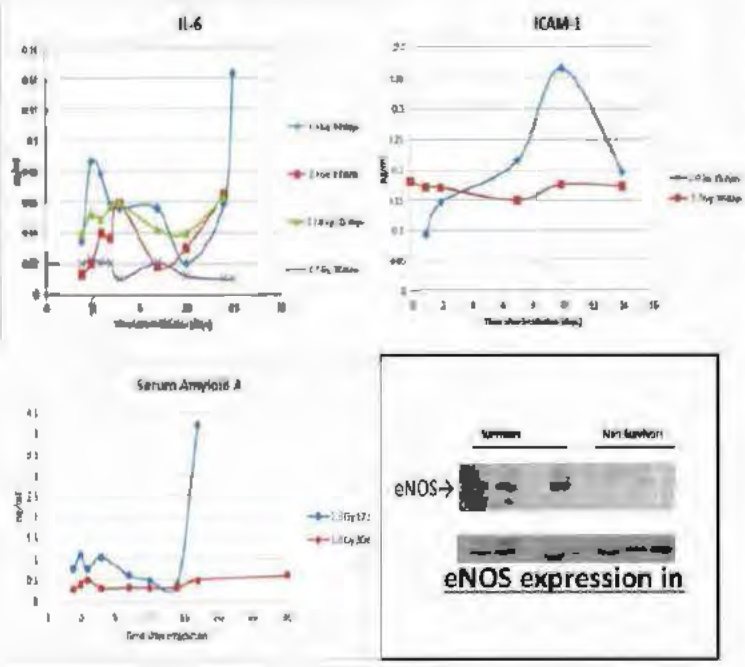

Our preliminary data suggest that moribund animals undergo a secondary acute inflammatory response, characterized by increase in pro-inflammatory cytokines (IL-6), acute phase proteins (CRP, SAA), inflammation of the endothelium (ICAM-1), and reduction in endothelial Nitric Oxide Synthase (eNOS) (Figure 2), possibly leading to impairment of the vascular tone, hypertension, edema, bleeding, and hemorrhages.

Figure 2: IL-6, ICAM-1, and SAA in plasma of irradiated G. minipigs; eNOS expression in heart tissue of irradiated G. minipigs. Doses and survival time or condition is indicated in each panel.

The cardiovascular protective role of IGF-1 is thought to be mediated by its regulation of C-reactive protein (CRP) (Liu et al. 2014). CRP is an acute-phase reactant protein and systemic marker of inflammation, which displays pro-inflammatory effects on endothelial cells through promotion of adhesion molecules, chemokine expression and vasoconstriction. IGF-1 activates eNOS signaling and improves vascular tone, while CRP promotes uncoupling of eNOS, thus favoring production of superoxide and oxidative stress instead of nitric oxide, and hypertension (Liu et al. 2014). Emerging evidence demonstrates that IGF-1 and CRP levels have an inverse correlation and opposing roles in endothelial cell activation (Liu et al. 2014). Unexpectedly, in the irradiated Gottingen minipig, IGF-1 parallels high levels of the inflammatory markers C-reactive protein and serum amyloid A (SAA) (Figure 3).

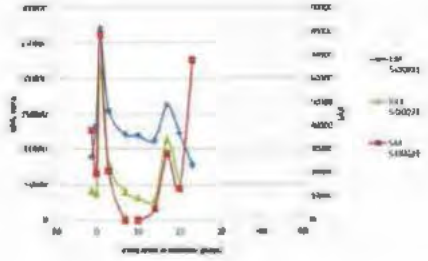

Figure 3: Levels of IGF-1, CRP and SAA from the same plasma sample from one irradiated G. minipig. The animal survived only 23 days.

The roles of IGF-1 and CRP are important in understanding potential mechanisms of sensitivity to radiation, as well as the radiation-induced vascular damage observed in the Gottingen minipig. Surprisingly, results from the serial sample analysis in our lab suggests that the Gottingen minipig may become IGF-1 resistant or that a U-shape relationship exists between IGF-1 and survival, since high

levels of IGF-1 are associated with poor prognosis. Indeed, our preliminary analysis indicates in age matched groups of minipigs suggests that IGF-1 levels are higher in the Gottingen with respect to the Sinclair (Hormel Minnesota), a strain reportedly more resistant to irradiation based on one study with 14 day old Minnesota miniature piglets (Mandel et al. 1980).

The Sinclair minipig was developed by the Hormel Institute at the University of Minnesota in 1949 (Sinclair Bioresources, n.d.). It is the first miniature swine stock developed specifically for research purposes. The Sinclair has a slow growth rate, but is larger than the Gottingen minipig. It has been used in multiple research areas, cardiovascular, musculoskeletal, urogenital, oncology (melanoma), immunology, reproduction toxicology, teratology, dermatology, gastroenterology, respiration, nutrition, pediatrics, *etc.* One lineage of the Sinclair miniature swine develops a malignant spontaneously regressing melanoma (Sinclair Bioresources, n.d.).

Here, we propose to confirm our preliminary results on IGF-1, as well as to evaluate both strains of minipigs in terms of radiation sensitivity and expression of IGF-1. We will determine: i) if different strains of minipigs have the same sensitivity to irradiation; ii) the relationship between IGF-1 levels and sensitivity to irradiation; iii) the relationship between IGF-1, CRP and vascular function/integrity, and iv) if there are late effects detectable within 120 days after exposure to radiation in the Gottingen minipig.

II.2.5. Results of Search

BRD The database was not available during the period 8/17/2015 to 9/2/2105

RePORTER: The results of the research found a few projects dealing with Toll receptors in macrophages and dendritic cell activation, development of medical devices or diagnostic tools, induction of stable B-cell tolerance to transplantation antigens, application of gene based therapy, identification of biomarkers for application other than radiation biodosimetry, and assessment of CD47 function in response to radiation-induced burns.

PubMed: Several publications were found with the key words radiation and minipig; several were from our own laboratory. One article described the hematopoietic radiation toxicity in the Tibet minipig; another studied the effect of fractionated radiotherapy on the parotid gland of the Brazilian minipig. However, no publication described a comparative study between strains; no publication reported assessment of IGF-1 as a potential mechanism of radiation sensitivity; no publication investigated the relationship between radiation, IGF-1 and vascular damage.

III. OBJECTIVE / HYPOTHESIS

Our hypothesis is that (i) the Gottingen and the Sinclair minipigs display different sensitivity to irradiation; (ii) a relationship exists between survival, circulating levels of IGF1, acute phase proteins (*i.e.* CRP, SAA), and vascular function/integrity; and (iii) late effects of irradiation (*i.e.* atherosclerosis, fibrosis) can be observed within 120 days after exposure.

In order to test our hypotheses, we will:

1. Expose Gottingen and Sinclair minipigs (total body irradiation, TBI) to several radiation doses, and compare survival. In addition, we will establish the time course for IGF-1 and acute phase proteins in both strains irradiated at two radiation doses, and perform histological assessment of major organs for vascular integrity, as assessed by presence of edema and hemorrhages, for all animals.
2. Irradiate Gottingen minipigs with partial body irradiation (PBI) sparing 5% of bone marrow (5% PBI), determine survival and time course for IGF-1 and acute phase proteins, and perform histological assessment of heart, lungs, and gastrointestinal tract to assess presence of markers indicative of tissue injury attributable to late effects of irradiation.

   Experimental details are reported in Section V Materials and Methods.

IV. MILITARY RELEVANCE

According to the DoD Chemical and Biological Defense Program 2009 Annual Report to Congress (6): "Although the overall number of nuclear weapons continues to decline because of Russian and U.S. treaty commitments, the United States anticipates an increase in weapon numbers in China, India, and Pakistan. Motivated by economic and strategic interests, Russia and China (or political entities in each) and North Korea continue to supply technologies and components that are dual use and could support weapons of mass destruction and missile programs, especially in the Middle East and South Asia. Iran continues to develop its enrichment program in defiance of United Nations (U.N.) Security Council resolutions and also continues to build a heavy water reactor in Arak, which will be capable of producing plutonium that could be weaponized. While North Korea has halted portions of its nuclear program, it is possible that it has stockpiled several nuclear weapons from plutonium produced at Yongbyon. Non-nuclear radiological dispersal devices (RDD) and radiological exposure devices (RED) pose a significant potential threat especially in the hands of non-state groups. Contamination and recovery issues associated with operating in a radiological environment remain significant concerns for military operations and underscore the need for robust detection, protection, and decontamination systems."

Both early and late health effects of radiation exposure are major concerns for the military. Developing countermeasures to radiation exposure is a top priority for the US Department of Defense. Effective countermeasures would expand the options available to field commanders operating Ionizing Radiation (here defined as IR) threat environments, and improve the morale of personnel at risk of exposure to IR. DoD Defense Technology Objective MD.18 states: "Effective mitigation of health consequences [of IR] will (1) reduce casualty load at medical treatment facilities, (2) sustain a more effective operational force after a radiation exposure event, (3) allow commanders to conduct operations in radiation field environments without undue risk of decremented performance of personnel due to acute tissue injury, and (4) reduce the negative psychological impact on personnel tasked to operate in contaminated environments."

An important barrier to advanced development of radiation countermeasures is the paucity of large, long-lived, non-rodent animal models of radiation injury. The only choices at present are nonhuman primates (NHPs) and canines. The higher sentinent status of NHPs, their expense and danger (occupational health hazards) of working with NHPs, are also disadvantages. Canines are notoriously sensitive to NSAID and

vomiting (Swindle et al. 2012). The addition of miniature swine as a large animal radiation injury model would facilitate development of promising countermeasures for both military and civilian use.

V. MATERIALS AND METHODS

V.1. Experimental Design and General Procedures

V.1.1. Experiment 1 Dosimetry

Animals may be required for finalizing dosimetry measurement for Cobalt and LINAC exposure. After the required period of quarantine/acclimation (see Section V.5.1.), animals will be sedated as described in section V.4.1.2.1. Anesthesia / Analgesia / Tranquilization, and transported to the Cobalt and/or LINAC facility, placed on a sling or a table, and measurements such as animal dimension while lying in the sling used for irradiation and CT scans will be taken. For dosimetry measurements, the animals will not be exposed to ionizing radiation. At completion of Experiment 1, animals will either (i) be used for Experiment 2 if final calculations for dosimetry are completed within 7-10 days, or (ii) will be euthanized and blood and tissue samples collected as non-irradiated controls, for model development.

Number of animals requested for Experiment 1 = 8 total (4 Sinclair + 4 Gottingen).

Table 1
Experiment 1: experimental plan

Dose (Gy)	Gottingen	Sinclair	Study Endpoints	Total
Non-irradiated	4	4	Dosimetry measurements	8

V.1.2. Experiment 2 Strain comparison study

After the required period of quarantine/acclimation (see Section V.5.1.), we will irradiate (TBI) Gottingen and Sinclair minipigs using LINAC or Cobalt-60, and we will collect study endpoints according to the Table 2. Animals irradiated at the same dose and exposed to the same radiation quality *(i.e.* either X-rays from LINAC or gamma-photons from Cobalt-60), to enable comparison of survival data between strains.

Table 2
Experiment 2: experimental plan

Doses (Gy)*	Gottingen	Sinclair	Study Endpoints	Total
1.8 (TBI)	4	4	30 d survival, CBC, IGF-1, acute phase proteins, gross- and histo-pathology	8
2.5 (TBI)	4	4	30 d survival, CBC, IGF-1, acute phase proteins, gross- and histo-pathology	8
Dose TBD (hematopoietic range)		4	30d survival, CBC, IGF-1, acute phase proteins, gross- and histo-pathology	4
Dose TBD (hematopoietic range)		4	30d survival, CBC, IGF-1, acute phase proteins, gross- and histo-pathology	4
Total	8	16		24

* Doses other than 1.8 Gy and 2.5 Gy will be determined based on survival data of the Sinclair minipigs

As this is the first time that we irradiate the Sinclair, the dose response of this strain is unknown to us. To compare the two strains, we will irradiate both strains at a dose corresponding to the approximate LD70 for the Gottingen (1.8 Gy), as well as one supralethal dose (2.5 Gy, this dose is above LD100) for side by side comparison between the two strains of pigs. Doses other than 1.8 Gy and 2.5 Gy will be determined based on survival data of the Sinclair minipigs. Blood will be collected according to section V.4.4.2. Biosamples, and used to obtain CBC/differential and plasma samples for further processing. Blood for CBC/differential and plasma will be collected the week before irradiation and the day before irradiation (or 1 hour before irradiation) and, considering Day 0 the day of irradiation, on days 0, +1, +2, +3, +7, +10, +14, +17, +20, +23, +27, +30. Time points may be shifted by 24 - 48 hour, or dropped in case of unforeseen circumstances. Additional blood draws may be taken, per veterinarian request, if needed to assess health of the animal.

Blood will be collected from either a Vascular Access Port (VAP) (b)(4) (b)(6) or an externalized catheter, or from peripheral veins (see list of potential sites under section **V.4.4.2. Biosamples "Collection of blood samples"**; See VAP or externalized catheter placement under section **V.4.3.2. Procedure (s)**). We have perfected the techniques to collect blood samples from VAP as well as peripheral veins for the Gottingen minipig, but we do not have experience with the Sinclair minipig. Optimal modality of blood collection will have to be determined empirically.
Animals will be observed for 30 days. Moribund animals will be euthanized according to pre-established euthanasia criteria (V.4.5); animals completing the survival study will be euthanized at day 30 - 34 after irradiation. Euthanasia will be carried out according to section V.4.6 Euthanasia. Tissues and blood samples will be collected for further analysis (V.4.4.2).

Number of animals requested for Experiment 2 = 24 total (8 Gottingen + 16 Sinclair).

V.1.3. Experiment 3 Long term effect of radiation

After the required period of quarantine/acclimation (see Section V.5.1.), we will expose Gottingen minipigs to X-rays using LINAC, while protecting about 5-10 % of the bone marrow (5-10% PBI). Partial protection of bone marrow is expected to increase survival at doses otherwise lethal, and allow assessment of late effects of radiation. We will irradiate minipigs with 2.0 Gy and 2.5 Gy (Table 3). These doses are 100% lethal under total body irradiation, but are not sufficient to induce the gastro-intestinal Acute Radiation Syndrome (b)(4) (b)(6) Animals irradiated at 2.0 – 2.5 Gy display extensive bone marrow suppression, vascular damage, and increased CRP. Therefore we expect that such doses will not be lethal under 5-10% bone marrow sparing, and will be suitable for studying long term damage associated with radiation-induced bone marrow toxicity.

Table 3
Experiment 3, experimental plan
Distribution of animals per irradiation doses and endpoints

Doses (Gy)	Gottingen	Sinclair	Primary Endpoints	Total
2.0 (5-10% PBI)	4	0	120 d survival, IGF-1, acute phase proteins, atherosclerosis	4
2.5 (5-10% PBI)	4	0	120 d survival, IGF-1, acute phase proteins, atherosclerosis	4
Total	8	0		8

Animals will be observed for 120 days. Blood for CBC/differential and plasma will be collected the week before irradiation and the day before irradiation (or on day 0 before irradiation) and, considering Day 0 the day of irradiation, on days +1, +3, +7, +10, +14, +17, +20, +23, +27, +30 and up to twice a week thereafter. Time points may be shifted by 24-48 hour, or dropped in case of unforeseen circumstances. Additional blood draws may be taken, per veterinarian request, if needed to assess health of the animal. Blood will be collected from either a Vascular Access Port (VAP), or an externalized catheter, or from peripheral veins (see list of potential sites under section **V.4.4.2. Biosamples "Collection of blood samples"**; See VAP or externalized catheter placement under section **V.4.3.2. Procedure (s)**). Moribund animals will be euthanized according to pre-established euthanasia criteria (V.4.5); animals completing the survival study will be euthanized at day 120 - 124 after irradiation. Euthanasia will be carried out

according to section V.4.6 Euthanasia. Tissues and blood samples will be collected for further analysis (V.4.4.2).

Number of animals requested for Experiment 3 = 8 total (8 Gottingen + 0 Sinclair)

V.2. Data Analysis

Experiment 1. Four animals are sufficient to provide medians and means with standard deviations, which will allow calculation of 95% confidence intervals. These miniature swine, produced for research, are of homogeneous size when matched by age. The variation in size is expected to be very small.
Experiment 2 and 3. Experiment 2 is a pilot study, to be followed by a fully powered study if results are as expected and funds are available. There is not enough evidence available on the difference in sensitivity between Sinclair and Gottingen to justify a fully powered study at this point to demonstrate that one strain is more sensitive than the other. Preliminary proportion data at each radiation dose for the two strains can be used to determine sample size needed for fully powered studies.
Four animals, however, will be sufficient to provide medians and means with standard deviations, and provide the possibility to remove one potential outlier in the dataset for each parameter and time point. Differences in means between groups will be assessed using Student's T-test or ANOVA. Strength and direction of association between variables will be estimated using the Pearson Product Moment correlation coefficient, the Spearman coefficient or the Kendall rank correlation, depending on the distribution and level of the variables.

V.3. Laboratory Animals Required and Justification

V.3.1. Non-animal Alternatives Considered

The purpose of this project is to determine the effect of radiation on survival and expression of hormones and acute phase proteins. There is no computer model or tissue culture that can mimic the effect of radiation on the whole organism and predict lethality. Survival depends on an intricate network of organ cross-talks and cellular microenvironment that cannot be recreated *in vitro.* Consequently, administration of supportive care to cellular components grown *in vitro* will not allow any assessment on survival.

We do not know all of the cell types and tissues involved in radiation injury or how radiation injury causes lethality. The concept of multi-organ failure has been suggested, but how the injured organs affect each other's vital functions is unknown. The present state of the art of tissue culture is still incapable of reproducing the *in vivo* relationships. Computer modeling is similarly limited by lack of full characterization of the biological elements and interactions under study.

These considerations are consistent with the FDA requirement for preclinical research in both small and large mammals before granting approval for drug testing in humans.

V.3.2. Animal Model and Species Justification

Large, long-lived, non-rodent animal models are required for drug studies submitted to the FDA for licensure applications. The close similarity to humans in anatomy and physiology of organs such as the liver, pancreas, kidney and heart has made the pig the primary species of interest as organ donors for xenographic procedures. Minipigs are routinely used for toxicity testing. As such, further and rapid characterization at physiological, molecular and genetic level of the minipig is likely to occur, thus increasing acceptance of this model and facilitating advanced drug development. We have been developing the Gottingen minipig as an additional large animal model for the study of the ARS and advanced development of radiation countermeasures. The current study will help to further characterize the model in terms of natural history of ARS, and to understand the reasons behind inter-individual sensitivity to radiation. Studies on the Sinclair minipig will increase the choice of animal model available to mimic the condition in humans, overall increasing the chances of obtaining a FDA approved drug for the mitigation and treatment of the ARS and eventually decreasing the number of animals required for research. Our previous studies have employed male Gottingen minipigs to develop a probit curve; female minipigs of a corresponding age (approximately 4 months old) are more sensitive to irradiation, based on data from other laboratories. Since we are using our own historical data as one of the terms of comparison, we will continue to use male minipigs for this study

V.3.3. Laboratory Animals

V.3.3.1. Genus / Species *Sus scrofa domestica*

V.3.3.2. Strain / Stock Gottingen miniature swine and Sinclair miniature swine

V.3.3.3. Source / Vendor Marshall BioResources/Marshall Farms Group Ltd, 5800 Lake Bluff Road, North Rose NY 14516; Sinclair Bio Resources, LLC, P.O. Box 658, Columbia, MO 65205.

V.3.3.4. Age 3-5 months

V.3.3.5. Weight Weight appropriate for age (6-14 kg for the Gottingen, and 12-30 kg for the Sinclair)

V.3.3.6. Sex Male

V.3.3.7. Special Considerations NA

V.3.4. Number of Animals Required (by species)

Exp 1: 4 Gottingen, 4 Sinclair
Exp 2: 8 Gottingen, 16 Sinclair
Exp 3: 8 Gottingen
Additionally, we would like to request an additional 10% (4 pigs of either strain as needed) due to unforeseen complications or unexpected deaths.
Total: 20 Gottingen + 20 Sinclair miniature swine + 4 pigs = 44

V.3.5. Refinement, Reduction, Replacement (3 R's)

V.3.5.1. Refinement

The study data-points currently mandated by the FDA for approval of radiation countermeasures under the Animal Efficacy Rule is mortality. Hence the primary study data-point in our development of Gottingen minipigs as a model for ARS is survival. Moribundity will be used as a surrogate for mortality, and euthanasia will be used in order to minimize pain and distress, using an extensive set of criteria (see animal endpoints, paragraph V.4.5 – Lethargy, weight loss, temperature, respiratory distress, food intake, bleeding *etc.*). Animal care and use procedures will only be performed by trained personnel. We have considerable experience in the care and handling of minipigs. Extensive human interaction every weekday will reduce stress in the animals. Use of slings, topical anesthetics, and anesthetics will minimize distress during blood collections and the animals will be gradually acclimated to the slings for these procedures. VAP design and the blood collection have been refined during multiple iterations of previous studies to minimize discomfort to the animals.

V.3.5.2. Reduction

Blood samples obtained from minipigs before irradiation will serve as controls, thus reducing the number of animals required for this study. Use of historical controls will reduce the number of animals needed for this study.

V.3.5.3. Replacement NONE

V.4. Technical Methods

V.4.1. Pain / Distress Assessment

2	8 Gotingen, 16 Sinclair			24	24
3	8 Gottingen			8	8
	Unexpected complications/losses (either strain)			4	4
Totals:			8	36	44

V.4.1.2. Pain Relief / Prevention

V.4.1.2.1. Anesthesia / Analgesia / Tranquilization

We are planning to use anesthesia/sedation at the time of blood sampling (if necessary), prior to irradiation, surgery (if applicable), and prior to euthanasia. Anesthesia/sedation regimen for these procedures is outlined in Table 4. Atropine will be added for any procedure that requires intubation.

Table 4
*Anesthesia/sedation regimen**

Blood sampling, emergency medical care	i	Midazolam (0.1-0.5 mg/kg s.c.or *i.m.*)
	ii	Acepromazine (0.03-1.1 mg/kg *i.m.)*
	iii	Isoflurane 1-5% (face mask or endotracheal tube)
	iv	Xylazine (2.2 mg/kg) + Telazol (2-6 mg/kg) i.m.
	v	Telazol 2 - 8 mg/kg *i.m.*, with or without isoflurane 1-5% (face mask or endotracheal tube)
	vi	Telazol (4.4 mg/kg *i.m.*) + dexmedtomidine (0.05-0.1 mg/kg *i.m.*) or ketamine (5-20 mg/kg IM)/xylazine (1-2 mg/kg *i.m.*), with or without isoflurane 1-5% (face mask or endotracheal tube)
Irradiation, Surgery, Euthanasia	vii	Telazol (2 - 8 mg/kg *i.m.*), with or without isoflurane 1-5% (face mask or endotracheal tube), Atropine (0.04 mg/kg s.c., i.m.or i.v.) (when intubated)
	viii	Telazol (4.4 mg/kg *i.m.*) + dexmedtomidine (0.05-0.1 mg/kg *i.m.*) or ketamine (10-20 mg/kg IM)/xylazine (1-2 mg/kg *i.m.*), with or without isoflurane 1-5% (face mask or endotracheal tube), Atropine (0.04 mg/kg s.c., i.m.or

	i.v.) (when intubated)
ix	Xylazine (2.2 mg/kg) + Telazol (2-6 mg/kg) i.m. with or without isoflurane 1-5% (face mask or endotracheal tube), Atropine (0.04 mg/kg s.c., i.m.or i.v.) (when intubated)

*Agents will be selected and doses may be refined based on veterinarian's discretion

At the end of the irradiation procedure or surgery, once the animals are back in their cages, dexmedetomidine can be reversed by atipamezole *i.m.* (same volume as dexmedotmidine) to facilitate recovery.

V.4.1.2.2. Pre- and Post-procedural Provisions

Body weights and health check status

Body weights and standard animal health check status (hydration status, hair coat, skin quality, vitals) will be determined at least once prior to irradiation, and on days of blood collection. Data will be recorded on the Animals' Clinical Observation at Blood Collection Form (c) (see Section VIII Enclosures).

Animals will be monitored daily for general indicators of animal health (activity, posture, stool, vomit, respiratory activity, respiratory rate, anorexia and temperature). Monitoring will occur at least once in the morning (am) and once the afternoon (pm) throughout the duration of the study. Monitoring in the critical period of sick animals will be performed with increased frequency, as described in V.5.2.1. Routine Veterinary Medical Care. Daily observations will be recorded on study specific form, Animals' Daily Observations Form (d) (see Section VIII Enclosures).

Supportive care

We will administer prophylactic empirical antibiotic regimen to reduce the risk of infection. Regimen is based on prototype medical orders during a radiation incident and follows guidelines from the Department of Health and Human Services Radiation emergency medical management and the Radiation Injury Treatment Network, RITN (Department of Health and Human Services, Radiation emergency medical management, 2013). For trigger points, will follow guidelines for treatment of afebrile neutropenic patients from chemotherapy and from ablative radiation treatment for hematopoietic stem cell transplantation, as recommended by the American Society of Cancer Oncology, ASCO, National Comprehensive Cancer Network (ASCO, 2011; Flowers, 2013). Furthermore, we will define neutropenia as neutrophil counts <500/microL, and we will use this parameter as trigger point to start/end treatment.

We will start treatment at absolute neutrophil counts (ANC) <500/µL or expected to decrease to <500/µL within the next 48 hours, with or without concurrence of fever (Table 5). We will administer ciprofloxacin plus amoxicillin/clavulanate (p.o.) for a minimum of 3 days. Treatment will continue until bone marrow recovers and ANC remain stable above >500/µL for 2-3 consecutive time points. In case of resistance to ciprofloxacin (temperature higher than 39° Celsius for >3-5 days during fluoroquinolone treatment), we will switch to a different class of antibiotic and we will use gentamicin in combination with amoxicillin/clavulanate (ASCO, 2011). If fever still persists for >3-5 days, we will switch to fluconazole. Oral administration of drugs is preferred over *i.v.* administration because of negative impact of venipuncture on animal survival. Oral administration is also likely to be preferred in case of mass casualties due to limited availability of infrastructure for *i.v.* administration of drugs. We reserve however the option to inject the drugs *i.m.* if oral administration is not feasible. The trigger points to start and end such treatment, as well as the dosage, are described in the Table 5 and Table 6 below -

Table 5
Prophylactic empirical antibiotic regimen: trigger points to start/end treatment

ANC<500/µL or expected to decrease to <500/µL within the next 48 hours	**Start** ciprofloxacin plus amoxicillin/clavulanate (continue for at least 3 days)
ANC stable above >500/µL (2 consecutive CBC reading at 3-4 days distance) and T<39° C	**Stop** treatment
If T > 39° C for >3-5 days while taking ciprofloxacin	**Substitute** ciprofloxacin plus amoxicillin/clavulanate with gentamicin plus amoxicillin/clavulanate. Administer until ANC stable above >500/µL (2 consecutive CBC reading at 3-4 days distance) and T<39° C
T > 39° C for >3-5 days while taking gentamicin	**Substitute** gentamicin plus amoxicillin/clavulanate with fluconazole plus amoxicillin/clavulanate. Administer until ANC stable above >500/µL (2 consecutive CBC reading at 3-4 days distance) and T<39° C

Table 6
Prophylactic empirical antibiotic regimen: drug dosage and modality of administration

Drug	Regimen/route
Ciprofloxacin	2.5 - 7.5 mg/kg, BID, p.o. *
Gentamicin	2-6 mg/kg SID, p.o. *
Amoxicillin/clavulanate	11-13 mg/kg every 12-24 h, p.o. *
Fluconacole (Diflucan)	10-12 mg/kg, SID p.o. *

*or i.m. if PO is not possible, at dosage prescribed by and in consultation with a veterinarian

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures

V.4.1.3.1. Sources Searched Altweb, AGRICOLA and Pubmed

V.4.1.3.2. Date of Search 9/2/2015

V.4.1.3.3. Period of Search All available

V.4.1.3.4. Key Words of Search swine, total body irradiation, partial body irradiation, ARS, sequelae, pain, distress, death as an endpoint, alternatives

V.4.1.3.5. Results of Search

Alternatives to toxicity testing in live animals have been proposed in the form of cell and tissue culture, which are not feasible for the purpose of this study where the cross-talk among organs and strain sensitivity is being investigated in relationship to survival after acute irradiation. Additionally, bioinformatics or *in silico* approaches applied to life science might be created ad hoc to validate studies; however these approaches cannot be adopted to model the complexity of multi-organ failure in a large animal, because the mechanisms of radiation injury are still for the most part unknown. Alternatives to

irradiation to study the ARS (total body or partial body) do not exist. We will however provide anesthetics and analgesics for pain management at the time of VAP and catheter implantation (See VAP or externalized catheter placement under section V.**4.3.2. Procedure (s)**), as well as during the days that follow surgery, to alleviate the pain produced by the procedures.

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification

Irradiation itself is not a painful procedure. Pain and distress are associated with the immune suppression, GI injury and bone marrow suppression post TBI. At equivalent TBI doses, pain and distress after PBI are expected to be less intense, because of the residual, spared, bone marrow which is still capable of producing blood cells. These animals may not have acute effects of irradiation (bleeding, infection *etc.*). Depending upon the irradiation dose, irradiated animals die due to compromised immune responses and opportunistic infections. The percentage of surviving animals is the indicator of the efficacy of a countermeasure. We cannot give systemic anesthetic agents to animals after the irradiation procedures, since they are known to interact with the immune system (see references in Jacobsen, K. O., V. Villa, V. L. Miner, and M. H. Whitnall. 2004. Effects of anesthesia and vehicle injection on circulating blood elements in C3H/HeN male mice. *Contemp Top Lab Anim Sci* 43:8-12.), and would confound the correlation of radiation dose with incidence of moribundity, resulting in a waste of animals. However, we are providing supportive care in terms of antibiotics, and fluids/ nutritional support. Use of supportive care is expected to mitigate the pain associated to the sequelae of irradiation.

V.4.2. Prolonged Restraint

Only short periods of restraint in the sling (<30 minutes) will be necessary for irradiation (in Cobalt facility) procedure, physical examination and blood collections. To minimize discomfort, we have designed a new type of sling that uses softer, elastic material to support the animal, and utilizes a more efficient restraint design that maintains the animal in place while reducing manipulation by technicians and consequently stress to the animals.

During the acclimation period, slings are used for physical examination. At this time, animals are acclimated to the sling for 5-10 minutes. Acclimation to the sling is very rapid and non-stressful; animals are petted and gently spoken to while restrained. It has been our experience that resting on the sling does not agitate the animal at all.

Animals are anesthetized/sedated and transported to the Cobalt Facility holding area before being put into sling for irradiation (<20 minutes). Animals will be kept under continuous observation while in the sling. Slings will be washed and sanitized at the end of each day.

V.4.3. Surgery

V.4.3.1. Pre-surgical Provisions Animals will be fasted overnight (approximately 16 – 18 h) prior to VAP implantation surgery. For antibiotic, Cefazolin sodium 20 mg/kg *i.v.* or ampicillin sodium 10-20 mg/kg *i.v.* will be given just prior to the surgery, or intra-operatively, for prophylaxis. At the time of surgery, a temperature microtransponder (Implantable Electronic ID Transponder IPPT-300, Bio Medic Data Systems, Seaford, DE) will be implanted subcutaneously behind the neck, over the shoulder opposite to the site of VAP surgery, to facilitate body temperature measurements.

V.4.3.2. Procedure(s) **VAP implantation**. VAP catheters (SoloPort subcutaneous access port, either PMID or MID model; Instech Solomon, PA) will be surgically implanted in the right external jugular veins under general anesthesia according to the principles of aseptic surgery.

Animals will be lying on their back; vital signs will be taken at regular intervals by vet techs. The catheter tip will be introduced through a 2-3 mm incision in the right jugular vein and advanced to the junction of the external jugular vein and vena cava. Prior to insertion, the VAP catheter will be flushed with locking solution (heparin lock flush solution, 100 IU/ml). Prior to securing the VAP catheter within the vein, 1 preplaced 2-0 or 3-0 vicryl (polyglactin 910) suture (Ethicon, Somerville, NJ) will be used to ligate the vessel just cranial to the insertion point of the catheter tip. A second and third vicryl ligature will be placed around the caudal portion of the vessel containing the VAP catheter and retention bead, with 1 ligature on either side of the bead. The port will be secured within the scapular incision site to the underlying musculature by use of 2-0 or 3-0 poldioxanone (PDS) (Ethicon, Somerville, NJ) at a minimum of 2 of the 5 anchor holes on the port. Catheter function will be confirmed intraoperatively through aspiration of locking solution and withdrawal of a blood sample via the septum. The port reservoir and catheter will be flushed

again with saline and locked with a heparin lock flush solution (100 IU/ml). All subsequent lock solutions will be heparin (100 IU/ml).

During closure of the surgical sites, special attention will be given to eliminating dead space around the port and around the catheter loop on the neck. The muscle and subcutaneous layers will be closed with 2-0 or 3-0 PDS II (polydioxanone suture; Ethicon). Skin incisions will be closed with 2-0 PDS II (Ethicon) in a continuous intradermal pattern. Tissue glue (VetBond, 3M, St Paul, MN) may be used to help seal surgical sites as necessary to help prevent contamination.

Externalized catheter implantation. If needed, an externalized catheter will be placed in the external jugular vein as described above in the VAP catheter placement. However, in this case, the catheter will be tunneled to an exit site on the dorsum of the animal without a VAP. A coil of the catheter will be left underneath the skin and a subcutaneous purse-string suture will be placed around the catheter to secure it at the exit site. Skin will be closed using 2-0 PDS.

V.4.3.3. Post-surgical Provisions

VAP surgery or externalized catheter surgery. Postoperative intramuscular buprenorphine (0.01 to 0.02 mg/kg; Buprenex, Reckitt Benckiser, Richmond, VA) or Carprofen (2.2 mg/kg) will be provided for analgesia before full recovery from anesthesia. Additional post-operative analgesia will be given as Carprofen (2.2 mg/kg *p.o.* BID) for three days starting the day after surgery, or as recommended by an AFRRI veterinarian in consultation with the PI. Alternatively, fentanyl transdermal patch at 5 mcg/kg/hr or buprenorphine sustained release 0.12 – 0.27 mg/kg SC for analgesia can be used as determined by the veterinarian. The fentanyl patch, if used, will be applied to a shaved portion of skin and secured. It takes approximately 12 hrs for the fentanyl patch to take effect. Animals will continue to be monitored until fully recovered from anesthesia; they will be returned to their home cage when ambulatory. Supplemental heat may be provided in the home cage post-operatively (e.g. Bair Hugger warm air blanket, heating pads).

After surgery, 25-50 mg/kg trimethoprim-sulfa *p.o.*(or 5mg/kg *i.m.*), *SID*, will be given for 5 days or more as determined by veterinarian to lessen the risk of post-op infection. Alternatively, enrofloxacin 5-10 mg/kg *i.v./p.o./i.m.* can be given every 24 hrs for 3-5 days or more if needed as determined by the veterinarian. Convenia 5-10 mg/kg *s.c.* may be used as an antibiotic as determined by the veterinarian. The advantage of this antibiotic is that the single injection provides protection against the bacterial infection for several days.
Postsurgical recovery and pain will be monitored twice daily by visual examination of the incisions and overall conditions of the animals. Parameters monitored will be food and water intake, activity, alertness, vocalization, guarding, and response to human contact. Topical antibiotic ointment may be applied at the surgical site. Animals will be allowed to fully recover from the surgery before irradiation is done. The recovery period may last for 2-4 weeks.

V.4.3.4. Location

VSD surgical suite

V.4.3.5. Surgeon

Surgeons will be AFRRI/HJF veterinarians.

V.4.3.6. Multiple Major Survival Operative Procedures NA

V.4.3.6.1. Procedures

V.4.3.6.2 Scientific Justification

V.4.4. Animal Manipulations

V.4.4.1. Injections

All injections will be administered *i.m*, or *s.c.*, or *i.v.*, using sterile needles (19-25 gauge, ¾"-1½") and syringes.

V.4.4.1.1. Pharmaceutical Grade Drugs

Lidocaine (5%), topical
Telazol®
Xylazine
KetamineAtropine sulfate
Cefazolin sodium
Ampicillin sodium
Heparin lock, IV
Saline
Buprenorphine
Carprofen
Fentanyl transdermal patch, topical
Metamucil
Enroflaxacin
Augmentin
Ciprofloxacin
Amoxicillin
Midazolam
Acepromazine
Cetacain topical spray
Atipamezole (Antisedan, Pfizer)
Dexmedetomidine (Dexdomitor, Pfizer)
Convenia (Cefovecin sodium, Pfizer)
Isoflurane
All the drugs listed above are ordered from veterinary product distributors by VSD and they all are pharmaceutical grade drugs.

V.4.4.1.2. Non-Pharmaceutical Grade Drugs NA

V.4.4.2. Biosamples We will collect blood samples throughout the duration of the study, as well as tissue samples at necropsy, for use in our laboratory and for sharing with collaborators. Blood will be used for CBC counts and isolation of plasma/serum for laboratory assays. Tissues will be used for histology as well as molecular laboratory techniques as applicable (*i.e.* Western blot, PCR, ELISA, *etc.*). Tissue samples, to include organs, blood and hair may be taken at the time of euthanasia for tissue blocks and for frozen tissue repository.

Mean blood volume for minipigs is 61-68 ml/kg. (Diehl, 2001) Up to 1% of total blood will be drawn in a single day, and no more than 7% of total blood volume in a week (Walter Reed Army Institute of Research. 1997. Investigators' Handbook. Section I: Handling Techniques and Noninvasive Procedures).

Weight (kg)	Total blood volume (ml)	1% total blood volume (ml)	7% total blood volume (ml)
10	650	6.5	45.5
12	780	7.8	54.6
14	910	9.1	63.7
16	1040	10.4	72.8
18	1170	11.7	81.9
20	1300	13	91
22	1430	14.3	100.1

Collection of blood samples. We will obtain blood samples from externalized catheter (if applicable), or from VAPs (if applicable), or from peripheral veins.

Blood draw from VAP. Before accessing the VAP site, 5% lidocaine ointment USP will be applied topically 15 min prior to sampling, to minimize animal discomfort. Before placement of a non-coring needle, the port injection site will be scrubbed with povidone iodine and 70% isopropyl alcohol until all gross debris is removed (3 to 5 scrubs). To collect a sample, approximately 1 ml fluid will be withdrawn from the catheter and port until blood no longer appears to be mixed with saline. This fluid will be discarded. The blood sample will be collected into a new syringe and placed in appropriate vials for analysis. Next, 3 ml heparin lock flush solution (100 IU/ml) will be infused into the port and catheter as a locking solution. A standard protocol will be followed for obtaining a sample from a problematic catheter. First, external pressure will be applied to the non-coring needle where it entered the port to ensure the tip of the needle is all the way through the septum and into the reservoir. Second, high-pressure turbulent flushing will be attempted with a change in the animal's position. A second person will be needed to extend the neck of the animal by raising it or flexing it away from the side that contains the VAP. Third, the non-coring needle will be replaced; at times the blood may be clotted inside the lumen of the needle. Fourth, if the described series of interventions fail to return the VAP to functioning, the sample will be collected from accessible peripheral vessels using one of the anesthesia regimen as described in section V.4.1.2.1.

Blood draw from externalized catheter. If an externalized catheter is implanted in the external jugular vein (section V.4.3.2) and used for blood collection, the catheter will be flushed with1-5 ml saline and the first 0.5 ml of blood will be discarded. Blood samples will be collected using a new syringe. After blood collection, catheter will be flushed again and locked with 1-3 ml of heparin lock (100 IU/ml).

Blood draw from peripheral veins. Alternatively, we will collect blood from peripheral veins such as auricular, femoral, cephalic, saphenous *etc.* An i.v. catheter may be placed in one of the peripheral veins. Animals will be sedated at the time of blood sampling according to section V.4.1.2.1 Anesthesia/Analgesia/Tranquilization, if necessary. All procedures will be entered into the experimental record. Lidocaine (5%) may be applied topically to the site of venipuncture to minimize discomfort to the animals about 15 minutes before starting the procedure; site will be cleaned with 70% alcohol.

Collection of samples will be performed with the minipig restrained in a sling or on a sedated minipig in the cage; at the same time, we will take vitals. The entire procedure takes less than 30 min. After blood draw, animals will be returned to their cages and checked to ensure that the needle puncture wound is closed and the blood has clotted.

V.4.4.3. Adjuvants NA

V.4.4.4. Monoclonal Antibody (MAb) Production NA

V.4.4.5. Animal Identification Tattoos or ear tags and cage cards/tags

V.4.4.6. Behavioral Studies NA

V.4.4.7. Other Procedures

Temperature transponder. At the time of irradiation, VAP surgery, or catheter implantation, while the animal is anesthetized, a temperature microtransponder (Implantable Electronic ID Transponder IPPT-300, Bio Medic Data Systems, Seaford, DE), will be implanted subcutaneously behind the neck, over the shoulder opposite to the site of VAP surgery, to facilitate body temperature measurements.

Dosimetry. Animals will be sedated, and taken in covered transporting cages to the Cobalt or LINAC facility, where they will be placed on a sling or a table and body measurements will be taken. Sedation will be administered as appropriate.

V.4.4.8. Tissue Sharing Bio-samples (as described in section **V.4.4.2.**) will be collected, to be used for CBC counts, plasma/serum isolation, histo-chemistry/protein/molecular assays among others, and to be shared with collaborators upon request and as experiments permit.

V.4.4.9. Animal By-Products NA

V.4.5. Study Endpoint Moribundity will be used as a surrogate for mortality, and euthanasia will be used in order to minimize pain and distress. The determination of the moribundity must be made in consultation with a veterinarian.
Euthanasia will be carried out either after completion of the observation period (30 day for experiment 2, or 120 day for experiment 3), or when the animal(s) shows at least one of the absolute criteria for moribundity, or a combination of four criteria for non-absolute moribundity. Absolute criteria will be lack of responsiveness (lying down, no effort to get up when people enter the cage, no ability to stand without support), continuous prolonged dyspnea (>30 minutes), body weight loss (loss of greater than 20% of expected weight), and hypothermia (<36°C). Non-absolute criteria will be hyperthermia (>40°C), anorexia (skip 3 consecutive meals), anemia/pallor, petechiae/ecchymosis, vomiting/diarrhea, lethargy, seizures or vestibular signs, and prolonged hemorrhage. Attainment of 4 non-absolute criteria will qualify for immediate euthanasia.

Absolute	
1	Non responsive, assuming the animal has recovered from anesthesia
2	Dyspnea (fast respiration rate, shallow breathing, labored breathing), continuous, prolonged >30 minutes)
3	Loss of 20% of expected weight** (See Appendix)
4	Hypothermia (<36°C) (rectal temperature)
Non-absolute	
1	Hyperthermia (>40°C) (rectal temperature)
2	Anorexia (skip 3 consecutive meals – pig chow)
3	Anemia/pallor, CRT > 2 seconds.
4	Vomiting/diarrhea
5	Lethargy
6	Seizures or vestibular signs (falling, circling or head tilt, paddling)
	Prolonged hemorrhage (hemorrhage = any sign of internal or external bleeding, including presence of petechiae/ecchymosis, bleeding from snout, eye, mouth, anus; presence of blood in the cage; presence of blood in the stool. Hemorrhaging can be also determined by drop in HCT %).

*Attainment of 4 non-absolute criteria will qualify for immediate euthanasia
**Based on Marshall Bio-resources growth chart –weight versus age

Animals will be euthanized according to current American Veterinary Medical Association (AVMA) guidelines.

V.4.6. Euthanasia Animals will be euthanized according to current American Veterinary Medical Association (AVMA) guidelines. Animals will be anesthetized with Telazol® (2-8 mg/kg) *i.m.*, or ketamine (10-20 mg/kg)/xylazine (1-2 mg/kg), *i.m* or 1-5% isoflurane via mask or any one of the combinations described in section V.4.1.2.1. Animals will then be euthanized with Euthasol® (sodium pentobarbital, a minimum dose of 1 ml/4.5 kg, *i.v.* or *i.c.*) or another commercial euthanasia solution. In the rare event that a moribund animal is not responsive and necessitating of immediate euthanasia, euthasol may be injected without prior anesthesia. Animals will be deeply anesthetized with 1-5% isoflurane (via face mask) in addition to the injectable anesthesia during intra-cardiac injection of euthasol. Death will be confirmed by AFRRI veterinarian or veterinary technician via auscultation of the

heart, with cessation of sounds for at least 2 minutes or longer as per current SOP. See item V.4.5 for euthanasia criteria before the end of the study.

V.5. Veterinary Care

V.5.1. Husbandry Considerations Animals will be acclimated for ≥1 week prior to beginning of procedures. Minipigs will be housed in stainless steel cages/runs, in tactile, visual and olfactory contact with adjacent animals. During quarantine/acclimation period, up to day of surgery, if applicable, minipigs may be group-housed. After surgery, they will be singly housed to prevent damage to the VAPs and to allow individual assessment of feed consumption and fecal/urine/blood production. Minipigs will be singly housed after irradiation. Room environment will be maintained as per VSD SOPs.

V.5.1.1. Study Room

Minipigs will be located at AFRRI vivarium for the duration of the study. They will either be in a VSD surgical suite for VAP /catheter implantation if applicable, in transit to and from the Cobalt facility/LINAC in a covered transport cage, in slings for irradiation in the Cobalt facility, or in their housing cage or a VSD prep room for blood collections or euthanasia.

V.5.1.2. Special Husbandry Provisions Filtered tap water will be provided *ad libitum*. Commercial diet will be provided as per vendor's recommendation. Diet may be supplemented with yogurt, metamucil, pumpkin mash, apple sauce, milk formula, and pedialyte may be given, in addition to, or in place of, fresh fruits and vegetables.

Supportive care will be provided after irradiation to all animals, according to Tables 5 and 6.

No treats in the form of marshmallow, peanut butter, crackers will be offered to these animals. Instead, fresh fruits, vegetables, and/or yogurt will be offered 5-7 days a week.

V.5.1.3. Exceptions NA

V.5.2. Veterinary Medical Care

V.5.2.1. Routine Veterinary Medical Care Each animal will be observed at least twice daily for evidence of pain or distress. Body weights will be determined at least once a week and on days of blood collection. Animals will be qualitatively assessed at least twice daily (a.m. and p.m.) for general behavioral status and food consumption by study staff or VSD personnel. Unless the animals are deteriorating, daily observations may not be recorded during weekends, emergency closures, and holidays. Daily observations will be annotated on the Animals' Daily Observation Form (d).

The critical period is defined as day 14-30 post-irradiation. Monitoring of sick animals will be performed with increased frequency during this time to include: an early morning check (before 9 a.m.), a mid-morning check (between 9 a.m. and noon), an afternoon check (between 1 p.m. and 3 p.m.), and a late afternoon check (between 4 p.m. and 6 p.m.). If animal conditions are deteriorating rapidly during the day, an additional evening check (after 8 p.m.) will be done, followed by an early morning check at < 10 hours apart. Rapidly deteriorating conditions are defined as follows: activity score of 2, >1°C change of body temperature per hour, respiratory activity of 1 with continuous dyspnea for more than 10 consecutive minutes, complete anorexia for more than 12 hours, single instance of vomiting/diarrhea, single instance of seizure or vestibular signs, mild hemorrhaging for longer than 6 hours).

V.5.2.2. Emergency Veterinary Medical Care Emergency veterinary medical care is available 24/7 and will be provided based on the restrictions approved in earlier sections of this protocol

V.5.3. Environmental Enrichment

V.5.3.1. Enrichment Strategy

Physical and occupational enrichment will be done as per the VSD minipig enrichment SOP, except single housing after catheter/VAP implantation if applicable, and irradiation. Dietary enrichment will be done as per section V.5.1.2.

V.5.3.2. Enrichment Restrictions

Minipigs will be single-housed after surgery (if applicable) and after irradiation until completion of the study, to avoid mechanical and infectious complications related to implanted catheters, but they will be in visual, olfactory and auditory contact with other minipigs in the same room. Animals may be group-housed during quarantine.

X. ASSURANCES

Protocol Title: A STRAIN COMPARISON STUDY ON SURVIVAL, VASCULAR DAMAGE, AND LONG TERM HEALTH EFFECTS IN IRRADIATED MINIPIGS (*Sus scrofa domestica*)

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made every effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with a qualified individual who evaluated the experimental design with respect to the statistical analysis, and that the minimum number of animals needed for scientific validity will be used.

D. Biohazard / Safety: I have taken into consideration and made the proper coordinations regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R", namely, "Responsibility," which the DOD has embraced for implementing animal use alternatives where feasible and conducting humane and lawful research.

G. Scientific Review: This proposed animal use protocol has received appropriate peer scientific review and is consistent with good scientific research practice.

H. Painful Procedure(s): I **AM / AM NOT** conducting biomedical experiments, which may potentially cause more than momentary or slight pain or distress to animals. If applicable, potential pain and/or distress **WILL / WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

AFRRI SCIENTIFIC RESEARCH PROTOCOL NUMBER:

I. NON-TECHNICAL SYNOPSIS Radiologic or nuclear events are serious threats to our safety, which can come from sources including devices which spread radiation (including explosive devices), sophisticated nuclear weapons, nuclear power plants, and stolen or mishandled medical sources which are dangerous to health. While the DoD is taking many measures to protect military members and U.S. citizens against these dangerous threats, no drug is currently available to protect people from radiation effects before exposure. Recently, studies by AFRRI scientists have conclusively shown that a single injection of delta- or gamma-tocotrienol (DT3 or GT3) to mice confers a striking survival benefit against irradiation. Both protect mice against injury of the hematopoietic and gastrointestinal systems. Preliminary studies show minimal efficacy by GT3 when administered orally before radiation. (b)(4)
(b)(4)
(b)(4) Some of the advantages of this formulation will include biodegradability, none or very low toxicity, high stability at ambient temperature, significantly high cellular uptake, and feasibility of various routes of administration. The (b)(4) formulation has been tested for stability at various temperatures. Here, we propose to test a promising lipid-based nanoparticle formulation to increase the radioprotective efficacy of tocotrienols following oral (PO) administration.

The current paucity of radiological medical countermeasures warrants serious concern in consideration of credible assessments of potential radiologic or nuclear threat that our military members and first responders are facing. This proposal will evaluate a promising and safe product for use when given orally for protecting against ionizing radiation before sending the U.S. troops in harm's way.

II. BACKGROUND

II.1. Background Threat characterization for radiologic and nuclear events (intentional or accidental) is defined by the nature of the incident [1]. Threat devices or sources include radiologic dispersal devices, radiologic exposure devices, a sophisticated

nuclear weapon, improvised nuclear devices, nuclear power plants, and stolen or mishandled medical radiologic sources [2-5]. AFRRI has been in the forefront in evaluating radiation countermeasures against the deleterious effects of ionizing radiation[(b)(4)]

Tocols as radiation countermeasures: AFRRI investigators and their collaborators have extensively studied tocols including tocopherols, tocotrienols, esters such as tocopherol succinate, and found those to be radioprotective when administered subcutaneously prior to the total body radiation exposure[(b)(4)] Currently no FDA approved countermeasures are available for oral administration. This protocol will allow us to test several formulations of tocols for oral administration with the support of a commercial partner,[(b)(4)] that has interest in advancing tocols as radiation countermeasure.

AFRRI management formed a "tocol" team to initiate studies in collaboration with[(b)(4)] [(b)(4)] has been in consultation with the tocol team to develop[(b)(4)] that might be approved by FDA (use of Generally Regarded as Safe [GRAS] emulsifiers) for human use. These[(b)(4)] [(b)(4)] and will be tested at AFRRI using the current protocol.

II.2. Literature Search for Duplication

II.2.1. Literature Sources Searched NIHRePORTER, PUBMED, Embase

II.2.2. Date of Search 10-15-2015 to 10-22-2015

II.2.3. Period of Search The search period extended from 2009-present for NIHReporter, 1970 to present for PubMed, 2006 to present for Embase.

II.2.4. Key Words of Search Each individual term: Annatto-derived, [(b)(4)] + (radiation), + (radioprotection), + (radioprotection+mice) + (oral) + [(b)(4)] [(b)(4)]

II.2.5. Results of Search Table 1. Literature search resulted the following hits as tabulated below:

KEY WORDS	PUBMED	NIHRePORTER	Embase
Annatto-derived	1	0	0
[(b)(4)]	0	0	0
[(b)(4)] + radiation	0	0	0
[(b)(4)] + radioprotection+mice	0	0	0
[(b)(4)] + oral	0	0	0
[(b)(4)] + oral + [(b)(4)]	0	0	0

Summary of the Search: The only literature found for 'Annatto-derived' was on effect of[(b)(4)] in postmenopausal osteoporosis. There was no study evaluating radioprotective efficacy of[(b)(4)]

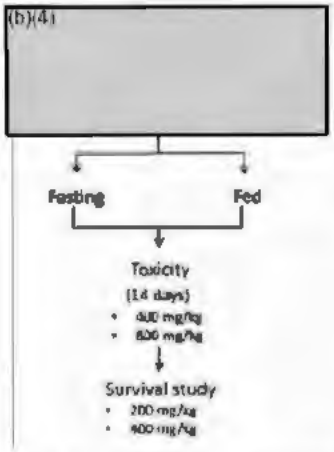
III. OBJECTIVE / HYPOTHESIS The objective of the present protocol is to test the radioprotective efficacy of three oral formulations of (b)(4) (b)(4)

IV. MILITARY RELEVANCE The issue that we will address in this proposal is the urgent need to protect first responders deployed in a radiation field for rescue and recovery military operations, resulting from accidental or intentional nuclear/radiological detonations. Currently there is no drug approved by the FDA to protect first responders deployed in a radiation field for military operations. This is a serious capability shortfall that needs to be addressed. Drugs under various stages of development in small and large animals are found to be toxic at effective doses [3, 4]. Therefore, there is an immediate need for non-toxic radioprotectants useful for military personnel and civilians who may be exposed to a nuclear/radiological scenario [4]. The present proposal directly addresses this need by moving forward with the development of a promising drug delivery approach to increase radioprotective efficacy of oral tocotrienols (T3s).

V. MATERIALS AND METHODS In this study we will test the oral efficacy of (b)(4) (b)(4) using the male CD2F1 mouse model. Drugs will be administered orally to two groups of mice, one with fasting [13] for 5-8 h (fast) and the other without fasting (fed). Fasting of mice is a common procedure performed in association with many different types of experiments mainly in order to reduce variability in investigatory parameters or to facilitate surgical procedures. Since many physiological parameters are regulated by circadian rhythms, fasting initiated at different points in the circadian rhythm has different impacts and produces different results [14, 15]. The oral absorption of tocotrienol is affected by dietary tocopherol content (b)(4) In this study the focus is on absorption of tocols under fed and fasting conditions. Tocopherol is structurally similar to tocotrienols hence competes during absorption. Therefore, we are proposing to evaluate the effect of fasting on radioprotection by tocotrienol. An arm of normal animals will be used as control. Before conducting the efficacy study, we will study the safety of these formulations by conducting a 14-day acute toxicity study [16, 17].

V.1. Experimental Design and General Procedures

General experimental design: In this protocol (b)(4) formulations will be used. All drugs will be administered orally (po). Blank (b)(4) (b)(4) and natural emulsion (NE) will be used as respective negative controls. A schematic diagram of the experimental design is given below:



The experimental design for this protocol is divided in to 2 subsections.

Section v.1.1.: Basic toxicity
Section v.1.2.: Survival studies

Section V.1.1. Basic AcuteToxicity

By the term 'Basic' here means limited toxicology study. The term 'Acute' is used to indicate immediate (short term) toxicity. To evaluate a safe dose of orally administered tocotrienols, we will perform Optimal (non-toxic) Drug Dose for screening (ODDs), which has been used in evaluating several drugs in other IACUC protocols at AFRRI. The purpose of using the ODDs method is that it allows testing in one gender (males in the present proposal), and requires fewer animals when compared to conventional Maximum Tolerated Dose (MTD) study. We will start with four times the dose chosen for survival studies (4X) (e.g. 400 mg/kg) as the starting dose [18-20]. Choice of 4X concentration of the drug for toxicity is from the experience with the (b)(4) screening project, where 4X concentration gave a good window to test efficacy safely. It is also helpful while planning dose optimization studies. Drug will be administered via orogastric gavage (see Section V.4.4.2) once daily for four days to accumulate a steady state concentration of the drug because of its fast clearance after oral delivery. Animals will be divided in two groups, with and without fasting. Animals will be fasted for 5-8 h hours before drug administration (by removing food from those cages. Food will be replaced once the drug has been administered). A maximum of six animals per drug dose will be used to evaluate toxicity, and will be monitored daily in accordance with IACUC policy #10 (Guidelines for establishment of early endpoints in experiments with expected mortality) for acute (1 to 4 h) and chronic (up to 14 days after final dose of the drug is administered) signs of toxicity after administration of drug. Signs of toxicity include decreased activity, squinting eyes, hunching, labored breathing, weight loss or mortality. If the 4X drug dose shows no toxicity in mice, the dose will be escalated to 8X (Table 1). Animals will be euthanized on day 14 and gross necropsy and histopathology will be carried out for any abnormal pathology in all major organs. Maximum tolerated dose (MTD) will be determined from this study.

Serum biochemical and whole blood hematological tests: Whole blood will be collected under anesthesia on day 14 after last dose of drug administration (see section V.4.4.2 for Blood collection) and blood will be transferred to EDTA tubes (200 µl) for

hematological analysis. The rest of the blood will be transferred to serum tubes (300-400 µl) for serum collection for biochemical analysis. Hematological parameters (CBC/differential) and serum biochemistry will be analyzed using an Advia 2120 hematology system from Siemens Corporation, or replacement analyzer, if necessary.

Table 1. Basic Acute toxicity study (14 day) after four doses of T3s (once daily) administered orally.

Drug Dose (mg/kg)	Groups	Diet Condition	# of animals	End point (whole blood)
4X	(b)(4)	Fasting	6	CBC/Differential, Serum Biochemistry
			6	
			6	
Controls			6

(b)(4)

V.1.2. Efficacy of DG, nano-DGs as radiation countermeasures - survival studies

For survival studies, 16 mice will be used in each group. Mice will be exposed to whole-body γ-radiation. $LD_{70/30}$ dose of radiation will be used such that survival in the control group falls in the range 10% to 50% at 30-days post-irradiation. The exact dose for CD2F1 mice will be obtained from the probit curve (will be determined in Feb 2016 under P(b)(6) . There will be three test article-treated groups and two control groups (Table 2). Drug dose will be determined based on the results obtained from toxicity studies. To see the reproducibility of the results, the experiment will be repeated once, and end point will be 30 day survival. One GT3 in 5% Tween®-80 group (subcutaneous [sc] administration) will be included as positive control.

Table 2. Survival efficacy of oral (b)(4)

Groups	Treatment	Multiplier
1 radiation dose	$LD_{70/30}$	1
3 drug groups	(b)(4) , po	3
3 vehicles (used for drugs)	2 (b)(4) po	4
1 positive control*	GT3 (100 mg/kg, sc, -24 h) and 5%Tween80-saline as its vehicle	2
Drug dose	1/4th of MTD determined by Toxicity study	1

Drug regimen	-3 d, -2 d, -1 d, and -4 h	1
Mice/group	16	16
1 time point	30 day survival	
Fasting/fed	2	2
Iterations	2	2
	Total no. of animals required	**448**

Mice calculation = Rad dose (1) x groups (3+3= 6) x drug regimen (1) x mice (16) x 2 treatments (fast and fed) x iteration (2) =384

*Positive control = 2 groups (GT3 sc, vehicle) x 1drug regimen x 16 mice x 2 iterations = 64

Experimental/Control Group	**Totals**
ODDS safety/toxicity study	120
Radiation survival studies	448
Extra	25
Total # of animals	**593**

Grand total of 593 including 25 additional mice (<5% of total no. of mice required for the protocol) to compensate for incidental loss during the experiment. Based on our previous studies and collection of data, we determine an additional requirement of 25 animals and particularly owing to the de novo nature of studies this becomes even more imperative to account for any unanticipated outcomes. The animals will also serve and support training purposes.

V.2. Data Analysis All data will be reported as means with standards errors or percentages where applicable.
Basic Toxicity (ODDS) – This is a qualitative study so no additional statistics will be conducted.
Preliminary survival study - Based on the power analyses, the sample size (n=16) is adequate to provide 80% power required to detect significant difference between two groups, if any, given 5% type I error and delta/sigma of at least 1.03, where delta is the estimated mean differences between two groups and sigma is the standard deviation. Previously (b)(6) n=24 was used in30-day survival studies to determine if there is 30% improved survival in the drug group compared to vehicle at LD70/30 dose of radiation. Data will be represented as Kaplan-Meier survival curves. Comparison of the survival curves will be made using Log-rank test. A p value of < 0.05 will be considered significant. Experiments will be conducted a maximum of 2 times with 16 mice per group. Due to the *de novo* nature of the study, 25 additional animals have been included to compensate for incidental loss and these animals will be used in the study and also for additional training.

V.3. Laboratory Animals Required and Justification

V.3.1. Non-animal Alternatives Considered Although high throughput screening and computer modeling have advanced significantly in recent years in identification of promising drugs, it would be simplistic to assume that cell systems or artificial intelligence modeling can replace the data that can be generated by using an animal model. Irradiation of animals will result in a cascade of changes including death of stem and progenitor cells in bone marrow, alterations in signal transduction pathways,

multiple organ dysfunctions, etc. due to differing radiosensitivities of organs. Currently, there are no alternatives in existence that can predict or compute the complexity of the response to total body irradiation.

V.3.2. Animal Model and Species Justification Recent advances in molecular techniques have allowed significant improvements in understanding the cellular and biochemical processes. These advances are possible only due to whole animal modeling of human ailments. The mouse, in particular, has high sequence homology to humans at a genomic level as well as similar hematological and immunological response to radiation. Mouse models not only confirm primary pathological processes but have also provided a venue for studying basic molecular, cellular, biochemical, and cytological processes. Furthermore, there are extensive data on the mouse for comparison, review and analysis. The practicalities of breeding and housing these small mammals have made the mouse model invaluable. The Principal Investigator's group at AFRRI has significant training and experience in handling mice in radiation countermeasure studies. In this protocol, we will use male CD2F1 mice since this is a historical strain AFRRI has been using for last 30 years. The PI also has used this strain in previous studies. To compare the previous data with this study, PI will use only male CD2F1 mice.

V.3.3. Laboratory Animals

V.3.3.1. Genus / Species Mouse. *Mus musculus*

V.3.3.2. Strain / Stock CD2F1

V.3.3.3. Source / Vendor VSD approved vendor (Harlan Inc preferred for CD2F1 mice)

V.3.3.4. Age (Procurement) 7-8 weeks

V.3.3.5. Weight (delivery) 22-24 grams

V.3.3.6. Sex Males have been used historically and will continue to be used in this study.

V.3.3.7. Special Considerations Commercially procured animals must be adventitious disease free (see Appendix 2).

V.3.4. Number of Animals Required (by species) Table

Animal (genus, species and common names)	**Original**
CD2F1	593

V.3.5. Refinement, Reduction, Replacement (3 R's)

V.3.5.1. Refinement The PI will take necessary steps for all personnel in the project to be rigorously trained in handling techniques (Tail-tattooing, ear-punch, injections, blood

collection, orogastric gavage and routine cage-side observations) to minimize distress and pain to the animals. Specifically, during capture and restraint of the rodents, care will be taken to ensure that handling does not contribute to distress.

V.3.5.2. Reduction Although basic toxicity and survival will be carried out on all three formulations, additional studies such as dose and time optimization and DRF will be done with the best formulation determined from the survival study. Additional studies will involve various doses of drug as well as various doses of radiation ranging from 100% survival to 100% lethality. Positive controls and negative controls will be used to confirm robustness of experimental conditions. In addition, control groups (such as vehicle) will be shared whenever possible between formulations that are dissolved in similar vehicles. In classical toxicology testing, groups of 10-20 mice of both sexes are routinely used. Optimal (non-toxic) Drug Dose for screening (ODDs), which has been used in evaluating several drugs in other IACUC protocols at AFRRI. In ODDs method testing is done in one gender (males in the present proposal), and the number of animals are 6 per group, a thereby reducing animal numbers significantly.

V.3.5.3. Replacement It is not feasible to use non-animal systems, nor a less-sentient model, in place of the rodent animal models to address the questions in this project.

V.4. Technical Methods

V.4.1. Pain / Distress Assessment

V.4.1.1. APHIS Form 7023 Information

V.4.1.1.1. Number of Animals 593

V.4.1.1.1.1. Column C ___0__ (# of animals)

V.4.1.1.1.2. Column D ___0__ (# of animals)

V.4.1.1.1.3. Column E ___593__ (# of animals)

V.4.1.1.1.4. Pain Category Assignments

Exp. #	Experimental/Control Group	C	D	E	Totals
V.1.1.	ODDS safety/toxicity study			120	120
V.1.2.	Radiation survival studies			448	448
	Extra			25	25
Totals:				593	593

Even though we don't expect any pain or distress during toxicology studies, we would like to keep the animals in category E as we don't have that information.

V.4.1.2. Pain Relief / Prevention Animals might experience pain and distress. Minimizing and alleviating pain in laboratory animals without compromising the methodological integrity of a research project is important both ethically and legally. Mice often exhibit pain and distress with only subtle changes in their behavior [21]. Potential signs associated with pain and distress in mice includes decreased food and

water consumption, weight loss, self-imposed isolation/hiding, rapid breathing, open-mouth breathing, abdominal breathing, decreased movement, abnormal posture, muscle rigidity, twitching, trembling, tremor, etc. as included in Appendix 1 (sample scoring sheet for clinical observations with criteria for rodent euthanasia) in IACUC policy #10 (Guidelines for establishment of early endpoints in experiments with expected mortality).

V.4.1.2.1. Anesthesia / Analgesia / Tranquilization The protocol will not use anesthetics or analgesics during radiation since they will adversely affect the outcome of the experiments or during oral administration of drug. The proposed study is to determine the effects of radiation and countermeasures on the function of the immune and blood forming systems. Use of any analgesics and anesthetics would interfere with the function of the immune system and therefore compromise the interpretation of the results [22]. Topical antibiotics will be applied if wounding occurs via in-cage fighting, under the guidance of the clinical veterinarian in accordance with standard treatment measures.
Anesthesia using standard Isoflurane apparatus under the guidance of the VSD will be carried out in mice for blood collection. All personnel will be extensively trained for efficient administration of the agents as well as to minimize handling stress.
Animals will be placed in the Isoflurane chamber and delivered a metered amount of 3-5% Isoflurane mixed with 100% oxygen (at the flow rate of 500-1000cc/min) until all voluntary motor movement ceases and the animal is recumbent for 10 seconds. Animal's respiration rate will be closely monitored through the Plexiglas chamber during induction of anesthesia. When animals are recumbent, they will be removed from the chamber and their nose/mouth placed in the anesthesia apparatus breathing/gas administration cone for maintenance of anesthesia at 1-3% Isoflurane and 100% O_2.

V.4.1.2.2. Pre- and Post-procedural Provisions Mice will be housed under standard conditions both before and after radiation procedures in accordance with current VSD rodent husbandry Standard Operating Procedures (see section V.5).

V.4.1.2.3. Paralytics N/A

V.4.1.3. Literature Search for Alternatives to Painful or Distressful Procedures

V.4.1.3.1. Sources Searched AGRICOLA, PubMed. EMBASE

V.4.1.3.2. Date of Search 11/19/2015 to 11/20/2015

V.4.1.3.3. Period of Search AGRICOLA: 1987-2014, EMBASE 1974-present
PubMed ~1970 to present.

V.4.1.3.4. Key Words of Search Radiation and pain, [b](4) toxicity and pain, analgesia, alternative, humane, alternative methods to blood collection by cardiac stick and inferior vena cava.

In order to increase specificity of literature review, several combinations such as radiation plus specific drug, radiation plus specific drug plus mice, alternatives to blood collection, (b)(4) AND toxicity AND pain were evaluated.

V.4.1.3.5. Results of Search

Table 2:Summary of Database Keyword Searches

Keywords	Hits		
	PubMed	AGRICOLA	EMBASE
(b)(4) AND radiation AND pain	0	0	0
(b)(4) AND analgesia AND pain	0	0	0
Radiation AND mouse AND pain	234	0	224
(b)(4) AND toxicity AND pain	0	0	0
Alternatives to blood collection by cardiac stick and inferior vena cava	0	0	0
Pain AND analgesia And mice	1873	52	2236
Radiation AND mouse AND pain AND alternative	5	0	11
Radiation AND humane	12	0	34

There are no alternatives to irradiation. While radiation itself does not cause pain or distress, it induces a number of changes in the body that alters immune response and destroys hematological tissues, resulting in opportunistic infections, and multiorgan dysfunction leading to death. It is anticipated that animals exposed to high lethal radiation doses will become moribund. Unfortunately, literature clearly demonstrates that use of analgesics alters radiation response and therefore leads to increase in animal number for better statistical results or for iteration of entire experiments. Since the purpose here is to compare the efficacy of the three experimental drugs we will be unable to use analgesics and anesthetics because they may interfere with the innate system [17].

V.4.1.4. Unalleviated Painful or Distressful Procedure Justification Because exposure to irradiation is potentially lethal or causes debilitating effects in humans, it is ethically impermissible to test the effectiveness of radiation countermeasures on human volunteers. Irradiation compromises the immune and blood forming systems leading to mortality. The radiation-induced mortality and potential percentage increase of survivors over 30 days using potential radiation countermeasures are study endpoints for this protocol. Administration of drugs and analgesics is not an option since it is well documented that they interact with the immune system which will confuse the interpretation [23-25]. Pain relieving measures are not used because such measures may compromise the experimental integrity of the study. All moribund animals will be euthanized by CO_2 inhalation and confirmatory cervical dislocation (see Section V.4.6 Euthanasia).

V.4.2. Prolonged Restraint The experimental animals will receive radiation at a dose rate 0.6 Gy per/min in the AFRRI Cobalt 60 gamma radiation facility. Animals will be irradiated in Lucite boxes (8 animals/box) and arranged in an array (according to the latest dosimetry map) using plastic racks. Mice will be inserted into the standard radiation boxes just prior to irradiation (~15 min of exposure time) and taken to the cobalt facility for irradiation. Animals will be restrained for no more than 60 min and returned to cages at the end of the irradiation period. They will be monitored daily following IACUC policy #10 (Guidelines for establishment of early endpoints in

experiments with expected mortality) (at least three times a day during critical period with no more than 10 h interval between late night and morning check and at least twice a day during non-critical period) for 30 days and euthanized at the completion of the observational period.

V.4.3. Surgery N/A

V.4.3.1. Pre-surgical Provisions N/A

V.4.3.2. Procedure(s) N/A

V.4.3.3. Post-surgical Provisions N/A

V.4.3.4. Location N/A

V.4.3.5. Surgeon N/A

V.4.3.6. Multiple Major Survival Operative Procedures N/A

V.4.3.6.1. Procedures N/A

V.4.3.6.2 Scientific Justification N/A

V.4.4. Animal Manipulations

V.4.4.1 Ear punch: Three animals/ shoe box for toxicity studies and four animals/ shoe box for survival studies will be housed. They will be identified either by ear punch or tail tattoo.

Procedure for ear-punch

a. Soak the ear punch (Fine Science Tools, Cat# 24212) in a disinfectant (100% ethanol) before use and between animals.
b. Place the device on the pinna of the ear (external ear) where the skin is thin avoiding the cartilage.

Press firmly to punch a circular hole through the ear

Tattoo procedure: Tattooing will be done either with a machine from Labstamp system following the SOP provided by the company or any other machine certified by VSD.

Irradiation: These will follow the standard AFRRI protocol with mice placed in restrainers shortly prior to exposure, irradiation at the cobalt facility and return to VSD for further monitoring. Briefly, the experimental animals will receive radiation at a dose rate of 0.6 Gy per/min in the AFRRI Cobalt 60 gamma radiation facility. Exact dose of radiation will be determined based on the probit curve. Animals will be irradiated in Lucite boxes (8 animals/box) and arranged in an array (the latest dosimetry map) using plastic racks. Animals will be restrained for no more than 60 min and returned to cages at the end of the irradiation period. They will be monitored daily following IACUC policy #10 (Guidelines for establishment of early endpoints in experiments with expected

mortality) (3-4 times a day during critical period with no more than 10 h interval between late night and morning check and at least twice a day during non-critical period) for 30 days and euthanized at the completion of the observational period.

V.4.4.2. Oral gavage: Oral administration will be done by orogastric gavage undertaken using 18-20 gauge gavage needle (animal feeding needles, disposable-sterile, non-toxic and nonpyrogenic, 1 ½" length). Non-disposable, metal ball ended, oral gavage needles of similar gauge and length are included as an alternative to the disposable needles. Drug volume will be 0.1 - 0.2 ml (maximum volume 10 ml / kg). The animal will be restrained in a vertical position to align the spine straight. The bulb will be introduced into the mouth horizontally. Using the needle as lever, the syringe will be moved into a vertical position and the needle dropped down the esophagus into the stomach. The needle contents will be administered when the needle hub touches the animal's mouth. All precautions will be taken to ensure that the placement of the needle is properly positioned and that the animal is not in distress. No forceful feeding will be done to prevent perforation of the esophagus.

Injections: Subcutaneous injections will be given with either a 23 or 25 G needle to the nape of the neck of 0.1 ml (maximum volume 1 ml for 25 to 38 g animals). A disposable sterile needle will be used for all sc injections. One needle will be used per cage containing generally 4 animals. Endotoxin testing for all drugs will be completed prior to any animal testing at AFRRI and a report submitted for IACUC/VSD review and approval. The endotoxin tests are conducted by Charles River Laboratories. At the same time, pH will be tested to ensure that it falls in the range (6-8 for sc administration) stipulated by IACUC. It is expected that the osmolality will not be more than AFRRI IACUC's recommended levels (IACUC Policy #9: Non-pharmaceutical grade experimental drug formulations to be used in experimental animals).

Blood collection: Mice will be anesthetized as described under section V.4.1.2.1. (Anesthesia). Blood draw for hematology is collected either by cardiac stick or from the inferior vena cava (IVC). The animals will be deeply anesthetized in the rodent anesthesia machine; the tail will be pinched for reflexive movement, indicative of insufficient anesthesia. If there is no response, the animal will be moved to the station with individual nose cone for continued anesthesia. An incision will be made on the right side below the abdomen of the animal, closest to the IVC, the vein exposed and blood withdrawn with a 23 - 25 G needle. Similarly, a 23 - 25 G needle will be used to perform cardiac stick while the animal is positioned under nose cone anesthesia. In both cases, the animals will be immediately euthanized on completion of blood draw by cervical dislocation.

V.4.4.1.1. Pharmaceutical Grade Drugs

V.4.4.1.2. Non-Pharmaceutical Grade Drugs Research grade (b)(4) (b)(4) and will be tested at AFRRI using the current protocol (using AFRRI intramural funds for animal studies). The following formulations will be supplied by (b)(4) (b)(4)

(b)(4)

V.4.4.2. Biosamples Blood and tissue

V.4.4.3. Adjuvants N/A

V.4.4.4. Monoclonal Antibody (MAb) Production N/A

V.4.4.5. Animal Identification Generally, cage cards will be used to distinguish drug-treated and control groups. Animals will be randomly distributed in groups. Animals will be identified by ear punch or tattoo at investigator's discretion. Ear punch will be performed as described in V.4.4.1.

V.4.4.6. Behavioral Studies N/A

V.4.4.7. Other Procedures N/A

V.4.4.8. Tissue Sharing
V.4.4.9. Animal By-Products N/A

V.4.5. Study Endpoint The time frame for experiment V.1.1 (basic toxicity) will be 14 days after final drug dose administration. The radiation survival studies will span 30 days after radiation exposure (V.1.2).
It is anticipated that the animals involved in these studies may succumb to death either due to a drug administration or radiation or a combination of the two. To maintain a suitable baseline for humane treatment of the animals while adhering to the study objective, the IACUC recommendations stipulated in IACUC policy #10 (Guidelines for establishment of early endpoints in experiments with expected mortality) with some minor modification (as stated later in the paragraph) will be implemented for judging morbidity and moribundity. The moribund condition is defined as a clinically irreversible condition leading inevitably to death. Signs of morbidity in the mouse include difficulty in breathing, ruffling of hair; drying of lacrimal fluid, fall in body temperature, loss of appetite with/without diarrhea. A modified IACUC policy #10 (Guidelines for establishment of early endpoints in experiments with expected mortality) will be used to record the scoring of clinical signs of pain in animals (attached Appendix 1). PI would like to change the score for the "Changes in breathing" from 3 to 2 and add an in between score of 6 for "Dyspnea / labored breathing" under "Respiratory rate". Description of the score 12 will be "Abdominal breathing/ gasping – open mouth breathing". Previously there was a large jump between a score of 3 (change in breathing) to 12 (abdominal breathing/ gasping – open mouth breathing). From the experience gathered from the studies performed recently, the PI thinks by adding a score of 6 in between 3 and 12 would enhance efficiency of the scoring system giving a fair advantage to the study outcome. PI will seek veterinarian's input for training the staff adequately to learn the suggested scoring system.
a) Body weights will be recorded prior to radiation.

b) Once animals reach a cumulative score of 6, concern cards ("green cards") will be put up, weights will be recorded and monitored with each subsequent scoring change.
c) Animals that exceed 35% body weight loss with any other clinical signs are scored at a 12 and will be euthanized immediately.
To adhere to the policy of preventing animal distress, the PI will facilitate the late PM and early AM checks (not more than 10 h apart) in addition to two times a day checks during the critical lethality period (early morning, late morning, and late afternoon and evening). During non-critical periods, we will continue to check animals except late night. All morbid mice will be monitored carefully and their conditions scored for documentation (Appendix 1, revised scoring sheet).
PI will use a scoring card for each animal in the critical period and scored in each observation. Cumulative Scores below 6 will not be recorded in the scoring sheet. Mice will be euthanized if there is a score of 12 in a single category or a cumulative score of 12 in multiple categories.
No supportive care is proposed, however, moribund animals will be immediately euthanized. VSD veterinarians will be consulted for all matters regarding the animal welfare.

V.4.6. Euthanasia It is anticipated that at high radiation doses, animals will demonstrate varying degrees of morbidity and moribund, which makes it critical to define the criteria for euthanizing the animals without undermining the study objective.
In toxicity studies, if any animal shows discomfort (hunching, decreased activity, inappetence, separation from cage-mates), that animal will be under careful observation on consultation with the attending VSD veterinarian. Mice found moribund (defined in V.4.5.) or meeting the criteria for euthanasia following a modified IACUC policy #10 (Guidelines for establishment of early endpoints in experiments with expected mortality) (score sheet attached) will be euthanized by CO_2 inhalation plus confirmatory cervical dislocation by investigator/technician according to the directives of the VSD-SOP (VS0211: Rodent Euthanasia Guidelines) and in accordance with current AVMA Guidelines on Euthanasia [26, 27]. At the conclusion of the experimental time frame, all animals that survived the procedures of irradiation, drug intervention and controls, will be euthanized by CO_2 inhalation plus confirmatory cervical dislocation and their carcasses disposed of according to VSD regulations. An alternate method of euthanasia by cervical dislocation after exsanguination (by cardiac stick or inferior vena cava) under deep isoflurane anesthesia will be applied in experiment V.1.5 (see Section V.4.4.2 Blood collection).

V.5. Veterinary Care

V.5.1. Husbandry Considerations The AFRRI vivarium follows stringent protocols for the housing and care of all animals. The PI and designated team members will adhere to all the policy and guidelines set forth by standard operating protocols of the VSD. The specific requirements for mice housing should meet the following criteria of opportunity for social interaction, opportunity to carry out normal behavior and the opportunity to rest and withdraw from each other [28]. Mice are social animals and hence will be caged together in groups of 4 or 8. Nestling pads will be provided in each cage during bedding changes. In cage shelters will also be provided as an enrichment strategy at the discretion of the PI depending on experimental conditions. Animals will receive

Harlan Teklad Rodent Diet 8604 and water *ad libitum*. Acidified water (pH 2.5 – 3.0) is routinely provided to AFRRI mice used in radiological experiments. Cages will be regularly changed and cleaned by VSD staff in accordance with Standard Operating Procedure. Animals will have 12 h light/dark cycle. Animals will be habituated to their surroundings and routine procedures prior to experimentation. In the event of procedures that last into the night cycle, care will be taken to minimize exposure to light by using red-lens flashlights.

V.5.1.1. Study Room As assigned by VSD

V.5.1.2. Special Husbandry Provisions N/A

V.5.1.3. Exceptions Mice will be socially (group) housed as described above, except when there is a possibility that during survival studies cage mates may be lost through attrition and for a period of time the sole surviving mouse may remain singly housed until the end of the 30-day study.

V.5.2. Veterinary Medical Care We do not project routine veterinary medical care of animals for injuries/inflammation related to injection site inflammation. In case of minor injuries arising from fighting, topical application of antibiotics is acceptable with consensus from the PI and VSD.

V.5.2.1. Routine Veterinary Medical Care Experimental animals will be observed daily by either the investigator or technician or both as outlined in the **Section V.4.5. Study Endpoint.**

V.5.2.2. Emergency Veterinary Medical Care Moribund animals (gasping, recumbent, non-responsive to mild stimulus) will be euthanized by trained personnel.

V.5.3. Environmental Enrichment: The husbandry staff provides hutches to animals not on active experiments whereas cotton nestlets are provided to animals on active experiments.

V.5.3.1. Enrichment Strategy Nestling pads will be provided in each cage during bedding changes as per AFRRI-VSD SOPs.

V.5.3.2. Enrichment Restrictions

VI. STUDY PERSONNEL QUALIFICATIONS AND TRAINING

NAME	DEGREE	TRAINING	DATE	PROCEDURES	YRS/MOS EXPERIENCE
(b)(6)				1, 3, 4b, 5	(b)(6)
				1, 3, 4, 5	
				1, 3, 4b, 5	
				1, 3, 4b, 5	
				1,3b,3c,4,5	

Procedure and manipulation codes:
Code 1= Animal handling and euthanasia

Code 2= Surgery (aseptic technique) pre- and post-operative care
Code 3= Injections (3a–ip, 3b-sc, 3c-gavage) - can say 3 if trained in all manipulations or add 3d-iv
Code 4= Blood collection under anesthesia (4a-cardiac, 4b-posterior vena cava)
Code 5= Tissue collection (after euthanasia) - doesn't need to be specific
Code 6 = Implantation (provide details)
Code 7 = Others - (provide protocol specific manipulations or procedures for e.g., retro-orbital bleeding, tail vein injection, or drug delivery)

VII. BIOHAZARDS/SAFETY All personnel working in the protocol have undergone necessary training in handling experimental animals. The amount of drug used will be small and standard safety precautions will be taken while handling them in the laboratory and in the vivarium. All personnel listed in the present protocol have been trained as general radiation users on a regular basis. All investigators and personnel will use appropriate protective gear while in the vivarium as described by the VSD. All listed personnel are current in safety training and medical surveillance.

X. ASSURANCES

Protocol Title: A novel nanoparticle oral formulation of tocotrienols as radiation countermeasure: a pilot study in mice, Mus musculus.

As the Principal Investigator on this protocol, I acknowledge my responsibilities and provide assurances for the following:

A. Animal Use: The animals authorized for use in this protocol will be used only in the activities and in the manner described herein, unless a modification is specifically approved by the IACUC prior to its implementation.

B. Duplication of Effort: I have made every effort to ensure that this protocol is not an unnecessary duplication of previous experiments.

C. Statistical Assurance: I assure that I have consulted with a qualified individual who evaluated the experimental design with respect to the statistical analysis, and that the minimum number of animals needed for scientific validity will be used.

D. Biohazard / Safety: I have taken into consideration and made the proper coordinations regarding all applicable rules and regulations concerning radiation protection, biosafety, recombinant issues, and so forth, in the preparation of this protocol.

E. Training: I verify that the personnel performing the animal procedures / manipulations / observations described in this protocol are technically competent and have been properly trained to ensure that no unnecessary pain or distress will be caused to the animals as a result of the procedures / manipulations.

F. Responsibility: I acknowledge the inherent moral, ethical and administrative obligations associated with the performance of this animal use protocol, and I assure that all individuals associated with this project will demonstrate a concern for the health, comfort, welfare, and well-being of the research animals. Additionally, I pledge to conduct this study in the spirit of the fourth "R", namely, "Responsibility," which the DOD has embraced for implementing animal use alternatives where feasible and conducting humane and lawful research.

G. Scientific Review: This proposed animal use protocol has received appropriate peer scientific review and is consistent with good scientific research practice.

H. Painful Procedure(s): I **AM** / **AM NOT** conducting biomedical experiments, which may potentially cause more than momentary or slight pain or distress to animals. If applicable, potential pain and/or distress **WILL** / **WILL NOT** be relieved with the use of anesthetics, analgesics and/or tranquilizers. I have considered alternatives to such procedures; however, I have determined that alternative procedures are not available to accomplish the objectives of this proposed experiment.

(b)(6)

Principal Investigator (Printed Name) Principal Investigator (Signature) (Date)

Appendix 1.
Clinical Observations with Criteria for Euthanasia (Rodent)

Criteria:	Description:	Score
Appearance:		
	Normal (smooth coat, clear eyes/nose)	0
	Hunched and/or fluffed	1
	Ocular discharge, and/or edema	3
	Soft stools (fecal matter around anus)	5
	Pale, white mucus membranes/skin	6
	Bloody diarrhea	9
	Blue mucus membranes/skin (cyanosis)*	12
Respiratory Rate:		
	Normal breathing	0
	Change in breathing (an increase or decrease in respiratory rate from normal baseline)	2
	Labored breathing/ Dyspnea	6
	Abdominal breathing (gasping +/- open mouth breathing)/ Diaphragmatic breathing*	12
General Behavior:		
	Normal (based on baseline observations)	0
	Stretching of hind limbs with abdominal motion (writhe) or grimace (App. B and C)	1
	Decreased mobility	2
	Ataxia, wobbly, weak	6
	Inability to stand*	12
Provoked Behavior:		
	Normal (moves when cage is disturbed, runs from hand (mice) or investigates (rat))	0
	Subdued; responds to stimulation (moves away briskly)	1
	Subdued even to stimulation (moves away slowly)	3
	Unresponsive to gentle prodding	6
	Does not right when placed gently on side within 5 seconds*	12
Weight loss		
	0-35% with no other clinical signs	0
	≥35% weight loss	12

*** Regardless of score, immediately euthanize (death is imminent)**

Individual or Cumulative Score:

< 6	Normal
6 - 11	Morbid: See VI.D.2 and VI.D.4 in IACUC Policy #10 for guidelines
≥ 12	Moribund: Notify responsible personnel immediately for euthanasia (if no single criteria is 12*). Any single criteria of 12* euthanize immediately; consider as 'found dead.'

I. NON-TECHNICAL SYNOPSIS

The threat of a limited radiological attack on American cities (i.e. a "dirty" bomb), or a nuclear incident, requires the development of a radiation countermeasure capable of protecting military personnel and other first responders, who might have to enter the scene and perform their duties for an extended period of time in a contaminated area. This countermeasure should have the capability of mitigating gastrointestinal and hematopoietic syndrome lethality in the general population. At present, there is no effective treatments for the acute radiation gastrointestinal syndrome and only two FDA-approved treatment for hematopoietic syndrome, which requires close patient monitoring by a highly skilled medical team that may not be available during a mass casualty event.

Hematopoietic syndrome usually occurs in humans with a dose between 0.7 and 10 Gy (70 – 1000 rads) though mild symptoms may occur as low as 0.3 Gy (30 rads) and is accompanied by varying degrees of thrombocytopenia that depend on a number of factors including age and health of the individual. Hematopoietic injury that causes death from increased risk of sepsis due to a suppressed immune system and from hemorrhagic events due to depletion of platelets (thrombocytopenia). As the radiation dose escalates, symptoms of a compromised immune and coagulation system persist, along with the addition of damage to the gastrointestinal tract. The impaired integrity of the gastrointestinal epithelium further increases the risk of bleeding, dehydration and sepsis. The increase in radiation dose also involves injury to other late responding tissues such as lung, skin, and kidney making the situation progressively worse and less medically manageable, and ultimately incurable. This study will employ cobalt-60 γ-radiation and utilize the well-defined, nonhuman primate (NHP) model of drug development. The first objective is to estimate radiation dose that will result in 50 - 70% lethality for NHPs after exposure to the AFRRI cobalt-60 γ-radiation source while receiving minimal supportive care defined in our protocol as antibiotics, fluids, and analgesics while excluding the administration of blood products. This would reflect the medical management expected to be available in the field during the first few days after a mass casualty incidence. The second objective is to assess the [(b)(4)] [(b)(4)] efficacy with and without granulocyte colony-stimulating factor (G-CSF) as improved survival following a lethal radiation exposure in NHPs.

II. BACKGROUND

II.1. Background

Military and civil defense organizations have an urgent requirement for medically effective radiation countermeasures. Only two drugs, granulocyte-colony stimulating factor (G-CSF) and pegylated G-CSF, have been cleared by the FDA as a treatment for the hematopoietic acute radiation syndrome (ARS). Another molecule, (b)(4) displays promise as a radiation countermeasure. (b)(4) the countermeasure that is being evaluated in this study, is a (b)(4) (b)(4) has shown multiple potential radioprotective effects in more than one vertebrate animal model. Its therapeutic benefits in preventing ARS appear to be a result of its ability to maintain hematopoietic cell viability [1], prevent apoptosis of irradiated bone marrow cells [2], cause expansion of the primitive progenitor population in combination with other cytokines [2, 3], enhance *in vivo* platelet and erythroid recovery following irradiation [4], reduce expression of endothelial adhesion proteins [5, 6], modulate platelet interactions with vascular endothelium [5, 7-9], prevent formation of petechiae, thrombin and microangiopathies [4, 5, 10-13], reduce fibrinogen and endotoxin levels [5], and enhance bone marrow hematopoietic cell mobilization into peripheral blood [14].

Agonistic activity at the (b)(4) (b)(4) appears to play an important role in modulating the cascade of events resulting in improved survival and reduced morbidity through direct interactions at multiple sites including vascular endothelial cells, bone marrow, and platelets. Administration of (b)(4) at 4, 6 or 24 h after exposure to lethal radiation increased survival and ameliorated radiation induced toxicity in the mouse, rat, and canine, and (b)(4) increased survival in NHP model (see Table 3). The mechanisms by which (b)(4) exerts its protective effects have not been fully characterized, but as summarized above, it has been shown that (b)(4) exerts a broad range of pharmacological effects. Figure 1 illustrates potential pathways by which (b)(4) increases survival in animal models of ARS. Administration of (b)(4) after irradiation acts through its receptor, c-MPL, which is expressed on multiple cell types including primitive hematopoietic progenitors, megakaryocytes, platelets and endothelial cells. Thus apart from restoring platelet production, (b)(4) may prevent radiation-induced vascular damage in a number of sensitive tissues and may enable improved production of endogenous (b)(4) by the irradiated liver.

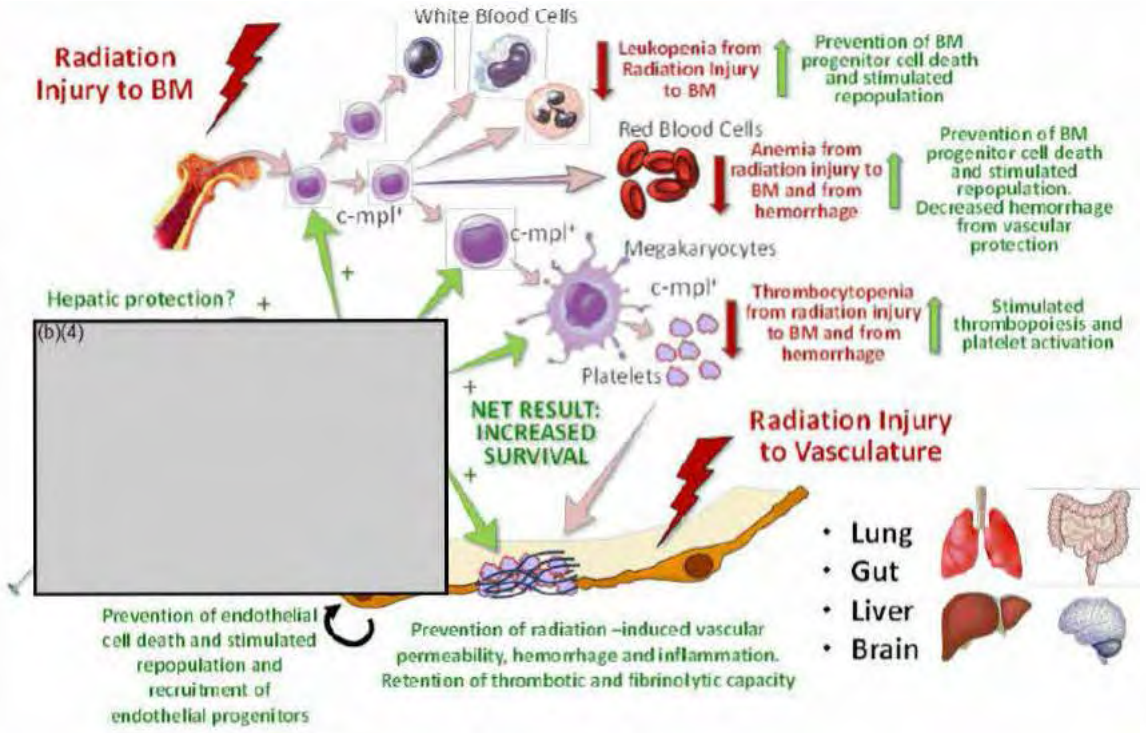

Figure 1: Schematic diagram illustrating the pathways by which (b)(4) may increase survival and reduce morbidity associated with ARS (original creation).

Data showing the impact of (b)(4) on overall survival and in reducing morbidity are described in the sections that follow.

Toxicity and pharmacokinetic studies: A single intravenous (iv) dose of (b)(4) (30 to 300 µg/kg) resulted in an increased platelet count in rats that reached a maximum after 6 days and returned to baseline after 12 days. The pharmacokinetics of (b)(4) were evaluated in studies conducted in rats, rabbits, and canines after single-dose iv administration, and in studies conducted in rats or canines after multiple-dose (once-daily or twice-daily) iv or subcutaneous (sc) administration. The half-life ($t_{1/2}$) of (b)(4) after single or repeat-dose iv administration was between 8 to 31 h in rats, ~26 to ~36 h in rabbits, and 18 to 56 h in canines. The long $t_{1/2}$ of (b)(4) in canines corresponded to a low clearance (CL). In all species, the volume of distribution was low, indicating that (b)(4) resides primarily in the vascular compartment.

The toxicity of (b)(4) was evaluated after a single iv dose (3 mg/kg) in rats, daily iv doses (0.3 mg/kg/day) for 1 week in rats and canines, weekly iv or sc doses (0.3 mg/kg/wk) for 4 weeks in rats and canines, and weekly iv doses (0.3 mg/kg/wk) for 13 and 26 weeks in rats and 13 and 39 weeks in canines. The main findings were increased megakaryocytes in spleen and bone marrow, platelet counts, and mean platelet volume, which were dose-related in rats and canines, increased spleen weights in rats, and increased intravascular platelets in the lung vasculature of canines (13- and 39-week study). These findings were considered to be expected pharmacologic responses. Bone marrow fibrosis and hyperostosis (new bone formation) observed in rats (only in the 1-week and 4-week studies), but not canines, were considered secondary to exaggerated pharmacologic responses. All findings were reversible. In addition, there were no

antibodies to (b)(4) detected in rats or canines given weekly iv doses for up to 26 and 39 weeks, respectively, or weekly sc doses for 4 weeks.

(b)(4) was negative for genotoxicity. In iv and sc studies evaluating immunogenic potential in mice (once weekly doses) and rats (twice weekly doses), no antibodies against the (b)(4) were detected with no cross reactivity with endogenous (b)(4) Similarly, antibodies were not detected in the 4-week iv and sc (weekly doses) toxicity studies in rats and canines.

Mouse Survival Data: (b)(4) was administered by sc injection to mice 6 and 24 h after exposure to an $LD_{50/30}$ or $LD_{70/30}$ total body dose of γ-radiation from a ^{137}Cs source. Each treatment group had 10 males and 10 females (total of 20 animals). Survival was monitored for 30 d. When (b)(4) was administered 6 h after an $LD_{50/30}$ or $LD_{70/30}$ dose of radiation, mice were completely protected (100% survival) against lethal radiation (Figure 2). When administered 24 h after an $LD_{50/30}$ dose of radiation, 90% survival was observed, compared with 75% in the vehicle treated control group. When (b)(4) was administered 24 h after an $LD_{70/30}$ dose of radiation, 75% survival was observed, compared with 55% survival in the vehicle treated control group.

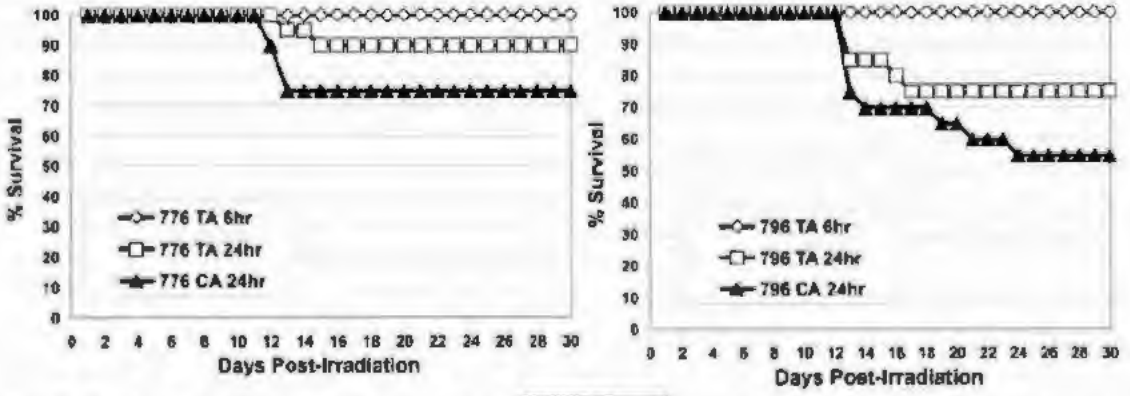

Figure 2. Survival of mice (n = 20) treated with (b)(4) or vehicle (CA) following two doses levels of lethal total body exposure to γ-radiation (776 cGy – Left Figure and or 796 cGy – Right Figure).

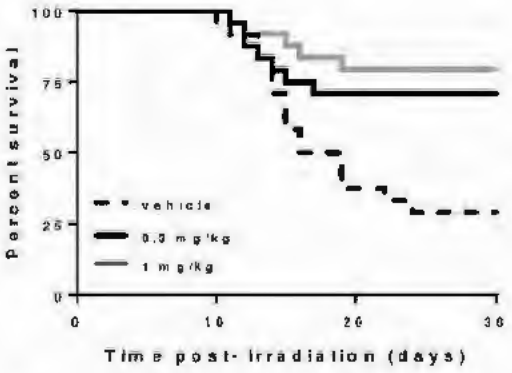
Using the same manufacturing batch that will be used in the proposed NHP studies, an additional acute radiation study was recently conducted at AFRRI in a different strain of mice (12-14 week old CD2F1 male mice) that were exposed to ^{60}Co TBI (9.3 Gy, $LD_{90/30}$, 6 Gy/min). Mice were administered a single injection (300 or 1,000 µg/kg) of (b)(4) sc, prior to irradiation, 4 and 24 h post-irradiation. Post-irradiation survival was monitored for 30 d. A statistically significant survival benefit was observed in all groups that received (b)(4) (at 24 h: 71% survival for 300 µg/kg (b)(4) 79% survival for 1,000 µg/kg (b)(4) versus 29% survival of saline group, (Log rank test $p = 0.0013$).



P value	0.0013

Figure 3: Survival of mice (n = 24) treated with (b)(4) at two doses levels (0.3 and 1 mg) or vehicle of lethal total body exposure to radiation (9.3 Gy – ^{60}Co TBI)

The positive and rapid onset of activity observed for (b)(4) drug substances in this initial screening in mice warrants further evaluation in the large animal model. These results are consistent with those obtained with recombinant human (b)(4) in the NHP model.

Rat Pilot Radiation Study: (b)(4) was administered sc to female rats (n = 8) at 6 or 24 h after exposure to an $LD_{70/30}$ TBI dose of γ-radiation (Gammacell 3000 irradiator). Survival was substantially increased in the animals that received 3,000 µg/kg of (b)(4) compared with animals that received vehicle or 30 µg/kg of (b)(4) (Figure 4). Survival of animals receiving (b)(4) at 6 and 24 h post-irradiation are similar but both are significantly higher than that of rats receiving (b)(4) at 48 h post-irradiation.

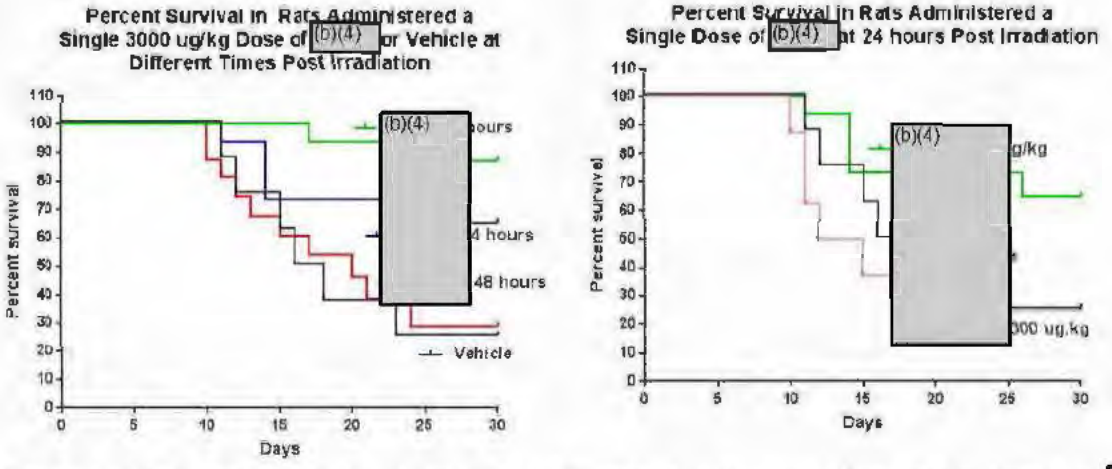


Figure 4. Pilot survival study in rats (n = 8) treated with escalating single doses of (b)(4) administered at 6, 24 or 48 h or vehicle following lethal total body exposure to γ-radiation. In the left panel only the 24 h control data has been plotted for clarity. All controls for other time points (6 hand 48 h) had similar survivors.

Canine Survival Data: A pilot radiomitigation study was conducted in canines with (b)(4) These are initial results as dose had not been optimized for canine and they are

known to be less sensitive to the platelet elevating effects of (b)(4) compared to other species. Results are presented in Table 1 and Figure 5.

Table 1. Effects following a single 10 mg/kg dose of (b)(4) or vehicle administered to canine 24 h after total body radiation exposure.

Endpoint	Vehicle	(b)(4) Treated
Mortality	9/12	7/12
Mean survival time (days)	17	36
Diarrhea	4/12	2/12
Blood transfusions	2.25/animal	1.25/animal
Severe neutropenia duration (days)	8.3	5.4
Neutropenia nadir	0.02 x 10^9/L	0.09 x 10^9/L
Days of febrile neutropenia	2.92	1.08
Mild to severe hematopoietic bone marrow hypocellularity	10/12	6/12
Mild to moderate necrohemorrhagic bronchioalveolar or minimal subacute bronchioalveolar inflammation	10/12	6/12

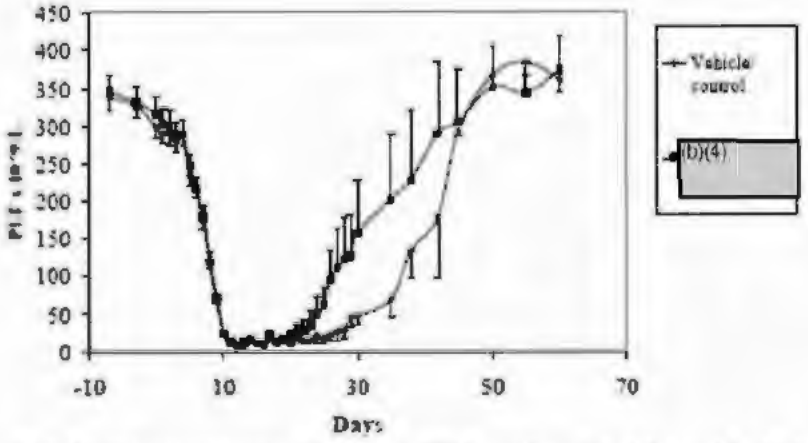

Figure 5. Time course of platelet concentrations following TBI in canines administered a single sc dose of saline vehicle or 10 mg/kg (b)(4) 24 h after irradiation (n=12, 2.7 Gy).

NHP Data with (b)(4) NHPs were exposed to 7 Gy of γ-radiation and then administered vehicle, (b)(4) (b)(4) 10 µg/kg) sc at 0.5 and 24 h post-radiation. Blood transfusions were administered to all treatment groups except (b)(4) As shown in Table 2 and Figure 6 (b)(4) treatment significantly promoted hematopoiesis recovery, improved the quality of life and additionally simplified supportive care in ARS rhesus monkeys [15].

Table 2. Survival and selected clinical observations following TBI to NHP.

Group	No. of Animals	No. of Survival Animals	Average No. Of Days to Mortality	No. of Animals with Fever	Transfusion Volume (ml)	Highest Body Temp (°C)
IR = Vehicle	6	2	19.4±1.7	6	135 ± 31.5**	40.4
(b)(4)	6	5	17.0	2	120 ± 37.9**	40.7
	6	6	-	1	0	39.8

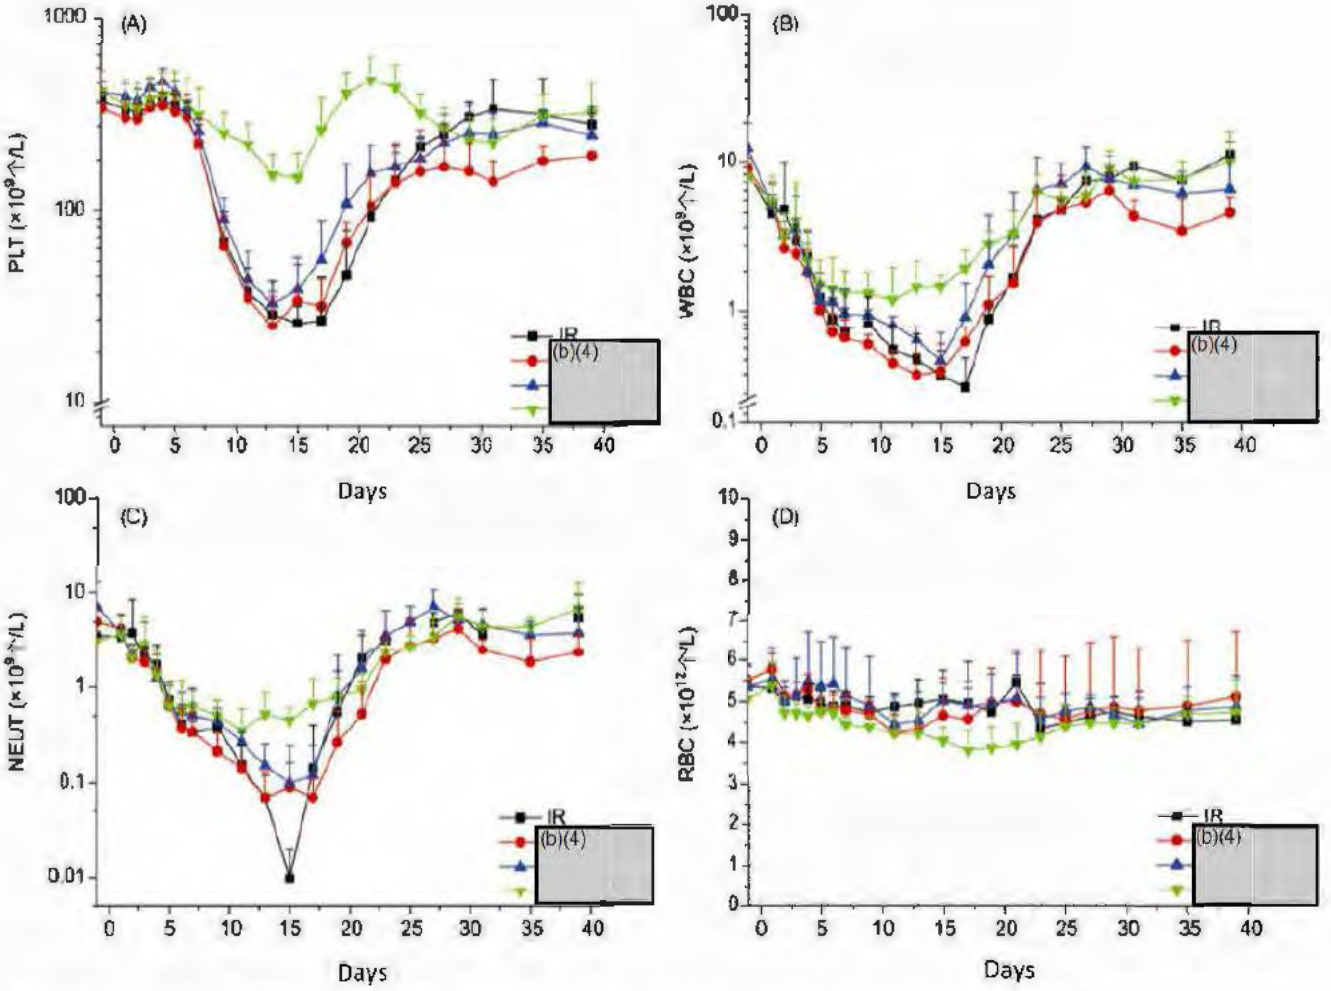

Figure 6. Platelet, WBC, neutrophil and RBC counts vs. time in days post-irradiation (7 Gy) to Rhesus macaques followed by either (b)(4) (10 µg/kg) sc at 0.5 and 24 h post-radiation.

Differences in potency resulting in platelet count elevation amongst species

The (b)(4) dose required to achieve maximal platelet elevation in humans, mice, rats, canines and rhesus macaques is shown in Figure 7. The dose required to achieve a 2-3-fold elevation in humans is ~100-fold lower compared to mice, ~1,000-fold lower compared to rats and >10,000-fold lower compared to canines and NHPs. The maximum platelet elevation was greater than 3-fold for all species except canine is the least in which the maximum platelet elevation was ~1.7 fold, suggesting that the canine is the least responsive species. Figure 8 shows the platelet elevation in NHPs vs. time following a single dose of (b)(4) at 0.5, 2, 10, 20 or 40 mg/kg. The species differences in potency has been described for *other* (b)(4) in the literature and is attributed to differences in receptor affinity (b)(4) Despite the differences in dose, there is clear evidence that comparable maximum platelet response are observed in some species with (b)(4)

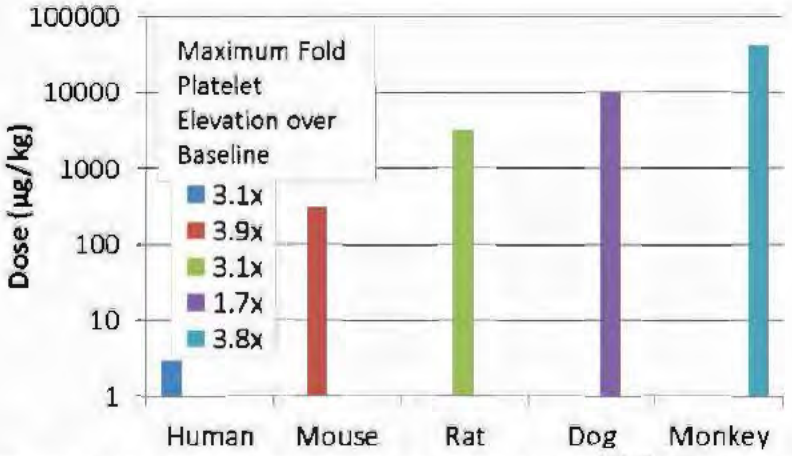

Figure 7. Cross species comparison of the dose of (b)(4) required to achieve the maximum platelet elevation compared to baseline.

(b)(4),(b)(6)

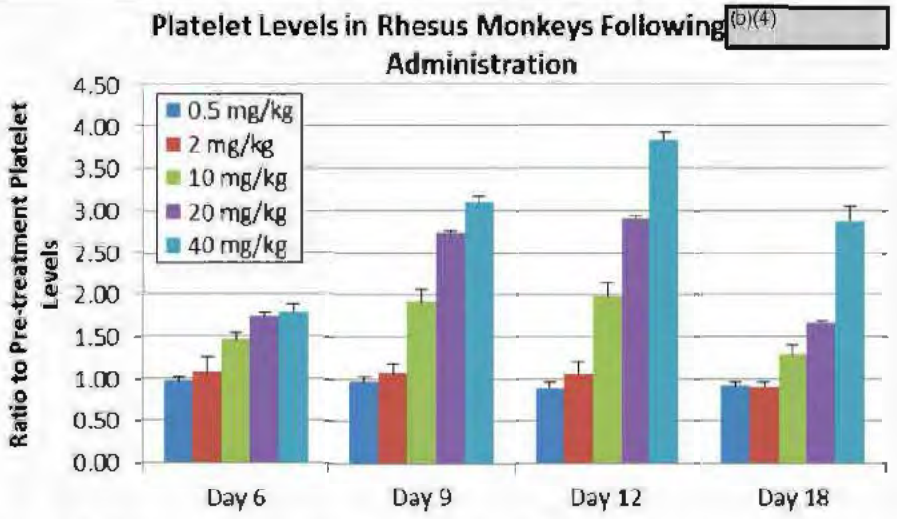

Figure 8. Ratio of the platelet concentration to the pre-treatment platelet concentration following a single dose of (b)(4) to Rhesus monkeys.

(b)(4),(b)(6)

Clinical studies: (b)(4) has been investigated in two human studies. The safety, tolerability, pharmacokinetics, and pharmacodynamics of single ascending iv doses of 0.375, 0.75, 1.5, 2.25, and 3.0 µg/kg (b)(4) administered to 40 healthy men were

evaluated in the first clinical study (b)(6) and it was found to be safe and well tolerated. In the (b)(6) study conducted in subjects with cancer treated with platinum-based chemotherapy, results of analysis of platelet counts in subjects who received (b)(4) at the 2.25 and 3.0 µg/kg dose levels indicated a reduction in chemotherapy-induced decline in platelets and a faster recovery relative to placebo, suggesting potential efficacy for (b)(4) in the prevention of chemotherapy-induced thrombocytopenia.

Justification of dose for NHP study

A 30 mg/kg dose of (b)(4) is proposed for this NHP whole body irradiation study and it is based on different activities between (b)(4) This dose is justified based on platelet elevation in unirradiated animals and survival data following whole body irradiation (see above). In these studies, doses that produce a minimum of 3 fold increases in platelet's concentrations in unirradiated animals appear to consistently produce a survival benefit in irradiated animals (Table 3). Where survival benefit has been demonstrated (b)(4) administration, there is also an estimate of ~3 fold change in platelet concentration. A 30 mg/kg dose of (b)(4) in Rhesus macaques is expected to increase platelet concentrations 3.3 fold of the baseline (Figure 8). The difference in the magnitude of the dose for (b)(4) (0.02 mg/kg) compared to the proposed dose of 30 mg/kg for (b)(4) in NHPs is a result of (b)(4) (b)(4) (b)(4) Because of its sequence homology to endogenous (b)(4) (b)(4) Species differences in potency have been described for other (b)(4) (b)(4) Nevertheless, despite the substantial species differences in dose required for platelet elevation, there is enhanced survival in mice and rats treated with (b)(4) at these doses.

Taken together these data (specifically data from NHP studies) support the hypothesis that administration of (b)(4) at a dose of 30 mg/kg will provide a survival benefit in this study. The platelet response to (b)(4) at 30 mg/kg in non-irradiated NHPs will be verified in an initial study before comparing the NHP response to (b)(4) after irradiation and before studies to assess a survival benefit. The (b)(4) response may be diminished in irradiated animals compared to non-irradiated NHPs due to the depletion of hematopoietic progenitors caused by radiation exposure.

Table 3: Summary of survival results for (b)(4) and vehicle treated animals at different time points post irradiation in animal models of ARS and corresponding elevations of platelets at the doses indicated in unirradiated animals.

Species	Strain	n	Radiation Dose (Gy)	Drug	Dose (mg/kg)	Drug Administration Time Relative to Irradiation (Hours)	Maximum Platelet Elevation in Non-Irradiated Animals (fold increase)	Survival Treatment	Survival Vehicle	Ref#
Mouse	C57BL/6	20	7.76	(b)(4)	0.3	6	3.9	100%	75%	a

II.2.5. Results of Search

Summary of Results

Several studies have been conducted using other (b)(4) mainly (b)(4) but mostly for chronic immune thrombocytopenia or thrombocytopenia induced by liver disease or chemotherapy. Administrations of (b)(4) (b)(4) resulted in adverse effects in clinical trials, however were successful at increasing platelet concentrations. (b)(4) (b)(4) have been successful in the clinic for treating idiopathic thrombocytopenia purpura and are FDA approved for these indications.

The safety and pharmacokinetics (PK)/pharmacodynamics (PD) of (b)(4) in humans has been evaluated in healthy human volunteers. Platelet levels in patients treated with (b)(4) showed dose-related elevation as compared to results with placebo. The pharmacokinetic profile was characterized for doses of 2.5 and 3.0 µg/kg, although the dose relationship could not be fully elucidated.The two highest doses of (b)(4) appeared to increase burst-forming units-erythroid and colony-forming unit counts, indicating some effects on progenitor lineages. (b)(4) was well tolerated, with

no evidence of antibody formation in this single-dose study. A non-clinical safety assessment of (b)(4) was completed in rats, dogs and rabbit model.

III. OBJECTIVE / HYPOTHESIS

The first objective is to define a dose level that is determined to be close to the $LD_{50\ 70}$ for NHPs after exposure to the cobalt-60 γ-radiation while receiving minimal supportive care including antibiotics, fluids and analgesics. The second objective is to assess the (b)(4) efficacy with and without G-CSF as improved survival following a lethal radiation exposure in NHPs. This study is to investigate the beneficial effects of radiation countermeasures such as (b)(4) (either alone or in combination with G-CSF) as measured by significant increase in 60-day post-irradiation survival when the drug administered post-irradiation (as a radiomitigator) in an NHP model with minimal supportive care (antibiotics, fluid, analgesics). This study also includes studying hematopoietic recovery including neutrophil and platelet profiles, mean survival time (MST), incidence of febrile neutropenia, thrombocytopenia, infection, and incidence/severity of diarrhea in NHPs.

To achieve the above objective, we need to determine the radiation doses close to estimated $LD_{50\text{-}70}$ value of cobalt 60 γ-radiation source for NHPs under minimal supportive care. Though experiments have been performed in the past for evaluation of various radiation countermeasures without any supportive care using historic values from other institutions, the level of lethality for cobalt-60 source at our institute has not been determined under minimal supportive care as mentioned above. This objective is necessary before proceeding to an efficacy study with the proposed radiation countermeasure. In addition, to use an appropriate drug dose in the efficacy study, PD of the drug need to be evaluated. Hence, we will be investigating PD of the countermeasure in both non-irradiated and irradiated NHPs before proceeding to the efficacy study.

We hypothesize that (b)(4) (alone or in combination with any additional countermeasure used in this study) will be an effective radiation countermeasure in NHPs and administration of this agent post-irradiation will enhance survival over and above the protection provided by the vehicle control group with minimal supportive care.

IV. MILITARY RELEVANCE

The search for treatments to counter potentially lethal radiation injury has been underway for the past several decades, resulting in multiple classes of radiation countermeasures. However, to date only G-CSF and pegylated G-CSF have been approved by the US FDA for the treatment of neutropenia associated with acute radiation syndrome (ARS). Though G-CSF has already been procured, along with GM-CSF, for the strategic national stockpile for use in a radiological emergency [18], the adverse consequences of G-CSF (exacerbation of long-term stem cell damage through excessive differentiation stimulation, exacerbates delayed lung damage in animal model of ARS) which need to be taken into consideration. Thus there is a need for developing additional radiation countermeasures to address thrombocytopenia associated with ARS. Follow-on studies may be needed to address the potential interaction with or synergism with concomitant G-CSF administration.

The problem has become more acute in recent times due to the unpredictable nature of terrorist attacks. Recognizing this urgent need, the U.S. Department of Defense has assigned top priority to the "development of medical countermeasures to radiation exposure" against both early and late arising health effects. The current proposed studies are conducted with interagency collaboration and funding support from (b)(4) These concerns imply the urgent need to develop an appropriate countermeasure for radiation injuries potentially sustained by troops during combat operations and enable commanders to make judicious decisions in troop deployment. There are several drugs at different stages of development. This study will perform essential research and development of promising radiation countermeasures for potential injuries sustained by military personnel who have been exposed to ionizing radiation.

V. MATERIALS AND METHODS

V.1. Experimental Design and General Procedures

We propose to carry out the following experiments to estimate the LD_{50-70} value of cobalt-60 γ-radiation in NHPs receiving minimal supportive care (antibiotics, fluid, and analgesics) and to (b)(4) (alone or in combination with G-CSF).

V.1.1. Experiment 1: Determination of estimated radiation dose that will result in 50 - 70% lethality in a minimal supportive care (antibiotics, fluid, and analgesics) NHP model

A recent publication suggests that a lethality curve of NHPs exposed to various qualities of radiation (with and without supportive care) has only been determined to a limited extent [19]. To the best of our knowledge, there is no published report detailing either a full lethality curve or $LD_{50/60}$ value of NHPs receiving cobalt-60 γ–radiation and minimal supportive care (antibiotics, fluid, and analgesics).

Based on extensive discussion with the statistician, we propose to use two different doses of radiation (7.0 Gy and 7.4Gy) with 10 NHPs in each group. It is important to note that we have recently conducted an experiment using 7.2 Gy in 16 NHPs receiving exactly the same supportive care proposed in the current protocol resulting in 43% mortality within 60 days post-irradiation. Data of this study along with data resulting from two additional doses of radiation proposed in this protocol will be used to estimated radiation dose that will result in 50 - 70% lethality.

Table 4. Blood sample collection for LD_{50-70} estimation study

Time in relation to irradiation	Blood			
	CBC 0.5 ml		Biochemistry 0.5 ml	Total blood ml
-7 d	+		+	1.0
-4 d	+		+	1.0
-1 d	+			
0 d (Irradiation)				
1 d	+		+	1.0

4 d	+		+	1.0
7 d	+			0.5
10 d	+		+	1.0
13 d	+			0.5
19 d	+		+	1.0
25 d	+			0.5
31 d	+		+	1.0
38 d	+			0.5
45 d	+		+	1.0
52 d	+			0.5
60 d	+		+	1.0

We will be well within the acceptable published blood collection volumes [20] that are followed at AFRRI. According to these guidelines 1% blood (2.8 ml per day for 4 kg NHP – the minimum body weight of NHPs in this experiment) can be withdrawn every 24 h. Up to 10% of circulating blood volume can be drawn in a single day repeated every 3-4 weeks. For the entire span of the study, the total blood volume drawn will be well below the recommended maximum limits as outlined in section V.4.4.2 Biosamples.

V.1.2. Experiment 2: Determination of pharmacodynamics of (b)(4) in sham irradiated and irradiated NHPs

One 30 mg/kg dose (20 mg/ml in 0.9% saline solution administered at a dose volume of 1.5 ml/kg) of (b)(4) will be tested in four NHPs for PD. The (b)(4) will be administered sc (dorsal scapular region – midline, injection details under section V.4.4.1. Injections) 24 h after sham irradiation to factor in relevant stress in the hematopoietic parameters. Blood samples for PD (CBC – platelet counts) will be collected as shown in the table given below and as outlined in section V.4.4.2 Biosamples. Each animal will be observed twice daily by Veterinary Science Department/research staff for evidence of pain or distress. Hematology and body temperature will be monitored throughout the study. Body temperature via implanted microchips, blood pressure via arm cuf/Doppler, body weights and pulse will be taken at the time of each blood collection.

Table 5. Blood sample collection for PD study with sham irradiation

Time in relation to drug injection	CBC (0.5 ml)	Total vol (ml)
- 7 d	+	0.5
- 4 d	+	0.5
- 1 d	+	0.5
0 d (Sham irradiation, 0 Gy)		
1 d	+	0.5
3 d	+	0.5
6 d	+	0.5
9 d	+	0.5
12 d	+	0.5
18 d	+	0.5
24 d	+	0.5
30 d	+	0.5

For the entire span of the study, the total blood drawn will be well below the recommended maximum limits [20].

After a 30 d or more wash-out period, the same four animals will be used to determine PD of (b)(4) in an irradiated model. NHPs will be irradiated with 7.2 Gy and one dose of (b)(4) (30 mg/kg) will be administered sc 24 h after irradiation. Blood samples for PD (CBC – platelet count) will be collected as shown in Table 6 given below.

Table 6. Blood sample collection for PD study with irradiation

Time in relation to irradiation	CBC (0.5 ml)	Total vol (ml)
- 7 d	+	0.5
- 4 d	+	0.5
- 1 d	+	0.5
0 d (Irradiation)		
1 d	+	0.5
3 d	+	0.5
6 d	+	0.5
9 d	+	0.5
12 d	+	0.5
18 d	+	0.5
24 d	+	0.5
30 d	+	0.5

For the entire span of the study, the total blood volume drawn will be well below the recommended maximum limits [20] as outlined in section V.4.4.2 Biosamples.

V.1.3. Experiment 3: Investigate the radiomitigative efficacy of (b)(4) in a pilot study in NHPs

The radiomitigative potential of (b)(4) will be evaluated in irradiated NHPs. Based on the results from Experiment 1, we will be targeting a radiation exposure dose that will contribute to a lethality rate between 50 – 70% (not above 8 Gy). Once the value is determined, PI will provide a memorandum to the IACUC notifying them of the radiation dose that will be used for the drug efficacy studies (Experiment 3 and Experiment 4). We will be irradiating 16 animals (8 animals for (b)(4) using 30 mg/kg and 8 animals for control using an equal volume of normal saline) first with both groups injected sc 24 h after irradiation as outlined in section V.4.4.1. Injections. This will be repeated once (for a total of two iterations using a total of 32 animals) to assess reproducibility. Here our interest is to develop a radiation countermeasure that is effective when administered 24 h after radiation exposure, the assumed time frame required to make radiation countermeasures available to victims in the event of mass casualty scenario. Blood samples will be collected as presented in Table 7 as outlined in section V.4.4.2 Biosamples. This is the pilot phase of the multiyear interagency agreement between (b)(4) and AFRRI. We will be irradiating 16 animals (8 for control and 8 for (b)(4) first.

Table 7. Blood sample collection for (b)(4) pilot efficacy study

Time in relation to irradiation	Blood		
	CBC 0.5 ml	Biochemistry 0.5 ml	Total blood ml

-7 d	+		+	1.0
-4 d	+		+	1.0
-1 d	+		+	1.0
0 d (Irradiation)				
1 d (drug administration)	+		+	1.0
4 d	+		+	1.0
7 d	+			0.5
10 d	+		+	1.0
13 d	+			0.5
19 d	+		+	1.0
25 d	+			0.5
31 d	+		+	1.0
38 d	+			0.5
45 d	+		+	1.0
52 d	+			0.5
60 d	+		+	1.0

For the entire span of the study, the total blood volume drawn will be well below the recommended maximum limits [20].

V.1.4. Experiment 4: Investigate the radiomitigative efficacy of (b)(4) with and without G-CSF (standard of care) in NHPs

After evaluating the efficacy of (b)(4) in a pilot study (experiment 3), (b)(4) will be evaluated with and without G-CSF, the current standard of care, using a larger sample size. There will be four groups (Vehicle control (normal saline), (b)(4) G-CSF, and (b)(4) + G-CSF) with 20 NHPs in each group. (b)(4) will be administered sc (30 mg/kg) 24 h after irradiation (injection details under section V.4.4.1. Injections).

The US FDA recently approved G-CSF (Neupogen/filgrastim) for the treatment of radiation-induced myelosuppression (hematopoietic acute radiation syndrome) in patients following a radiological/nuclear incident [21]. The route, dose, and schedule of G-CSF administration in this study is based on the currently licensed indication and the recent publication demonstrating its efficacy in irradiated NHPs [22, 23]. G-CSF (10 μg/kg/d) will be administered sc at 24 h after irradiation and then daily until the ANC ≥1,000/μl for 3 consecutive days or if at any time the ANC is ≥10,000/μl. If at any point the ANC falls <500/μl again, daily injections will be reinitiated the same day and continued until the ANC is ≥1,000/ μl for 3 consecutive days.

Table 8. Blood sample collection for (b)(4) efficacy study in combination with G-CSF, standard of care

Time in relation to irradiation	Blood			
	CBC 0.5 ml		Biochemistry 0.5 ml	Total blood ml
-7 d	+		+	1.0

-4 d	+		+	1.0
-1 d	+		+	1.0
0 d (Irradiation)				
1 d (drug administration)	+			0.5
4 d	+		+	1.0
7 d	+			0.5
10 d	+		+	1.0
13 d	+			0.5
19 d	+		+	1.0
25 d	+			0.5
31 d	+		+	1.0
38 d	+			0.5
45 d	+		+	1.0
52 d	+			0.5
60 d	+		+	1.0

For the entire span of the study, the total blood volume drawn will be well below the recommended maximum limits [20] as outlined in section V.4.4.2 Biosamples.

Experiment 4 will be conducted as proposed if the survival benefit of the drug in experiment 3 is at least 25%, even if the benefit does not reach statistical significance. If the survival benefit is < 25% we will contact IACUC and discuss the matter to take decision about experiment 4. The proposed sample size is based on an expected survival advantage of 45% (which is conservative, but we expect that a recalculation of sample size based on the results of experiment 3 may allow a smaller sample size in expt 4). We have no way to estimate the survival advantage before doing the experiment as this is the first experiment with combination of these drugs. NHPs will be irradiated in a minimum of, but not limited to, 4 cohorts, based on existing situation.

V.2. Data Analysis

For experiment 1, the $LD_{50\text{-}70}$ will be estimated. The proposed sample size (10 per group at 7.0 and 7.4 Gy, to be analyzed with existing data on 16 animals at 7.2 Gy) will yield a 95% confidence interval for the $LD_{50/60}$ with an expected width of 0.4 Gy, assuming mortality is less than 50% at 7.0 Gy and between 50-70% at 7.4 Gy. The likelihood of a confidence interval wider than 0.6 Gy is about 5%. Estimates are based on simulating 500 random data sets with the above probabilities and sample sizes and estimating a probit model for each.

For experiment 2, statistical analyses will be primarily descriptive. Data may be compared over time using paired *t*-tests or repeated measures ANOVA as appropriate. A sample size of 4 animals will have 80% power to detect a difference of 2 standard deviations between time points or conditions if the within-subject correlation is 0.6, based on a paired *t*-test with 5%, two-sided significance level.
